Introduction

The *Encyclopedia of Nineteenth-Century Photography* is a unique publication, one that is an essential reference work for anyone interested in the medium of photography. This text is the result of diligent primary research by many of the world's leading researchers and writers on the subject. Their scholarship has revealed many long established 'facts' to be fictions, established the role of many hitherto unrecorded figures, measured the achievements of many of the leading practitioners against contemporary critical appraisal of their work, and placed the history of photography's first century within a social and economic context. What these researches have produced is a reference work of significant scholarship that in addition to standing as a critical work of reference, offers many highly perceptive essays that significantly develop current critical debate on the role, the nature, and the merits of nineteenth century photography.

We have devoted considerable space to key figures like Daguerre, Talbot, Fenton, Herschel, Brady and others to place their achievements in context. Similarly, major inventors, manufacturers, organisations, and supporters of the medium have been examined in extended essays. In its totality the encyclopedia contains1197 entries: 610 major entries of 1000 to 5000 words, and an additional 587 shorter entries on minor and emerging figures; together these provide readers an expansive history of nineteenth century photography. This text ranges from shorter 200 word entries that provide snapshots of photographic figures and other key elements of nineteenth century photography to large, 5,000 word entries that provide detailed, analytical scholarship for our readers.

The encyclopedia offers a number of access points to information. Photography's history can be explored by date, by named image-maker, by area, or by process to name but four, with each of these themes offering a fresh perspective on the history of the medium.

How to Use This Book

The *Encyclopedia of Nineteenth-Century Photography* contains **both alphabetical and thematic tables of contents** for easy reference. These sections allow researchers to quickly and easily locate topics of interest or a group of similar entries under a specific theme. **See Also**s at the end of many entries provide cross-references to guide the reader to associated entries. Readers also have the pleasure of viewing the **197 images** placed throughout this work to aid their understanding of nineteenth-century photography. Included as well with every major entry is a **Further Reading** section in which authors have listed referenced texts or other works giving additional content on that topic. A thorough, analytical **index** increases the ease of navigating these two volumes.

National and Regional Surveys allow readers geographically oriented access, enabling them to learn about location-specific issues—from the overly humid conditions of South Asia to the arid environment of Egypt. These sections provide a fresh framework by which to read, separating true history from the conventional western-oriented understanding of history that has dominated photographic historiography for a century.

Societies, Groups, Institutions, and Exhibitions offer a unique view of the popularisation of photography and its encouragement by local and national groups and organisations, and show how exhibitions were used to draw together photographers from other countries. In these entries short- and long-term interest groups and exhibitions are discussed from conception to either their conclusion or present day. These discussions often include the photographers and patrons who were critically involved in the success of these groups and of photography in the nineteenth century. Readers will see a global interconnectedness emerge from these entries as the histories of these groups are revealed.

Publications looks at both illustration- and word-based texts. Word-based publications often focus primarily on the art and science of photography itself. Necessary to a comprehensive understanding of the appeal of photography in the nineteenth century is that illustration-based publications provided not just images of foreign lands to people who could not afford to travel, but they created images for discussion, research, and further review as well. The emergence of the photographic press served not only as a means of disseminating information for the practical application of photography but also for its chemistry, techniques, processes, and equipment. The photographic press also functioned as a platform for the publication of criticism and debate. Through these increasingly widely-read journals, problems concerning the manipulation of early processes were often resolved through readers' letter pages.

Photographers, Inventors, Patrons, and Critics, the most conventional of the texts' themes, offer the reader extended biographies of leading names in the development of the art and science of photography. The figures located under this section have often contributed critically to the success and proliferation of photography internationally; however, this section includes minor figures as well whose involvement were nonetheless important in the development of photography.

Although there is both an alpha and thematic table of contents, the entries are sequenced alphabetically, ensuring that the information contained in these volumes can be accessed easily by the reader. This encyclopedia offers a total overview of the history of photography's first century. Many of the earliest encyclopedias served as compilations of photographic history and practice for the benefit of the working photographer in pre-Great War Britain and America, however this encyclopedia is a comprehensive reference work on photography's first century for the benefit of a growing body of not just photographic historians, academics, professionals, and enthusiasts worldwide but students as well. Primary amongst our requisites for this encyclopedia was that it be the reference work we would want students and upcoming scholars to use in researching photographic history.

A century ago photographic history was the pursuit just a few. Very few eminent photographers of the day were interested in the work of their antecedents, a notable example being Alvin Langdon Coburn, , who was fascinated by the work of early Scottish photographers David Octavius Hill and Robert Adamson, and the Scottish amateur Dr Thomas Keith. Today however a much wider body of people—including photographic historians, nonspecialists, and students—seek to develop a deeper understanding of photography's history to place it within the wider context that this encyclopedia provides.

Readers can also explore the history of the companies, devices and techniques that were invented, developed, and marketed by individuals and companies such as Bausch & Lomb, R & J Beck, Jonathan Fallowfield, Kodak, J Lancaster, Marion & Co, Ross, Voigtlander, and Alfred Watkins all of which are discussed in detail in the entries that follow. The breadth of this encyclopedia's list of entries reaches not just the science or art of photography, but also the practicality of it. For instance, between the announcement of the daguerreotype and the end of the nineteenth century, the weight of a camera had been reduced from more than one hundred pounds to just a few pounds, and the total equipment a photographer needed to carry on location had been reduced from enough to fill a small carriage to less than would fill a small knapsack. These entries narrate the progression and evolution of photography for the historian, constructing a dynamic, fundamental understanding of photography starting from kitchen-sink chemistry where each photographer was exclusively responsible for the manufacture of his or her sensitive materials, to the beginning of mass manufacturing towards the end of the century. These discussions highlight the emergence of companies like Kodak and Agfa, which were already firmly established in the industry as the nineteenth century drew to a close and which would later dominate the twentieth century.

It has often been said that at the time of the introduction of the first viable photographic processes, photography was a solution in search of a problem. Although the inventors of the medium were confident in their predictions of the huge potential of photography, none could have foreseen the range of applications, and the innumerable approaches and styles that would emerge before the end of the nineteenth century. Nor could anyone have foreseen the number of processes that would be introduced, or predict the success of some and the failure of others. Those applications, approaches, styles, and processes, minor as well as major, are explored and discussed within the pages that follow, as are their photographic inventors, supporters, and exponents. This comprehensive text provides researchers with this material in an easy-to-navigate, meticulously organized reference work.

This *Encyclopedia of Nineteenth-Century Photography* encompasses the enormous range and depth of nineteenth century photography, both art and science. There are many entries on major and minor figures whose achievements have previously been under-reported, providing readers with a much fuller history than was available hitherto. This is the first comprehensive reference work to introduce and celebrate these obscure,

misremembered photographers, and clarify enduring confusion over names. For example there were three photographers operating under the name William Bell, all of whom were in the forefront of nineteenth century American photography. Our contributors have clearly identified all three and separated their achievements. Similar diligence has been applied all the entries to ensure the histories included herein are thoughtful, useful, and clear, and that they establish an accurate nineteenth century photographic history.

Photography's first century is one of invention and innovation, intense debate and the development of an increasingly sophisticated visual language. The academic study of photographic history is a surprisingly young subject, despite the fact that over a century and a half has passed since its first published history. It is one of photographic history's failings that some of the misinterpretations that are bound to be present in any early attempt to document a history have remained unchallenged for so long. That many such misunderstandings have been replicated from one book to another, and are now repeated on countless websites, underlines the importance of a publication as exhaustive as the *Encyclopedia of Nineteenth-Century Photography*. This text contains explorations and discussions by leading theorists, historians, and critics of the innovations, and the debates and implications of photography in the nineteenth century. These contributors have painstakingly researched these topics to simplify and delineate these issues for our readers. The commissioning of leading experts to research and compile this encyclopedia, with many of them offering fresh and often challenging readings of the subject, has made this text essential reading.

As mentioned earlier, one of the strengths of this encyclopedia is the inclusion of many figures whose contribution to the development of the medium have been unacknowledged, but yet another is the commitment of the writers to return to primary source material and review many of the assumptions and misconceptions in the history of the subject. Because of this return to primary material several of the 'facts' published in many past works have been revealed as misunderstandings based on only partial information. An example is the discovery of hand-written patents in the Scottish and Irish Patents Offices, negating the widely published assertion that Richard Beard did not patent the daguerreotype in either country, which scholars have often cited as an explanation for why there were in the 1840s more daguerreotypists in Scotland than in England. That he patented the process throughout Great Britain, but apparently did not enforce his patent rights except in England and Wales, opened up new understanding and interpretation of his career included in his entry in this text.

Furthermore, the encylopedia's scope encompasses more than just American, Great Britain, and France to include countries not often thoroughly discussed in photo-historical texts. The history of photography contained in this encyclopedia is the product of a photo- instead of Anglo- or Euro-centric approach, and one that encompasses extended accounts of the emergence of photography in many areas of the world including Russia, China, Japan, Central and South America, Africa, and the Ottoman Empire and also offers biographies of leading figures in each of these areas. These countries and regions have been covered in depth to establish a history of photography's expansive influence upon, and importance in, cultures throughout the world. Researchers using this text will read entries by authorities based in the countries about which they are writing, introducing them to many photographers whose work will now be recognized to be as important as some of the image-makers whose place in the pantheon of photographic history is already established.

Although photography existed in its own right worldwide, photography's inventors were predominantly from France, Britain, and America, and as such, these nations were primarily responsible for the dissemination of the medium. British and French travellers and military personnel played a pivotal role in taking photography to Asia, Africa, and the Antipodes, with American photographers taking the medium to South America and the Pacific.

These travellers introduced photography to the first generation of indigenous practitioners in each country, many of whose achievements are published within this text for the first time. As local photographers matured in their understanding of the medium, and developed their own locally relevant aesthetic—often drawn from national trends and styles in painting the exhibitions they organised, and the societies and groups they established, developed their own national momentum. Essays mapping the emergence of these exhibitions, institutions, and organisations are crucial in establishing the contexts within which the first and second generations of photographers operated.

The diversity of perspectives provided for readers includes the exploration of the role played by major and minor figures in the emergence of historical and critical writing on photography, from Henry Snelling to Helmut Gernsheim. Documented as well are accounts of pioneering advocates of the medium who understood the importance of the photograph as historical artefact. Key amongst those advocates are the early collectors, whose understanding of the importance of collecting visual material then ensured that the available evidence of photography's history would be as rich as it is today. Thus readers will find entries for those who established the collection at the South Kensington Museum, now

the Victoria & Albert Museum—and those who initiated the collecting of photographs at the Library of Congress and elsewhere.

Our enduring impressions of the nineteenth century including the Crimean War, the American Civil War, and other mid-century conflicts are informed by the images offered by surviving photographs. These images were often constrained by the limitations of available processes and technology, by the photographers' interpretation of contemporary sensibilities and by the photographers' recognition that sales of the resulting images had to conform to the tastes of the purchaser. When with an understanding of their time, however, these images serve as valid historical documentation from which anyone reading this text can gain not only a more intimate knowledge of these events, but also of how responsive photography was in certain circumstances.

Just as influential in dictating the nature and content of photographs of news and current affairs were the constraints placed on mid-nineteenth century photographers by the nature of the processes they were using. The inability of the medium to capture action resulted in an abundance of staged portraits. Thus, in offering a real understanding of the images produced during the nineteenth century, we have sought in compiling *The Encyclopedia of Nineteenth-Century Photography* to present factual material within its contemporary nineteenth century context. Reading mid-Victorian images with a twenty-first century mindset is to misunderstand much of what is to be seen.

The publication of both the *Encyclopedia of Nineteenth-Century Photography* and the companion three-volume *Encyclopedia of Twentieth-Century Photography*, document the magnitude of nineteenth century photographers' vision, and the extent to which their early predictions for photography have been achieved and surpassed. These two texts present in a set of reference books what will become the standard sources of students for years to come. These volumes will also by their breadth and content undoubtedly drive further photo-historical research in many of those areas of study.

Acknowledgments

In bringing this project to completion, I am indebted to the vision of the original editor, Pamela Roberts, and to the Advisory Board made up of leading academics and curators worldwide, who established the basic principles of the project and drew up the original list of entries. I have deviated only slightly from their list, adding a few emerging figures as the project progressed. To realise their vision required the scholarship of the many leading authorities on nineteenth century photography who have written the entries, and the many collections from which the illustrations have generously been made available.

The contributions of many people have been equally crucial in completing this project and we owe them each, individually, a debt of gratitude for their perseverance. To name but a few, I am especially indebted to Ron Callender, Alistair Crawford, Malcolm Daniel, Anthony Hamber, Michael Hallett, Colin Harding, Kathleen Stewart Howe, Gael Newton, Michael Pritchard, Pam Roberts, Larry Schaaf, Graham Smith, and Mike Ware for their knowledge and their advice, and for their generosity with their time in helping me unravel some of the complexities of identification, and helping me to find authoritative writers for many of the more challenging entries that have significantly expanded the boundaries of published knowledge. That we have found accomplished researchers adds to the integrity of the project. Special thanks to Mark Georgiev, Acquisitions Editor, and also to Beth Renner, Development Editor at Routledge, who has had the unenviable task of keeping track of all the assignments, cajoling writers who missed their deadlines, liaising with me every step along the way, and helping us get back on track needed.

Despite its trials, this has been one of the most rewarding projects with which I have been involved. During it, I have had the pleasure of meeting and discussing photographic history with countless remarkable people. The highs have been very high, but the lows would have been a lot lower without the support and encouragement of my wife, Kath.

JOHN HANNAVY

A

ABBE, ERNST (1840–1905)

German-born Ernst Abbe was one of the pioneers in optical physics. In 1866, while a Professor at the University of Jena, he met Carl Zeiss, later becoming Director of Research at the Zeiss Optical Works in Jena.

Abbe and Zeiss later became partners (1875), and were responsible for the development of many innovative optical systems for the microscope, and for developments in optical design which were far-reaching—none more so than the development, with Otto Schott, of the world's first apochromatic lenses (1886), the first to eliminate chromatic aberration.

Abbe's command of optical theory was a significant factor in the establishment of the worldwide reputation of Zeiss optics, as all his lens designs were based on precise, and theoretically sound calculations. Together with Otto Schott, who he met in 1881, Abbe played a significant role in the evolution of new formulations for the manufacture of optical-quality glass.

One of Abbe's many significant contributions to the understanding of how lenses worked was his system of 'Abbe numbers' which gave a numeric value to the extent to which glass disperses light of different wavelengths. These figures varied from around 25 for flint glass, to over 60 for crown glass—the lower the number, the greater the loss of quality due to refractive dispersion.

JOHN HANNAVY

ABDULLAH FRÈRES
Vhichen (1820–1902), Kevork (1839–1918). and Hovsep (1830–1908)

Vichen Abdullah was an Ottoman Armenian who began his photographic career touching up photographs at the studio opened by Rabach in Istanbul in 1856. When his brother Kevork returned from studying at the Murad-Raphaelyan School in Venice in 1858, together with a third brother, Hovsep, they took over Rabach's studio, which became known as Abdullah Fréres.

The brothers became official royal photographers after taking a portrait of Sultan Abdülaziz (1830–1876) in 1863.

They took portrait photographs of Edward, Prince of Wales, who visited Istanbul in 1869, and Empress Eugénie (1826–1920) of France.

The Abdullah brothers were masters at both studio and outdoor photography.

When the Ottomans were defeated in the Ottoman-Russian War of 1877–1878, the Russian army made its headquarters at San Stefano near Istanbul on 26 February 1878. Grand Duke Nicholas (1831–1891) commissioned Kevork Abdullah to take a group photograph of 107 people. Angered by this, Sultan Abdülhamid II prohibited the brothers from using the royal monogram and keeping the portraits of the sultan they had taken.

In 1866, at the invitation of the Khedive of Egypt, Tevfik Pasha, Kevork, and Hovsep opened a branch studio in Cairo.

In 1890 Sultan Abdülhamid II restored the right of the Abdullah brothers to use the royal monogram, and the studio flourished once again.

In 1895 the brothers closed down the Cairo studio, and at the end of 1900 they sold the Istanbul studio to Sébah and Joaillier.

ENGIN ÖZENDES

ABNEY, WILLIAM DE WIVELESLIE (1843–1920)

English photographic scientist

Abney was born in Derby, England on July 24, 1843, the eldest son of the Rev. Edward Henry Abney and Catherina Abney (formerly Strutt). His father was the vicar of

St Alkmands, Derby (later the prebendary of Lichfield). Through his mother, Abney was the great great grandson of Jedediah Strutt, a partner of Richard Arkwright, inventor of the waterframe spinning machine.

Abney was educated at Rossell school and then the Royal Military Academy, Woolwich. He was commissioned as a Lieutenant in the Royal Engineers in 1861 and served in India until invalided home in 1867. As photography's practical applications became of increasing value to the army, Abney was encouraged to develop his boyhood interest in the subject, which had become a serious study as early as1862. In 1871 he was appointed Assistant Instructor in Telegraphy at the School of Military Engineering at Chatham but within a year was transferred to a similar post with sole responsibility for chemistry and photography. Abney produced a small pamphlet, *Instruction in Photography,* as an aid in his classes. This was later to become the basis of an invaluable guide for innumerable students of the art beyond the army. In 1873 he developed the papyrotype photolithographic process and was promoted to Captain in the same year. In 1874 Abney was selected to organise the photographic observation of the transit of Venus in Egypt. His book, *Thebes and its Five Great Temples* (1876), was written following this trip. Abney left Chatham in 1877 to become a Civil Servant in the Department of Science and Art. However, he was not formally retired from the army until 1881 and continued to be known as Captain Abney until he was Knighted in 1900.

On joining the Department of Science and Art in 1877, Abney became an Inspector of Schools and soon became a respected figure. He was promoted to Assistant Director for Science in 1884 and Director for Science in 1893. One of his major tasks was the organisation of grants for the establishment of school laboratories. He was convinced that practical instruction in the sciences was a vital component of a modern education. He later claimed that this period was largely "missionary work" for science Abney retired in 1903, following changes brought about by Balfour's Education Act.

During his time as a Civil Servant, Abney was based at the South Kensington Museum in one of the of the metal buildings know to Londoners as the "Brompton Boilers." It was from his laboratory here that he undertook most of the scientific and photographic work for which he is remembered. He made important investigations into the alkaline development of photographic images in 1877 and in 1880 he introduced hydroquinine as a developing agent. More significant was his work on the improvement of photographic emulsions along with the development of printing processes and of photographic printing paper. With Charles Bennett and D.B.van Monkhoven, he was largely responsible for the widespread introduction to England of the rapid gelatin emulsions that made so called 'instantaneous' photography possible. In 1881 Abney introduced the gelatino-citrochloride emulsion printing process that later became the basis of POP (Printing Out Paper), an immensely popular product in the growing amateur market. Abney also found time to publish *Emulsion Processes in Photography* (1878), later retitled *Photography with Emulsions* and the popular *Treatise on Photography* (1878) which reached its tenth edition in 1905.

Other investigations included tests on the speed and efficiency of shutters and probably the first quantitative density measurements of a photographic image. This latter work was to lead him to question the accuracy of the experiments of Hurter and Driffield. As Editor of the *Photographic Journal* however, he considered their investigations important enough to be published and was content for the matter to be judged by his peers. Abney also undertook work in colour analysis and colour vision, which naturally led to an interest in colour photography. In 1905, he introduced a tricolour system of colour photography, which employed three separate lenses and colour separation positives. Abney later published *Trichromatic Theory of Colour* (1914) which was based on his original research.

Abney's achievements in science extended beyond photography. His work on emulsions led him to produce a photographic emulsion sensitive to the infrared region of the electromagnetic spectrum. This allowed him to record the infrared spectrum of the sun. More importantly, with Robert Festing, he studied the absorption spectra of chemical compounds, work that was to play a key role in the development of spectroscopy. He made numerous contributions to other sciences and was elected a Fellow of the Royal Society in 1876.

Abney's interests in the aesthetics of photography were overshadowed by his contribution to its science. Nevertheless, he did not ignore the artistic aspects of the subject as is evident from his publications. He was a keen traveller and produced many fine photographic views both in England and in the Swiss and Italian Alps. Abney was also a competent watercolorist.

Abney held prominent positions in several scientific societies and served as President of the Royal Photographic Society in 1892–94, 1896, and 1903–1905. He published over twenty books and innumerable articles and papers. He promoted a national collection of photographic history at South Kensington, which later became the Science Museum Photography Collection, the forerunner of the National Media Museum at Bradford.

Abney was a taciturn but charming man who despised snobbery in any form. He married Agnes Mathilda, daughter of Edward William Smith of Tickton Hall in Yorkshire in 1864. They had one son and two daughters. Following Agnes's death in 1888, he married Mary Louisa, daughter of Rev. Eward Nathaniel Mead of East

Barnet, Hertfordshire. The second marriage produced one daughter. For many years, Abney lived in South Bolton Gardens, close to his South Kensington laboratory, but moved to Folkstone in 1920 because of failing health. He died there of bronchitis and kidney failure on December 2, 1920.

JOHN WARD

Biography

William de Wiveleslie Abney was born on July 24, 1843 in Derby, England. He was given a scientific education at the Royal Military Academy in Woolwich. The army also encouraged him to develop a boyhood hobby of photography and he later instructed officers and men in the subject. Abney became a Civil Servant in 1877 and from his laboratory at the back of the South Kensington Museum undertook most of the work for which he is remembered today. He undertook significant researches into the nature of gelatin silver halide emulsions at a time when they were being widely adopted by photographers. His most important practical innovations were the introduction of hydroquinone as a developing agent in 1880 and silver gelatin citrochloride emulsions for printing-out paper (POP) in 1881. However, Abney was at the forefront of many aspects of photographic research during a period of great innovation in photography. He devised new techniques of photomechanical printing and conducted significant researches in the fields of colour photography, photochemistry and spectral analysis. Abney published prolifically throughout his career. He was instrumental in establishing what became the Science Museum Photography Collection, now at the National Museum of Photography Film and Television at Bradford. Artefacts relating to Abney are preserved at Bradford and in the Science Museum, London. Abney died in Folkstone on December 2, 1920.

See also: Emulsions; and Hurter, Ferdinand, and Driffield, Vero Charles.

ACKLAND, WILLIAM (1821–1895)

English optician and photographer

William Ackland was connected for nearly forty years with the firm of Horne and Thornthwaite up to his death. He directed the optical works of the firm and in later years gave much attention to equatorial stands and reflecting telescopes.

Ackland was the author of several pamphlets on photographic matters including *How to take stereoscopic pictures* (1857) and *Hint's on Fothergill's Process* (1858) which were all published by Horne and Thornthwaite. He also wrote on the collodion process on glass in 1857 in Horne and Thornthwaite's catalogue. As part of his wider involvement in optics he wrote *Hints on Spectacles. When to wear and how to select them* (1866).

Dr Ackland became a member of the Photographic Society in 1869 and was for many years a member of the Society's Council. Shortly before his death he was made an Honorary Fellow. From 1856 he wrote several articles for the *Journal of the Photographic Society* mainly on different processes and was an active participant in the Society's meetings. He was a Fellow of the Institute of Chemistry.

His interest in photographic matters continued throughout his life and he designed a Photographic Exposure Scale, a form of exposure calculator, in 1888. He applied for a patent for this in 1891 under the title 'Registering Photographic Expsoures' (British patent number 12409) which was subsequently abandoned.

Ackland died in Brixton aged 74 on 30 March 1895.

MICHAEL PRITCHARD

ACRES, BIRT (1854–1918)

American photographer

Born in the U.S. to British parents, 23 July 1854. Trained in art and science in Paris and was a frontiersman on the North American plains. Moved to Britain in the early 1880s. In 1888 Acres lectured on the use of isochromatic (color sensitive) plates for correct representation of tones, projecting his own examples to acclaim. His slide subjects included European cathedrals, boats, and the sea. Married Annie Elizabeth Cash, 1891. Working as a photographer, he eventually became manager of

Elliott & Son, photographic plate manufacturers in Brent, north London. Long interested in representing motion by photography, in 1893 he patented a slide changer for projecting a sequence of slides in quick succession, simulating movement. The patent also allowed for the device to be used for photography. In 1892 his "Story of a Cloud" (showing changing formations) was projected with the rapid slide-changer to the Royal Photographic Society.

Acres apparently made sequence photographs on 2¾ inch unperforated celluloid c.1894. In association with engineer Robert Paul he eventually achieved motion picture success with a camera using perforated 35mm film. He left Elliott & Son in 1895, but the partnership with Paul quickly ended in acrimony. Acres made films in Germany in 1895, was the first to project a film publicly in England, and gave Britain's first Royal Command Film performance in July 1896. His 1895 films include "Oxford and Cambridge Boat Race," "Rough Sea at Dover," and "The Comic Shoeblack." He later designed the first small-format home movie system, the Birtac, marketed in 1898. Unhappy with the showbusiness (rather than educational) exploitation of motion pictures, Acres concentrated on filmstock manufacture and processing in later years, but suffered severe financial setbacks. Bankrupted twice, he died 26 December 1918.

STEPHEN HERBERT

ACTINOMETERS AND EXPOSURE MEASUREMENT

The researches of Ferdinand Hurter (1844–1898) and Vero Charles Driffield (1848–1915) in the 1880s and 1890s established the basic principles of densitometry and sensitrometry that they applied to photographic exposure measurement. Their work was based on extensive observation and experimentation and was the first attempt to systematically relate light intensity and the density of exposure on the photographic plate. It was not the first attempt to produce a method of determining exposure by calculation or measurement but it allowed commercial manufacturers to produce photographic plates of consistent sensitivity to a widely adopted standard that allowed exposure measurement devices to become practical.

The first photographic exposures tables were published by C.F. Albanus in 1844 and journals and manuals would often include such tables as a guide to exposure. They were usually based on observation and were subjective and susceptible to variants in the sensitivity of photographic emulsion, optics and geography, as well as the rigour with which the author conducted his tests. W.K. Burton issued a comprehensive series of tables based on practical tests in 1886 that were still in use at the end of the century.

Antoine Claudet produced his Photographometer to measure the intensity of light details of which were published in March 1849 of the *Art Journal*. The device was also exhibited at the 1851 Great Exhibition and mentioned in several contemporary handbooks. Formal measurements were first conducted and published by Bunsen and Roscoe in 1858 which connected sunlight with the position of the sun to time of day and year. This work was expanded and developed by Hurter and Driffield who published extensive tables in 1888. Their work produced a H&D number that was used to indicate sensitivity and crucially they showed that each dry plate could be allocated a number which could form the basis of an exposure calculation. The commercial outcome of this work was their Actinograph, a calculator, which was patented in 1888 (British patent number 5545) and sold from 1892 by Marion & Co for a range of different latitudes and longitudes.

A range of other calculators appeared after this. J.A. Scott of the Britannia Works Co (later Ilford Ltd) patented a disc form calculator (British patent number 17642) and this became the main form of this type of calculator until their demise in the later 1950s. Hurter and Driffield refined their Actinograph in 1897 to a flat disc design. Cadett and Neall claimed sales of 10,000 for its own calculator by November 1897 and sales of nearly 20,000 for Dibdins exposure meter by July 1899.

Actinometers, also known as tint-meters, relate the time taken to darken a piece of light-sensitive paper to match a standard tint. A variant is to expose the paper for a fixed time under an optical wedge with steps of increasing density. The strength of the light is then indicated by the densest step under which exposure has taken place. W.H.F. Talbot noted the idea for an actinometer on 30 March 1840 to measure the time required to print out a negative and the idea was put to good use with many such devices in the later nineteenth century, especially for the carbon and platinum processes where the progress of printing could not be inspected directly as it could with ordinary silver printing.

Formal experimentation and measurement of light was published by Bunsen and Roscoe in a series of papers from 1858 to 1862 read to before the Royal Society and they established a standard grey tint of one thousand parts of zinc and one part soot. Earlier devices using a standard grey colour on silver chloride paper were produced by Jordan and Malagutti in 1839, Heeren in 1844, Hunt in 1845, Claudet in 1848, and Schall in 1853.

It was the work of Bunsen and Roscoe together with more consistent commercially produced sensitised materials that aided the spread of reliable actinometers. Before the mid-1860s paper and plates were coated

with sensitised chemicals that had been made by the photographer or commercially in small quantities. Their sensitivity varied until more consistent chemical production, larger production batches and consistency between batches and standardisation of lens apertures allowed reliable exposure measurement devices became feasible.

Louis Bing's provisional British patent of 13 September 1866 described an improved mode of and apparatus for determining the actinic power of light. In this actinometer a sheet of sensitised paper was exposed under a grid of mica squares of varying thicknesses for a standard time. The intensity of light was gauged by the number of mica layers through which it had passed. The patent was produced commercially as Bing's Universal Self Registering actinometer from 1866. Vogel's Photometer of 1868 was used as a printing meter and Woodbury's Photometer of 1879 was a comparison actinometer where a darkening strip of sensitised paper was compared against six standard tints. The time taken to match a particular density, chosen on the basis of previous experimentation gave an indication of the required exposure.

By the 1880s watch-form actinometer's gave exposure measurement a more practical air. Green and Füidge's 1884 actinometer (British patent number 14457) gave seven comparison tints and a transparent aperture behind which was a disc of sensitive paper that was exposed for one minute. Both this and the Woodbury actinograph required the photographer to calibrate his plates to the meter. Stanley and Sargeant's actinometer (British patent number 4624) of 1886 was designed to be suspended from a watch chain and held a ribbon of photographic paper sufficient for 500 measurements.

The two most commercially successful actinometers of the later nineteenth century was Alfred Watkin's Standard meter of 1890 (British patent number 1388) which was a short tube containing sensitised paper next to a standard tint which was exposed for one minute using the time the cap on a pendulum chain completed it's swing. The exposure was determined using a series of rings on the outside of the barrel. The Watkins meter was refined into the 1895 watch form and Bee meter from 1902 that was available up to 1939 and sold in very large numbers. The main competitor to the various Watkin's meters was G F Wynne's Infallible meter of 1893 (British patent number 10,617) which was in the form of a pocket watch containing a disc of sensitised paper and scales to determine the exposure. Variants of these basic designs appeared in Germany, France and the United States.

Although actinometers were popular there were other forms of determining exposure that saw some success in the nineteenth century although many of these re-emerged in the twentieth century to greater commercial success. Visual or extinction meters worked by viewing the subject to be photographed through a variable density filter. The last point where the subject could be seen gave a number which could be applied to a calculator to determine the exposure.

One of the first visual meters was demonstrated to the Société Français de Photographie in 1856 by Lanet de Limenci. His Lucimètre used a series of squares of different density number 1 to 16. The first successful such meter was J Decoudin's meter (British patent numbers 13332 of 1887 and 11578 of 1888) which was widely available. Others appeared usually in the form of tube that was held to the eye. The disadvantage of all visual extinction meters was the subjective nature of determining the reading to be applied to the calculator.

One alternative that found some favour was the comparison photometer where the brightness is measured against a standard light source. Leon Warnerke's (died 1900) device described by Eder as 'the first practically serviceable device for measuring exposures' was the subject of British patent number 185 of 1880 and was placed in the market in England. It used a disc of phosphorescent material activated by light and the extinction principle was used to determine a numeric value. Other devices such as H D Taylor's Photometer of 1885 used a candle. Wernerke's Actinometer as it was called allowed dry plate manufacturers and photographers to obtain a precise measurement of the sensitivity of silver bromide plates rather than the guesswork which had been common until thenand it was adopted as a standard in 1881. The Warnerke sensitometer was displaced in 1894 by rotating wheel densitometers.

With the precise measurement of sensitivity given by Warnerke's device to a common standard, later supplemented by the longer-lasting H & D and German Scheiner scales (adopted from 1899) a clear basis had been established to determine exposure by calculator, extinction or comparison methods, culminating in the twentieth centuries ASA and ISO measure of film sensitivity.

ADAM-SALOMON, ANTOINE-SAMUEL (1818–1881)

French sculptor and photographer. Born at La Ferté-sous-Jouarre, Seine-et-Marne,

Adam-Salomon was destined for a mercantile career when in his youth he entered the Fontainebleu factory of Jacob Petit as a modeler. When his talent for sculpting was discovered, he received an official scholarship to study in Paris. Salomon turned to photography in midlife and continued to practice both art forms. By the time his portrait work came to public attention at the Paris International Exhibition of 1867, Salomon had already been practicing photography for eight or nine years, accumulating 15,000 negatives of the most estimable sitters. His portraits, three-quarter length figures, and some full-length, reveal his marvelous arrangement of light and shade.

Working in a 10 5/8" × 8 1/4" format, Salomon's prints were renowned for their deep rich blacks, pure whites, and continual tonal gradations between these extremes. Discussed in terms of their "brilliancy, boldness, and relief," his portraits often took one hour to pose, fifteen-seconds to shoot, and up to three hours to print. Salomon observed, "It is far more difficult to produce a good photographic portrait than a painted portrait."

Solomon used special lighting techniques which may have accounted for his rich graduated tonal range. In his studio, even overall light emanated from the ground-glass ceiling and light from clear-glass sides could be modulated by a curtain. Equally, his inventive props adjusted to the subject's height making the sitter comfortable and the pose appear more natural. His illustrious client list included: the architect Charles Garnier, French philologist, Joseph Ernest Renan, the dramatist Emile Augier, and journalist and novelist Alphonse Karr. He was praised and photographed by his contemporary Nadar.

Margaret Denny

ADAMSON, JOHN (1809–1870)

British photographer and physician

As a member of the British scientific community in the 1840s, John Adamson was an early innovator in photography, producing the first calotype photographs in Scotland and making key technical changes to stabilize the process and improve results. Though he never practiced photography professionally, Adamson instructed and encouraged many others, helping establish the primacy

Adamson, John, "Portrait of woman seated in profile." From the album "Photographs A.A. Bell." 27 mounted and 9 unmounted prints.

of Scottish photography in the medium's early years. Most notably, in training his younger brother Robert Adamson, he contributed to the celebrated collaboration between Robert and David Octavius Hill that set the standard for artistic achievement in photography.

Adamson was born in Fife, Scotland in 1809, the first of 10 children to Alexander Adamson and Rachel Melville, farm owners from Burnside, Scotland. He studied medicine at St. Andrews University and the University of Edinburgh from 1826 to 1829 and concluded his studies in Paris in the early 1830s. After working as a ship's surgeon in Asia, he returned to Scotland to open a medical practice in St. Andrews in 1835. He befriended the eminent scientist Sir David Brewster while lecturing part-time in chemistry and natural science at Madras College, St. Andrews University, between 1837 and 1840.

It was probably as a member of the St. Andrews Literary and Philosophical Society—founded by Brewster in 1838—that Adamson first became acquainted with photography. As a confidante of photography inventor William Henry Fox Talbot, Brewster showed early examples of Talbot's "photogenic drawings" at meetings of the learned society in 1839. In May 1841, Talbot disclosed the details of his recently-patented calotype

process to Brewster and, since Talbot's patent did not extend to Scotland, Brewster shared the information with his St Andrews colleagues. Adamson immediately embarked on learning the process.

Although he had already taken photographs with the rival daguerreotype process, for the first few months neither Adamson nor his colleagues had much success with calotypy, despite numerous experiments. By autumn, Adamson had produced several negatives but still encountered difficulties in making durable positive prints. Nonetheless, Brewster found Adamson's work promising enough to send several examples to Talbot in November.

It was not until May 1842 that Adamson executed a satisfactory calotype print, which was not only the first such photograph made in Scotland, but also one of the earliest accomplished by anyone other than Talbot. A very faint half-length portrait of his sister Melville, Adamson noted it required a two-minute exposure in "bright sunshine [... with a] temporary camera obscura made with a common small lens or burning glass" (Michaelson, 34).

The breakthrough encouraged Adamson to undertake further experiments and in his enthusiasm he taught the process to his brother, Robert, an engineering student who soon envisioned becoming a professional photographer. The pair collaborated closely on many experiments and photographic excursions throughout the summer of 1842 and into the beginning of 1843, by which time Robert felt skilled enough in the process to move to Edinburgh and open a commercial studio.

Unlike Robert's eventual business partnership with Hill, the Adamson brothers' collaboration was an amateur effort as concerned with resolving the technical shortcomings of Talbot's fledgling process as with producing visually stimulating compositions. The cooperation between the two brothers during this short, but intense period, resulted in crucial improvements to the process that served as the means to Robert's stunningly rich prints as a professional.

Adamson sent a small presentation album of his and his brother's best work to Talbot in November, 1842, perhaps to gain the inventor's approbation for his brother's professional aspirations. Another album (in the collection of the National Museums of Scotland) is organized like a working notebook and clearly illustrates the technical and aesthetic evolution of their pioneering achievement. Amidst considerable discrepancies in print quality, Adamson's accompanying notes document the constant chemical and procedural improvisations that marked their efforts.

The Adamson brothers made family portraits, architecture studies and even some scenes of local fishermen that acknowledged the older Adamson's medical concern with sanitation reform among fishing communities. These possibly served as the source for Robert's later series with Hill on the fishing families of Newhaven. Many of the photographs, like "The Priory and the West Gable of the Cathedral" (c.1842), exhibit a flattened perspective and awkward framing that suggest they were made primarily to work out photo-processing problems, but the more inventive framing found in images like "A Farm House" (c.1842)—with its elevated and angled view—attests to the brothers' growing awareness of compositional issues.

Even after Robert's partnership with Hill was well-established, Adamson continued making calotypes and may have had more than a passing relationship with the Edinburgh studio, perhaps even aiding the partners on occasion. As it were, even after two years of working with Robert, Hill still saw the brothers as a formidable pair when he conjectured that "both from [Robert] and his brother [John] much new improvements may yet be expected" (Stevenson, 54).

Upon Robert's untimely death in 1848, Hill briefly may have hoped to engage the older Adamson brother as successor. Despite an enduring interest in the medium, Adamson never considered it as a full-time profession and was not willing to sacrifice his established medical practice for the uncertainties of running a studio. Nonetheless, he remained on good terms with Hill and pursued portrait photography on a more modest scale, both individually and in conjunction with his former student and photography assistant, Thomas Rodger, who owned a studio in St. Andrews.

Adamson's photograph of a bare-chested athlete (c.1850) demonstrates an artistic talent that he perhaps too often ignored in pursuit of his scientific inquiries. The subject's determined stride and flexed muscles project a classical strength verging on the heroic. Though such striking images were the exception in his work, even as late as 1867 he was producing personal portraits of his family for a commemorative album for his nephew, in perhaps his last project before his death in St. Andrews in 1870.

While Adamson's contributions to photography were significant, especially in its technical development, his amateur status and public diffidence left him relatively neglected in subsequent histories of the medium. It is only since the early 1980s that his work has received greater consideration, not only in its importance to the achievements of his brother and others, but on its own terms.

STEPHEN MONTEIRO

Biography

John Adamson was born in Fife, Scotland in 1809 and studied medicine at the University of Edinburgh, St. Andrews University and in Paris (1826–early1830s).

He was a professor of chemistry and natural science at St. Andrews University and served as a medical officer for the town of St. Andrews, publishing a study of local public sanitation measures. He took up calotype photography in 1841 and taught his brother Robert, as well as Thomas Rodger and likely others. He produced Scotland's first calotype in May 1842 and collaborated extensively with his brother on perfecting the process. Although his efforts slowed once his brother opened a professional studio with David Octavius Hill in 1843, he remained involved in photography and took portraits individually and with Rodger until shortly before his death. He contributed photographs to the Edinburgh Calotype Club in the 1840s and was a member of the Literary and Philosophical Society of St. Andrews, serving as its museum curator from 1838 until his death. He was married to Esther Alexander and had a daughter, Tetty. He died in St. Andrews, Scotland, in 1870. His work is in the National Museums of Scotland, the J. Paul Getty Museum, the St. Andrews Preservation Trust and the St. Andrews University Library.

ADVERTISING OF PHOTOGRAPHIC PRODUCTS

In general photography was no different to other manufacturing and retailing sectors in the way it approached its advertising. Different methods were adopted for advertising throughout the nineteenth century reflecting the different markets for photographic products and the changing nature of photography itself. The methods that the photographic studio used to advertise itself directly to the general public were different to that adopted by photographic manufacturers who were appealing to professional photographers and, later, directly to amateur photographers and a wider public.

The announcement of the daguerreotype in 1839 generated an enormous amount of editorial coverage in newspapers and more specialised Victorian periodicals. *The Times* newspaper, *Art Journal* and publications such as the *Athenaeum* regularly reviewed photography, covered developments and the activities of, mainly, London-based photographers. From the early 1850s this coverage declined rapidly as photography became established as a trade and there were fewer significant technical developments of interest to the general public. The growth of specialist photographic journals and a trade press from 1853 and 1854 respectively meant that these developments could be dealt with internally. Throughout the rest of the century photography was only of limited editorial or news interest and photographers had to undertake more extensive marketing activities to promote their business.

Studios

The principal studios in London and other cities and towns from the early 1840s regularly advertised. They made use of newspaper and periodical classified advertisements, directories and more specialist publications such as *Bradshaws* railway timetables to maximise their audience reach and to ensure that new visitors would have awareness of them. This was increasingly important with the rapid growth in the number of studios from the early 1850s. Often these advertisements were simple text, but with more commercial success or more creative copy writing the text would carry recommendations, details of patrons or mention of medals and prizes won by the photographer.

The growth of an affluent middle class and eager consumerism from the 1850s and a depression in demand for photographs in the mid-1860s all provided an added impetus for photographers to promote their services. Price cutting was used to increase sales and claims exaggerated to create demand. As early as the late 1850s, a number of photographers were spuriously claiming royal patronage, which was recognized as supporting a studio's commercial success and prestige. It was not until 1895 that the issuing of Royal warrants was firmly regulated.

Other more subtle forms of advertising was undertaken, for example, the offering of free sittings to members of society, statesmen, literary figures and celebrities whose portraits could then be sold as *carte de visite* or

cabinet cards. The resultant publicity, both free and paid for, could generate sales of tens of thousand for a single *carte*, each carrying the photographer's details on its back. The *carte de visite* craze and new standard styles of presenting photographs supported a specialist stationary trade supplying customized mounts, envelopes and studio paperwork branded with the photographers name and studio details. Marion & Company and the London Stereoscopic Company both of London and Percy Lund & Company of Bradford were perhaps the best known. The growth of chains of studios in the later nineteenth century, such as A & G Taylor which had twenty-five branches across Britain by 1880 offered the public familiarity and, perhaps, a consistency in the style of work produced. Such studios advertised extensively.

Photographic manufacturers and retailers

If the photographic studio was focused on reaching the general public, then photographic manufacturers and retailers from 1839 until the later 1880s were more interested in reaching photographers, photographic studios and the serious amateur or art photographer to sell equipment, sensitized materials and photographic requisites. Occasional advertisements in specialist art journals were used but manufacturers often used more targeted means of reaching their markets. The specialist photographic press would carry advertisements (which were frequently discarded when the loose issues were bound) and year books carrying formulae and reference material which would be kept for longer periods of time carried extensive advertisements from the 1860s especially as the photographic trade began to specialize. Some firms such as Horne & Thornthwaite, J.J. Griffin and others had their catalogues bound into the back of photographic manuals or books; in some cases the company would commission the book or a staff member would write it. Firms such as Negretti and Zambra, Fallowfield and Houghtons amongst many issued their own separate catalogues particularly from the later 1860s. By the end of the century some of these were over 1,000 pages carrying thousands of different products.

The later 1880s and especially the 1890s saw the advertising of cameras and photographic goods in more mainstream publications and targeted at the consumer. This was partly facilitated by the growth of a popular press able to print with lithographed illustrations. *The Illustrated London News* and *Punch* for example, all carried extensive display advertising. The key driver for this change in emphasis was the growth of popular photography epitomised by the Kodak camera of 1888 which by the early 1890s was extensively advertised outside of the traditional photographic press directly to an amateur audience. The company saw branding as essential in ensuring that a consistent, familiar, image was given to its customers: everything from the Kodak name itself to its retail shops was part of this. In the late-1890s George Davison, Kodak's managing director in Britain, asked designer George Walton to style its shops. The Kodak girl was introduced in 1901 to appear in advertising to emphasise style and the simplicity of Kodak photography. Other manufacturers moved some of their advertising into more mainstream publications: the main British companies of Lancaster, Thornton-Pickard, Houghton and Butcher all targeted the amateur directly with their cameras and photographic products before the century was over. Well-known illustrators were used to prepare advertisements.

The photographic trade's early focus of mainly targeting professionals and the serious amateur had, by the end of the century, broadened into a much wider consumer strategy as the amateur and family photographer began to grow in commercial importance. Cameras and sensitized materials were being mass-produced and sold directly to the consumer and advertising played a key part in this process.

MICHAEL PRITCHARD

ADVERTISING USES OF PHOTOGRAPHY

During the late nineteenth century, manufacturers began placing visual images in the mass media to create and promote brand-name products. Advertisers began to understand that images could be designed to sell products and services by making irrational appeals to consumers' needs and desires. Photography's aptitude as a factual and persuasive tool to sell goods and services to potential customers, grounded in the perceived "truth" of camera images, is what gave the medium such potential to be coupled with advertising text.

Photography in service of product illustrations and sales aids had its earliest beginnings in daguerreotypes, calotypes, and in the collodion era, ambrotypes, *cartes de visites*, cabinet cards, and stereographic cards. The precedent for illustrating product through photography appears in Louis Jacques Mande Daguerre's *Still-Life*, 1837 and *Shells & Fossils,* 1839, daguerreotypes of objects arranged in his studio. Equally, the calotype process provided opportunities for documentary product photography in the early days of the medium. In *The Pencil of Nature*, published between 1844 and 1846, William Henry Fox Talbot had demonstrated that the camera was an excellent tool for documenting sculpture, china and glassware, and even a sample of lace. In essence his serial publication was an advertisement for the calotype process of photography itself.

Photography's earliest influence upon illustrative art for print media was exerted through the process of the woodcut. The photograph's initial role relating to adver-

Bierstadt, Charles. Point View, Niagara, New York.

tisement during the mid-nineteenth century was to serve as a template for wood engravers to make a wood block print. Later photomechanical printing techniques such as the woodburytype and photolithography attempted to reproduce the appearance of the continuous range of tones found in a photograph. Interim printing processes such as the collotype and photogravure all required photography to be separately printed and mounted or tipped into the text.

From the mid-nineteenth century on, photographic images were coupled with advertising on posters, trading cards, and stereographs or in promotional volumes such as trade albums, patterns books, and business directories. An early application concerned the sale of real estate property around Paris. In 1854, *La Lumière* reported new applications of photography when the Bisson Brothers' photographs of residences for sale were attached to promotional posters and hung in train stations.

Ambrotype views by Mrs. Bethia Mead formed the basis for engravings to promote commercial real estate in Chicago. In 1857, her photographs of the prestigious Iron Block Buildings along the city's Lake Street business district appeared reproduced in the elite journal *Chicago Magazine*.

By 1858 the British photographic team of Padbury and Dickins, specializing in product photography, recorded centerpieces, church furniture, and toast racks on stereographic cards. Photography in this practice was a benefit to the middlemen, traveling salesmen, as they could show their potential customers product images instead of carrying around heavy samples.

In 1865 cartes de visites were affixed to wanted posters advertising the $100,000 reward for the capture of President Abraham Lincoln's murderers: John Wilkes Booth, David C. Harold, and John H. Surrat. The posters were commissioned and distributed by the United States War Department.

By the 1870 and 1880s cabinet cards promoted disparate product such as weaponry as in L. Lafon, *Rapid Fire Hotchkiss Cannon, 37mm*, for Hotchkiss Arms and scientific laboratory apparatus for the Wood & Comer Ltd. (with a printed guarantee on the reverse) Various kinds of trade albums and business directories survive. In 1870 the French photographer Lafon was commissioned to document the Hotchkiss line of military equipment. Lafon's work differs from many product albums of the day as his showed the goods in service; his photographs showed French soldiers and sailors demonstrating the operation of guns. Another promotional album, the *Illustrated Catalogue of Locomotives*, Philadelphia: J. B. Lippincott & Co., 1871, featuring locomotives built by the Baldwin Locomotive Company of Philadelphia illustrates the many types of products enhanced by photography.

In the same city, the *Gallery of Arts and Manufacturers of Philadelphia*, a directory illustrating the wares of fifty-six businesses, issued in 1871 by the photographic firm of Wenderoth, Taylor & Brown, and publisher William Ritter, constitutes an advertising project on a grand scale. Products represented in the *Galler*y, luxury goods such as jewelry, watches, and perfume and utility items, drugs, chemicals, sewing machines, dental tools, and stationary, were featured with city businesses, for instance, Wanamakers and Brown's Oak Hall, one of the nation's first department stores, and the Continental Hotel, one of the first in the country to install an elevator

and electricity. Traveling salesmen carried the bound album of albumen silver prints surrounded by advertising text to show prospective customers the availability of products and services.

The creation of business directories integrating photographs of city streets, establishments, and shops signs became a viable method for promoting local merchants. An outstanding example of the photographically illustrated business directory is Isaiah W. Taber's *View Album and Business Guide, of San Francisco, Photographically Illustrated*, published around 1884. An example of Taber's promotional cabinet card couples an interior factory view of San Francisco's largest printing firm, Schmidt Label and Lithographic Co. with architectural renderings of their three-story structure before, during, and after having recovered from an 1884 fire. Taber linked much of his photographic work to the tourist trade. His two album set, *California Scenery and California Scenery and Industries*, were part of a commercial endeavor and contained images from Taber's extensive files linked to advertising text.

The introduction and practical application of the half-tone printing process by the 1890s revolutionized print illustration and established photography in its practical and preeminent role as illustrator for the advertisement industry. In 1897 the *New York Tribune* became the first publication to reproduce halftones daily. In its much perfected state, the half-tone was capable of nearly faithful reproductions of the tonal ranges and shadows of the original photograph for magazine and newspaper prints.

At the turn-of-the-century, the history of photography and advertising history coalesced yet further with the proliferation of cheap widely distributed magazines, and their ability to bring advertised product directly to the customer. *McClure's, Munsey's,* and *Ladies Home Journal,* as well as a score of other magazines emerged in the late 1890s based on the literary principle that individuals could be encouraged to buy and read magazines if the content was designed to catch their interest. Principally, the larger circulations gave impetus to manufacturers to advertise their products and publishers began to realize 80% of their income from advertising revenues. Halftone brought new creative freedom to layout design by making it possible to seamlessly combine photography, line drawing and typography into a unified composition.

During the last decade of the nineteenth century, with the rise of manufacturers prone to want their articles shown worn or used by living models, in preference to drawings or lithographs, studio photographers discovered advertising photography to be a profitable business. For his or her role in the imaging of products and services, the photographer needed to make everyday objects aesthetically pleasing and marketable. Many photographers came to advertising from portrait studios and found they could enliven the object with the addition of a human presence.

By the 1890s product photography shows the industry preference for live models demonstrating product benefits such as the Munsingwear advertisement for Northwestern Knitting Co. and Smith's Bile Beans.

In an era when few women ventured into photography as a profession, Kate Matthews of Pewee Valley, Kentucky, located a short distance from Louisville, made a name for herself when her photographs were used in advertisements of the Old Flour Mill Company and the J. B. Williams Company. Likewise, Chicago photographer Beatrice Tonnesen successfully entered the field of advertising photography as an extension of her portrait photography beginnings. Tonnensen's advertising work began in the late 1890s when a manufacturer sought out her photography skills to produce a corset ad. From these auspicious beginnings Tonnesen ran a successful studio for nearly a quarter of a century photographing products ranging from butter to lawnmowers, always using attractive models, young women and children, to enhance the subject being advertised.

As the demand for "realism" in advertising images grew, the new industry of modeling agencies sprung up to support photography's role in advertising. Equally, the demand on the part of the manufacturer to continually show a "pretty woman" and the perceived importance of a "fresh face" to demonstrate the benefits of their products and services required modeling agencies to continually look for new models. To solve this problem photographer Beatrice Tonnesen operated her own modeling agency, one of the country's largest—providing easy access to new subjects for her growing advertising business.

The early history of advertising photography remains a verdant field for further examination. In archival collections, advertisement photographs have quite often been hidden from view as they were typically not signed and end up buried along with other still-lifes or scenic views. To protect and promote their enterprises, some in the industry like Chicago photographers Beatrice Tonnesen and J. Ellsworth Gross stamped the lower corner of their photographs with a copyright.

Leading trade journals, *Printer's Ink* and *Progressive Advertising*, began publication in 1891 and continued to advance the advertising industry well into the twentieth century.

AERIAL PHOTOGRAPHY

Prior to the advent of airplane flight early in the 20th century, the only means of obtaining aerial photographs was via birds (mainly carrier pigeons), flying devices (balloons, dirigibles kites, gliders, or rockets), or by elevating the camera itself through various means such as artificial structures—ladders, cranes and buildings—, or geographic features such as hills and mountains. Aerial photography today is most often associated with powered aircraft flying at altitudes usually starting at 1,000 feet. Air photography today incorporates two types of orientation to the ground: vertical and oblique. Rupert Martin and other photo historians argue that the vertical aerial photograph and an appreciation of it as an aesthetic art form is a modernist viewpoint reflected in society's consciousness of powered flight. The oblique aerial photograph as an aesthetic convention extends back to the very first photographs taken by Daguerre in 1839. His daguerreotype, "Boulevard du Temple, Paris," looking down at the street from within or on top of a building is also heralded as the first to capture a human figure. Another version of the daguerreotype exists in which the man is not visible and a wagon or cart appears parked opposite the shoeshine stand. Daguerre also took several other daguerreotypes of Paris from an aerial perspective. Some photographers even experimented with a vertical perspective when appropriate such as views down geyser holes or mineshafts, and early pioneers in balloon photography and aerial photogrammetry such as France's Nadar (Gaspard-Félix Tournachon) worked on the problem of stabilizing the camera in a vertical position. He patented a device in 1858 to maintain the camera in a vertical orientation.

While innovative photographers such as Nadar and the Boston photographer James Wallace Black took great personal risks in balloon photography, historians acknowledge that aerial photography in the 19th century from anything other than artificial, fixed structures or geographic features was more of a novelty than a reality. Nadar took the first aerial photographs from balloons in 1858 at heights ranging from 262 feet (his first showing the village of Petit Bicêtre) to 1,600 feet (the one most often published showing Paris). He was honoured for this achievement by his cartoonist friend Honoré Daumier (1808–1879) who produced a satirical illustration titled in English "Nadar Raising Photography to the Height of Art." Nadar, in addition to devoting considerable energy towards solving some of the problems of aerial photography by manned balloon, also promoted aerial travel. He founded the Société d'encouragement pour la navigation aérienne and published his own magazine *L'Aéronaute*. His famous and short-lived passenger balloon *Le Géant* (The Giant), which made only two ascents from Paris in October 1863, included a two-story passenger compartment along with a photographic darkroom. On 31 July 1868 the French magazine *Le Petit Figaro* published a reproduction based on an aerial photograph Nadar took which showed the Arc de Triomphe.

Nadar was not the only photographer conducting experiments with cameras and balloons, both unmanned and controlled remotely from the ground. James Wallace Black took the first photograph from a balloon in the U.S. of Boston on 13 October 1860 at a height of 1,200 feet. One early book on the history of ballooning credits the British scientist aeronaut James Glaisher (1809-1903), accompanied by balloonist Henry Coxwell, with the first unsuccessful attempt on 5 September 1862 to photograph a cloudscape from above the clouds. This was on the historic ascent on which they reached the highest yet elevation in a balloon and nearly perished from oxygen deprivation: around 37,000 feet (7 miles). Photographer Henry Negretti (Negretti & Zambra) chartered Henry Coxwell's balloon *Mammot*h in 1863 for a flight near London. Due to the gondola's rotation, none of the wet-plates were successful. English inventor Walter Bentley Woodbury patented a camera in 1877 which could be controlled from the ground through an electric cable. Inventors in other countries such as the Russian Viacheslav Sreznevskii also designed aerial photography cameras; whether this was in 19th century is not clear. The introduction of dry-plate technology and better camera equipment meant photographers could concentrate on image taking rather than the preparation time for taking a photograph. The French photographer Jean Nicolas Truchelut is credited with taking the first photographs using a dry-plate camera on a balloon flight over Paris in 1879; his name is sometimes misspelled as Triboulet. Other early French successes in aerial photography with dry plate technology are credited to photographer Paul Desmarets in 1880 over Rouen and the work of writer and photographer Gaston Tissandier

Black, James Wallace. "Boston, as the Eagle and the Wild Goose See It." *Courtesy: The Metropolitan Museum of Art, Gilman Collection, Purchase, Ann Tenenbaum and Thomas H. Lee Gift, 2005 (2005, 100.87) image. © The Metropolitan Museum of Art.*

in the mid-1880s. The earliest known air photograph from a balloon taken in Canada was taken in 1883 via remote control by Royal Engineer Captain Henry Esdale in Halifax, Nova Scotia, in August 1883. This image is a vertical, not an oblique, perspective from an altitude of 1,500 feet. Upon his return to England he continued to experiment with balloon photography. The English photographer C.V. Shadbolt also took vertical photographs of London from a balloon in 1883. J.M. Bacon credits himself and J. N. Maskelyne with patenting a late 19th century (prior to 1902) aerial photography invention: "a small captive [balloon], carrying aloft a photographic camera directed and operated electrically from the ground." By the early 1890s with even more sensitive dry plates and smaller cameras, photographers such as Philadelphia's William Nicholson Jennings boasted of excellent results given the right weather conditions and a tethered balloon.

Besides its use as a novel viewpoint for photographers adventurous to take flight, there were three main categories of aerial photography from balloons: surveying, military observation and exploration, including scientific observation. François Jean Dominique Arago, the man who publicly announced Daguerre's invention, first referred to the use of photography in 1840 for mapmaking or phototopography. Nadar around 1853 connected the use of balloons for aerial surveying or aerial photogrammetry. The first successful experiments in photo topography were conducted in 1849 by Colonel Aimé Laussedat (1819–1907), a French army engineer. Laussedat, simultaneously but separately from Nadar's promotional work with aerial photography by balloon, experimented with aerial surveying using kites and balloons. At the Exposition Universelle, Paris in 1867 he exhibited the first map compiled from a stereographic aerial image. Laussedat's work, along with that of other surveyor innovators in the 1860s and 1870s, was extended by the Canadian Dominion Lands Surveyor General, E.G.D. Deville (1849–1924) in the mid-1880s. He published the first book about the subject, *Photographic Surveying* in 1889. His technique later proved far more efficient than traditional survey methods during an early 1890s international boundary survey in the southeast Alaska mountains. The term "photogrammetry" was coined in 1893 by Dr. Albrecht Meydenbaur (1834–1921). C.B. Adams, a U.S. Army officer, was granted a patent in 1893 for an aerial photogrammetry method involving two balloons and cameras to produce

overlapping photographs which could be converted into topographical maps.

Military applications, while obvious to scientists, photographers and balloonists themselves, were not immediately apparent to many military officers. There does not appear to have been any attempt made by either the British-led allied army or the Russians to photograph from balloons during the Crimean War (1854–1856) which was the first international conflict closest to photography's birth. The British balloonist Henry Coxwell failed to convince the British War Office to use balloons in the Crimea. The United States Civil War was the first large-scale military action in which balloons played a role on both sides. While their presence made no difference to the outcome of the war, the first and successful use of balloons by the Union (Northern) Army is inspired the Confederate (Southern) Army to establish its own balloon corps. There appears, however, to be disagreement on whether photographs were taken from balloons during the United States Civil War. F.S. Haydon, who published the first detailed study of military ballooning during the war, concluded that absence of evidence meant evidence of absence. Another author came to a another conclusion based on Union Army reports which described the use of aerial photography to create a map-like image used by ground commanders and the aerial observer.

The U.S. Civil War is acknowledged to be the source of British air power developed under the leadership of the Royal Engineers who also operated in Canada and elsewhere in the Empire. A Royal Engineer observer of balloon operations took his experience back to England. Because of the public expense and the somewhat impractical nature of maneuvering and transporting balloons, the British Army, of which the Royal Engineers is a part, only slowly yielded to the inevitable. It took nearly two decades for a balloon detachment to be incorporated into the British Army chain of command. With typical British thoroughness, however, in the early 1880s "The training of the aeronauts incorporated aerial reconnaissance, photography and signalling…." (Mead, 1983, p. 19). Like Great Britain, France also established a special school for instructing its military in ballooning and photography.

Military conflicts in which aerial photography was practiced or thought to have been used via balloons/dirigibles, kites, gliders, rockets and pigeons were the 24 June 1859 French action under Napoleon III at the Battle of Solfernia, Italy; the Spanish-American War of 1898; and the South African (Boer) War of 1899–1902. Lord Baden-Powell, who invented a man-carrying kite, had a non-manned version used during the South African War at Modder River for photographic reconnaissance. A British Army balloon section was sent to China during the Boxer Rebellion in 1900 but saw no action.

One of the more unusual accounts of photography and ballooning occurred during the Siege of Paris in the Franco-Prussian War (1870–1871). Although Nadar was in charge of the balloon corps during this conflict, aerial photography by balloons does not seem to have been utilized. Microphotography, however, was employed in the Siege of Paris to reduce the size and weight of letters carried out by carrier pigeons. A Paris photographer, René-Patrice Dagron (1819–1900), perfected the microphotography technique and was smuggled out of Paris with his equipment on 12 November 1870. The balloons, one of which held the microphotography equipment, were named *Niepce* and *Daguerre*. The first carrier pigeon camera was patented in 1903 by the German experimenter Julius Neubronner; he also developed a panoramic camera for the birds in 1912.

The most tragic association between ballooning and aerial photography is the story of the Swedish adventurer Salomon August Andrée's fatal 1897 expedition in his balloon, the *Eagle*, along with two companions, to reach the North Pole by air. The remains of the expedition, including undeveloped photographs, were only discovered in 1930 on White Island, Spitzbergen. Some of the photographs taken by Andrée and his companions were developed by G. (or J.) Hertzberg, a detailed account of which appears in a book commemorating the journey. Expedition member Nils Strindberg, who was the principal photographer, built his own camera.

If photography from balloons can be considered a partial success in the 19th century, then photography from other aerial contrivances such as kites and rockets was, at best, even more of a novelty. The introduction of roll film by the Eastman Kodak company permitted further kinds of experimentation with aerial photography because cameras were considerably lighter. Kite photography was primarily used for meteorological experiments and military observations, and were conducted to this end beginning in the 1880s. Amateur experimenters invented their own ingenious kite and photographic systems. In some cases the camera was triggered from the ground, and in other cases, particularly with early rocket photography, the camera was on a timer. The photographic results were completely unpredictable and mainly served as experimental evidence. Probably the most celebrated figure in kite photography is Arthur Batut (1846–1919) of Labruguière, France. He is sometimes credited with being the first to take a successful photograph using a kite in either 1887 or 1888. Batut published the first book on kite aerial photography: *La photographie aérienne par cerf-volant* (Paris: Gauthier-Villars, 1890). The Musée Arthur Batut in Labruguière preserves his work and celebrates his genius. Other early kite photography experimenters were E.D. Archibald (England, 1886), Emile Wenz who worked with Batut (France, late 1880s), U.S. Army Lieutenant Hugh D.

Wise (1895), the American William A. Eddy (1895), and Lord Baden-Powell (England, pre-1900). Early camera-carrying rockets include an 1888 model invented by Amedee Denisse (France) and another in 1897 by Alfred Nobel (Sweden). One of the first successful rocket cameras was patented in 1903 by Germany's Alfred Maul.

Despite the considerable and often dangerous ballooning activities experienced by photographers, high-altitude aerial photography from unpowered flying machines proved to be mainly a form of experimental photography and impractical until the advent of more stable aerial platforms (rigid airships or dirigibles, and airplanes) and more advanced photographic technology. The French engineer Henri Giffard flew the first self-propelled dirigible on 24 September 1852. Led by the English émigré Frederick Marriott (1805–1884), the first successful American experiment of a self-powered, rigid airship, the *Avitor¸* occurred in California in 1869. Captain Charles Renard and Captain Arthur Krebs,' airship, *La France*, flew several times near Paris in August 1884. Count Ferdinand von Zeppelin's self-powered, rigid airship, made its first successful flight at Lake Constance, Switzerland, in July 1900. None of these early dirigible experiments, however, appear to have involved aerial photography.

Aerial photography did not emerge as a separate, highly specialized branch of photography until it had fully proved its worth during World War One (1914–1918). In North America, Canada is regarded as a leader in the peaceful application of aerial photography in the first two years after the war. Many of the men who flew the aircraft and staffed the special cameras in freezing conditions were war veterans.

AFRICA (SUB-SAHARAN)

Sub-Saharan Africa is a nineteenth-century term used to describe those countries of the African continent that were not considered part of North Africa, but synonymous with "the Dark Continent" for Europeans. In today's post-colonial world, it is a troubled and somewhat artificial term which, in the case of the history of photography on the continent, could perpetuate a fragmented and distorted view. Equally problematic is a unified history that, in the aim for comprehensiveness, risks concealing the diversity of national and regional expressions behind a mask of homogeny. For a fuller picture of the developments of photography in Africa as a whole, please also refer to the entries for Africa, North and Egypt.

Photography was introduced to Africa by European travellers as early as October–November of 1839. Frenchman Frédéric Goupil-Fesquet accompanying his uncle, the painter Horace Vernet and Swiss Pierre Joly de Lotbinière made daguerreotypes of ancient monuments in Egypt. Their photographs were photomechanically reproduced for Noël-Paymal Lerebours' *Excursions Daguerrians* (Paris, 1840–44) and Hector Horeau's *Panorama d'Egypte et de Nubie* (1841). Both publications catered for a well-established European market for Orientalist art that had developed since the late eighteenth century.

Steamships first brought photography to coastal cities and towns of sub-Saharan Africa. Advertisements in newspapers from the 1840s testify to daguerreotypists at work in major African ports of call on the maritime trade routes between Europe and Australasia. They appeared in the West African city of Freetown in Sierra Leone

by 1845.These early photographers were itinerants, producing mainly portraits for European settlers and locals for a few weeks at a time before moving on. While travelling daguerreotypists continued to service small towns, permanent photographic studios began to be established in busier locales from the mid-1840s. The most direct route to India and Australia was round the Cape of Good Hope, so photographers set up permanently along the South African coastline, and even inland, earlier than elsewhere in sub-Saharan Africa. In 1846 Parisian Jules Léger opened the first studio in Grahamstown, and Carel Sparmann, assisted by E. Jones and Dr S.N.H. van Sweel, established one in Cape Town. By 1861 there were around 40 photographic studios in South Africa. Also en route to India were the islands of Mauritius and neighbouring Reunion, where studios were first opened by Evariste Letourner at Port Louis in 1843 and by François Cudenet at Saint-Denis in the 1860s, respectively. From the late 1860s, West Africa saw the establishment of permanent studios run by Europeans, Africans and photographers of mixed origins. Washington de Monrovée opened the first studio in St-Louis (Senegal) in 1860 and was followed by Decampe the next year. Gerhardt L. Lutterodt, operating between Freetown (Sierra Leone) and Douala (Cameroon) in the 1870s, trained his nephew Freddy (1871) and son Erick (1884–1959) who opened studios in Accra in 1889 and 1904, respectively. Many of East Africa's early permanent studios were established by photographers of Indian origin. In 1868 A.C. Gomez from Goa opened the first studio in Zanzibar, branching out from his existing photographic business in India.

As elsewhere, early African commercial studios were not always profitable so photographers often supplemented their income by continuing to work in related professions, such as opticians, chemists, jewellers, printers, publishers and booksellers. Using imported materials and equipment of European manufacture, they kept up to date with developments in photographic technology and styles. Studio owners practiced a variety of photographic processes, including the calotype and wet-plate from the mid-1850s. However the potential explosiveness of the collodion (guncotton in ether) required for the preparation of the wet-plate negatives made shipping dangerous. The studios offered cased, *cartes de visite*, cabinet and hand-tinted photographs. Portraits, rural landscapes and scenes of life and new constructions in the rapidly growing towns were available for purchase by wealthy locals, Europeans and other foreign settlers. Unfortunately, due to the detrimental effects of the climate, few of these early photographs have survived.

From the late fifteenth century Europe had contact through trade with sub-Saharan Africa, yet by the early nineteenth century the peoples, cultures and geography away from the coasts and southern tip remained largely unknown to Europeans. The invention of photography coincided with the growth of European travel inland and the new medium was used enthusiastically, if not always successfully to document the pioneering explorations. The first photographs of the interior of sub-Saharan Africa were taken during Dr David Livingstone's (1813–1873) Zambezi expedition of 1858–1864 by its official photographer and cartographer Charles Livingstone (1821–1873). Journal entries by the expedition leader and other members recount Charles's lack of knowledge and skill with the wet-plate process and subsequent poor results. The expedition's doctor and naturalist Dr John Kirk (1832–1922) was more successful. He experimented with different techniques, and found waxed negatives most effective as they did not require the distilled water the expedition lacked. Kirk's subjects were chiefly buildings, boats, and vegetation. The Royal Geographic Society in London holds stereoscopes made in Zanzibar by James Augustus Grant (1827–1892) during John Hanning Speke's (1827–1864) Nile expedition from the island, through Uganda, to Gondokoro (Sudan) between 1860 and 1863. Grant's photographs show the British Consulate staff and buildings, slave markets, emancipated slaves and other local people. However, he appears to have abandoned photography in favour of coloured sketches once on the mainland.

Expedition and travel photography was beset by numerous difficulties. Transportation of all the necessary equipment, including a large and cumbersome camera, chemicals, plates and dark-room facilities, proved problematic in a climate and conditions which foreigner travellers found inhospitable. The intensity of the African sun, which the French publication *Moniteur Universal* had presumed as early as the 14th January 1839, would give instantaneous, sharp daguerrian images, caused over-exposure of plates. Camera and tripod were unbalanced by strong winds. Heat and dust played havoc with wet collodion. Dirty water deposited a film of mud and sand on developed plates, which were further damaged by the humidity. Processing had to be done at night, in the usually stifling and malodorous environment of a wagon covered by blankets and skins. Not only problems of a technical nature were encountered. Wild animals terrorised travellers. Diary entries also recount the reluctance and sometimes refusal of Africans to be photographed. Unlike their littoral counterparts, who had been photographed and practised photography from the 1840s, inhabitants of localities little visited by Europeans were understandably suspicious and sometimes fearful of the camera. That this was not always the case is exemplified by Thomas Baines' humorous diary entry for July 1862. He recounts a chieftain situated near Lake

Ngami refusing to be photographed because he was not suitably attired and bartering his consent for items of the explorer's clothing.

Since the 1798 publication and subsequent translation of Scottish explorer Mungo Park's (1771–1806) best-selling book about his travels on the Gambia River, the courageous adventurer had become a familiar and romantic figure in nineteenth-century European popular imagination. From the late 1870s travellers capitalised on this existing taste for tales of the 'Interior' by publishing photographically illustrated personal accounts and memoirs in books, contemporary newspapers and magazines. Henry Morton Stanley's (1841–1904) photographs from his second Central African expedition of 1874, which were probably the earliest produced by the dry-plate process in sub-Saharan Africa, contributed to the illustration of his *Through the Dark Continent* (1878).

Photography was also employed by the numerous missionaries who came to Africa. Taking advantage of local unfamiliarity with the technology, they made show-like photographic demonstrations to impress and gain influence in often volatile political climates. In 1862 William Ellis (1794–1872) of the London Missionary Society and author of the photographically illustrated *Three Visits to Madagascar* (1858) was embroiled in a political scandal surrounding the attempted assassination of the island's King Radama II. Another British missionary Henry Aaron Stern's (1820–1885) *Wanderings Among the Falashas in Abyssinia* (1862), an account of his conversion of Jewish Ethiopians illustrated by his photographs of the country and its people offended Emperor Theodore II (1818–1868) during a critical period for Anglo-Ethiopian relations. In 1863 Stern was arrested, beaten and imprisoned at Gondar and later Magdala.

Photography also served missionaries as a teaching and conversion aid. Lantern-slide shows of photographic images, created or borrowed by missionaries, were used to demonstrate the benefits of conversion and to teach biblical, moral and other educational stories. Shows were even used to compete with and distract from 'heathen' activities such as tribal dancing. Publicity, support and fund-raising for their missions in Europe were furthered by juxtaposed, staged photographs of naked and dirty, clothed and orderly 'natives' before and after conversion. Missionaries also contributed to the dissemination of photography on the continent by passing on their techniques and equipment to African assistants and friends. German administrator, Heinrich Klose, recorded teaching Meppo, a young Togolese boy to develop film in 1897.

Photography was also employed for ethnographic studies. The founding of Ethnological Society of London in 1843 was symptomatic of a growth in European interest in human races and their classification through the study of distinguishing external features and inherent characteristics. In Africa and elsewhere travellers and missionaries photographed native people to provide 'scientific' proof for the emergent disciplines of anthropology and ethnography. In 1866 the Royal Geographical Society, London appointed photographer and travel writer John Thomson (1837–1921) to instruct explorers in photography to improve the accuracy and professionalism of their visual records. Three years later the British Colonial Office ordered governors to collect and send to London photographs documenting the empire's various native races. Travellers took bust and full-length photographs in profile, back and front of nude indigenous people. French explorer and archaeologist Claude-Joseph- Désiré Charnay (1828–1915) produced a study in this style of the ethnically mixed population of Reunion in 1863, which is now held in the island's Natural History Museum. In Hamburg between 1873–1874, Carl Dammann (died 1874) gathered images of peoples of the world, sent by missionaries and travellers. Portfolios like Dammann's *Anthropologisch-Ethnologisches Album in Photographien* (1873–1876), organised portraits according to nationality and race and presented them in a grid-like chart that facilitated pseudo-scientific observations of 'racial' characteristics and the creation of taxonomies of ethnographic types. European categorization of 'natives' conveniently justified their subjection to authoritarian and colonial powers.

Photography was integrated into colonial administration, both aiding and documenting European expansion in sub-Saharan Africa. Applied to surveying, map-making and the reproduction of plans, it greatly increased European knowledge of the terrains into which they ventured. The usefulness of the medium for recording military operations was recognised early on in Britain where the War Department appointed Charles Thurston-Thompson (1816–1868)), Superintendent of Photography at the South Kensington (later Victoria and Albert) Museum, to train the Royal Engineers in photography in 1856. During the Abyssinian Expedition of 1868, they photographed their camp, soldiers and their activities along the 400 mile journey inland from Zula, Eritrea to the mountain citadel Magdala. The photographs are in the Victoria and Albert Museum, London. The Anglo-Zulu wars of 1879–1884 and the British expedition to Benin in 1897 were also documented. George T. Ferneyhough, who was the first non-military professional photographer to accompany the British troops in the field, covered the Anglo-Zulu wars and published his work in an album of views. War photojournalists corresponding for newspapers were rare until the early twentieth century. Filippo Ledru, who reported the Italian landing in Massawa in 1885 was one early exception.

Photographers were employed to record engineering feats, such as the building of railways, roads and bridges, symbols of the civilising effects of the colonial endeavour. In the 1880s Cape Railways employed T.D. Ravenscroft. In the late 1890s William D. Young, official photographer for Ugandan railway, covered the construction of the Mombasa-Kampala line. From the 1880s publication of photographic albums of these infrastructural projects, such as J.A. da Cunha Moraes' *Africa Occidental* (1885–88), Robert Harris' *South Africa Illustrated* (1888) and *The Queen's Empire* (1897), increased. They depicted an idealized picture of the European presence in Africa to garner support for the colonial agenda at home. Colonial administrators also used photography to check and control native populations subjected to their rule. As early as the 1860s partners Acly and Lecorgne took identity photographs of African, Indian and Chinese immigrants disembarking at Mauritius point of arrival, Coolie Ghat, for the island's government.

Taking pictures as a hobby was popularised by the introduction of dry-plates and small hand-held cameras in the 1880s. Enthusiastic amateur photographers, including women, formed camera clubs, creating a forum for the exchange of information, advice and aesthetic ideas which they gained from the increasing number and range of photographic journals published. In sub-Saharan Africa, the first camera club meeting was held in Kimberley, South Africa in 1890. Contacts with the club movement in Britain were formed. Sir Benjamin Stone (1838–1914), President of the Birmingham Photographic Society, addressed the Cape Town Photographic Society in 1894. Previously, in 1882 a member of that club, C. Ray Woods, was the first in South Africa join the Royal Photographic Society in 1882. The clubs acquired premises with studio and dark-room facilities, exchanged prints and lantern slides, organised outings and participated in competitions. From 1896 a national salon organised by the Cape Town Society became an annual event. By 1895 there were in total eleven photographic societies in South Africa and just two elsewhere in the continent, at Constantine and Oran, Algeria.

In comparison with photographs taken by colonial officials, scientists and amateurs, commercial photographers catering for a European market for travel photography that had greatly expanded by the 1880s, created less authentic images of Africa and its peoples. Large photographic companies operating in sub-Saharan Africa, such as Naretti (Abyssinia), Lazarus (Mozambique) and Harris (South Africa), produced appealing, saleable photographs by carefully staging subjects to adopt certain poses and wear 'typical' clothes and ornaments. Their manipulated representations contributed further to a stereotype of Africa and Africans. In the nineteenth-century photography's relation to sub-Saharan Africa was predominantly as a transmitter to the outside world of a view of the continent that was anything but unbiased and informs prejudices to this day.

AFRICA, NORTH

Photography in the countries of North Africa—present day Algeria, Morocco, Tunisia, Syria, and Libya—may logically be considered separately from photographic practice in the Near East—the Holy Land and Egypt—in the nineteenth century. The number of visitors to Egypt and the Holy Land—initially explorers and antiquarians, followed by travelers extending the Grand Tour, and ultimately tourists lured by package tours and a highly developed tourism industry—accelerated and amplified photographic activities in those areas. Other regions of North Africa experienced the arrival of photography in the hands of European travelers and the subsequent establishment of indigenous commercial photographic studios at different paces.

The earliest photographers of North Africa were motivated primarily by the documentary interests of architects, antiquarians, and archaeologists who focused initially on Greco/Roman ruins. The site of Baalbek in present day Lebanon was photographed frequently by visitors and commercial photographers; a list that begins with Joly de Lotbiniere (1839) and Gerault de Prangey (1842), followed in short order by Maxime DuCamp (1850), and later commercial photographers such as the Bonfils Studio. Lerebours' *Excursions Daguerriennes* (1841–44), the first book with engravings

from daguerreotypes included views of Algiers, Beirut, Damascus, and Baalbek.

For the French, an interest in the architectural patrimony of France begun under the Commission for Historic Monuments and photographed by the *Missions Heliographique* extended to expeditions to document the remains of the line of castles built by the Frankish Kingdoms following the Crusades. In 1859-60, and on a second journey (1862–63), Louis De Clercq (1836–1901) accompanied historian Emmanuel-Guilluame Rey and photographed Crusader castles in present day Syria, Lebanon, and Libya. His work is contained in six albums of 222 photographs, entitled "Voyage en Orient," which also included volumes devoted to Egypt, Jerusalem and Palestine, and Spain. As part of his multi-volume studies of architecture, Pierre Tremaux photographed throughout Asia Minor and North Africa including Tunis and Tripoli. In Aleppo, Albert Poche (1842–1930) photographed archaeological sites, the castles of the Crusaders, and ancient Christian churches from Aleppo and northern Syria. By the 1860s there were a number of photographic studios in Beirut and Damascus. The Bonfils studio (1867–1918) in Beirut was responsible for one of largest bodies of photography of the Near East including North Africa. Georges Saboungi established a Beirut studio in 1863 and published technical papers and manuals in Arabic. And Suleiman Hakim's studio in Damascus in the 1870s produced both tourist views and portraits.

The French colony of Algeria—the north came under French domination in1830 and the French extended control to the south in the following decades—and its capital city Algiers, only a day's journey from Marseilles, received large numbers of colonial administrators and visitors. Photographers documented the colonial apparatus, as well as archaeological sites. Delamotte and Alary made daguerreotypes of Meddea and Biskra in 1850. The young photographer and archaeologist John B. Greene photographed in Constantine and accompanied an 1856 expedition to excavate the ancient tumulus tomb known as the Tomb of the Christian. He made a series of photographs that thoroughly documented the mound prior to its excavation. The Parisian commercial photographer Felix Moulin, visiting Algeria at the same time, reportedly made photographs with the expedition, although those photographs have yet to be found. Moulin placed in commercial release a number of photographs which documented the colonial presence in Algeria, scenes from Bedouin life, and a number of erotically charged photographs of dancing girls that answered an avid market for Orientalist fantasies of the harem. The latter continued the subject and treatment of photographs that he had staged in his Parisian studio and offered as studies to artists. Charles Marville (1816–1880), after completing the commission to document the changes to Paris under Baron Haussman, photographed the colonial and urban fabric of Algeria.

The erotic fantasies of the Orient supplied by Moulin were elaborated by local studios later in the century and can be read as a statement of colonial control. Malek Alloula's (1986) critical study of the cabinet cards and later postcards that constituted an entire class of colonialist images in Algeria is a landmark in post-colonial studies. Alloula's work examined the vernacular images of semi-nude, erotically posed Algerian women within the context of colonial systems of power and control. The hundreds of photographs in circulation from the 1880s on indicate they number of commercial studios participating in their creation.

Extensive photography in Tunisia, Morocco, and Libya was delayed relative to that in Algeria or the coastal regions. Tunisia was generally considered an extension of Algeria, although without a French garrison stationed there until late in the century it was considered less stable and thus was visited less frequently by the casual traveler. A full-blown trade in images for tourists, as exemplified by the volume of views of Tunisia published by Cairo booksellers Lehnert and Landrock, *Picturesque North Africa*, 1900, did not emerge until the end of the century. Morocco, more closely associated with Spain than France, also emerged as a photographic site late in the 19th century. Moroccan views were frequently appended to collections of views of Moorish Spain, such as those by August Jacob Lorent. The photography of Libya followed a bifurcated path. The great Greco-Roman ruins near Tripoli—Leptis Magna and Sabratha—were frequently included in the itinerary of archaeologist/photographers, De Clerqc for example, but exploration further inland was limited. The first major expeditions to be photographed were those made by of Gerhard Rohlfs. A 1869 expedition along the Libyan littoral was photographed by Emil Salingre. Rohlfs himself photographed the 1873–74 expedition to which traveled between oases in the Libyan Desert (*Drei Monate in der Libyschen Wuste*, 1876). The occupation of Libya by Italian forces at the beginning of the twehtieth century provided the impetus for the first major photographic survey and archive of Libya accomplished by Luca Comerio (1878–1940).

AGFA

AGFA is the acronym of "Aktiengesellschaft fuer Anilinfabrikation" (stock corporation for anilin fabrication) composed at the union of two chemical companies in 1873: The chemical corporation Dr. Jordan in Berlin which produced potassium ferricyanide since 1850, and the "Society for Anilin Fabricates" founded by Carl A. Martius and Paul Mendelsohn-Bartholdy in 1867, as well in Berlin. The acronym was not in use before 1897 when it was made a trademark with the logo that lasted to the very end of the company in 2005. AGFA's photographic history began in 1887 with the installation of a photographic department under Dr. Momme Andresen, a chemist who gained three patents on developping agents within four years: in 1888 for Para-phenylene-diamine, in 1889 for Eikonogen, and in 1891 for Paramidophenol. The same year 1891 saw three more patents for Andresen and the company, and it marked the beginning of the production of "Rodinal," a developper in practical use for more than a century. In 1892, the company and Andresen launched the first fixing agent that only had to be dissolved in water. The instant success of all these substances instigated the company's concentration on photographic materials, and in 1893, Momme Andresen succeeded in establishing the production of dry plates. In 1895, these plates were undergoing substantial development by the addition of an anti-halation layer after a patent by Otto Magerstaedt. The "Isolar" plate was such a success that the final AGFA acronym and logo had to be launched in 1897, a year before the production of celluloid-based films was started. By 1899 the AGFA was able to offer roll films in sufficient lengths for film productions. The production of film rolls brought AGFA into competition with Eastman Kodak and the Lumière brothers but the production quality suffered from the steam of a nearby railroad line in Berlin; several areas were tested until the final move of the company to Wolfen in 1909. By this time the production of synthetic colours for which AGFA had been founded was completely abandonded.

In 1896, the optician A. Heinrich Rietzschel founded a manufacturing company for optical devices in Munich; in 1900, it began to produce cheap cameras for amateurs. In 1921, this company was bought by the "Chemical Company hitherto known as Friedrich Bayer" in Leverkusen which had installed its own production line in photographic films and papers by taking over Eduard Liesegang's establishment in Dusseldorf in 1904. With the installation of "I.G. Farben" (Industrial Society in Colours) as the union of Bayer, BASF, and others chemical companies, AGFA was made the prime photographic branch of this group; Rietzschel began to market its cameras under the AGFA branding in 1927. Between 1927 and 1945, AGFA was the biggest photographic manufacturer in Germany. With the destruction of "I.G. Farben" in 1945, AGFA was made a company of its own, to be united in 1964 with the Gevaert holding, set up in Antwerp in 1894 by Lieven Gevaert; at the same time the Perutz company was made part of the new holding and seized to exist as a trademark of its own.

AGNEW, THOMAS AND SONS

English art dealer, publisher, and patron

The Agnews were well established Manchester art dealers and print publishers long before their involvement with Roger Fenton and the photography of the Crimean War. The company regularly commissioned work from the leading artists of the day. Examples included the Lake District artist J.B. Pyne in 1853 and the Crimean War artist Thomas Jones Barker in 1855.

William Agnew (later Sir William) was already acquainted with Fenton when the idea of sending a photographer to the war was first mooted, the art dealers became involved in the project because they could see the commercial potential of such a series of images. Agnew's decision to engage Fenton pre-dates the often-quoted reports by William Howard Russell which had caused considerable disquiet when published in the *Times* in November and December 1854. Agnew's investment in the project was considerable, and due to the time taken to publish the works after the war, their return was limited.

In September 1855, the works were exhibited at London's Water Colour Society, and William Agnew and Fenton travelled to Osborne to present a set of prints to Queen Victoria and Prince Albert, and to St. Cloud, Paris to show them to Napoleon III. In 1858, the Agnews published albums of photographs by Caldesi and Montecchi

of the Manchester Art Treasures Exhibition of 1857, in collaboration with P&D Colnaghi.

AGUADO DE LAS MARISMAS, COMTE OLYMPE-CLEMENTE-ALEXANDRE-AUGUSTE (1827–1894) AND VICOMTE ONESIPE-GONSALVE (1830–1893)

The brothers, Olympe and Onésipe Aguado de las Marismas epitomize the body of amateur enthusiasts in the early 1850s who reveled in exploring the potential of photography. Of the two brothers, Olympe was without question the one who was most involved. Their father, Alexandre Aguado, marquis de Las Marismas del Guadalquivir, born in Spain, had become one of the richest bankers of aristocratic Paris and one of the figures of the Restoration and the monarchy of July. After having fought the Napoleonean armies, he left Spain to emigrate to France and was naturalized in 1828. About 1810, he married Maria de Carmen Victoire Moreno, Spanish like him. They had three sons: Alexandre, Olympe and Onésipe. Olympe Clémente Alexandre Auguste Aguado was born on February 3, 1827 in Paris and his younger brother Onésipe on May 9, 1830 in Evry. With the death of their father in 1842, a considerable fortune as well as many vacation resorts were bequeathed to the three sons. The life of Olympe Aguado, like that of his brother Onésipe, was divided between socialite activities, family intimacy and photography.

The reasons that pushed Olympe, and to a lesser extent his brother Onsésipe, whose activity was much more limited, to practice photography were, as was the case very often within the confines of noncommercial practice, difficult to define. A favorite recreation of distinguished and wealthy people, photography became for Olympe an occasion to affirm the artistic sensitivity acquired from father. According to surviving records from 1848–49. Olympe Aguado was introduced to photography at the same time as Vicomte Joseph Vigier, and like many amateurs in paris at the time, learned the rudiments of photography from Gustave le Gray.

Aguado's beginnings as a photographer remain associated with the daguerreotype, however there is only one plate testifying that he used this process [*Intérieur d'un hôtel particulier*—Paris, Société Francaise de Photographie]. According to the testimonies provided by the critic Ernest Lacan, others' works cunducted using the daguerreotype attest to the beginnings of a regular and varied practice. Parallel to the use of the daguerreotype, it seems that in 1850 Aguado attempted the new technique of negative paper as shown in *Composition avec outils de jardinage* (Composition of youth with tools for gardening) which is preserved at the Getty Museum

in Los Angeles. Lastly, probably around 1850 or 1851, Aguado practiced collodion on glass specifically adapted for portraits and instantaneous photographs. Olympe Aguado had rather quickly acquired the knowledge of the principal through varied practice. Olympe Aguado's production increased significantly from 1853–1854. In addition to the two principal techniques that he used, negative paper for the landscapes, and collodion on glass for portraits and images of the like, he increased the frequency of his technical experiments, and regular exposures as part of being an active emmber in the new Société Française de Photographie.

One of the least-known aspects of the career of Olympe Aguado is without doubt, the role of experimentation that he had with the emergence of new photographic processes. It is indeed he who, in 1854 and in the company of Edouard Delessert, developed the invention of the carte-de-visite, which was eventually patented the same year by Eugene Disderi. In the carte-de-visite format, Olympe Aguado even created a certain number of self-portraits along with portraits of his close relatives and an imperial couple, as well as various indoor scenes. According to writings of the time, he was also involved in some of the first attempts at photographic enlargement in which he carried out some spectacular images; unfortunately there remain no known examples to date. He also had an important role to play in the formation of

the Société Française de Photographie, which he joined in 1854 as a founding member.

What has reached us of the photographic production of the two Agaudo brothers is, as in many cases, certainly quite less than all they produced. The diversity of the results is, however, enough to measure the extent of the subjects they confronted: deserted interiors, studies of trees, pastoral scenes, dramatized portraits and vibrant scenes, reproductions of works of art, and lastly snapshots of sailboats. It is difficult to determine chronologically the list of these images. It is believed though, that they were taken simultaneously at meetings and other places in one or around their many properties throughout Frances territories. Regarding the diversity of the subjects in these images, it is necessary to emphasize the two brothers' originality as undeniably expressed in these images.

A series of portraits is for this reason exemplary. From the years 1852–1853 the two brothers arranged a workshop in their apartment in the Place Vendôme in Paris where they carried out a series of portraits in front of painted canvasses, anticipating the use of decorative elements which would dawn on the Parisian commercial studios under the Second Empire. In 1853, parallel to the series of portraits, Olympe Aguado launched out in an important series of scenes that he carried out for the most part on his property of Grossouvre, located in the county of Cher. Among them were images of farm animals, but also of scenes of carts and cattle drivers copied on the compositions of animals that can be found at the same time in works by painters like Constant Troyon or Rosa Bonheur. During this period, Aguado started his studies of trees, underbrush and edges of rivers which he continued throughout the 1850s. On this occasion he is revealed as one of the more enlightened landscape photographers of his generation, drawing still from the pictorial model the sources of its compositions. But the originality which, without question, distinguishes the Aguado brothers from the remainder of their contemporaries, appears in the few surviving images that they created at the end of their photographic careers, at the end of the 1860's. By subtle staging the Aguado brothers regulated all the details and they reconstituted, with the assistance of characters, a series of fascinating images of their family. Thus *Admiration!* [Musé d'Art moderne et contemporain de Strasbourg] with aspects of *La Lecture* [Musée d'Orsay], *Jeu de Solitaire* [private collection] or even *L'album de photographies* [collection Maurice Dussartre, Paris] form an elegant but bitter criticism of the mores of the Second Empire which falls under the tradition of the visual satires of middle-class problems then in vogue in the French press, or the caricatures of Honore Daumier.

The mid-1860s marks the end of the photographic career of the two brothers. The Getty museum has preserved an album from 1866 in which appear a certain number of small prints in albumen attributed to Olympe and Onésipe and whose subjects—small pastoral scenes carried out in the family circle—announce the formal vocabulary of instantaneous photography. Undoubtedly the multiplication of the regular commercial practices of photography and the renewal of occasional photographers are not inconsistent with the gradual disinterest of the two brothers in a practice that they approached in an indifferent way and outside of any normative prescriptive framework. The younger brother, Onésipe, died in Paris on May 19, 1893, followed one year later by Olympe who died in Compiegne on October 25, 1894.

AHRENDTS, LEOPOLD (1825–1870)

German photographer

Leopold Ahrendts, born Friedrich Leopold in Dessau on 16 June 1825 to master plumber and subsequent factory owner Leopold Friedrich Heinrich Ahrendts and his wife Caroline, worked first as a painter and lithographer in Dessau, before moving to Berlin around 1850 where he presented lithographs at the Academy of Arts Exhibitions of 1850 and 1852. In 1856 he began work at the portrait studio of court photographer Philipp Graff's widow, a studio later acquired by August Beer. Ahrendts is best known for his photographs of Berlin views and architecture. He also documented the urban transformation in events like the laying of the foundation stone of Berlin's Town Hall on 10 June 1861. In 1865 he exhibited his city views at the "Erste Internationale Photographische Ausstellung" [First International Photographic Exhibition] under the name of the Graff Studio, for which he continued to work until his death on 19 March 1870. His photographic work is preserved in a portfolio "Berliner Ansichten" [Berlin views] in the Berlin Staatsbibliothek, in the Stiftung Stadtmuseum Berlin and in the Berlinische Galerie Photographic Collection.

Stephanie Klamm

ALBUMEN PRINT

Albumen printing paper was the medium of choice for the majority of photographic printers for more than thirty years following its introduction in the mid 1850s.

Showing exceptionally fine detail and the longest tonal range of nineteenth century processes, albumen dominated the field until the rise of emulsion-type gelatin and collodion papers from the late 1880s. Because of its unique qualities, however, it remained in widespread use until the closing years of the century.

The use of albumen in photography can be traced to the anonymous 'H.L.' who proposed the method in the May 1839 issue of *Mechanics Magazine*, but never provided further details. The man generally credited with the invention is Abel Niépce de Saint-Victor, who conceived the idea of making photographs on glass and reported his experiments in *Comptes Rendus* in June 1848. His albumen on glass negative process offered very fine detail, but a sensitivity which imposed long exposures on its users and thus restricted its use.

Searching for improvements to the salt-paper printing process, where the image was carried within the upper thickness of the paper, Louis-Désire Blanquart-Evrard added chlorides to albumen thus containing the light sensitive chemistry within a surface coating, a major factor in the fineness of detail for which then paper became renowned. The coating of albumen also helped protect the silver salts from the corrosive effects of air, and was believed to offer the potential of great stability for a correctly processed print than offered by the salt-paper process. In fact the effect of residual sulphur in the egg-white actually left the untoned albumen print more prone to discolouration and fading.

Blanquart-Evrard presented his discovery to the French Academy of Sciences on 27 May 1850. In 1851 he opened a printing company in Lille for the mass production of photographic prints, a mechanisation not possible with comparatively fragile salted-paper.

At this time the majority of prints were exposed until the image reached the required density by the action of light alone, before being fixed, washed and dried —a very slow process. Blanquart-Evrard's technique of developing prints instead of the conventional printing out process led to a much faster output of prints. Photographers were quick to try out this new method for positive prints and it became an almost instant success. Edouard Baldus and Roger Fenton, amongst others, found the sharp definition of albumen paper to be ideal for architectural photography.

Blanquart-Evrard's original formula for the preparation of albumen paper was white of egg beaten to froth with 25 per cent by weight of a saturated salt solution. The mixture was allowed to settle overnight. A sheet of paper was then immersed in the solution. The dried paper was not light sensitive and would keep indefinitely in the albumenized condition.

After drying, the albumenized sheet was sensitized to light by being immersed in or brushed with a silver nitrate solution. The paper was then exposed to sunlight

Emonds, Pierre. Maison, rue Saint-Paul.

for several minutes or hours—the length of exposure depending upon whether the print would subsequently be developed or not. The resulting image was rinsed, usually toned with gold, fixed, and then rinsed again. If the prints were not completely divested of their salt fixing agent, sodium-thiosulphate, they were very likely to fade or bleach out.

Since silver prints are extremely sensitive to any chemistry that includes sulphur or its compounds, exposure to the sulphurous atmosphere of industrialized cities in the 1850s and 1860s was potentially damaging to the photographs. In May 1855, the Photographic Society of London (later to be the Royal Photographic Society) established a committee to examine the fading of positive prints. The results of the investigation cited sulphur and moisture as the prime causes of photographic fading but claimed that proper care and conservation could make silver prints last indefinitely.

The earliest albumen prints appeared reddish brown or chocolate brown in color, while later ones are usually warm brown, purplish brown, purple, or purplish black. Approximately 85 percent of prints show some readily noticeable yellow stain in the whites and highlighted areas. The presence of highlight yellowing and

characteristic surface texture are two of the most readily apparent and reliable indicators that a given print is an albumen print. Another indication of albumenized paper is a surface texture that may possess a "crackled" appearance. Prints of the period 1850–1870 are usually less glossy than those of the period 1870–1890 because of the use of burnishing and rolling machines to smooth the prints after mounting and the increased use after 1870 of double-coated paper. A very large percentage of the albumen paper produced during the period 1870–1900 was tinted various shades of pink, purple, and blue by adding aniline dyes to the albumen before coating it on the raw stock. The first such paper appeared on the market in 1863 and attained great popularity in the 1870s and 1880s. Tinted paper was mainly used for portraits and pink was the most popular shade. Because the dyes used had poor stability to light, most of the dyed paper is difficult to recognize today. In some cases, although nothing remains of the original tint, a peculiar buff or chamois coat identifies albumen prints originally made on tinted paper.

Albumen became a favored process because it produced a glossy print and many photographers experimented with the procedure to yield an even shinier image. Many experimenters discovered that partially decomposed albumen yielded a glossier and more even coating. Decomposed albumen passes into an acid condition and forms a homogenous mixture without the uneven viscosity and stringiness of egg white. Some albumenizers went so far as to actually allow the albumen to naturally ferment at elevated temperatures for several days to achieve the desired effect. This technique later became standard practice in the Dresden, Germany factories which, beginning in the early 1870s, supplied the majority of the world's albumen paper.

Close to the sources of raw stock and enjoying an abundant supply of low-cost eggs, Dresden Germany became the center of world production by 1870 because it also had the advantage of lower labor costs than English or American competitors. The procedure of albumenizing paper began with the freshest available eggs—only clear white was saved without slightest contamination from the yolk, blood, or stringy tissue known as the chalazae. The whites were heated to froth with the approximate amount of ammonium or sodium chloride (ammonium chloride was most commonly used in the nineteenth century). The amount of chloride used had a definite relation to the sensitivity and to a small extent the contrast of the paper. Papers with a low (1-1.5 per cent) chloride content showed less sensitivity.

Workers, generally women, would fill a tray to a depth of approximately two-thirds to three-quarters of an inch with the albumen solution and float the paper on the surface for 1 and a half minutes. Only one side of the paper would be coated before drying and, if dried quickly at a high temperature, the result would be glossy. In the nineteenth century, temperatures of 30–50 degrees Celsius were maintained. The sensitized and dried sheets of albumen paper were then hung in a closed box and subjected to the vapors of ammonia. The fumes were supplied by placing strong ammonia in a dish in the bottom of the box. The process continued for 5–10 minutes and its purpose was to make the paper more sensitive and to obtain richer, more brilliant prints. Although fuming formed a common part of the American process, it was rare in Germany. Tedious to produce and slow to develop, albumen paper disappeared as a commercial article in 1929.

ALEXANDRA, QUEEN (1844–1924)
English photographer

Queen Alexandra of England, christened Alexandra Caroline Marie Charlotte Louise Julia Oldenburg, was born on December 1, 1844 in Copenhagen to Prince and Princess Christian of Glucksburg. She married the Prince of Wales on March 10, 1863. Her parents acceded to the throne of Denmark as King and Queen Christian IX later that same year. At this time, Princess Alexandra became involved in charity work and philanthropy in Britain and also began to take photographs. Her pictures were first exhibited at a Kodak exhibition in London in 1897, and she later participated in two more exhibitions at Kodak Galleries. After her husband was crowned King Edward VII in 1902, the Daily Telegraph of London published *Queen Alexandra's Christmas Gift Book, Photographs from My Camera* (1908). The book included 136 snapshots taken, selected and captioned by the Queen herself. It presented the public with informal

pictures of the Royal Family and photographs from the Queen's travels. The majority of the photographs were taken in England, Denmark, Greece and Norway. Proceeds were donated to over thirty different charities. Queen Alexandra died on November 20, 1924, fourteen years after the death of her husband, and was survived by four of their five children.

ANDREA KORDA

ALINARI, FRATELLI

Italian firm operating since 1854 to the present day

The firm of Alinari Bros was founded at Florence in 1854 by the brothers Leopoldo (1832–1865), Giuseppe (1836–1890), and Romualdo (1830–1890). Leopoldo had already been working for a number of years as an apprentice of the chalcographer Luigi Bardi. In the first half of the nineteenth century Bardi's firm had produced photographic views of Florence in addition to the traditional copper engravings. These were the years in which copper engraving was giving way to photography, which was cheaper and therefore more accessible. Bardi's views bore the blankstamp "Luigi Bardi Firenze," and today they are attributed to Leopoldo Alinari, who learnt his photographic technique from Bardi. Some of Leopoldo's views were printed in Eugène Piot's *L'Italie monumentale*, which was published in Paris in 1851. Bardi continued to encourage Leopoldo and got him to open a shop next-door to his in Via Cornina (today Via del Trebbio) at Florence, to sell pictures to tourists. From 1854 onwards the pictures sold in Leopoldo's shop bore the stamp "Fratelli Alinari/Fotografi/Firenze/presso Luigi Bardi" (Alinari Bros/Photographs/Florence/near Luigi Bardi's), a sign of Leopoldo's continuing collaboration with Bardi.

Later Leopoldo was to have the main part in the organization of the firm and in deciding its cultural policies; Giuseppe supervised the technical aspects, and Romualdo was involved in the administration. The first known printed catalogue, printed in French in 1856 (*Collection des Vues Monumentales de la Toscane en Photographie par les Frères Alinari*, Florence, Louis Bardi, Avril 1856) shows that initially production was concentrated on views of monuments and panoramas of cities in Tuscany, in particular of Florence, Pisa, Siena and Arezzo. Some of these views were exhibited at the Exposition Universelle, Paris, in 1855, where the Alinaris won second prize and thus qualified as one of the important firms of photographers in Europe. In an exhibition at Brussels in 1856 they won the gold medal.

For the negatives they used the collodion process. They devoted their attention to portraits and, from 1858, specialized in reproductions of works of art, achieving excellent results. Their first photographic campaign in this area was in 1858 and it concentrated on fifty drawings in the Uffizi at Florence . The photographs made a great impression and were praised by eminent scholars including John Ruskin. He extolled their descriptive clarity and precision, qualities which thenceforth were the unmistakable hallmarks of Alinari production. In the same year Queen Victoria's husband Prince Albert commissioned the Alinaris to reproduce Raphael's designs in the Accademia di Venezia and in the private collection of Archduke Karl in Vienna. These three pieces of work were greatly admired, and Luigi Bardi published them in a single volume (*Disegni di Raffaello e d'altri maestri esistenti nelle gallerie di Firenze, Venezia, e Vienna riprodotti in fotografia dai Fratelli Alinari*) (*The drawings of Raphael and other maestri in the galleries of Florence, Venice, and Vienna photographically reproduced by Alinari Bros*). Of these three enterprises there remain today some negatives in the Alinari archives at Florence, and these, together with some family portraits, form the oldest nucleus of the firm's photographs that exists today. In 1861 the Alinaris took part in the Esposizione Italiana, Firenze, showing views and portraits of the royal family. By now the Alinaris' fame was such that they had been invited

to photograph the ruling house of Italy. In 1863 they opened a new shop in Via Nazionale 8 (today Largo Fratelli Alinari) and, when Florence became the capital of Italy, in 1865, their business grew.

Leopoldo died on the 9th of November 1865, and the firm carried on under Giuseppe and Romualdo. In September 1865 the *Catalogo generale delle fotografie pubblicate dai Fratelli Alinari di Firenze* (*General Catalogue of the Photographs published by Alinari Bros of Florence*) came out, and it included reproductions of drawings of the Uffizi, Venice and Vienna in different formats, stereoscopic views and portraits. The firm specialized in the production of negatives on large-sized glass plates, up to 105 by 76 cms. In 1873 a new catalogue came out with variations and additions, in which were mentioned the main shop in Via Nazionale, the new depositories in Via dei Tornabuoni 20 and the premises which had been opened in Rome, in Via del Corso 90. The firm had a well-organized plan for the photographic documentation of the whole of Italy, with particular emphasis on art collections and the principal works of art. In Florence they took new photographs of the frescoes in the sacristy of San Miniato, and of those in the choir and sacristy of Santa Croce. Appendices to the 1873 catalogue came out in 1876, 1881 and 1887. In the appendix of 1881 it is stated that up to that moment the firm had produced 12,945 negatives, and had gradually replaced collodion negatives with gelatine ones. The firm obtained recognition at many exhibitions: Vienna 1873, Paris 1878, Milan 1881, Turin 1884. At the Exposition Universelle, Paris, in 1889, they won the gold medal.

In May 1889 the Società Fotografica Italiana was founded. From the beginning, also through its "*Bullettino*," it has been the means by which the state of photography in Italy can be assessed, and problems regarding photographers rights and copyrights of photographs can be sorted out. In February 1890 Vittorio Alinari (1859–1932), the son of Leopoldo, and his uncle Giuseppe joined the Society. Both became leaders in the debate about Italian photography, and the "*Bullettino*" of the Society published several of their articles and photographs.

In 1890 the brothers Giuseppe and Romualdo died within a short time of each other. Vittorio then took over the direction of the firm. Under him its photographic production was widened to include all aspects of the Italian countryside, costume, and life in the cities. They reorganized their material and replaced many old negatives with more recent ones; from 1892 all were renumbered. They also published tourist guides and volumes about art. In 1893 a new catalogue was devoted to Florence, Umbria, and Rome. In 1894 they published a work on Venice and the Veneto. In 1892 they photographed the frescoes in the Raphael rooms in the Vatican, for which they used isochromatic negatives. In 1899 they completed the set of photographs of the Sistine Chapel which they had started between 1876 and 1880. The extremely high quality they obtained, considering objectively the difficulties of execution, marks an important milestone in the firm's photography of works of art. The Alinaris now sold to a vast public, from the most eminent scholars, especially those of the history of art, to wealthy foreign tourists. In 1899 they also took part in an exhibition of the Società Fotografica Italiana at Florence. They expanded their portrait section, where the main specialist was Mario Nunes Vais (1856–1932). He was one of the few photographers of the firm to put his own initials on his photographs. He executed splendid portraits, which show great sensitivity in their composition, and some were published in the famous magazine *La Fotografia artistica*. From the beginning of the twentieth century, the firm expanded its colour section, and its photographs of works of art were highly praised for their quality and fidelity to the original.

After the death of his son Carlo in 1910 and the outbreak of the First World War, Vittorio reorganized the firm's activities. In 1920 he sold out to a group of Florentine businessmen whose head was Baron Luigi Ricasoli Firidolfi. The firm continued with new enterprises and changed its name to "Fratelli Alinari I. D. E. A. (Istituto di Edizioni Artistiche)" ("Alinari Bros I. D. E.A. Institute of Editions of Art"). Vittorio continued, however, with his photographic work, and opened a shop in Via Strozzi specializing in art publishing, the Vittorio Alinari editions. In 1921 he edited *Paesaggi Italici nella Divina Commedia* (*Italian Landscapes in the Divine Comedy*), printed by Giorgio and Piero Alinari. Many of the photographs in this book are the result of a long and dedicated research into the Italian countryside, which Vittorio had carried out in the previous years. These photographs contributed enormously to people's increased knowledge of the Italian countryside and Italian art, through the use of precise expressive codes deriving from the perspective of the Renascence.

Under the direction of Augusto Socci, in the twenties and thirties of the twentieth century, the firm grew and perfected its colour printing and collotypes, thanks also to the photographer Vincenzo Balocchi (1892–1975), who was in charge of the photomechanical division. In 1954 it celebrated its centenary and had branches in all the largest cities in Italy. It acquired the archives of important photographers such as Brogi, in 1958, and, in the sixties, Anderson, Chauffourier, and Fiorentini.

In 1985, on the firm's initiative, the Museo di Storia della Fotografia was opened in Palazzo Rucellai at Florence. In the eighties it acquired the archives of other famous photographers such as Lattuada, Wulz, Trombetta, von Gloeden, Michetti, Zannier, Balocchi, Van-

nucci Zauli. Today the Alinari archives are in Florence, Largo Alinari 15. Here are kept about 780,000 original photographs by Italian photographers and those of other nations, as well as old photographic equipment.

ALLEGORICAL PHOTOGRAPHY

The presence of a specifically allegorical photography in the nineteenth century has been the subject of a great deal of attention since the late 1970s, even if the aesthetic category of allegory has not always figured in the debates in question. Oscar Rejlander, Julia Margaret Cameron and, perhaps, William Lake Price produced self-consciously allegorical images; it has also been argued that, works by William Henry Fox Talbot, Louis-Jacques-Mandé Daguerre and Hippolyte Bayard are best understood allegorically.

Allegory is the subject of extensive theoretical debate and is not easy to define; nevertheless, two key features can be isolated for our purposes. Firstly allegory is a 'twice-told tale,' in which a literal, or explicit, level of representation is accompanied by a second, implicit, meaning. In order for there narrative content to be legible, allegorical images frequently require knowledge of some prior representation (the Bible, Romantic poetry, etc.). Secondly, allegory is typically contrasted with, another aesthetic category, the 'symbol': whereas symbols are said to convey meaning immediately, allegories unfold over time; the symbol is usually seen as an organic whole, whereas allegory contains a gap, or disjunction, between the literal depiction and the accompanying narrative; the symbol is clear and transparent, allegory is inherently ambiguous. These characteristics sometimes figure prominently in hostile accounts of staged photographs: reviewing submissions to an exhibition by Lake Price and Rejlander in 1856, Robert Hunt suggested: 'They are all wonderfully clever, but after all they are but images of actors posed for the occasion; they all want life, expression, passion...' (Hunt, 'Photographic Exhibitions'). Three years later, the poet and critic Charles Baudelaire made much the same point about French photography. These criticisms draw attention to the fissure between what is actually depicted and narrative allusions in the allegorical picture. The consideration of a particular image will, no doubt, help to put flesh on these bare bones: in Rejlander's double self-portrait: *Rejlander the Artist Introducing Rejlander the Volunteer* (c.1871) the artist at his easel gestures towards the same person wearing military uniform. Seeing the same man in two guises, we recognise that Rejlander was both artist and member of the volunteer movement. However, the literal presence of two Rejlanders is accompanied, at another level of reading, by the suggestion that artist and volunteer equally participate in patriotic defence of state and empire: the artist records and glorifies the deeds of the citizen-soldier, while embodying the values that require defending from the supposed barbarians. Here, the probable date of 1871 is highly significant (figuring as it does the Franco-Prussian war and the subsequent Paris Commune). As an allegorical image Rejlander's picture goes beyond a portrait of a particular man (in two forms), invoking the unity of the middle class in face of both foreign and domestic threat, as well as the solemn duty of the artist. The disjunction between the two characters mirrors the gap between literal and allegorical meaning.

Work of this type was anathema to modernist critics (from Helmut Gernsheim to John Szarkowski), because it went against what they saw as the inherent proper-

Fredericks, Charles DeForest. "Political Allegory with Flowers."

ties of the medium. However, the rise of 'postmodern' staged photography associated with Victor Burgin, Cindy Sherman, Jeff Wall and Olivier Richon has led to a revival of interest in this mode of work that, by the later nineteenth century seemed *retardataire*. During the 1980s and 1990s a number of writers argued that at least some early photographs needed to be viewed, not simply as plain transcriptions of things, but as densely textured reflections on the process of representation. Geoffrey Batchen, for example, has argued that Bayard's *Self-Portrait as a Drowned Man* (1840) should be seen as a meditation on his own marginalisation in photographic culture (Batchen, *Burning with Desire*). Carol Armstrong's feminist investigation of the work of Julia Margaret Cameron as an exploration of gendered identity is particularly significant, because, alongside the revival of staged photography from the 1970s, feminist scholarship played a crucial role in this revaluation of 'allegorical photography.' Feminist accounts, like that advanced by Armstrong, stress the performance of gender, arguing that the complex layering of meaning available in staged images enabled women to explore their own ambivalent relation to the cultural conventions of femininity (Armstrong, *Scenes in a Library*). Cameron's work obviously plays a leading role in these debates, but readings of decorative photographic albums complied by aristocratic and bourgeois women could equally figure as examples. Similarly, one account of F. Holland Day, articulated from the perspective of queer theory, puts the weight of interpretation on his coded departure from hetero-normative sexuality (Crump, 'Suffering the Ideal'). Mike Weaver's Christian reading of Talbot provides an account of allegory and photography, which stands as an exception to this theoretical trend. For Weaver, in *The Pencil of Nature*, Talbot produced self-conscious pictures in the emblematic tradition. According to him, *The Open Door* and *The Ladder* (both 1843) are to be understood, not only as everyday images of work at Lacock Abbey, but also as allegorical meditations on the soul's salvation, in which broom, lamp, ladder and doorway all carry long-established Christian connotations (Weaver, 'Henry Fox Talbot: Conversation Pieces').

However, there are problems with these accounts of allegorical photography, only two of which can be raised here. Firstly, it is not easy to distinguish between allegorical images and a photographic art of moralised genre. Whereas Rejlander's *The Two Ways of Life* (1857) and his picture discussed above are intentional allegorical pictures, many of his other photographs conform to the model of 'scenes from everyday life' common at the time. Similarly, while Henry Peach Robinson typically produced genre pictures, *Little Red Riding Hood* (1858) and *The Lady of Shalott* (1860–1) are most probably allegories. There is no stable or clear cut distinction between these aesthetic modes. This distinction is further complicated, because genre pictures can be read for implicit moral, or ideological, content—indeed, this is their point. In fact, almost any act of interpretation entails a second moment of reading in which the literal, or 'denotative,' depiction of things and events is complemented, or overlaid, by implied, or 'connotative,' associations. The second problem revolves around the question of anachronistic interpretation. recent critics often unreflexively project their own values back into the nineteenth century, attributing forms of their own self-consciousness to photographers for whom they were simply unavailable. This is to say, in much of the existing literature there is insufficient attention to the distinction between allegory (images intentionally designed to be read in two registers) and allegorisis (allegorical reading in which the critic generates the second interpretation). Allegorisis is an important critical method—particularly in debates relating to history and identity as they are being formulated at the beginning of the twenty-first century—but it is an approach that foregrounds the interpretive act rather than the initial context of production or first use. This important distinction is often, unhelpfully, elided in discussions of these photographs.

An alternative approach to nineteenth-century allegorical photography might entirely forego the arty, staged image and suggest, instead, that allegorical mean-

ing is to be found in the plain and ordinary image; in the mass of photographic documents and portraits. Images of this type may seem too immediate to be considered allegorically, but in other ways they directly relate to some of the classic features of the allegorical mode. Like allegory, these images are repeatedly described as 'mechanical,' whereas their counterpart, the staged picture, is usually viewed as an 'organic' composition (that is to say, the staged picture might be viewed as a symbol). Futhermore, it is evident that the central allegorical categories of time and death circulate around ordinary record photographs: images produced then, but, when looked at now, frequently induce a typically allegorical moment of melancholic reflection on the passing of time and the all-too transitory character of life.

ALLEN, FRANCES STEBBINS (1854–1941) AND MARY ELECTA (1858–1941)

American photographers

The two sisters Frances and Mary Allen, from Deerfield Massachusetts, took up photography in the 1880s after their careers in teaching were cut short by the onset of deafness. Their pictorial images earned them the accolade from one reviewer in 1901 of being numbered amongst "the foremost women photographers in America."

Although the height of their success came in the early years of the twentieth century, the sisters were exhibiting and selling their work by the 1890s—Washington 1896, Philadelphia 1900, Paris 1900, Chicago 1908—their subjects ranging from romantic images of the period buildings in their native Deerfield, to landscapes in the emerging pictorialist tradition, and romanticised groups of local people—especially children—at work and play, their subjects often dressing up in period costumes.

Drawing inspiration from the works of contemporary painters as well as photographers, the Allen sisters created a fine body of rich platinum prints which has, until very recently, been overlooked by historians.

The *Springfield Daily Republican* newspaper in 1901 reported that "The Misses Allen use their camera with the same spirit with which a painter uses his brush, and their sense of composition, of the dramatic moment, is as eminent a qualification for their art as for his."

A major collection of the sisters' delicate platinum prints is held by the Memorial Hall Museum in Deerfield, Massachusetts.

JOHN HANNAVY

ALMA-TADEMA, SIR LAWRENCE (1836–1912)

English patron

Born Lorens, or Laurens, Alma Tadema in Holland, Alma-Tadema as he became known in Britain, was one of the most prolific and successful artists of his day. He was knighted by Queen Victoria in 1899.

His huge output drew much of its inspiration from classical themes, and his work was purchased and exhibited widely.

He was not a photographer, and as far as can be ascertained, he never took a photograph—but he used photography extensively, having evolved, with Belgian photographer Joseph Dupont, a novel application for the medium. Alma-Tadema, concerned about the tonal relationships within his painting, collaborated with Dupont in making photographs of partially completed canvases. Alma-Tadema believed that the reduction of the full colour of the painting to the sepia hues of the

photograph allowed him to assess the composition's tonal balance. However, in 1866, the limited spectral sensitivity of Dupont's wet collodion plates produced a significant tonal distortion which we now know would seriously compromise the results. However, he is reputed to have carried out further work on canvases to improve whatever shortcomings he believed the photographs revealed. Undeterred, he is believed to have used this technique throughout his life.

A copy by Dupont of Alma-Tadema's painting *The Sculpture Gallery*, signed by the artist himself, survives as evidence of their experiments. Whether or not such photographs were offered for sale is unclear, but highly likely.

JOHN HANNAVY

ALOPHE, MENUT ALEXANDER (1812–1883)

French photographer, lithographer, and painter

A Parisian and student of both Camille Roqueplan and Paul Delaroche, Alophe epitomizes the mediocre painter turned commercial lithographer and photographer. From 1838 to 1879, he regularly exhibited paintings at the Salon (second class medal in 1847). A prolific lithographer, he created portraits and sentimental subjects for such publishers as Aubert, and Goupil or for magazines (*L'Artiste*).

Alophe took an interest in photography in 1856, eliciting lessons from Nadar and renting an apartment at 35, boulevard des Capucines, where Gustave Le Gray was already installed. Upon Le Gray's bankruptcy in 1860, Alophe occupied his studio (Nadar arrived in the building that same year). Alophe remained there until 1873, producing portraits and genre scenes in the same vein as his graphic work. He also copied some of Le Gray's portraits and sold them as cartes de visite. He moved to 25, rue Royale in 1874.

Alophe exhibited at the *Société Française de Photographie* (1859, 1861, 1863). Ernest Lacan found his portraits "remarkable" but lacking in "natural" qualities and with too much retouching: "We are not at the Salon" he wrote (*Moniteur de la photographie*, June 15, 1861: 49). Alophe published a treatise, *Le passé, le présent et l'avenir de la photographie*, wherein he advocates photography as high art.

PIERRE-LIN RENIÉ

ALTOBELLI, GIOACCHINO (1814–1879) AND MOLINS, POMPEO (1827–c. 1893)

Studio owners, Italy

Altobelli (born Terni) and Molins (born Rome), originally portrait and historical scene painters, like many others, turned to photographing the tourists sites where 'new' money could be made. They shared a studio in Rome, 1860–1865, producing Vedute di Roma photographs, with their characteristic posed figures, very unusual at the time, and signed 'Altobelli e Molins.' They were also employed as photographers by the French Academy in Rome and by *Opere d'arte per la ferrovie Romane*. The partnership ceased in 1865 and Altobelli, one of the most important of the early Roman photographers, until 1875 ran Enrico Verzaschi's studio on the Via del Corso. Verzaschi was famous for his satirical anti-clerical and anti-royalist photo-montages. Altobelli continued to photograph on his own account. In 1870 he posed soldiers outside the Porta Pia gate to commemorate the breach of the Roman walls in the revolution on 20 September 1870 which marked the end of the Pope Pius IX's rule, in 1878 he documented his funeral. He became also known for his stunning 'Night Views'—a product of the darkroom and the retoucher, for example, 'The Roman Forum by night,' c. 1866, was obviously made for the tourists who had read their Goethe. Molins was commissioned along with others by the British publisher and archaeologist John Henry Parker (1806–1884), founder of the British and American Archaeological Society of Rome, 1865, on his mammoth project which resulted in *A Catalogue of Three Thousand Three Hundred Photographs of Antiquities in Rome and Italy* (1879). Molins acquired most of Parker's negatives on his death but in 1893 his studio burned down and all were lost.

ALISTAIR CRAWFORD

AMATEUR PHOTOGRAPHER

The first issue of the weekly magazine *Amateur Photographer* appeared Oct. 10, 1884. The title speaks to the growing ranks of individuals who took up photography as a hobby or pastime in the 1880s. Smaller cameras, ready-to-use manufactured dry plates, and prepared paper had simplified photography to a point where increasing numbers of men and women could purchase the equipment necessary to make quality photographs with little scientific background and minimal instruction. Photography was seen as a challenging and positive pursuit, and there were many who actively photographed, took part in the numerous local and national societies, aspired to exhibit their photographs, and looked for ways to continue to learn about the medium. *Amateur Photographer* was tailor-made for these enthusiasts. The magazine was pitched to the educated middle class, those with the leisure time and money to photograph. In January 1885 the editors wrote,

> It has been our aim from the first to give to *Amateur Photographer* no mere trade organ, but a journal of

> distinctly literary character. The term amateur implies leisure … our goal is to meet the needs of educated and intelligent readers.

Amateur Photographer aimed to educate and encourage all levels of amateur photographers, including the neophyte. The journal provided articles on technical matters, and every aspect of the photographic process was discussed, from printing techniques to equipment reviews. Readers technical questions were answered each week by the staff in an "Answers and Queries" column, and by 1889 the editor reported that 2000 questions had been answered the year before. The audience was primarily British (including Australia and the British colonies) but questions came in from the United States as well. Each week the journal would publish minutes of the various (and numerous) meetings of clubs and societies in England, and in fact the journal was publicized as the Official Organ of the Amateur Photographic Societies of Great Britain and the Colonies. At various times competitions were held, with the winner's prints published along with a critique of the aesthetic and technical merits of the print. The occasional column "Holiday Resorts and Photographic Haunts," in which contributors would describe a recent trip and the photographs they took, encouraged travel to interesting locales to photograph.

The first editor of the journal was J. Harris Stone. He was a member of and exhibited with the Royal Photographic Society. By 1889, Charles W. Hastings and T.C. Hepworth, well known author of books on lantern slides for amateurs, were joint editors. The journal took up art and aesthetic issues from the start, and the first decade was the site of some of the Peter Henry Emerson/H.P. Robinson debate. In 1893, A. Horsley Hinton, a founding member of the Linked Ring takes over until his death in 1908. The appointment of Hinton is significant; he brings a more ardent interest in fine art photography, and during the next 15 years *Amateur Photographer* becomes the primary journal for the aesthetic photography movement in Britain.

In January 1889 the editor reported that circulation had doubled and he hoped to print 10,000 by the end of the year. The title still exists, and although it has gone through numerous changes in publisher and editor, it still serves the same audience—the enthusiastic amateur.

AMATEUR PHOTOGRAPHERS, CAMERA CLUBS, AND SOCIETIES

The history of 19th century photography is dominated by amateur photographers. This designation is not applied in retrospect, very early the literature of photography uses the term self-consciously to distinguish a certain type of practitioner. An amateur's interest in the medium fell outside professional and financial concerns. Some could be considered casual hobbyists, but many made photography an avocation, a serious pursuit to which

they dedicated many hours. The story of amateur photography is a story of influence—influence on the course of technological advances, influence on the art, and influence on the photographic manufacturing industry. No distinction is without its myriad exceptions, so the boundaries blurred at times: a few amateurs eventually turned to making money while some that worked with photography for a living brought an amateurs enthusiasm to the medium.

The two men most associated with the birth of photography, Daguerre and Talbot, can both be considered amateur photographers. In the years immediately following the announcement of the daguerreotype and Talbot's paper calotype process many individuals took up photography who would fall under the classification amateur scientist-inventor. Well into the 1840s, photography called for an individual to have some basic understanding of chemistry. The technology required patience and precision, and was more akin to the experimentation of the scientific process than the technological process of today. Results were not guaranteed. Early photographers were mainly "gentleman," with the education, time and money to take up photography. They were professionals and men of accomplishment in other fields: scientists, doctors, professors, lawyers, clergymen, publishers, as well as artists. Amateur pursuits of all kinds made up part of the culture of the wealthy and educated of the time; men of means and professionals strived to be learned in many areas, engaging in the arts and following and contributing to scientific developments, and photography fit quite well into this well-established tradition, with photographers seeing themselves as part scientist and part artist. Many of these individuals made important contributions to photography, furthering the science, refining technique, and developing applications for the new medium. Some of the names associated with this era, men like Samuel F.B. Morse, Sir John Herschel, Charles Wheatstone, Edmund Becquerel, Sir Charles Eastlake, and Eugene Delacroix formed part of an international cultural and scientific elite of the time.

An important element of amateur practice was communication—in order to learn about new developments and share ideas. Modeled on traditions long established in science and the arts, coming together as a group—for both social and practical reasons—was adapted early on by photographers. Gentleman of mutual interests met regularly for discussion of artistic and scientific matters, print comparison, and development of friendships. In the United States the moral and educational value of photography were also stressed. In the 1840s discussion among amateurs took place informally or within the established scientific community, under the aegis of the Royal Society in Great Britain, the Franklin Institute, and the American Philosophical Society in the United States, and the Académie des Sciences in France. In the early 1850s photographic clubs and associations formed in England, France and the United States, the main centers of photographic activity and many more emerged over the next ten years. The earliest mentioned in the literature is the Photographic Club or Calotype Society, a small group that formed in England in 1847. The membership consisted of influential practitioners in England, including Robert Hunt, Frederick Scott Archer, Dr. Hugh Diamond and possibly even Roger Fenton. In France, the Societé Heliographique, considered the first photographic association, formed in 1851. The Leeds Photographic Society was formed in 1852, and predates the Photographic Society of London (later the Royal Photographic Society), and the Liverpool Photographic Society, both established in 1853; and the Societé Française de Photographie took the place of the Société Héliographique in Paris in the same year. In the United States the American Photographic Society was formed in 1859, and was followed by the formation of the Photographic Society of Philadelphia in 1862. From the beginning these groups were never the exclusive domain of amateurs, they existed to serve all photographers, and consequently a mix of amateurs and professionals, people more interested in science and technology, and artists all came together under one umbrella. Nevertheless, the discussions, centering on technical and artistic matters ultimately served the non-professional more than those that made a living through photography.

The associations and clubs sponsored many activities. Meetings were held regularly, often at a society headquarters that had meeting rooms, a library, and workrooms, providing the space and time for social interaction and discussion of photographic progress. From the time of their founding, the groups sponsored salons and exhibitions. Most of these exhibitions included scientific as well as artistic work, all shown together. The exhibitions received extensive coverage in the photographic literature, and the popular press regularly reviewed exhibitions as well, bringing notoriety to certain photographers and attention to photography in general. Coming together did not necessarily require physical proximity. Print exchanges, the sharing of work among widely scattered individuals was another activity undertaken by small groups or sponsored by clubs and associations and the exclusive domain of amateurs. In England the Photographic Exchange Club was organized in 1855 and conducted an exchange a year over four years. In the United States the Amateur Photographic Exchange Club operated form 1861 to 1863, with members in Pennsylvania and New York. Various arrangements existed, but the basic activity called for each member to distribute their own prints to all the other members at specified intervals,

enabling each person to view a wide range of work and processes. The Amateur Photographic Exchange Club asked that photographs be labeled with a title, date of printing, and process. In return a letter might be sent, with criticisms, questions, advice and perhaps a print, and a personal correspondence would ensue. The general tenor of the exchange clubs was one of congeniality and active sharing of information, more of a recreation than a scientific pursuit.

Communication among amateur photographers became more formalized in the 1850s. Many of these organizations began publishing their own journal, and independent titles appeared as well, all of which functioned as a central distribution point for information to an increasingly far flung membership. In these pages photographers found the texts of papers and transactions of meetings and debates of the societies, articles and news about every aspect of photography, pages where the editor supplied answers to readers queries concerning practical problems, as well as advertisements for equipment and supplies.

While scientific and technical concerns mainly occupied the early amateurs, many saw themselves as artists as well. Particularly in Europe, amateurs worked to have photography accepted as a fine art, on an equal footing with painting and sculpture. Photographers created genre scenes, landscapes, and still lifes, borrowing from accepted traditions in painting and printmaking to make similar subjects and compositions. British photographer Julia Margaret Cameron took photography to a new level of artistry with her staged scenes from literary works and softly focused portraits of cultural luminaries, while in France in the 1850s, amateurs like Charles Nègre and Henri Le Secq, using the paper negative process for artistic ends, created beautiful landscapes and architectural photographs which have been compared to Impressionist paintings.

The growth of the field called for increased specialization and professionalization, and eventually the early amateurs were displaced by trained scientists with an education more focused on photographic chemistry and optics, while manufacturers took over many of the developments and improvements in apparatus and supplies. With the introduction of the wet collodion process in 1851, and its widespread adoption by the 1860s, the field hits a sort of plateau, and photographic methods change only subtly for the next two decades. More and more men and women take up photography as a pastime or hobby, and the number of clubs and societies grows, with groups forming in many major cities. The most important technical contribution by amateurs in this period is the effort to develop a dry plate negative process that did not require sensitization and processing of plates while still wet in the field. Individuals initially experimented with dry collodion, and upon the announcement of a silver bromide emulsion developed by Richard Maddox in 1871, continued using that formula as a basis for their research. The journals of the period are filled with reports of their successes and failures, leading eventually to a commercially viable dry plate process.

A major change in amateur practice occurs in the 1880s. By this time, reliable gelatin dry plates have been developed and mass marketed by manufacturers. The speed of the plates allowed for hand held cameras, and manufacturers came out with "detective" cameras, named after their ability to be used inconspicuously. New, more sensitive printing papers also eased the photographer's burden, and equipment in general becomes less expensive. George Eastman, founder of the Eastman Kodak Company brought about the next important advancement. In the 1880s his company developed a roll holder and flexible film that resulted in the 1888 Kodak camera, which allowed even greater simplification of the process, essentially opening up photography to any level of practitioner. Photography was definitely no longer for the wealthy and the learned but appealed to a broader section of society, allowing people of more modest means and education to take up the hobby. Photography caught the fancy of the late nineteenth century middle-class. People joined clubs in droves, and the number of organizations grew exponentially yet again. As earlier, the clubs served both technical and social needs of amateurs. They usually had offices with meeting rooms, and spaces for dark rooms and printing with communal apparatus. Lantern slide shows by individuals were regularly presented, offering a chance to show personal work and share travels. There is a revival of postal print exchanges in the last decade of the century as well as lantern slide exchanges among clubs. Manufacturers understood the financial power of amateurs, their keen interest in the newest cameras and equipment, and became more involved with their practice. They sponsored contests and marketed heavily to them, fostering a symbiotic relationship. New journals appeared such as the *British Amateur Photographer* and *American Amateur Photographer*, which catered specifically to amateur interests, as well as manuals which brought simpler instructions and a lighter attitude. Women joined clubs which did not allow them previously, and their presence becomes common. The American photographer Catharine Weed Barnes Ward became a spokesperson and advocate for women photographers, and wrote on subjects of interest to amateurs in her many articles in American photo-journals, in particular her column for women in the *American Amateur Photographer*, which she eventually coedited. She published several illustrated books and regularly contributed to journals before becoming coeditor, with her husband H. Snowden Ward, of the British journal *The Photogram* and several other periodicals.

The last decade of the century saw renewed and heightened discussion around the question of aesthetics and art photography. This preoccupation caused a strain among classes of amateurs. Those who considered themselves more serious photographers felt compelled to distinguish themselves from the legions of snapshooters that used a simple Kodak camera to photograph trips, special occasions, and family and friends; they also differentiated their practice from professionals, whose reputation for quality had fallen in recent years. Another, very visible group of amateurs aspired to make more aesthetic photographs, and separated themselves from those more interested in making technically good, but fairly conventional photographs from the standpoint of composition and choice of subject matter. Artistic matters became central to their practice and they took on critical issues of traditional aesthetics and followed certain principles of painting and printmaking. The photographic press also joined the discussion, and journals like the *American Amateur Photographer* advocated taking more time with the artistic side of photography and encouraged their readers to "elevate" their art. The photographs created are variously labeled artistic, expressionistic, or pictorial, the latter term now used to distinguish this particular type of artistic photograph created during the late nineteenth and early twentieth centuries.

The 1890s saw fervent debate over what constituted a pictorial photograph, and whether personal expression and artistry should be emphasized over the cameras ability to record precise detail. Peter Henry Emerson's 1889 book *Naturalistic Photography for Students of the Art*, emphasized selective focusing, which more naturally imitated human vision, with impressionistic compositions that showed an idealized nature. Another group, identifying with the work of H.P. Robinson, emphasized the artistic possibilities of photography through combination printing, traditional principles of composition, and subject matter borrowed from painting. Photographers experimented with old and new printing methods, and processes like gum bichromate and platinotype gained in popularity. Watercolor and other textured papers were used, and negatives and prints were manipulated by hand, allowing for more variation as well as more painterly effects.

Exhibitions and salons continued, many sponsored by the camera clubs and associations. They took on added importance as artistic debates intensify. Splinter groups, devoted to the aesthetics of photography formed in major European cities. The first Photo-Club de Paris formed in 1889. In England photographers protest the lax aesthetic standards of the Photographic Society of Great Britain salon and in 1892 formed their own invitational group, The Brotherhood of the Linked Ring. *The International Ausstellung Kunstlerische Photographie*, organized by the Club der Amateur Photographen in Vienna in 1891, is considered first international photographic exhibition limited only to artistic photography. Subsequent art photography exhibitions were sponsored by The Photo Club de Paris, The Linked Ring in England and the Camera Club of New York, which was founded in 1897. In 1898 the Pennsylvania Academy of the Fine Arts hosted a joint salon with the Photographic Society of Philadelphia with a selection committee consisting of painters and photographers, including Alfred Stieglitz, leader of the fine art photography movement in the United States. The jury chose only works showing "artistic feeling and sentiment," and the exhibition was a popular success. With these exhibitions and formation of aesthetic groups, an international circle of amateur photographers formed the first international fine art photography avant-garde movement. They sought to identify more with the contemporary art world, finding inspiration in Art Nouveau, Symbolism, Impressionism, and contemporary literature: their ultimate dream to raise the stature of photography to the level of fine art —an equal to painting and sculpture.

Amateur photographers, the groups they formed, the publications they fostered, and their contribution to scientific and artistic developments made them the leaders of 19th century photography. In fact, the history of 19th century photography is largely the history of amateur activity. From Talbot and Daguerre to Alfred Stieglitz, many of the most important figures came to photography because they loved the medium; and their devotion can be seen in the many hours they spent experimenting, tinkering, inventing, theorizing, writing, exhibiting, developing, printing, and of course, photographing.

AMERICAN JOURNAL OF PHOTOGRAPHY

The *American Journal of Photography* began publication in New York City as the *American Journal of Photography and the Allied Arts and Sciences* in 1855. The journal was founded by Charles A. Seely, professor of analytical chemistry at the New York Medical School, who had also worked at *Scientific American* before starting the journal. Henry Garbanati, Seely's partner in the photographic chemical business, and a fellow member of the American Photographical Society, joined him as publisher in 1859. Seely edited the journal until 1867.

The bi-weekly journal had a wide subscribership beyond New York City and drew correspondence from a readership of amateurs and commercial photographers across the United States. In 1859 the journal began publishing the minutes of the American Photographical Society; it shared the concerns of the society's founders, among them chemist and physician John W. Draper, his son, astronomer and photographer Henry C. Draper, Henry Hunt Snelling (publisher of *The Photographic and Fine Arts Journal*), commercial portrait photographer Abraham Bogardus, astrophysicist and astronomer Lewis M. Rutherford (who first photographed the moon in 1858), Peter Cooper, founder of Cooper Institute, and Robert MacFArlane, editor of *Scientific American*, primarily with science and photographic chemistry.

Scientists such as John W. Draper had been working on the chemistry of photography even before the advent of the daguerreotype, and in subsequent decades continued to experiment and advance photographic science. Articles explaining and evaluating photographic chemistry, with titles such as "On Washing Gun-Cotton" and "How to Use the Nitrate Bath," complete with chemical formulae fill the journal. The leadership of the society were the most active writers for the journal. Largely chemists drawn from scientific elite of New York City, correspondence in the journal suggests that, in contrast, its readership was either commercial or "practical" photographers or amateurs whose had less interest in the science of photography for its own sake. One such subscriber wrote to the journal that its penchant for debating and publishing multiple chemical formulas and printing instructions were "bewildering" to the point of being "useless."

The journal regularly reported on and evaluated photographic trade manuals published in the U.S. and abroad. Several manuals, including Lake Price's *A Manual of Photographic Manipulation* (London, 1858) and C. Jabez Hughes' *The Principles and Practices of Photography* (London, first edition 1858?) were excerpted or serialized in the journal.

Seely used his "Editorial Miscellany" column as a compendium of observations on the medium in and around New York. Exemplary comments extended from the social uses of the medium, such as his visit to see the city's "Rogue's Gallery" ambrotype portraits of criminals, to gauging public response to new processes such as cartes de visite. Seely frequently noted the relationship between economy and the photographic profession. Seely's commentaries on the state of photography reinforce the scientific point of view expressed by the journal's articles on chemistry. In his view, science, not art, would be the discipline that furthered photography.

In keeping with printing practices of the time, the journal relied heavily on reprints and excerpts from other publications. Notably all the cultural commentary on photography is reprinted from other sources. For example, originally printed in the *Atlantic Monthly*, Oliver Wendell Holmes' "The Stereoscope and the Stereograph," and "Sun Painting and Sun Sculpture" were excerpted in the journal. An appraisal of Brady's photographs of the House of Representatives was drawn from the *New York Daily Times*, and *Scientific American* was also a source for reprints. The journal also reprinted

commentaries, reports and lectures from British and French publications, including *Photographic News*, *The Saturday Review*, and *The Liverpool Photographic Journal*, which was also known as *The Liverpool and Manchester Photographic Journal* and *The Photographic Journal.*

The journal also reported on technological innovation from the United States, Britain and France, in lenses, studio design equipment as well as cameras, and printing techniques. For example, the journal published detailed descriptions, including measurements of the skylight (facing south, fourteen feet square) at Marcus Aurelius Root's former New York studio, are extremely valuable accounts of commercial portrait technology, which, in this case, yielded a sitting of "less than one second with lens at full aperture."

The pages of the journal reveal how many questions about the technology and social implications of photography were debated in the 1850s and 1860s. Questions of invention, ownership and intellectual property, for example, can be traced through the coverage of patent disputes. Along with the two other New York photographic publications, *Humphrey's Journal* and *The Photographic and Fine Arts Journal*, the journal also discussed the social uses of the medium and the appropriate interests and concerns of photographers, split in their ranks between intellectual and educated amateurs and no-nonsense commercial operators. In an 1859 editorial, Seely decried the pecuniary interests of New York's "practical photographers" and noted their absence at Photographic Society meetings. In these discussions of a photographer's ideal, the authentic advocates of the medium were represented as the men of science, who dominated the society, and sought to enrich the artistic reputation of the medium through scientific inquiry. Seely contrasted these elevated concerns with those of men who saw photography only as a business.

Such debates offer rich sources and insights into discussions of the social and cultural purposes that photography should serve in its early decades.

Several important figures in 19th-century American photography contributed to the journal, including the Philadelphia photographer Marcus Aurelius Root, engineer Coleman Sellers, grandson of painter Charles Willson Peale, and chemist M. Carey Lea.

The history of the journal illustrates the precarious nature of the photographic press. In 1860, the journal absorbed *Snelling's Photographic and Fine Arts Journal*; Seely sold his journal in the spring of 1867 but it faltered under new ownership and was absorbed that same year by the competing *Humphrey's Magazine*.

Secondary literature in the history of photography has used the journal to trace the technological and social history of photography. Robert Taft used the trade journals in his 1938 *Photography and the American Scene; in the 1980s and 1990s*, citations to the journal appear in newly contextualized studies of photography's founding figures, such as Mary Panzer's 1997 cultural biography of Mathew Brady, as well in essays that applied new methodologies from cultural studies to the history of photography, exemplified by Alan Trachtenberg's 1991 "Photography: a Key Word," and in 2000, "Cartes de Visite and the Culture of Class Formation" by Andrea Volpe.

AMICI, GIOVANNI BATTISTA (1786–1863)

Italian astronomer, botanist, microscopist, and inventor.

Giovanni Battista Amici invented the Amici Prism, which combined three prisms for use in refracting spectroscopes. This system is still used today in modern spectroscopy to differentiate light into its separate spectral components. Amici collaborated with Bertrand to design the Amici–Bertrand lens, which could view an objective's rear focal plane. This meant it was possible to view, for example, interference patterns produced by birefringent crystals (e.g. in plastics). Amici also devised an achromatic lens and designed reflecting telescopes. Amici was Professor of Mathematics at the University of Modena from 1815-1825, until being appointed Head of the Astronomical Observatory in Florence in 1831. Amici established a friendship with William Henry Fox Talbot, from meeting in 1822; they corresponded for more than twenty years. Talbot wanted his work on nega-

tive-positive paper photography to be known throughout Europe and he chose Amici to be one of the Italian scholars that he would entrust examples of his work to. In 1822 Talbot, after seeing examples of Amici's work, requested that Amici design a reflecting microscope for him; then, shortly afterwards, a microscope micrometer. Talbot's work was promoted in Florence by Amici and Talbot's sisters, Caroline and Horatia, in the 1840's, in Talbot's absence. As a result of Amici's friendship with Talbot's sisters, Talbot's work gained the recognition he desired without his presence. In 1840 Amici devised an oil-immersion system that improved the optical aberrations found in microscopy. He then went on in 1855 to improve on this with his water immersion lens.

JO HALLINGTON

ANDERSON, JAMES (1813–1877)

British photographer of architecture and works of art

Part of a famous dynasty of photographers in Rome, after Alinari and Brogi in Florence, Anderson is known for his architecture views and reproductions of works of art. Born in England, Isaac Atkinson studied in Paris and got installed in Rome in 1838. He took the name of James Anderson the year after. He certainly began photography in 1845 and joined the group headed by Greco's. He sold his photographs in Joseph Spithover's bookshop situated 85, Piazza di Spagna.

Anderson contributed in 1857 to an album entitled *Rome* containing fourteen of his views. Two years after, he published a catalogue counting four hundred and fifty photographs. He took part in photographic exhibitions in Scotland in 1857 and in London in 1862. His images, well contrasted and clearly composed, gave a new vision of the city, far from picturesque, and closer to architectural layout and documentation. Very appreciated, Anderson is one of the first professional photographer active in the Peninsula. His son Domenico took back the firm successfully. In the 1930s, Anderson counted 40,000 negatives, but the activity stopped in 1960. The archives were bought in 1963 by Earl Cini who thus gathered Anderson to the Alinari collections.

ANDRIEU, JULES (active 1850s–1880s)

French photographer

The term "Paris Commune" (La Commune de Paris) originally referred to the government of Paris during the French Revolution. However, the term more commonly refers to the socialist government that briefly ruled Paris from 18 March (more formally from 26 March) to 28 May 1871.

The photographs made by approximately a dozen French photographers such as Andrieu during the Paris Commune of 1871 focus on the architectural ruins in Paris left in the wake of these conflicts. These images, especially Andrieu's are void of human figures or signs of life, and appear today as compelling representations of destruction and loss.

Because photography could sometimes be a form of objective documentation, this medium served as a means of propaganda, which generally denounced the reprisals against the communards. From 1871 on, 'collections' of demolished buildings were published: the Hôtel de Ville, and the Tuileries, etc. Various Parisian photographers such as Jules Andrieu traveled around Paris during the events to take photographs of the unfolding events. Andrieu was a photographer-craftsmen and laboratory

technicians who adapted to the "market" of photography. For technical reasons his exposure time was short. Paris seems deserted in most of his images with only a few people appearing them. In some images by Taupin, Ferrier, and Lecadre, fires and such are evoked by crude touching-up of the prints with paint.

This photographic production has a two-fold implication. The images not only serve as historical documents of the event, but they serve as documentation of historical problems of censure and politics as captured in the image and how that image was taken. The power of images like these resides in the reproducibility of them, a market which continued to grow in size and importance with the development of photography, especially cinema and television.

In this market, the Commune of Paris proved to have an economic ground that bore fruit. Reproductions of monuments on fire, of the Vendôme column, and of Paris completely devastated were sold as rolls in Provinces and abroad. In London particularly, these photographs achieved enormous popularity to the extent that the Agency Cook Travel began organizing visits for groups of people.

The photographs entitled "Desastres de la guerre" by Andrieu are silver prints on albumenized paper measuring approximately 29 by 38 cm, most probably made from wet collodion glass negatives, the technology overwhelmingly preferred at the time. To date, forty-seven separate images of "disasters" have been identified by their identical presentation and their shared dimensions and subjects of Parisian architectural ruins of 1870 and 1871. All these photographic prints are mounted on much larger blue-gray cardboard with a red embossed stamp, centered underneath the print, bearing the series title, Desastres de la guerre. It was on October 30, 1871, that Andrieu registered twenty-one prints with the Depot Legal, the government bureau regulating commercial prints, under a series title Desastres de la guerre, along with individual titles, which he numbered by hand from one to forty-four, skipping numbers. A photographic album now in the Canadian Centre for Architecture, La Guerre et la Commune, includes twenty-one of Andrieu's Desastres in conjunction with other pictures that offer a rare example of the manner in which such Commune photographs were sold and collected in the later nineteenth century.

Jules Andrieu and his studio were primarily devoted to the commercial production of the ruins of the among others such as Hyppolite Collard, Alphonse Liébert, Pierre Ambroise Richebourg, Disdéri and Pierre Edmonds, and others as well. The political actors in conflicts also used photography and called upon these studios to take images for them. The government of Common often had photographs taken of the killed National Guards whose identity could not be proven. As of April 1871, the authorities of Versailles made photography profitable in the identification and documentation of the Communards operations. The image served many purposes. Very quickly, censorship controlled the production of images that were still being sold years later. By the end of 1871, prohibition was enacted banning the intent to hawk and put on sale images and emblems likely to disturb public peace" and in particular the "portraits of the individuals charged or condemned for their participation in the insurrectionary facts." The only authorized exceptions were "reproductions, which are made from a purely artistic point of view of the fires of ruins of Paris."

Photography, like all media, is ambivalent and even ambiguous and is perhaps both at the same times and often a source of information and a tool of misinformation. An image of a tumultuous event is often more than just an image. The photographs of the ruins of Paris are images of war and the questions remains why did people start to collect and admire them. Recent historical approach has proposed political and class-based readings of the photographs of Andrieu. Historians of art, photography, and culture who are concerned above all with determining the political positions of the photographers have divided these images into pro-and anti-Commune camps, clarifying the ambiguity of photographs so that a consistent message can be sent instead of contradictons. Historians however have tended to privilege what they consider to be pro-Commune photographs and photographers, linking them to the proletariat. The so-called pro-Commune photographs constitute only a small proportion of contemporary Commune-related imagery, and these had indeed suffered in the earlier ideologically driven (that is, anti-Commune) illustrated histories of the political moment. Such scholarly efforts to recuperate these images have provided a fuller view of Commune representation, if not greater sensitivity to their broader meanings outside the specific politics of this radical movement.

ANGERER, LUDWIG (1827–1879) AND VIKTOR (1839–1894)

The brothers Ludwig and Viktor Angerer are variously described as being of Hungarian or Austrian nationality. They were born in Malaczka, Hungary.

Ludwig was trained as a pharmacist in the early 1850s, and some accounts state that he served as a pharmacist in the Austrian army, while others place him in the Imperial Pharmacy at Donauländern. Initially, photography was his hobby, but a series of views of Hungary and Austria, taken during his military service in the Danube countries in 1854, brought him to public notice, and apparently encouraged him to make his hobby his profession.

He moved to Vienna, probably in 1857, and opened a photographic studio in the city, quickly earning a reputation for high quality portraiture, both indoors and outside in the garden of his home.

By 1864 he was a member of the executive committee of the Photographic Society of Vienna, which, according to Eder, brought him into contact with Anton Friedrich, then manager of Voigtländer's premises in Vienna. This led to Angerer acquiring and working with Voigtländer's recently introduced and massive 8-inch diameter Petzval-style portrait lens. Indeed, it was Angerer's own lens which was displayed at the Berlin International Photographic Exposition in the following year. With this lens, he produced a series of very large format portraits, and his achievement was reported in the review of the exposition published in *Photograpische Korrespondenz*

> Ludwig Angerer exhibited portraits, busts and three-quarter lengths, taken with an eight-inch Voigtländer lens. From the technical standpoint, these were highly successful and vigorous without retouching, but, unfortunately, they were not as much appreciated as the difficulty of their production made them deserve…. The nucleus of his exhibit were the portraits, size 13 × 16 inches, taken with a six-inch Voigtländer lens.

That six-inch diameter lens, introduced in 1860 in two different focal lengths, weighed in at a massive 31 lbs! The weight of the eight-inch version must have been considerable. Indeed, so heavy was it that Angerer had to design a special tripod to carry the weight of the camera and its optic, with geared mechanisms to raise and lower the camera. Camera, lens and tripod reportedly weighed over two hundred pounds!

Angerer is credited with the introduction of the carte-de-visite into Vienna in 1857, and thereafter he produced and marketed many portraits of the Austrian Imperial family and celebrities in that format as well as the larger format prints for which he was already renowned.

His continued success led to expansion of his premises, and a larger studio, illuminated with blue glass skylights, was opened in 1867. It was in this studio that he was joined by his brother Viktor in 1872, or 1873. Viktor had previously operated his own highly successful studio since the early 1860s. Their partnership, as L & V Angerer, apparently lasted just over a year as Ludwig's health deteriorated and the operation of the studio passed solely to Viktor. Ludwig died in 1879, aged 52, and one of his sons and his daughter would, for a time, work as photographers in the family studio.

Viktor was a military engineer by training, having briefly operated a portrait studio in Bad Ischl at the age of twenty. On leaving the military, he returned to photography, eventually becoming Court Photographer to the Austrian Imperial Family. A pioneer in the production of photographic enlargements in Vienna, he reportedly visited Claudet in London in 1861 to familiarize himself with the challenges of using Woodward's solar enlarging camera. His photographic career spanned more than thirty years, and embraced both photography and the manufacture of photographic materials, during which time he produced celebrated portraits of Austrian celebrities, including a fine series of studies of Johann Strauss in the early 1890s.

A series of photographs exhibited in the 1863 exhibition of the Photographic Society in London, and identified only as by 'Angerer' were probably examples of both men's work. They had previously been exhibited in Paris, and were brought to the London exhibition by the Société française de photographie. Amongst them are two portraits of the Empress of Austria, probably by Ludwig, but the majority relate to technical experimentation which the two men undertook around that time. Amongst them, large format portraits of Voigtländer, Callaghan, and one of the Angerer brothers—and taken with Voigtländer lenses—are probably by Ludwig. '*A Photograph on albumenized paper, magnified eight times without being retouched, produced by means of the Solar camera*' clearly stems from Viktor's 1861–2 experiments with enlarging. The experimental nature of the images in this exhibit is underlined by the fact that, with the exception of the portraits of the Empress, the subject matter of the images was not catalogued, while lenses used are precisely described. Thus, the catalogue confirms, two images (subject unknown) were taken with the 'short-focus' version of Voigtländer's six-inch diameter lens.

In 1881 he is recorded as the proprietor of the Photographic Art Institute of Vienna, the most celebrated studio in the Austro-Hungarian Empire, for which he bought a licence from Karl Klic to use Kilic's heliogravure printing process, having received training at Klic's Photochemical Works. Printing, by heliogravure, collotype and photogravure, eventually became an important aspect of the studio's activities.

While Klic was refining his process, he used dry

collodion plates manufactured for him by Angerer's newly opened dry plate factory. Perhaps as a reaction against the uncertainty of mass produced materials at the time, Angerer had joined forces with another of Vienna's most celebrated photographers, Dr. Székely, to manufacture plates to their own exacting standards. The operation lasted only a decade, however, and by 1892 Viktor Angerer had built a new home and studio on the factory site. The Strauss portraits must have been amongst the first taken at the new premises. Viktor died in 1894, at the age of 55.

The studio finally closed at the outbreak of the Great War, 1914.

ANIMAL AND ZOOLOGICAL PHOTOGRAPHY

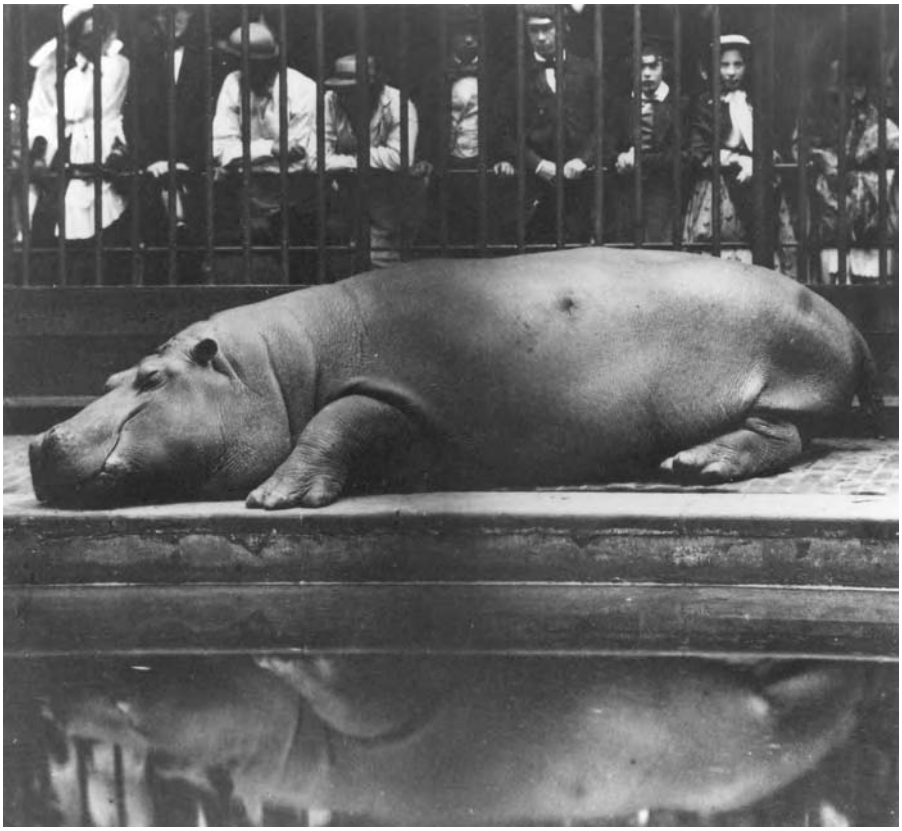
Due to the need for long exposure times in the first years of photography 1839–1845 only fossils, dead or stuffed animals could be photographed on metal and paper (some by use of the microscope) while from the mid-1840s domesticated animals in static poses appear in daguerreotypes by Bisson Frères and others. From 1851 access to exotic live animals in new public "zoological gardens" coinciding with the development of faster wet-collodion plates, was a boon to photographers and scientists alike. Spanish gentleman-amateur Juan de Borbón Comte de Montizon (1822–1887) exhibited numerous collodion photographs of beasts, birds and fish taken at the London Zoo between 1852–1858 and in Paris in 1860 Louis de Lucy (Louis Godefroy Lucy-Fossarieu, 1822–1892) was official photographer for an album for the new Zoological and Botanical Acclimatisation Garden in the Bois de Boulogne.

In *The Photographic News* of 23 February1866 Frank Haes (1832–1916) described the difficulties of working with slow speed plates and unpredictable subjects over two years work at London Zoo preparing his series of stereographs for sale. His difficulties were slight compared to those of explorer James Chapman (1831–1872) in Namibia who secured a few images of dead wild animals using a French stereograph camera in 1861–62.

The publication potential of the new negative-positive collodion process inspired the Paris Museum in 1853 to commission Bisson Frères (Louis-Auguste (1814–1876), Auguste-Rosalie (1826–1900) to make photographs for a serial publication *Zoologie photographique, ou représentation des animaux rares dés collections du muséum d'histoire naturelle* with 60 plates made using Niepce's photomechanical process. The British Museum followed suit in 1854 engaging Roger Fenton (1819–1869) but did not produce a zoological publication. Later publications such as that of the Harvard College Museum of Comparative Zoology in 1873–1874 had photographs by John Carbutt (1832–1905) reproduced in the superior photomechanical process of woodburytype.

A number of specialist pedigree animal photographers worked in Paris in the 1850s–1860s. Adrien Tournachon (1825–1903) made photographs at bovine and equestrian shows later using Adolphe Bertsch's rapid collodion plates with the salt paper process in the mid-1850s but his work was eclipsed by the scale and style of an equestrian *studio hippique* set up in the Bois de Boulogne in 1860 by Jockey-Club member Louis Jean Delton I (1807–1891). The latter posed clients on their steeds or in horse and carriage teams outdoors against a variety of stylish scenic backdrops. Léon Cremière (1831–1913) editor and illustrator of the sports journal *Le Centaure* (1866–1869) produced albumen and woodburytype photographs on lettered cards of pedigree dog in shows. Cremière published an album on bloodhounds; *La Vénerie Française* [*French Hunting*] on the show of 1865 and Delton an *Album hippique* [*Equestrian album*] in 1870.

The French studios practised a form of portraiture, while in Scotland from the late 1850s Horatio Ross (1801–86) used dead props to make pictures of hunting scenes enlivened with titles like "I have got him at last." Others like Willoughby Wallace Hooper (1837–1912) in India also catered to the hunter's desire for on the spot proof and souvenirs with staged hunting scenes in the late 1870s. John Dillwyn Llewelyn (1810–1888) in England in used stuffed animals in natural settings in the early 1850s but turned to his own oxymel "dry" preservative process in 1856 to do outdoor animal studies In Vienna photographer C. Wrabertz used taxidermy specimens for bird photographs in E. Hodek's *Europäische Raubvögel, serie 1* [*European Birds of Prey series 1*] in 1874 and Canada William Notman (1826–1891) a fine canine pet portraitist, used taxidermy in 1876 for his illustrations to H.G. Vennor's *Our Birds of Prey, or the Eagles, Hawks and Owls of Canada*. Taxidermy facilitated comic tableaux works such as those by cat



Juan de Borbon, Count de Montizon. The Hippopotamus at the Zoological Gardens, Regent. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Ann Tenenbaum and Thomas H. Lee GIft, 2005 (2005, 100.14) © The Metropolitan Museum of Art.*

specialist H. Pointer in England in the 1860s–1870s and melodramatic 'perils of the wilderness' 1890s stereographs in America by George Barker (1844–1894).

A substantial market developed in the 1860s for animal studies called *études* for use by artists and designers. One of the main publishers from the 1860s on was the Alsatian firm of Adolphe Braun (1812–1877) in Mulhouse which released many series on rural animals as well as and giant carbon prints of still-life studies of dead game. Achille Quinet (1831–1900) and Constant Famin (in France (1827–1888) produced picturesque farm animal studies and one of the most prolific animal specialists Charles Reid (1837–1929) in Scotland the 1880s, undertook extensive journeys to add types of animals to his inventory.

The ability to capture more than what the eye could see awaited the development of the dry-collodion plate in the 1870s and technical innovations in lenses and shutter mechanisms into the early 1880s. The great pioneers were Étienne-Jules Marey (1830–1904) in Paris from the 1860s and British-born Eadweard Muybridge (1830–1904) in California in the 1870s and 1880s. In 1878 Muybridge used fast Dallmeyer lenses and a line of cameras with trip wires to prove a horse's legs left the ground while at full gallop. Muybridge developed his zoopraxiscope an early form of cinematography which Marey saw in Paris and developed his pistol camera and sequential chronophotography process making some of the most beautiful and scientifically precise images of bird flight. Others including German Ottomar Anschütz (1846–1907) took up the new animal locomotion methods and designed his own rapid shutter and became a pioneer of cinematographic apparatus. In 1884 he published a sequential shots of a stork leaving its nest and over the next two years undertook hundreds studies of animals in the Posen Zoo and a private deer park. Using a hide and a race to confine the animals and possibly fake scenic backdrops, Anschütz's close-ups gave a powerful illusion of animals in the wild. At the same time in Paris Louis-Jean Delton's son Jean II (1850–after1917) trading as J. Delton, used the new rapid gelatin bromide dry-plate negatives to make 'instantaneous' photographs showing horses rearing and jumping. He published a series of albums of photogravures and platinum prints of riders in action in the Bois de Boulogne from 1882 and took one of if not the first, in situ race-finish photographs in 1885. In 1917 Delton II claimed to have been the first in Europe to capture horses in movement and had letters from pioneers like Marey attesting to his success.

In 1887 Muybridge having renewed his earlier experiments utilising an electro-magnetic device to trigger the shutters on his banks of cameras and made hundreds of animal movement studies, some of which were made at the Philadelphia Zoo and Gentlemen's Driving Park. The work was published in eleven volumes of collotypes

titled *Animal Locomotion. An Electro-Photographic Investigation of Consecutive Phases of Animal Movements*, a work that has continued to fascinate artist and the public ever since.

Photography was also pursued as part of the documentation of government sponsored natural history and geographic expeditions starting with the Spanish Pacific Scientific Expedition 1862–66 for which Rafael Castro y Ordóñez (1834–1865) was official zoological photographer but took mostly views. The British oceanographic study undertaken in the *Challenger* in 1872–1876 brought the first photographs of penguins in Antarctica to a wider audience, and Canadian geologist explorer J.B. (Joseph Burr) Tyrrell (1858–1957), a geologist employed by the Geological Survey of Canada, photographed massive caribou herds at Carely Lake in the Barren Lands in 1893.

Photography played a key role also in stimulating conservation campaigns. In Montana in 1879 military photographer Laton A. Huffman (1854–1931) recorded the mass extermination of bison in the 1880–1890s. The lesson of those losses affected former big game hunters such as the American Judge George Shiras 3rd (1832–1924) (an amateur naturalist, who urged adoption of the camera instead of the gun and promoted conservation. In 1898 Shiras developed a technique for photographing animals at night using trip-wired flash. German hunter Carl George Schillings (1865–1921) on safaris in East Africa in the late 1890s became a conservationist. His later work with flash would make him the best-known modern wildlife photographer.

In the 1890s an industry developed catering to both amateurs and professionals interest in 'wildlife' photography (though few faced predatory animals). Thomas Dallmeyer made a special naturalist's camera and introduced the first telephoto lens in 1891. In 1897 the first German natural history book on middle European game animals by Dr Wurm was marketed on the basis of its profuse illustration by 'snapshots from life' (some by Anschütz). However, the deluxe albums and high quality books were overtaken by half-tone reproduction process which supported an explosion in naturalist books and magazines. Beginning in 1895 with *British Birds' Nests* brothers Richard and Cherry Keaton showed how they had mastered close-up studies by their ingeniously camouflaged hides and other devices to reach inaccessible places.

From the outset of the development of photography in the 1840s, the value of applying photography to the study of creatures, domestic or wild, dead or alive, their habits and habitats on land, sea and in the air was predicted and partially fulfilled by the end of the century. The indispensable role of photography in popular journals such as *National Geographic* founded in 1898 awaited the new century fast mechanical shutters, rapid plates, reflex cameras and telephoto lenses and flashlights and orthochromatic plates.

ANNAN, JAMES CRAIG (1864–1946)

Scottish photographer and photogravurist

Annan was an important international figure in photography's fight for recognition as an art in its own right at the turn of the nineteenth century. Then anyone interested in Pictorial Photography would know his work, exhibited throughout Europe and the United States from St Petersburg in 1894 to Buffalo in 1910 and reproduced in many journals including *Die Kunst in der Photographie* of Berlin and *Camera Work* of New York.

He learned photography from his father Thomas Annan and went in 1883 to Vienna to learn photogravure from its inventor Karl Klíč. When in 1887 his father died the family firm became T. & R. Annan & Sons, Glasgow, Photographers and Fine Art Publishers. James became a partner specialising in photogravure for the reproduction of works of art, for example, *Sir Henry Raeburn: a Selection of his Portraits*, Constable, 1890, and for book illustration, an early example, G. Christopher Davies, *Norfolk Broads and Rivers*, Blackwood, 1883, and a macabre example, William Macewen, *Atlas of Head Sections*, Maclehose, 1893.

About 1891 Annan decided to make his own photographs. In 1892 a trip to North Holland produced what must have been a breathtakingly fresh exhibition in the firm's new galleries, its interior, furniture, and the picture frames designed by George Walton. The almost abstract "On a Dutch Shore" captures the roar of wind and sea as a catch of fish is auctioned on the open beach. "The Beach at Zandvoort," merely 4.6 cm by 23.3, has figures which at first appear like irregular notes of music pushed into a slanting line across the top of the composition. These two photogravures alone almost reduce The Hague School to costume painters.

Annan's trip in 1894 to North Italy produced in 1896 a folio of eleven photogravures, *Venice and Lombardy*. The minimal "Venice from the Lido" shows Annan following his own advice to set up, then watch and wait and wait, until, in this case, the shape of the drifting gondola came into a visual harmony with the posts in the channel and the distant towers of the city. Annan stated that he had no set of rules. He worked 'by the inspiration of the moment'.

1894 brought him astounding recognition. He was elected a member of The Linked Ring. He showed more prints than anyone else at the Photo-Club de Paris. He exhibited at the Joint Exhibition in New York and "The Beach at Zandfoort" was used as a frontispiece for *The American Amateur Photographer*. He exhibited in St Petersburg, and, at the London Salon, sold a 45.4 cm carbon of "The Lombardy Ploughing Team" for three guineas to Harold Holcroft, an early collector.

Annan was an early advocate of the hand camera. Stieglitz obtained one sometime in 1892–93. Annan had exhibited hand camera prints in 1891 and presented an entire exhibition "North Holland" in 1892. When in 1897 Stieglitz wrote about the hand camera he quoted from Annan's article in *The Amateur Photographer* of March 1896. Annan and Stieglitz were exact contemporaries. They enjoyed a long correspondence. Stieglitz owned sixty Annans.

Annan delighted in the seizing of the moment, for example, the practised glance of William Strang examining his etching plate, or the tiny, restless, almost eerie, movement of the white horse in the farmyard below Stirling Castle.

In photogravure the image is transferred to a plate to be worked on as an etcher would. Annan enjoyed this immensely. "The Etching Printer—Willam Strang, Esq," 1902, was heavily manipulated with its background and the wheel of the etching press washed out leaving the very subject of the work, Strang's eye and his plate, sharp. Annan explored other manipulations. Adding "Ex Libris Dorothy Carleton Smyth" to a print of her portrait resulted in a photographic book plate.

During its 1901 International Exhibition, Glasgow was the centre of Pictorial Photography. Annan assembled 201 pictorial works from Austria, Belgium, England, France, Germnay, India, Italy, Scotland, Russia, Switzerland, and the United States. In addition, he asked Steigltiz to select the American section. He provided, with a few exceptions, the works which in 1902 announced the arrival of The Photo-Secession. T. & R. Annan & Sons were also official photographers to the International Exhibition. Three years later they built the most handsome new premises in Sauchiehall Street.

Annan produced some fine portraits deeply redolent of their time. Anne MacBeth, who taught at Glasgow

School of Art, wears her wide collar heavily embroidered with roses and hearts. Jessie M King, the book illustrator, gazes out from under a huge bonnet. The image of the architect and designer C. R. Mackintosh known today is the one Annan created of him in tweed suit, flowing bow tie, minute kiss-curl on forehead. Annan's rotund G. K. Chesterton carries faint echoes of Hill and Adamson's "Professor Alexander Monro."

Annan could recall as a child meeting D.O. Hill and he knew well two volumes of calotypes which Hill's widow had presented to his father, a close friend. About 1890 he made a set of twenty photogravures from their original calotypes. He lent prints to Hamburg in 1899, to Stieglitz's '291' Gallery in New York in 1906, where Hill was presented as the Father of Pictorial Photography, to the Salon in London in 1909, and to Buffalo in 1910. He also supplied Stieglitz with photogravure prints of their work to appear in *Camera Work* in 1905, 1909 and 1912. At the very end of Annan's life Helmut Gernsheim, addressing him as "a great master of photography," asked for information about Hill. Annan corrected the account of Hill in Gernsheim's *New Photo Vision*, Fountain 1942, by mentioning Brewster and Adamson. However, Gernsheim gave Annan his due, "Hill was only thought of again when photography was rediscovered as an art by Craig Annan and his circle."

Principal collections of Annan's work: Metropolitan Museum of Art, New York; Museum für Kunst und Gewerbe, Hamburg; Royal Photographic Society; Scottish National Portrait Gallery; Staatliche Museen zu Berlin.

WILLIAM BUCHANAN

Biography

James Craig Annan, the second son of Thomas Annan and Mary Young Craig, was born on 8 March 1864 at Talbot Cottage, 15 Burnbank Road, Hamilton. He left school in 1877 when the family moved to Lenzie to set up a carbon printing works. About 1878 he attended chemistry lectures at Anderson's college. In 1883 he learnt photogravure from Karl Klíč in Vienna. On his father's death in 1887 he became a partner in the firm. About 1890 he made photogravure prints from Hill and Adamson calotypes. He lent these to exhibitions in Europe and the United States. He championed their work. Also about this time he decided to become a creative photographer. In 1894 he was elected a member of the Linked Ring. He exhibited, often by invitation, in New York, Paris, St. Petersburg, Brussels, Antwerp, Munich, Berlin, Philadelphia, Hamburg, Turin, the Hague and other places. His work was also widely reproduced in the many photographic magazines of the time. He remained a bachelor. He died on 6 July 1946 at his home, Glenbank, Lenzie.

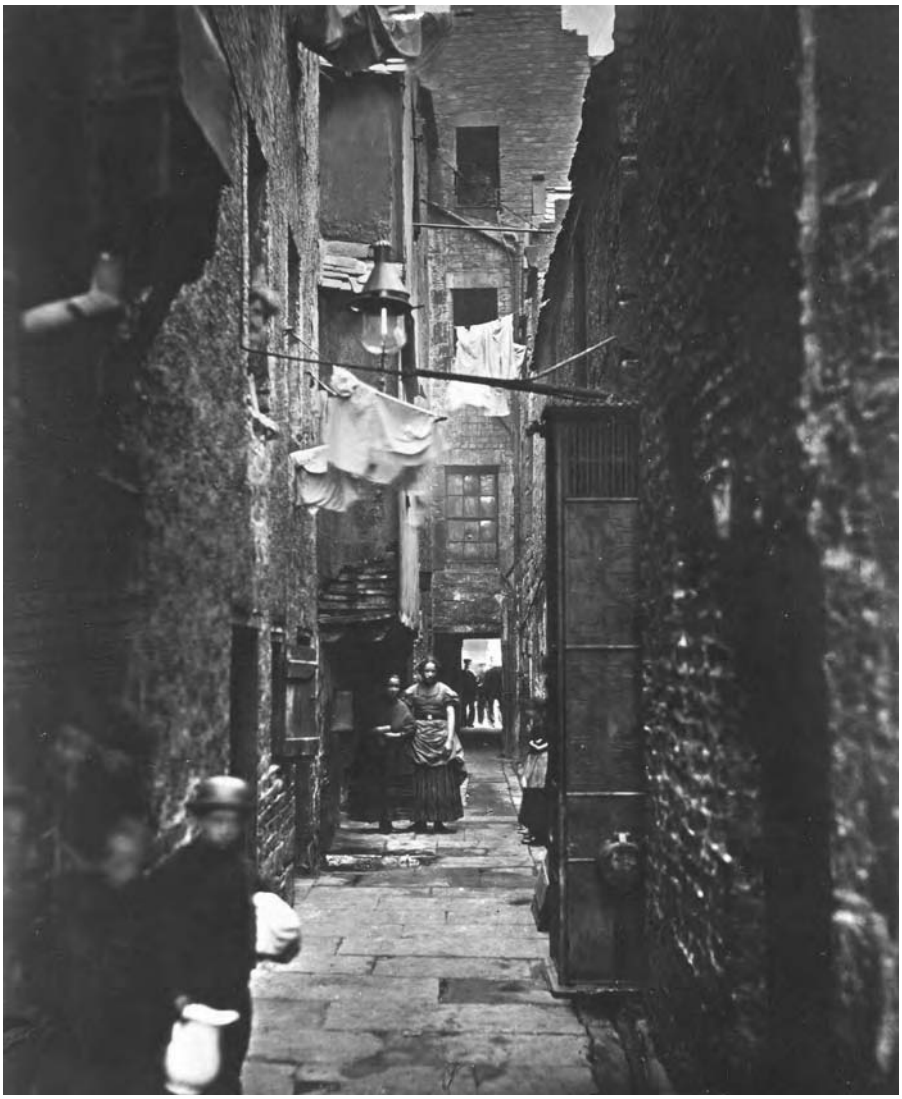
ANNAN, THOMAS (1830–1887)

Scottish photographer and founder of a photographic firm

Thomas Annan, who lived when the commercial aspects of photography were being explored, established his firm, T. & R. Annan, in Glasgow. His obituary in *The British Journal of Photography* noted his high reputation for the reproduction of works of art, as photography replaced techniques like engraving, but it made no mention of Annan's qualities as a photographer. He created some of the memorable images of his century.

In 1862 the Glasgow Art Union, to replace the usual engravings issued to its subscribers, asked Annan to produce photographic prints. These proved acceptable. Annan did not merely photograph a painting. He gave a print of it to the artist to work upon. This was then photographed and from that negative the prints were made. The reproductions of Noël Paton's "The Fairy Raid" were made this way.

Annan kept in the forefront of the new permanent processes. The rights to Joseph Swan's carbon process were bought by Braun for France and Belgium, by Hanfstaengl for Germany, by Annan in 1866 for Scotland and by the Autotype Company, two years later, for England. Swan's first major production was to make in 1866 from Annan's negative, carbon prints, in three sizes, each in an edition of 1,000, of D. O. Hill's painting "Signing the Deed of Demission." Hill had originally advertised (23 years before) that the reproductions would be engravings. These carbon prints were hung in many a pious Scottish household. When Annan heard



Annon, Thomas. Close, No. 37 High Street.

of photogravure he went to Vienna in 1883 with his son so that James (J. Craig Annan) could learn the process from its inventor Karl Klíč. Annan bought the rights of that process for Britain.

Annan turned photographer from engraver and lithographer in 1855. That year he photographed the first iron transatlantic steamer under construction, the gigantic 'Persia.' Very likely this was a commission from its creator Robert Napier.

Glasgow commissioned Annan to record two great civic enterprises. It constructed a new water supply which, daily, brought 50 million gallons from Loch Katrine through 35 miles of pipes to the city. This splendid piece of Victorian engineering is contained in the album *Views on the Line of Loch Katrine Water Works*, 1859 and *Glasgow Corporation Water Works: Photographic Views of Loch Katrine*, 1889, a record of sluices, salmon ladders, aqueducts, syphon piping, a gauge basin, etc., ending with a photograph of the water gushing in Kelvingrove Park from a fountain complete with the Lady of the Lake on top.

Glasgow also embarked on the demolition of its terrible slums. Unlike the crusading Jacob Riis in New York 20 years later, Annan's task was to record what was destined to disappear. Working in feotid and disease ridden conditions he produced the first thorough—and a most moving—account of the worst slums in Britain. "Close, No. 157 Bridgegate" is of dirt, decaying stone, grimy washing, the glint of effluent, yet by Annan's photography somehow made beautiful. The slum dwellers sometimes appear. In "Close, No.46 Saltmarket" they have been carefully assembled. At the centre is the figure of a boy set in front of the dark rectangle of a door. His stance, thin arms akimbo and surely not arranged by anyone, shows he has some determination left. What became of him?

Single prints of the slums were made. In 1871, the first edition, probably four sets of 31 albumen prints, was titled *Photographs of Streets, Closes, &c. Taken 1868–71*. The second edition, 1877, probably 60 sets, *Photographs of Old Closes, Street, &c., Taken 1868–1877* is of 40 carbon prints. The third edition, of 50

photogravures, was published in 1900 in two versions. One version, 100 copies, *Old Closes and Streets A Series of Photogravures1868–1899*, was published by Annan for the Corporation. The other version, 150 copies, *The Old Closes & Streets of Glasgow*, published by Maclehose were the only copies for sale. For the photogravure editions James sharpened the images.

Annan's landscapes, once highly regarded should be highly regarded again. In 1860 *The British Journal of Photography* found his "Loch Ranza" the best work at the Photographic Society of Scotland. In 1861 at the British Association in Manchester, "Aberfoyle" gained by common consent "the blue ribbon of merit." In January 1863 a review of the Photographic Society exhibition in London commented that Annan whose fine landscapes were little known in London, "from this time forth ... must take rank amongst our first-class artists." In January 1865 *The Photographic News* noted Annan's "deep poetic feeling," which is certainly evident in 'The Last Stooks of Harvest" and "Ferns" whose fronds are set against a carpet of tiny leaves. These two prints, 16 inches by 13, cost 7 shillings and sixpence each. In April that year Annan's "Dumbarton Castle" earned a silver medal from the Photographic Society of Scotland.

Annan was also a fine portraitist. His posse of Glasgow University Professors who appear in *Memorials of the Old College of Glasgow*, Maclehose 1871, are splendidly understated. Some handle a volume in the best manner of Hill and Adamson. Annan's most powerful portrait was taken in 1864 when the missionary and explorer David Livingstone was visiting his family who lived next door. Livingstone, anguish and suffering clearly visible on his face, sits at a table on which his consular cap is placed. Livingstone was then a hero. Annan created his sombre icon. Annan also photographed Livingstone's five year old daughter looking up at the strange man whom she had just met for the first time.

T. & R. Annan's *cartes-de-visite* were mainly of Free Church ministers but also included the "Rev. Dr Krummacher, author of *Elijah the Tishbite*, Berlin," two M.P.s, three artists, and from the Pacific 'Williamu, Chief Tanna Islands." They and 'Dr Livinsgtone, African Traveller" cost a shilling each.

Collections of Annan's work are in Glasgow University Library, the Mitchell Library, Glasgow and the Scottish National Portrait Gallery.

William Buchanan

Biography

Annan was born on 15 July 1830 in Fife. His "Dairsie Church" is a scene from his childhood. Under the bridge flows the River Eden. A laid led off to Lydox Mill, the family's corn and flax spinning mill. In the church yard lie his mother Agnes Bell and his father John Annan, Master Miller. In 1845 he left for Cupar to begin an apprenticeship in lithography and engraving. In 1849 he moved to Glasgow to work for a lithographic company. In 1855 he established a photography business though where he learned photography is not known. Two years later he moved into the first of several premises along Sauchiehall Street. Annan married Mary Young Craig on 27 July 1860. They had seven children of whom John and James (first and second children) worked for the firm. In 1864 he established a home, Talbot Cottage, and works at 15 Burnbank Road, Hamilton. In 1857 he moved to Lenzie to set up a carbon printing factory. Annan died at his home, Glenbank, Lenzie, on 14 December 1887. Two years later the firm became "Photographers and Photographic Engravers to Her Majesty at Glasgow."

ANSCHÜTZ, OTTOMAR (1846–1907)

German photographer and moving picture pioneer

History has not been kind to Ottomar Anschütz, a leading photographer of the later 19th century whose career was "almost forgotten," in the contemporary words of one critic, by the mid-1920s. Although he contributed many important technical improvements to photographic

work, significantly a practical focal-plane shutter that was in production for over 35 years in the cameras of C. P. Goerz in Berlin, and developed a moving picture viewer for his series chronophotographs that preceeded the Edison Kinetoscope, the rise of modernist aesthetics early in the 20th century and the unusual technology of his moving picture system combined wholly to eclipse his work. Until the 1990s there was neither any substantive research into his career nor any exhibitions devoted to it. One part of the problem in dealing with Anschütz is his own habit of secrecy regarding his work: he made an inviolable distinction between photographs that he considered artistic, and worthy of public exhibition, and those he considered commercial and therefore of little interest. As a result, he exhibited and also published his ground-breaking "instantaneous" pictures taken in 1883-1887 that captured the movements of animals, troops on manoeuvre, and, strikingly, storks in and around their nests, for almost 20 years until they became over-familiar and helped characterise his career as old-fashioned and passé. Another problem is found in Anschütz's extraordinary moving picture work, which absorbed him almost completely between 1886 and 1894: despite its success with audiences and its remarkable achievements in reproducing natural movement, his failings as a businessman led him to assemble huge debts by late 1892. This debt seriously threatened the social and economic standing of this provincial photographer who had risen to become the photographic instructor to the Kaiser's wife and family, and who circulated amongst the elite social and business personalities of Berlin. With imminent collapse facing both his reputation and his energetically led photographic business, Anschütz abandoned his pioneering moving picture experiments, even repressing its artifacts and pictures, so that this important part of his work also disappeared, leaving him at the end of his career between 1894 and 1907 in the superficial public record as a champion of amateur photography and defender of conservative genre photography. Obituaries noted the passing of one of the "old guard" of photography.

In the 1870s and 1880s, instantaneous photography, or exposures fast enough to capture quickly moving subjects in natural settings were the cutting edge of photographic technology. Photographers like the Graf von Esterhazy, Alfred Lugardon, and others took many prizes at international exhibitions for their often surprising mages of leaping dogs and jumping men, but it was Ottomar Anschütz who consistently led the field, principally by using a focal-plane shutter which he developed into a practical design in 1882, first used to take naturalistic photographs of troops during their field exercises. To aid his ability to work quickly, he etched a focussing scale on the outside of his lens tube, so he could change plates and make an accurate exposure very rapidly. His special camera, which Anschütz kept secret for seven years, also allowed him to develop a photographic method far in advance of its time: in an era when any photographic subject was universally subservient to the assumed demands of the medium, or to the imposed demands of the photographer's style, Anschütz gave his subjects complete freedom, his camera allowing him to simply follow their actions, whether farmers and workingmen around Lissa, which produced sequences of complete movements and activities, or animals from the Breslau Zoo photographed from a specially constructed blind, which produced informal images of foxes, leopards, monkeys and other animals. In this work, as the large collection of surviving prints with consecutive negative numbers at the Hochschule der Künste in Berlin illustrates, Anschütz with his plate camera anticipated the much later photographic practise of the leading photojournalists of the 1930s and 1940s with their fast-acting 35mm apparatus.

Anschütz turned to series chronophotography in 1886 with an impressive set of pictures of horses and riders taken at the Royal riding academy in Hanover. At first using a set of 12 cameras equipped with his focal plane shutter, the next year he developed a unique apparatus using 24 lenses and shutters but incorporating sophisticated adjustments so that complete, "closed" movements —where the first and last images would match when reproduced in a circular viewer like the zoetrope or phenakistiscope—could be recorded. Building his own electrically-based viewer called the Schnellseher, which used the intermittent flash of light from a Geissler tube to illuminate series photographs fixed to the rim of a rotating disk, Anschütz then began to exhibit photographic moving pictures in public, first at the Ausstellungspark in Berlin in 1887. Over the next five years some eight different models of this viewer were widely exhibited across Europe and America, often in "Schnellseher parlours" of a dozen or more machines such as those in New York City, Berlin, Hamburg, and London. For the commercial deployment of his Schnellseher, Anschütz made special entertainment chronophotographs, none of which survive, including subjects like *Skatspieler* (Card Players), *Mimenspiel* (Man with Changing Expressions), *Lustige Fahrt* (Funny Journey) and *Barbierstube* (Barber Shop Scene), several of which were precisely echoed in the earliest films of Thomas Edison, the Lumère brothers, and Georges Méliès. Because of an odd business agreement with the leading electrical firm of Siemens & Halske, which manufactured some 137 automat Schnellsehers for him, the financial collapse of the Electrical Wonder Company in London left Anschütz with a personal debt of over 47,000 Marks to the Berlin firm, and after the EWC's failure he repressed most of his chronophotographic work, including over 100 series of dancers intended for teaching and an

extensive series showing the work of the German Post Office. His only surviving chrnophotographs are those he sold as photolithographs beginning in 1887, those that were printed for zoetrope bands, and a collection of contact print leporellos at the Hochschule der Künste in Berlin that were probably included with a report to the Culture Ministry, who had financially supported his early work. Between 1894 and his unexpected death in 1907 he promoted amateur photography with lectures, teaching, and an elaborate studio and exhibition space opened in 1896. He devised and manufactured a number of photographic accessories, including a compact arc lamp, portable darkroom, changing bag, universal tripod head, and other apparatus; founded a commercial organization to resist the inroads of foreign photographic suppliers to the German market, particularly the Eastman Company; and accompanied the Kaiser and his family on a long trip through the Holy Land in 1898. His later photographs, still technically supeurb, were nonetheless often highly retouched in part and reflected the romantic imagery of an earlier era.

DEAC ROSSELL

Biography

Ottomar Anschütz was born on 16 May 1846 in Lissa in the Prussian province of Posen (today Leszno, Poland), the son of Christopher Berthold Anschütz, a respected local decorative painter who took up photography late in his career. Trained in drawing and painting, the young Anschütz studied photography with Maksymilian Fajans in Warsaw, Ferdinand Beyrich in Berlin, Franz Hanfstaengl in Munich, and Ludwig Angerer in Vienna before returning to Lissa to take over his father's business in 1868. In the late 1870s he built a travelling studio to expand his clientele, in 1881 he began working with dry plates, and the next year he photographed army manouvers with a camera of his own design incorporating a practical focal plane shutter and a focussing guide etched on the lens tube. With this camera, its innovations kept secret for years, he began to achieve a national and then European reputation for taking "instantaneous" photographs that captured quick movements in natural settings with both sharpness and clarity, with a series of photographs of storks in their nests receiving particular acclaim. He established a studio in Berlin in 1884, and in 1885 began to take series photographs in the manner of Muybridge using a set of 12 cameras, supported by a grant from the Prussian Ministry of Culture. In 1886 he devised a wholly new camera unit with 24 lenses and outfitted with complex adjustments so that a variety of subjects could be reproduced in a rotating viewer such as a zoetrope; he designed several new and innovative models of zoetrope, one of which carried three rings of viewing slots and allowed didactic examination of movement. The same year, Anschütz built his own viewing apparatus, called a Schnellseher, using a continuously rotating disk bearing between 17 and 24 images linked to a strobing light source to provide the necessary intermittentcy to register clear moving pictures for its spectators. Between 1886 and 1895 eight models of Anschütz Schnellsehers with his series photographs were widely exhibited in Europe and North America, seen by 14,858 people in five weeks in Frankfurt a. M. in 1891 and 56,645 people in Hamburg in 1895, but his arrangements for the commercial exploitation of his apparatus, through the specially-established Electrical Wonder Company in London, were drastically undercapitalized and quickly collapsed. From 1894 Anschütz gave up his decade-long obsession with moving pictures and devoted his energies to supporting amateur photography, especially amongst the social elite of Berlin, where he had long been the photographic teacher to the Kaiser's family. He continued to make commercial portraits, few of which have survived, led an industry boycott of "foreign" photographic products from the George Eastman Company, and died suddenly of complications from acute appendicitis on 30 May 1907. His studio in Berlin continued to operate under his name, often directed by his son Guido, until 1925.

ANTHONY, EDWARD (1819–1888) AND HENRY TIEBOUT (1814–1884)

For much of the nineteenth century the firm of E and H T Anthony was the dominant retailer and photographic manufacturer in the United States.

Edward Anthony (1819–1888) was born in New York and graduated from Columbia College in 1838. In December 1839 he paid to see François Gouraud's exhibit and lectures on the daguerreotype and the following year he became a pupil of Samuel F.B. Morse. He was given

Anthony, Edwards and Henry Tiebout. C. S. Soldier killed in the Trenches, at the storming of Petersburgh, VA., April . . . The wound is in the head caused by a Shell, by Timothy H. O'Sullivan.

his first important photographic job photographing the American/Canadian border for the US government and on his return in late 1840 or early 1841 he opened his first daguerreotype studio where he also sold daguerreian supplies.

During the 1840s Anthony formed numerous business partnerships and continued to expand his studio and retailing activities. Between December 1846 and 1848 Anthony undertook correspondence with William Henry Fox Talbot to encourage Talbot to patent his calotype process in the United States and license it with Anthony acting as agent. This failed and Talbot finally sold the US rights to Langenheim in May 1849.

In late 1847 Anthony moved to 205 Broadway, to focus on photographic manufacturing, wholesaling, importing and publishing. Increased competition from the Scovill Manufacturing Company, which had entered photographic manufacturing in late 1839, during the 1850s forced him to start making daguerreotype cases and he began expanding his manufacturing base. A substantial new factory was opened in early 1853 making cameras, tripods and equipment and photograph cases. It made use of production line methods which allowed prices to be kept low.

In 1852 with the need for more capital his brother Henry T. Anthony (1814–1884) joined Edward as an active partner in the firm with responsibility for the manufacturing and technical side of the business. In 1853 sales had reached $250,000. The firm changed its name to E&HT Anthony & Co in 1862 reflecting the increased role of Henry within the business. The company was the largest producer of photographic chemicals and new photographic processes during the decade offered significant new opportunities to expand the business.

Stereography played an important role in the company's product lines from around 1859 when it began producing sets of stereocards supported by an extensive distribution and retail network. By the early 1870s up to 11,000 views were offered, both retail and wholesale. Anthony published Mathew Brady's Civil War views from 1862 with over 2000 images from Brady and others eventually being offered for sale. In the 1870s W.H. Jackson's views of Yellowstone were one of the most popular series and views by other well-regarded photographers such a Timothy O'Sullivan and Thomas C Roche, who had a long business relationship with the company, were also being published. As interest in stereography waned the last sets were published in 1880 and the firm moved into magic lantern manufacturing and began to publish extensive series of lantern slide sets.

The period from 1865 to 1880 saw further enlargement of the business with wet collodion equipment and sensitized materials being manufactured and the firm putting considerable efforts into expanding sales throughout the United States and in Europe. A new factory was opened in 1860 for manufacturing albumen paper and the albumen paper manufacturing facilities of Chapman and Wilcox were acquired making Anthony the principal maker of albumen paper in the United States. In 1863 it was estimated that Anthony purchased

over 15,000 reams of paper and used over 10,000 eggs. During this period it was producing up to 3600 *cartes-de-visite* of celebrities each day with 4000 subjects being available. The company's sales had reached $600,000 by 1866. By 1871 the *British Journal of Photography* was describing Anthony as 'the largest photographic firm in the world.' It had extensive offices and three large factories.

Photographic cameras and equipment had been manufactured extensively either directly or by others for Anthony from the 1850s and the growth of amateur photography from the 1870s and the introduction of dry plates encouraged the development of further lines of camera. Hand and pocket cameras for the amateur market played an increasing role in the company's product lines from the 1880s with the Schmid Detective hand camera of 1883 being the first of its type. In the late 1870s Anthony started importing dry plates from England and started production of its own Defiance dry plates in 1880 but the firm found it difficult to maintain quality and keep prices low.

Anthony began selling George Eastman's dry plates from 1880 with Anthony's marketing and distribution network offering Eastman an unrivalled opportunity to expand his new business. When Eastman started paper manufacture in a serious way in 1884 Anthony employed Frank Cossitt who had operated Eastman's coating machine to design a similar machine. Eastman severed his business relationship with Anthony in 1885 and an intense rivalry operated for the rest of the century with Eastman frequently resorting to law to restrain Anthony's activities in sensitised goods production.

After Edward Anthony's death in 1888 the company began to suffer financial difficulties partly as a result of the costs of Eastman's law suits and a severe fire in 1888 which affected the its manufacturing facilities. In 1891 Anthony concluded a financial arrangement with Thomas Blair of the Blair Camera Company selling some assets in return for Blair stock. However, the further merging of the two firms was restricted by Blair's outstanding court cases with Eastman. Other law suits that involved Blair and Anthony, and Eastman further strained the company. In 1899 Anthony attempted to sell its capital stock to Eastman for $268,750 which Eastman refused and other unsuccessful attempts were made in 1901, 1904 and 1905.

In March 1900 Anthony established new offices at 122–124 Fifth Avenue, New York In July 1901 it combined with Scovill and Adams to buy a controlling interest in the Goodwin Film and Camera Company. The two rival firms formally merged on 23 December 1901 to form the Anthony and Scovill Company which also brought together other American firms controlled or owned by the two principals. The dominance and influence of the Eastman Kodak Company and the cost of on-going litigation had convinced both parties that their strength lay in combining forces. The Ansco trade name which was used from May 1902 became one of the best known in the American photographic industry until the late twentieth century. A major reoganisation of the business in 1907 changed the business name to the Ansco Company.

During the twentieth century Ansco continued to try and compete with Kodak but with limited success. It merged with General Aniline Works Inc, the American branch of the German chemical giant I.G. Farbenindustrie Aktiengesellschaft, to form Agfa-Ansco in 1928 and with the outbreak of war it became, in 1943, a division of the Americanised GAF. The postwar period saw a continued decline and in 1978 the Ansco name was sold to W Haking Enterprises of Hong Kong.

ANTHROPOLOGY

Both emerging in the second quarter of the nineteenth century, photography and anthropology have had parallel histories. Both changed radically in their range and capability by the end of the century and beyond as photographic technology became easier and the modern discipline of cultural anthropology emerged.

The boundaries of anthropological photography are not easily defined in the nineteenth century. Anthropology itself was not a discrete discipline but a fusion of scientists, travellers, folklorists, theologians, linguistics and archaeologists with a common interest in the study of mankind's cultural, social and biological dimensions. 'Anthropology' shifted meaning in the course of the nineteenth century and was used differently in different national traditions and at different times, terminology slipping between the terms 'anthropology,' 'ethnology' and 'ethnography.' In France 'anthropology' meant 'physical anthropology' as developed at the Laboratoire d'Anthropologie in Paris, whereas in Britain physical anthropology was usually called 'ethnology.' In Germany, as in Britain, 'Anthropologie' was initially the inclusive term, ethnography or *Völkerkunde* being the detailed description of manners and customs, whereas 'Ethnologie' came to mean 'folklore,' however 'Anthropologie'

came increasingly to mean physical anthropology as in France. In the United States the term 'ethnology' was eventually superseded by 'anthropology,' embracing physical and cultural anthropology and archaeology. These complexities of terminology were part of the search for methodologies to explain racial and cultural difference. Photographs made and used in these contexts were integral to this process. The shape of major collections of anthropological photographs were forged by these intellectual traditions for gathering and organising scientific knowledge and the specific political, economic and social agendas operating within the various national colonial policies and aspirations. For instance, German anthropological collections are generally founded on a more inclusive definition of 'anthropological interest' than British collections of the same date which include little travel photography which might be described as 'ethnographic,' such as that of Samuel Bourne or John Thomson, because it fell outside contemporary concepts of 'anthropological' data.

The dominant theories of cultural difference were evolutionary or at least progressivist—the best known and most influential being Darwinism. Within this culture was perceived as being biologically determined. Consequently photographs of culture were read through a racial grid and visa versa, in a way which makes it difficult to separate 'cultural anthropology' photographs from 'physical anthropology' or 'ethnology.' Closely related to other photographies of colonial expansion such as missions, travel and exploration, anthropological photography embraced both photographs taken with specifically anthropological intentions and those, because of their content, deemed to have 'anthropological interest' though they were not specifically scientific. The mutability of photographs gave them evidential value within different interpretative frameworks, In any case many photographs could be used as documents of both race and culture, for instance those of Japanese officials taken for the Musee de Paris by L. Rousseau and M. Potteau in the early 1860s. Much nineteenth century anthropological photography was thus defined through its subject matter and the way it was used rather than specific styles.

Whatever the different national and intellectual orientations in anthropology, photography was used with precisely similar intentions, to produce visual facts which combined the certainties of mechanical inscription with those of scientific observation. There were two interrelated purposes in the amassing of photographs. First, 'salvage ethnography' recorded cultural practices which were perceived to be 'dying out' in the face of inexorable cultural evolutionary advance. Second photography provided raw data which could be compared and contrasted within the scientific taxonomies of the day, by scholars in the interpreting centres of the universities and learned scientific societies of the Euro-American world. In these contexts, photographs were integral to the definition and reification of racial and cultural hierarchies. Yet there is a strong sense in which anthropological photography created its own object of study, focusing in the 'culturally pure,' primitive or traditional, excluding evidence of colonial influence or social change.

There were strong links between anthropology and colonial government. This was most marked in India. James Forbes-Watson and J.W. Kaye's great photographic compilation *People of India* (1868–1875) attempted to describe visually the people, manners and customs of the Indian sub-continent and their classification. Some of the earliest ethnographic books with photographic illustrations are on India, such as James Wilkinson Breeks *Account of the Primitive Tribes and Monuments of the Nilagiri* (1873). Although the systematic Ethnological Survey of India, suggested in 1882, was not realised until 1901, photography was nonetheless used extensively throughout the period to defined the colonial subject both racially and culturally. This relationship between anthropological photography and government was also more loosely instrumental in defining views of indigenous peoples in settler colonialisms of Africa, Australia and New Zealand.

Throughout the second half of the nineteenth century there were attempts to improve both the quality and quantity of data available to anthropologists. A number of publications gave guidance for collecting information, including the taking of photographs. Many specifically photographic instructions,, for instance those of Paul Broca in France (1864), were concerned with phyisical anthroplogy. The systematization of the social and cultural was more difficult, photography's utility in visualising such information was more often implied than explicit.

In 1874 the British Association for the Advancement of Science (BAAS) published *Notes and Queries on Anthropology* with questions ranging from physical anthropology to religious beliefs, marriage forms, morals, treatment of women, forms of greeting, presence of cannibalism, manufacture of pottery or the concept of art. The intended photographic section was never published, nonetheless questions elicited photographic responses; the earliest being by E.H. Man in the Andaman Islands (1876), who posed tableaux specifically to answer several questions about culture in one photographic frame. The third edition (1899) was the first to carry detailed photographic advice. Written by A.C. Haddon, it covered both technical matters, such as the problems of rubber parts in the tropics, and comments on the posing, aesthetics and social relations of photography. Similar methodological volumes and question lists appeared in France, although formal instructions

were dominated by the concerns of physical anthropology. In Germany, anthropology, with prehistory, was contained within broader instructions for scientific observation, *Anleitung zu wissenschaftlichen Beodbachtungen auf Reisen*. Produced under the auspices of Admiralty, first in 1875, this influential volume included detailed technical photographic instructions and discussion of desirable subject matter by Gustav Fritsch. Later instructions from Emil Schmidts (1888) and Felix von Luschan (1899) included photography within systematic field observation and collecting. Overall such manuals had the effect of structuring vision and thus photography through prescribing the significance of specific cultural traits.

In the United States the Bureau of American Ethnology (BAE) was founded by Act of Congress in 1878–79 to record and photograph America's indigenous cultures. As well as absorbing earlier photographs of Native American peoples, such as those by the James E.McClees Studio in Washington (1857–58), instructions were issued to photographers working for the BAE on the photographic procedures of portrait and genre studies. The first official photographer was John K. Hillers whose photographs of the Pueblos of the southwest (1879–82) combined scientific and aesthetic agendas. Between 1879 and 1888 anthropologists of the BAE were helped by professional photographers, such as William Henry Jackson and Charles Milton Bell. However after the Kodak revolution of 1888 anthropologists increasingly made their own photographs as part of fieldwork. Many of the great photographic documenters of indigenous culture of the late nineteenth century worked under the auspices the BAE at a time of profound change for Native American communities: James Mooney photographed the Cherokee and the Ghost Dances of the Plains (1890–91), Adam Clark Vroman and Victor and Cosmos Mindeloff photographed in the Pueblos of the southwest in the 1890s, the latter working with Frank Cushing of the Smithsonian Institution.

While the primary function of BAE was scientific, recording Native American cultured for posterity, there were also strong governmental agendas in gathering anthropological information, especially in the light of western expansion and the Indian Wars of the 1860s. By the late 1880s they had also become linked to national policies of cultural assimilation. Photographs made for anthropologist Alice C. Fletcher amongst Omaha for the New Orleans Exposition "Indian Civilzation" exhibition in 1885, typify this approach. The representations constructed cultural similarities, such as settlement and nuclear families, rather than stressing differences.

As elsewhere, outside the BAE, the universities and museums were also increasingly active in anthropology and thus photography. Franz Boas, perhaps the single most influential figure in the shaping of American anthropology, viewed photography as an important tool in his work. He both photographed himself and employed photographers, notably Oregon C. Hastings and George Hunt, a Kwakiutl photographer, to make images for him of, for instance, the Kwakiutl potlatches and Winter Ceremony from the mid-1890s on. Boa's cultural relativist view, which saw cultures as integrated wholes rather than a succession of comparable phenomena within an evolutionary framework, enlarged the potential for anthropological field photography.

Anthropological investigations encompassed not only other races but marginal groups at home: peasants, working class and internal indigenous groups whose culture was perceived as departing from an assumed norm. A wide range of material, from Knut Knudssen's photographs of the Sami of northern Scandinavia to Thomson's *Street Life of London* (1878), might be seen as inflected with anthropological ideas. While some were concerned with issues of class and criminality, others, through anthropology's study of culture and origin, were related to emerging national identities. Many European countries systematically documented their peasant cultures—France, especially in Brittany, Germany, Spain and Hungary. For instance, I.K. Inha's *Land of the Kalavala* (1890s) visualised the source of Finland's national epic, or indeed Sir Benjamin Stone, whose photographs constituted a cultural archive of an English past.

While many photographs were taken with anthropological intent throughout the colonised world, equally important were the huge numbers photographs of 'anthropological interest' made outside science, which became absorbed into anthropology. In France, Broca recommended those with scientific interests to purchase photographs of anthropological interest in the countries they visited. The learned societies, museums and universities who collected anthropological photographs provided a forum for the debate, viewing, collection and classification. Some were active in the dissemination of images amongst those with anthropological interests, such as the Berliner Gesellsachaft für Anthropologie, Ethnologie und Urgeschichte's project with Hamburg photographer Carl Dammann. This applied equally to internal ethnographies, for instance the 'Racial' Albums of the BAAS, which collected and classified carte de visite 'types' from all over the British Isles, from Highlanders to Suffolk flintknappers.

The large numbers of such photographs collected by scientists testifies to the anthropological importance attached to them. Cultural subjects by photographers such as J.W. Lindt, Kerry's Studios, J.W Beattie in Australia; Josiah Martin in New Zealand; Dufty Brothers, Burton Brothers, Thomas Andrew in the Pacific, Marc Ferrez in Brazil; Frank Rinehart and George B. Wittick in the U.S.; C. Kroehle in Peru, Lloyd & Co. or Middlebrook

Studios in Southern Africa; Bonfils' and Zangaki's Studios in North Africa and Middle East, Felice Beato in Burma and Japan—found their way into scientific collections in a research resource. Such photographs occupied the cusp between the popular and the scientific and photographers marketed their work, some times aggressively, in both markets. In many cases, the anthropological legitimated popular images of the exotic and erotic. Such photographic productions are found, repeated through many major collections, suggesting the global scale of the circulation of 'anthropological photographs'.

By the end of the century a clear break emerged between the amateur and antiquarian and the professionally trained university or research institute-based anthropologist who combined field study with clear theoretical analysis. This development was, in general terms, common to the various anthropological traditions and was reflected in the way in which photography was both produced and used in anthropology. The anthropological validity of commercially produced photographs of "native types" and scenes declined. Increasing stress was laid on photographs which resulted from direct scientific observation. Linked to this were shifts in photographic style from the controlled scientific specimen and its popular derivatives to a more naturalistic approach. These were exemplified by two papers which appeared in the pages of the *British Journal of the Anthropological Institute*. In 1893 Everard im Thurn (who photographed extensively in British Guiana from the late 1870s–90s) advocated the anthropological value for photographs of people in their natural conditions made from direct observation. A different view was presented in 1896 by M.V. Portman He advocated the arrangement of 'culture' within the photographic frame as visual answers to the questions in *Notes and Queries*, the approach he had used in his studies of Andaman Islanders. By the 1890s unmediated naturalism was becoming the dominant truth value in anthropological photography. In many ways these concerns resonate with debates concerning naturalism and intervention within the wider photographic community.

In photographic terms this was aided by increasing technical ease, although anthropologists tended to use well-built cameras and glass plates until well into the twentieth century because of the instability of film negatives in tropical climates. However, the possibilities for 'action' photographs by the 1890s accorded with emerging ideas of scientific truth premised on direct observation. This is demonstrated in the work of the BAE, for instance Matilda Coxe Stevenson, working with BAE stenographer May Clark, used a Box Brownie extensively at Zuni in 1891, producing snapshots of everyday life. material culture and ritual. The interdisciplinary university or museum-based expeditions with large photographic outputs became an important aspects of anthropology at this period, especially in the German and America traditions. The 1897 Jesup North Pacific Expedition, under Boas, used photography to record a whole range of daily and ritual behaviours, some of which were specially re-enacted for the camera and as was often the case with expeditions, photography was integral to the collecting of material culture for museums as well as the social description of indigenous peoples. The Second Cambridge Expedition to the Torres Straits of 1898, under A.C. Haddon, is especially important because of the centrality of the visual to its interests. As well as exposing over 500 photographic plates, they took first anthropological film to be made in the field and had hoped to experiment with colour photography using the Ives and Joly process (which fell victim to the travelling conditions and the tropical climate).

Increasingly, the dominant way of working in the early twentieth century, was that of the work of individual fieldworker. For instance, Baldwin Spencer and Frank Gillen produced photographs as a result of long acquaintance with the Aboriginal peoples of Central and Northern Australia from 1894 on, and the German Fritz Sarasin worked in with Veddah people of Ceylon (Sri Lanka), recording everyday culture in the 1890s. The emphasis in all these examples, and other contemporary

projects, was on direct field observation. It translated into an apparently naturalistic, non-interventionist photographic style, in which minimal aesthetic control was integral to its truth value within a recognisably proto-modern field method. However the individual colonial ethnographers continued to make photographs which became absorbed into anthropology, for instance the German Richard Parkinson, a planter and trader, who made a compelling series of photographs of the culture of the Bismark Archipelago. The two methods of anthropological photography did not finally disentangle until well into the twentieth century.

The role of anthropological photography in the public realm was also significant because it had a profound influence on contemporary perceptions of race and culture. Science was used to legitimate a wide range of cultural stereotypes and their photographic manifestations, although science itself had contributed to these ideas. The expositions, world fairs and music halls of the nineteenth century were important sites for both public dissemination of cultures and their photography. These cultural displays imported groups of indigenous peoples from all over the world. They 'performed' their culture in reconstructed villages on the exhibition site, many displays becoming more lurid and exotic as the century progressed, further reinforcing racial and cultural stereotypes. Nonetheless, they were also seen as sites of serious anthropological science. Photographs were made with both a scientific and popular audience in mind. The 1893 Columbia World Fair in Chicago, for which Boas was anthropological advisor, featured many cultures including Native Americans and Samoans. Photographs sold both as a book, *Portraits Types of the Midway Plaisence*, and as picture postcards. This dissemination extended the photographic focus of earlier shows for instance Prince Roland Bonaparte photographed Omaha people at the Jardin d'Acclimatation in Paris in 1884, and Australian Aboriginal group at the Folie Bergéres (1886), and Carl Gunther's photographs of Bella Coola from Canada's Pacific coast taken in Berlin in 1885.

Publications of popular anthropology such as Tylor's *Anthropology* (1881) or Friedrich Ratzel's *Völkerkunde* (1894) were illustrated with engravings made directly from photographs, which functioned as as an index of their truthfulness. The introduction of the half-tone brought about further dissemination of anthropological photographs. By the turn of the century there were many heavily illustrated educational magazines such as the British *Living Races of Mankind* (1902–3), or in France *Science et Nature,* or *L'Journal illustré*, which drew on the collections of anthropologists and learned societies. Anthropological photographs also were extensively disseminated as lantern slides at public lectures. For instance Cambridge anthropologist A.C. Haddon gave public lectures on 'Savage Life in New Guinea' or 'The peoples of North America' using photographs from his own field research. The dissemination of images of 'anthropological interest' also increased from the 1890s by the global market in picture postcards.

By the early twentieth century shifts in disciplinary practice brought about major shifts in the production and evaluation of anthropological photographs. The diversity of cultural behaviour, the subjectivity and random inclusiveness of photography meant that attempts at the systematisation proved impossible. The truth of anthrpological photography not only lay in its indexicality but increasingly in the contexts of its making. Although huge numbers of anthropological photographs continued to be made, photography was relegated largely to a visual notebook. The stress in scientific anthropology was on the observation of the trained fieldworker—the eye of the fieldworker, not the camera, become the site of anthrpological truth.

APPERT, EUGÈNE (1830–1891)

French artist, photographer, and photomontagist active during the Paris Commune (1871).

Ernest Eugène Appert was born in the Pays de la Loire, Maine-et-Loire, Angers, France on 1830. In 1869 he became an independent photographer and painter. Because he had no sympathy with the communards, the rebels participating in the Paris Commune in the spring of 1871; he produced a series of fake Versaille-propaganda photomontages called 'Crimes de la Commune'. Appert was the genius behind a whole series of photomontages meant to discredit the communards. It is likely that his images were not of actual people protesting, but instead of staged shots with actors.

After the rebellion, Appert took the portraits of hundreds of the individual communards while imprisoned in jail. He was not assigned this job by the authorities, but took the initiative upon himself to do this, which also happened to have a commercial motive. Indeed, his photographs were eagerly purchased and reproduced once and again. The police also benefited from his images by including them in their card indexes. Perhaps though Appert was attempting to photograph 'physiognomy,' which around 1870, became a very popular pseudo science, based on the idea that a person's physical appearance could convey his or her character and personality. Appert died in 1891 in the Provence-Alpes-Côte d'Azur, Alpes-Maritimes, Cannes, France.

JOHAN SWINNEN

ARCHER, FREDERICK SCOTT (1813–1857)

British sculptor, photographer, and inventor

Frederick Scott Archer was born in 1813 at Bishops Stortford in the English county of Hertfordshire. He was the second son of a butcher. Both Archer's parents died during his childhood leaving him to be brought up by friends and relations. While a boy he was apprenticed to a silversmith and bullion dealer, Massey of Leadenhall Street, London, who traded in antique gems and coins. Archer studied numismatics and became specialised in giving valuations. However, the artistic design of the coins, rather than their commercial value, interested him most inspiring him to copy their designs by modelling. It was this work which led him to make portrait busts and eventually to set up as a sculptor in Henrietta Street, London.

In 1823 he attended the Royal Academy Schools (RA) at the recommendation of the numismatist and keeper of coins, medals, prints and drawings at the British Museum, Edward Hawkins. From 1836 until 1851 Archer exhibited at the RA numerous works in sculpture. These were mainly busts of well-known people, such as the musician Sir George Smart (1839); the Dean of Manchester (1848); the Marquees of Northampton (1850); portrait medallions of the engineer Sir Isambard Marc Brunel (1841, 1842), and miscellaneous narrative or historical subjects *Falling Angels* (1836) and *A Young Briton Receiving Instruction* (1848). The sculpture *Alfred the Great with the Book of Common Law* was exhibited at Westminster Hall in 1844 to mixed reviews. His wall monument to Lady Albert Conyngham (1850) for Mickleham Church, Surrey, carved in the form of an urn, was illustrated by an engraving in the *Gentleman's Magazine* for May that year but was criticised as having been "too servilely copied from the antique" (510–11). Most of Archer's works in sculpture remain untraced in 2001.

Archer was often in poor health and it was through his doctor and friend, Dr Hugh Welch Diamond, a keen photographer, that he was introduced to William Henry Fox Talbot's calotype process in November 1847. Initially Archer used the photographic medium as an aid to sculpture to record his finished work and probably to photograph sitters from which he could model busts. He became increasingly fascinated with photography to the exclusion of sculpture and became an early member of the Calotype Club (from 1848 referred to as the Photographic Club). At that time the two main photographic processes in existence both had limitations. Daguerreotypes were highly detailed but required long exposures and produced a "one off" positive image; the calotype allowed many prints to be made from one negative but these were produced on paper and were therefore not as sharp. Archer wrote in *The Chemist* (March 1851, 257) that he was unhappy with "the imperfections of paper photography" and of his endeavours to find a negative material possessing "fineness of surface, transparency and ease of manipulation."

From 1848 Archer began experimenting with glass as a negative support. A light-sensitive coating of albumen (egg white) on glass had been used by others with some success but the solution was difficult to spread smoothly and was extremely delicate. Archer experimented instead with collodion. This was made from guncotton, a powerful explosive invented in 1846, produced by soaking ordinary cotton in nitric and sulphuric acid. This substance was then dissolved in a mixture of alcohol, ether and potassium iodide to produce the syrupy collodion that could be poured onto glass. This plate was then sensitised in a bath of silver nitrate solution and exposed in the camera while still wet. Archer's findings were first published in the *Chemist* in March 1851 in a communication dated 18 February. The new process was much faster than the calotype, reducing exposure times to seconds rather than minutes. It was also less expensive to produce than the daguerreotype. Importantly, it allowed superbly detailed negatives to be made of a

quality never before seen. By printing the new negatives on albumen paper new aesthetic possibilities and practical applications for photography were opened up.

Archer gained permission to show a few of his collodion negatives which were displayed to acclaim a few days before the closing of the 1851 Exhibition at the Crystal Palace, Hyde Park, London (*The Photographic Journal*, 1862, 149). Horne, Thornthwaite and Wood, opticians and philosophical instrument makers of London, arranged with Archer to sell his iodized collodion and took out newspaper advertisements in the autumn of 1851. Despite demand from other opticians and chemists Horne and Thornthwaite continued to be the sole distributor for several months. That same year an early enthusiast for Archer's process, Robert J. Bingham, photographed the prize winning exhibits of the Paris Industrial Exhibition to produce some 2500 collodion negatives in a comparatively short time. This convinced many other photographers of the practical viability of collodion beyond doubt despite the cumbersome equipment required for exposing the wet plates and developing them on location. Collodion photography gradually displaced most other processes and was prevalent from around 1855 to 1881 when it was superseded by the more convenient gelatin dry plates.

The widespread use of the wet collodion process can also be attributed to the fact that Archer did not patent his invention but shared his findings with fellow photographers and published it freely with no profit to himself. By contrast, throughout the 1840s and the early 1850s, Talbot maintained a stronghold over the licence of his calotype process and threatened legal action against those who breached his copyright. Martin Silvester Laroche refused to pay a license after Talbot challenged him which led to the court case of Talbot V. Laroche in 1854. In the case Talbot claimed that Archer's wet collodion method, being essentially a negative / positive process like his own, came under his 1843 calotype patent. The verdict was that although Talbot should be recognised as the inventor of the negative / positive process Archer's discovery was not covered by the calotype patent and thus free for all to use without restriction.

However, there were suggestions that Archer was not the only inventor to have come up with the idea of using collodion on glass. Bingham claimed that 'In a pamphlet on photography, which I published in London in January, 1850, I mentioned the employment of collodion in photography, and communicated the secret of this discovery to the most distinguished photographers of London' (*The Chemist*, July 1852, vol.3, no.34, 458). Archer did not dispute that others had suggested the possible use of collodion before him but he claimed priority to the publication of its practical application. In *Notes and Queries*, (1852 vol. vi, 612) Archer responded to a correspondent who ascribed the discovery of the collodion process to Gustave Le Gray:

> I was certainly the first who published the mode of using it, and gave the required proportions of the various chemicals necessary in the process. I have been repeatedly advised to advertise it as the Archerotype, but I was unwilling to do so, not because I doubted my right to the name, but I was satisfied with the general recognition of my claims, and left others to name it for me. Had I done it myself at once, the invention at this late hour would not have been claimed by another.

Archer was usually unassertive about his invention because he was a shy man. His character is described in *The British Journal of Photography* (5 February, 1875, 65) by a contemporary, John Beattie, a Bristol daguerreotypist who visited him in 1851 to enquire about the collodion process:

> Having got Mr. Archer's address, without any introduction but the simple plea of my curiosity and desire for knowledge, I called upon him. … I met a thin, pale-faced, over-thoughtful man, possessing a manner so free, unsuspicious, and gentle, that in a few minutes all idea of my being and intruder was entirely removed. … He was profuse in description (as if I had paid him a fee) and ended with the words, 'Perhaps you would like to see me make a picture?' … But Mr. Archer's generosity did not end there. He wrote me a list of chemicals which I was to procure, and told me to use his name at Horne and Thornthwaite's … He shook me by the hand as warmly as if I had been obliging him.

Archer chose to demonstrate the powers of the wet collodion process himself with images made in 1851 of the ruins of Kenilworth Castle, near Warwick in central England. Its red sandstone remains date from the various periods in its history from the twelfth to the sixteenth century. It was depicted by the watercolour artists of the late 18th and early 19th century such as Thomas Girtin, J.M.W. Turner and Peter De Wint who pointed the way to such suitable subjects for the new art of photography. Walter Scott found inspiration in the castle for his popular novel *Kenilworth* (1821). It was therefore an evocative location well known to the Victorian public for its romantic, medieval associations. The young Pre-Raphaelite painters such as John Everett Millais, and those associated with the movement such as John Inchbold, concentrated on paintings of minute detail in the early 1850s of vegetation encroaching on ruins. It is interesting to note that these artists' tastes for meticulous, lifelike observations corresponded with the exactitude that Archer's wet collodion negatives likewise allowed. His images of the castle are among the earliest photographs of the genre of ruined buildings that continued to be a popular subject for photographers throughout the 1850s and 60s.

Archer exhibited work in the first exhibition de-

voted exclusively to photography held in 1852 at the Royal Society of Arts. He was active in exhibiting many works at the photographic society exhibitions in Dundee (1854); Glasgow, British Association for the Advancement of Science exhibition (1855); Norwich (1856); Yeovil (1856) and London (1854, 1855, 1856, 1857). His numerous picturesque landscape and architectural subjects included views of locations such as Tintern Abbey, Warwick Castle, the Cambridge colleges, Rochester castle and cathedral, St. Albans and scenes on the Thames, in Wales and Monmouthshire. Prices for Archer's prints ranged from £1 and 1shilling to £1 and 15 shillings.

During the early 1850s Archer moved to 105 Great Russell Street, Bloomsbury, London to set up a business in photography. It was here that he published a full account of his invention, *Manual of the Collodion Photographic Process* in two now rare editions in 1852 and 1854 (copies are held at the British Library, The Gernsheim collection and the Museum of the History of Science, Oxford). In 1852, together with Peter Wickens Fry, Archer also devised the collodion positive, or 'Ambrotype' process which became extremely popular for portraiture. This was a variant of the wet collodion process in which an underexposed negative was backed with black paint, paper or velvet resulting in a unique positive image often presented in a velvet-lined, plastic or leather case. While Archer gained very little commercial success as a photographer he maintained his living working precariously as an inventor. His inventions included a camera inside which the various developing processes for the calotype could be self-contained (later adapted for Archer's own collodion process by his friend William Brown) and a variety of types of lenses. In 1855 he devised a technique for stripping off the collodion image and transferring this to other supports such as cloth and leather for which he was granted British patent number 1914.

Despite his significant contribution to photography Archer died in poverty on 2 May 1857 and was buried in an unmarked grave in Kensal Green Cemetery, London. *The Journal of the Photographic Society* (21 May, 1857, No. 54, 269) noted:

> Another victim has been added to the long catalogue of martyrs of science. Mr. Frederick Scott Archer, the true architect of all those princely fortunes which are being acquired by the use of his ideas and inventions, after struggling for some time for bare existence, has now departed from among us …

A subscription list, the Archer Fund, was established on 21 May by his friends Roger Fenton and John Mayall with other members of the Photographic Society of London, for the benefit of his family. However, Archer's widow died the following year and the subscription was closed in August 1859 with just £767 collected. His three children were granted a pension of £50 from the Civil List due to their father's photographic discoveries which it was noted had saved some £30,000 in the production of Ordnance Survey maps alone.

Archer's photographs remain scarce in 2001. The Royal Photographic Society collection contains thirty-three albumen photographs including an album of the Kenilworth Castle views. Also early experimental collodion positives printed on glass, cloth and leather, a wet collodion plate camera from 1852 and a collodion positive portrait of Archer (1855) by Robert Cade. A view of Sparrow's House, Ipswich was purchased in 1856 from the London Photographic Society Exhibition of that year by Henry Cole, the first director of the South Kensington, later Victoria and Albert Museum, London and remains in that collection. Further Archer material exists in the Gernsheim Collection, The Harry Ranson Humanities Research Center, University of Texas, Austin, USA. Six or Archer's Kenilworth views were offered for sale from the collection of the Earl of Craven (an early practitioner of the wet collodion process) in 2001 (Bearne's, Exeter, 12 May 2001).

Martin Barnes

Biography

Frederick Scott Archer was born in 1813 at Bishops Stortford, Hertfordshire, England. His career began as a sculptor in London but he turned to photography from 1847. He experimented with making negatives on glass and in 1851 published his process of wet collodion which revolutionised photographic practice with its rapid exposure times and ability to render fine detail. Archer chose not to patent his process and allowed it to be used freely. The same year of his invention he photographed with it the ruins of Kenilworth Castle, England. Thereafter the wet collodion process was adopted quickly world-wide and became the dominant form of photography throughout the 1850s until the 1880s. From 1852 to 1856 he exhibited numerous works at the photographic society exhibitions in London, Dundee, Glasgow, Norwich and Yeovil. While gaining very little commercial success as a practising fine art photographer Archer continued to work on inventions at his premises in Bloomsbury, London where he also published two manuals of the collodion process (1852 and 1854). His other inventions included improved cameras, lenses and photographic processes such as the collodion positive, or Ambrotype—a variant of the wet collodion process—which became widely used for portraiture. Despite his significant contribution to the advancement of photography Archer died in poverty in London on 2 May 1857.

ARCHITECTURE

Architectural photography is the depiction of buildings, their details, and their models. The representation of architecture in images is as old as painting and drawing. It had to fulfill a number of purposes, from the portrayal of castles for their proud owners (as in the Books of Hours by the Fréres Limbourg in the 14th century) over the documentation of historical structures (as in the drawings of Renaissances masters) to the autonomous subject (as in Dutch paintings of church interiours of the 17th century or in the 'Carceri' by Gianbattista Piranesi (1749/61)). As with writings on architecture, the representational delineation is not needed for the architectural process itself but is a matter of communication between laymen (and sometimes architects). This development is also responsible for painting and etching traditions of the 18th century, like the vedute which formed a common ground for the aesthetic invention of photography in both style and subject.

In the first art-critical account of the new technique, Jules Janin referred to the bible by forcing the towers of Nôtre Dame de Paris: "Become image!" With this short sequence, he combined two lines of interest—the new form of depiction not yet named photography, and building preservation, recently instigated as a common bourgeois concern by the Victor Hugo's novel on the cathedral of Paris. After Janin, every author on the invention of photography had to refer to the delineation of architecture for which the new medium seemed to be most appropriate. On the other hand, most inventors had introduced another motif unconsciously: the view on or through the studio's window. This was the utmost of romanticism as it defined the limitation of human vision by the individual eye, even on the base of a perspectively correct delineation. Both themes can be traced throughout the early history of architectural photography by a comparison between the daguerreotype and the calotype.

The daguerreotype with its over-exact details piqued the interest of scientists like the French Dominique François Arago or the German Alexander von Humboldt who emphasized its depicting qualities with the description of strays on a window sill. When the first set of cameras were delivered to Prussia, the first subjects of the new technique were buildings in and around Berlin. The photographs were not only of old buildings photographed as a method of preservation, but also of newer ones like Schinkel's new museum. Until the introduction of the wet collodion process, there was no doubt within Central European photography that the delineation of architecture belonged to the daguerreotype. This was not so for the United Kingdom and some of the American pioneers in photography: long pictorial traditions in landscape painting and aquatint graphics had settled an emphasis on the view "through the looking glass" and therefore concentrated on aspects full of atmosphere. This can be traced in the Scottish albums by William Henry Fox Talbot as well as in early attempts of David Octavian Hill and Robert Adamson.

In 1845, the young art critic John Ruskin spent a number of months in Venice studying the wealth of Gothic architecture. After seeing a daguerreotypist's work, he had his servant learn the technique and then used those images as proofs of his findings. He drew reproductions of the photogrpahs and then printed those drawings in his books on the 'Stones of Venice.' The book's transformation of architectural images from daguerreotype to etching was not entirely new as Noël-Marie Paymal Lerebours had already published his 'Excursions Daguerriennes,' surely known to John Ruskin but not regarded as sufficient help in his own field. The landmark in both architectural and photographic history set by the 'Stones of Venice' is that the author would not have been able to settle his argument without the aid of the new technique which was not yet a medium. It is exactly because of this, however, that the 'Stones of Venice' preserved no historical photographs of the architecture it represented.

In Ruskin's case, the time from taking the pictures to their publication was more than eight years, during which technical evolutions had accelerated substantially.

The wooden boxes and brass tubes of the earliest camera constructions had shaped into an unfoldable ‚traveling camera' which allowed separate movements of both the plate and the lens holder for perspective corrections. There were developments in the preservation of buildings, also. In 1837, the author and politician Prosper Mérimée had founded the 'Comission des monuments historiques' financed by the French state, and in 1838 he suggested an inventory of all buildings worth preserving. When the invention of photography was announced in January 1839, the forthcoming inventory was feeded by the hope to include images of these buildings, as was decided in the commission's meeting in March 1839. It took nearly ten years until Hippolyte Bayard was commissioned with the first few photographs of the restoration works at the cathedral of Nôtre Dame in Paris. Finally in 1851, the commission founded the first photographic documentation project: the 'Mission héliographique.' One of the founders was Léon de Laborde who in the same year of 1851 co-founded the Société héliographique whose interests were concerned with the publication of photographs that were important for commissions like the 'Mission'.

Six photographers received contracts for the 'Mission' in 1851: Edouard Denis Baldus who subsequently was to become Europe's first professional architectural photographer; Henri le Secq who already had taken images of the mediaeval cathedrals of Amiens and Reim; and Gustave le Gray who came from the Barbizon school of painting and was an acclaimed practicioner of photography. Hippolyte Bayard's earlier contract was renewed, and little in known about the fifth man, O. Mestral. A year later, the sixth photographer, Charles Nègre was installed by a new contract. As with le Secq and le Gray, Nègre had been a painter before and studied with Paul Delaroche, even so, his contribution to the 'Mission' remains somewhat elusive. The six photographers received lists of buildings taken from the 'Annales archéologiques'—the most important periodical of its field—and delivered roughly 150 photographs by the end of 1852. From then on, the Commission seemed to have lost its interest in commissioning documentary images but started to buy them from different sources like the Parisian scenes mainly from Charles Marville. At the same time, the Commission began to re-finance this program by selling prints loose or in albums. When the 'Mission héliographique' officially ceased to exist in 1880, there were some 6,000 photos on sale.

There is no other project like this in the history of architectural photography but, of course, there were a number of self-commissioned documentations on buildings worth being preserved by photography. William Henry Fox Talbot with the partnership of David Octavius Hill, Robert Adamson, followed by Benjamin Brecknell Turner, Thomas Keith, Thomas Sutton, and Roger Fenton formed the nucleus of the, Architectural Photography Association' which exhibited twice in London in 1858 and 1859. The first self-commissioned documentation with a scientific approach in art history in Germany was a comprehensive album created and printed in 1856 by Hermann Emden. It showed the interior and sculptures of the cathedral at Mainz. His efforts were prolonged by the work of Carl Friedrich Mylius, Friedrich Ferdinand Albert Schwartz, and Georg Boettcher in the German countries, by George Washington Wilson in Scotland, by Humbert de Molard and André Giroux in France, by Giacomo Caneva in Italy, and by a fast growing number of practicioners in each European country with relics of history. Even if all of these photographers started their work from an interest in preservation, they gradually were swept into a world-wide phenomenon that became the main result of architectural photography for the 1850s and 1860s: tourism.

Travelling the Grand Tour through Europe and around the Mediterrean Sea had become an integral part of any cultural education—if there was money enough in the family. By the efforts of a growing number of agents in the mid 19th century, the Grand Tour gradually altered into the forms of group tourism still well known today. Tourists often visited the cultural highlights of a country and then retreated to a resort for personal comfort, all within one travel. Also, everybody needed souvenirs as mnemic aids for later accounts of the travel to the family and neighbours. Photographs were obviously the best possible means of remembering, often representing the scenes visited with hitherto unknown accuracy. Travel photography was comprised of more than only architectural subjects but the main depiction of monuments seen consisting of buildings and places, and the conventions of travel photography were set by the first architectural photographs made of each edifice. Concerning the difference between architectural and archaeological interests in preservation of buildings and the use of the same motives for travel souvenirs, one has to consider a tiny time gap within the early 1850s, exactly at the same time the 'Mission héliographique' was on its way in France.

After Lerebours' photographers and their, more or less, vain attempts to collect the most important buildings of the world in the 'Excursions Daguerriennes' in 1839 and 1840, there was nearly a decade without photographic excursions. This was due, in part to the technical differences between the exact but unprintable daguerreotype and the reproductable but inexact calotype. Salt printing processes, however, had by 1850 developed a technical quality which enabled a number of photographers to travel with a camera. August Salzmann went to Palestine, John Shaw Smith, John Beasly Greene, and Maxime du Camp travelled to Egypt, and

Roger Fenton went to Russia, just to name a few out of dozens. They were accompanied by true amateurs seeking the splendour of antiquity in ruins depicted in the best quality possible. Among them are Robert McPherson, Frédéric Flacheron, and Jakob August Lorent in Italy, James Robertson in Greece, Wilhelm von Herford in Egypt, Wilhelm (Guilleaume) Berggren in Constantinople, and Désiré Charnay and Paul de Rosti in Mexico and Brasil. Most of these photographers had either been painters before and therefore developed an interest in the aesthetic qualities of ruins as a base of their drawings and studies, or they were archaeologists and art historians by training. One exception is the Prussian diplomat von Herford who refers to the large number of British amateurs in India, mostly military officers: Linnaeus Tripe, Captain Biggs, John Murray, and later John Burke and Melville Clarke.

The introduction of the wet Collodion process and the albumen print in the early 1850s brought the technological shift for photography from an artistic practice towards a medium of visual communication. Immediately, early entrepreneurs like Louis-Désiré Blanquardt-Évrard and Adolphe Braun star—among them a number of titles with architectural photographs. From the mid 1850s onwards, the production of larger quantities of copies reached a semi- industrial status; the times of the well-known suppliers of travel photographs began. Be it the brothers Alinari in Florence, Giacchino Altobelli in Rome, Carlo Naya and Carlo Ponti in Venice, Giorgio Sommer in Naples, Giacomo Brogi and Constantino Brusa in Milano, or the Studio Incorpora in Palermo—only for Italy one can easily name more than a dozen studios, each of them sending out dozens of their own photographers and processing thousands of prints a month by hundreds of employees. Within three decades, the brothers Alinari piled up a stock of 150.000 pictures; at least, one quarter of these are architectural photographs.

Important names and countries in this field include William J. Stillman, Petro Moraites and Dimitrios Constantinou in Greece, J.Pascal Sebah and the brothers Zangaki in Constantinople, Tancrède Dumas in Beirut, Francis Frith, Wilhelm Hammerschmidt, Antonio Beato, Désiré Ermé and the Bonfils family in Egypt, Charles Clifford and Vicomte Vigier in Spain, Charles Shepherd, Samuel Bourne and Lala Deen Dayal in India, John Thomson and Felice Beato in China, the latter in Japan where he sold his establishment to the Austrian Baron Raimund Stillfried who gave his studio to Kusakabe Kimbei. The stylistic approach of the architectural photographs from all of these sources is rather conventional and responsible for most of all forms of architectural photography still today. The building or complex is accessed by panoramic views from a higher stand-point. Then there are strictly axial views of each important facade from a middle height, followed by a number of details in ornament, doors, or sculptural additions. The scenes are mostly lit with bright sunlight and strong shadows, although the heavens stay white due to the emulsions' unsensitivity. A common practice these days was the combine printing of the architectural view with one or two negatives of cloudscapes fitting the subject and light given. Personnage is found on most images of architecture; as in industry, the humans depicted function as measurements of the edifices.

Travelling and collecting travel photographs was reflected in architecture after a short while - historism was the clear determination of the earlier preservation campaigns. "In which style should we build?" was the main question of the 1850s to World War I, and it was answered by the use of architectural photographs. Industrialisation and the movement of people from the land into the cities in the middle of the 19th century caused the erection of new quarters and buildings, and for this purpose architects were needed. Nearly all European countries installed a university specializing in training architects after the model of the Parisian Académie des beaux arts, and a growing number of Americans came to Europe to study, like Henry Hobson Richardson. The young architects of the early 19th century studied after the plans and portfolios of Jean-Nicolas-Louis Durand, and they now began to work from larger collections of photographs—mainly from the sources of travel photography but as well from local compendia like the 'Mission héliographique' or the new collection of the South Kensington museum.

When students started their own trips around Europe and the Mediterrean Sea to study architecture old and new, they drew after the originals and establish collections of images—and when some of these students became teachers, again these collections formed the ground of each curriculum. Gradually photography crawled into these collections, not only as a help in producing studies in perspective, but as a base of exact measurement, too. An integral part of study in architecture was an exact account of one building, like mediaeval cathedrals, cloisters, or antique structures and ruins. These accounts were to be delivered in outlines, transverses, and orthogonal projections of each frontage—the most hated work in the education of an architect. One of these students, Albrecht Meydenbauer, after a severe accident decided to introduce photography into this process of accounting. Architectural photogrammetry was born, the use of military cartography for the reconstruction of buildings. To finance his project which consisted of documenting, exactly every important historical building in Europe, Meydenbauer not only established the Preussische Messbildanstalt in Berlin but offered his photographs in subscription sales to universities, administrations, and private investors. When the Messbildanstalt was

closed in 1917, it owned a stock of more than 21,000 pictures in extremely high definition, most of them in the negative format of 40 × 40 cm.

Writing up the history of architectural training and practice in the second half of the 19th century, one can divide the exemplary images used within the common curricula into two structural components: the Messbild photographs and the collections of the 'Mission héliographique' and its successors; or the plans of Jean-Nicolas-Louis Durand as structural base of a new construction. Due to the new contruction at this time, the teachers and their students didn't have examples of edifices. Those planning and wanting to build houses needed examples to explain their wishes to their architects. After the erection, proud house owners ordered images from photographers to show around to their friends and family members. Large projects often requested an album dedicated to financiers and share holders—this tradition was started by the Baron Rothschild who commissioned Edouard Denis Baldus in 1853 to photograph all stations of the new railroad line between Paris and Toulon, and the tradition was prolonged by Prince Albert when he asked Philip Henry Delamotte for a complete record of the Crystal Palace's re-erection at Sydenham in 1854. Be it the Suez Canal, the line of bridges crossing the Rhine, any of the great Western railroads in the United States, or a construction hall at one of the Parisian world fairs, since the late 1850s each construction of great importance was photographed and had an album made from its image. Although they represent a common practice of their days, the most remarkable and widely published series of this kind is the album that Hyacinthe César Delmaet and Louis-Émile Durandelle photographed of the construction of Philippe Garnier's Paris opera house.

A predominant convention was that every large scale project that recieved country- or world-wide fame was imitated by those working on smaller scales. No court

house, town hall, opera house, musical theatre, bank or industrial site was opened without a luxuriously designed album of photographs showing facades and details, and sometimes images of the work in progress. Little is known about the photographers of these albums; in most cases they were local practicioners of the art with a good basic knowledge about the angles and light conditions to photograph buildings, but had little care of compositional structures developed in 18th century vedute imagery or in 17th century architectural painting. They saw their craft in portraiture, and thus most of their images tend to please their buyers as did average studio photography. But, as sets of portraits of important people were published with great success, some publishers thought of producing collections of recent buildings, sometimes with a certain success. In the late 1860s one could buy such collections as phototype prints in larger portfolios of what was named 'modern housing,' at least in cities like London, Paris, Berlin, New York and Chicago.

American cities, both on the northern and the southern continent, were looking for industrial entrepreneurs to settle in their environments. From the late 1860s on, one can find larger and smaller portfolios of these cities showing the beauty of their surroundings, the quality of their traffic connections, the opulence of their town halls, churches, or assembly buildings. Mostly these—anonymously manufactured—portfolios were conceived as leporellos with a panoramic view of 360° in twelve images on the front and twelve singular images showing individual edifices on the back. Today, these leporellos often mark the earliest records of the existence of these cities. They were shown and distributed at fairs and promotional tours through Europe. The last of these portfolios, made around 1900, show a new type of important construction—grain elevators which, through this form, found their way into European modernism. On the other hand, a pictorial representation was often necessary requirement of technical constructions like large bridges and railway installations not only for the financiers but for the copyright of the engineers as well. American and Canadian photographers like George N. Barnard, Timothy O'Sullivan and William Notman proudly recorded the wonders of technical engineering around the railroad lines, and some of their images look as modern as pictures from avantgarde constructivism of the 1920s. Photography even fulfilled a proof function in the test of a bridge construction. When a large arch of a bridge was spanned over a river or a valley, two photographs had to be made of it: one under the pressure of several locomotives on top of it, one without. If the difference of height between the two photographs was toomuch, then that indicated that the bridge had to be strengthened.

The practice of advertising new edifices by photographic reproductions was not only used by local authorities but also by the architects themselves. The architect Henry Hobson Richardson, who owed an important part of his vast success in the New England states to the fact that each of his new buildings was immediately published by magazines like *The American Architect*—at his own cost. Amongst Richardson's large collection of photographs were pictures whose composition was developed from specific criteria determined by himself. In these photographs, he gave the photographers working for his office specific directions on how to choose their stand-points and perspectives. Country houses designed by Richardson had to photographed from a low angle to make them more impressing, but the large Chicago department store which was his last design had to be shown from a middle height to give the impression of just another block in the city. Court houses, churches and town halls designed by Richardson were shown like singular masterpieces without any reference to their neighborhood whereas his villas were well integrated in the surrounding nature. Nothing is known about the photographers he employed but he surely had them trained by showing them his collection of travel photographs.

By 1900, photography had become an integral part of each architect's economy. The beginnings of modern architecture (Nikolaus Pevsner) were marked by the architects of the Arts-and-Crafts movement whose 'reform' houses were designed for a better living in harmony between humans and nature. Besides beautiful perspective drawings and etchings, these houses were marketed by photographs published in illustrated magazines which no longer addressed themselves to other architects but to the open public. Photographers like Henry Bedford Lemere in London, Waldemar Titzenthaler in Berlin, and Clément Maurice in Paris began with depicting luxurious interiors as samples for a bourgeois life-style just after historism and before modernism, thus practising modern tactics of public relation for design with forms belonging to the century passed. Careers of architects like Charles Francis A. Voysey, William R. Lethaby, Charles R. Ashbee, and even Charles R. Mackintosh would not have been possible without the aid of photography; by the beginning of the 20th century, these images of exemplary interiors were found in catalogues of the first retail stores.

But there were dark sides of the architecture, industrialization, and town planning in the late 19th century as well, and they were documented with equal intensity by photographers who had received their training in front of great architecture on travels or at home. Carl Ferdinand Stelzner and Hermann Biow had recorded the great fire of their home town Hamburg in 1842 on daguerreotypes but were unable to sell these images to the city. In the late 1850s, cities like Paris started

to commission photographers like Charles Marville to take photographs of all streets and places that were to be torn down by Baron Hausmann's new town plans —a matter of political legitimation. A decade later, his efforts were prolonged by Thomas Annan in Glasgow depicting the old closes and wynds of the city just prior to their demolition. Another decade later, his album was widened by a new set of images, and the company of Alfred and John Bool and Henry Dixon received a similar commission by the newly founded Society for Photographing the Relics of Old London.

All of these photographers, and dozens of their colleagues alike, felt conflicted about these buildings, on one hand it was clear that the photographed areas had to be destroyed for reasons of social welfare and hygienics, on the other hand the images represented a substantial loss of each city's morphology. The last and greatest photographer in this line is, without doubt, Èugene Atget who started his long series of Parisian 'locations of a scene' (Walter Benjamin) by 1890. His work, rediscovered by the Surrealists in the 1920s, in several ways marks the turn to modernism in both documentation and photography. His pictures belong to photography, in view and print, but belong to history in composition and perspective. Street photography as practised by Èugene Atget bore fruit to numerous others, and lesser known photographers aiming to sell their images to painters, illustrators, and the press. In Italy, Switzerland, and Germany, around 1900 one can find in any city at least one 'house photographer' who walked from street to street, from house to house, taken images of each house in order to sell it to the landlords and inhabitants.

Human beings served as an ornament of city photography which was partly unavoidable, but on the other hand partly served as picturesque additions to the moods evoked. Additionally, some of the later photographers conceived their series—commissioned or not—to show human poverty and misery as caused by bad housing conditions. Travel photographers like John Thomson made the streets of London appear more human, while painters like Georg Hendrik Breitner developed their interest in the iconography of human labour by photographing workers in the canals and places of Amsterdam. The New York police reporter Jacob August Riis, born in Denmark, employed the camera to change the situation of his fellow immigrants; his book on "How the Other Half Lives," published in 1890, led to major changes in the city's town planning. Well issued, his example was followed around the turn of the century by nearly every large city in the world; health insurance companies ordered photographers to document tenement conditions as well as their demolition. Riis and his colleagues were the first to introduce flash light into architectural photography as there was no other lighting source for their work. Just after the turn of the century, Lewis W. Hine started his career by finding symbolic forms and gestures for the imagery of social fate—as is the case with Atget and some of the Fine Art photographers, his work seems to mark crossing the frontier of historism and modernism.

Since the late 1880s, Fine Art photography arose as a movement of autonomous search for the social integration of the new technique and medium into the art world. Aesthetically, this movement was stuck to the classical subjects and motifs—including landscape which just had been added to the list after William Turner's efforts in establishing this subject within painting—and therefore architecture simply happened within certain images. Hugo Henneberg of the Vienna school had Italian palazzi included in his views on dark alleys; Peter Henry Emerson directed his camera to Norfolk and Suffolk farm houses; Constant Puyo showed small villages as integral part of his vertical and horizontal panoramas. A singular position within the whole movement is held by Frederic Henry Evans who started as a part of the British Arts-and-Crafts movement and shared the 'visionary spires' of the late 19th century Gothic revival. After a short period in close vicinity to William Morris and his Kelmscott Manor Press he found his life-time theme in English mediaeval church interiors which he photographed for their subtlety of light direction and for which he found the technical equivalent in using the platinum print.

The Fine Art photography movement, as represented by the Linked Ring brotherhood, did not regard architecture as a sufficient subject of criticism but there were a number of members within this movement who had an urban background and traced themselves within it. Alfred Stieglitz had begun with his own artistic work as a student of photo-chemistry and while travelling to the German south and Italy. His first attempts in Fine Art photography were taken in Berlin around 1890, and to a great deal they dealt with the urban growth of this city, both in the interior and in the exterior. When he returned to New York, his view on the Manhattan shore shaped his vision as well as Broadway by night—a concisely modern subject in architecture and photography. This vision was shared by several colleagues commuting between the American and the European continent, as Edouard Jean Steichen and Alvin Langdon Coburn did. Their photographs of the big city were widely acclaimed in exhibitions on the old continent and praised by critics as well.

Although they were made in 1904 and 1912, one should consider two architectural photographs as the last ones of the 19th century bearing in them all modern elements but showing themselves as typical prints of the century gone: Edouard Steichen's view on the Flatiron building on New York's broadway and Karl F. Struss'

image of the Brooklyn Bridge with its grids of wires. Both images are made at dawn and under bad weather conditions, both are gum prints in a brownish monochrome tone and not substantially sharp in detail. But both pictures show all elements of modern architectural photography: a basic composition beyond the classical forms of perspective and distance, a definition of time and space within the photograph itself by reference to weather, light and clouds. Beyond the function of advertisement for architects and building companies and besides the idea of a picturesque view on edifices unknown (and 'colossal' as the 19th century wanted it), these impressions present themselves as entities of their own. Architecture and its image had fallen into each other, modernism was on its edge.

ARCHIVES, MUSEUMS, AND COLLECTIONS OF PHOTOGRAPHS

The analysis and evaluation of the formation of collections of photography during the 19th century remains largely unresearched though it plays a significant role in the form, function and reception of the medium during the first half century or so of its existence.

The 20th century provides a litany of the loss and destruction of 19th century photographic collections ranging from the archives of both large and small photographic companies through public institutions and commercial companies to private individuals. Key to this was a matrix of value judgments. Firstly, some photographic archives simply became redundant for the purposes they had initially been set up. Advances in photographic technology also produced a degree of 'churn' whereby new, technically better and more relevant photographs replaced older equivalents. One only has to consider the replacement of photographs of paintings during the 19th century as isochromatic emulsions were introduced, that in turn were replaced by panchromatic emulsions and then by colour images. However, in some instances such collections failed to live even into the 20th century. One specific cause was ambient environmental conditions. Heat and humidity of many climates were instrumental in the deterioration and eventual loss of numerous 19th century photographic holdings. This has to a degree masked the history of photographic archives in many countries with tropical climates.

Perversely, while Web-based digital image databases and catalogues are in some respects rendering 'analogue' photographic collections redundant, thereby increasing the threats to their existence, information and communication technology has also acted as a catalyst that has opened up and highlighted the richness and diversity of 19th century photographic collections. Such interest has led to the re-discovery of significant but little known photographic archives ranging from major institutions to individuals.

The formal collecting of photographs covered a wide range of players; from private individuals through scholarly societies and public sector institutions to commercial companies and professional organisations. The manner in which photography was institutionalized within existing archives, libraries, museums and collections reflects the scale and scope of its application during the 19th century. However, the contemporary impact of 19th century photographic collections may never be fully revealed since so many have been dispersed and their administrative records lost. How such photographic archives were used by used by contemporaries and what influence they had still largely needs to be established.

To start with, the archives of photographers themselves remain primary sources for 19th century photography. Companies such as, Franz Hanfstaengl in Munich typified established lithographic printers and publishers who adopted photography and formed a large archive covering portraiture, art reproduction and topographic and architectural views. The archive of the firm of Fratelli Alinari—founded in 1852—forms a similarly rich coverage of 19th century Italy, though the historiography of the company's art reproductions remain central to its significance. In Great Britian, the archive formed by the Francis Frith Company between 1860 and 1970 formed a unique topographical record of Britain through the photography of some 7,000 towns and villages since Frith's photographers returned to redocument the locations over this one hundred and ten year period. However, the majority of the original negatives were destroyed in the early 1970s, though some 330,000 photographic prints survive. The significance of the archives of such 19th century photographers' companies has been occasionally recognized. For in-

stance, in 1904 the National Portrait Gallery in London purchased 12 volumes of the day books of the prominent portrait photographer Camille Silvy (1835–1910). These contain some 15,000 portraits of many key members of mid Victorian society.

Commercial photographic archives were also created during the 19th century, such as the one founded in 1877 by Adolphe Giraudon (1849–1929) that aimed to provide scholars with access to fine art and cultural photographs. Giraudon was not a photographic publisher in the mould of Adolphe Braun of Dornach, and his business model was based on the setting up of the first correspondent networks, comprising of photographers who were able to supply Giraudon with photographs taken throughout Europe and beyond. By 1900, Giraudon offered some 115,000 photographic views and the company archive still exists and operates commercially.

During the 1840s, photography formed a comparatively small amateur or commercial activity though contemporary commentators were speculating that it was likely that significant photographic collections would be formed by both those wishing to exploit the medium within their profession as well as amateur collectors. While the scale and scope of this activity is slowly being exposed, its full extent may never be known. However, collections of photographs were being formed through a variety of activities for a range of purposes from the 1840s.

In order to build a market, some photographers speculatively targeted institutions related to the graphic arts. Thus the British Museum received a number of speculative samples from photographers (or their agents) during the 1840s. These seem to have been deposited with the Department of Prints and Drawings though most of these images were not catalogued into the collection and have either been misplaced or been lost. In addition, the body of work undertaken during the 1850s by Roger Fenton to document the British Museum's collections—though highly significant—did not form the foundation of a clearly defined or substantial photography collection within the institution.

The photographic collections of private individuals during the 1840s, while comparatively small scale, provided a template that was extended during the remainder of the century. During the 1840s and 1850s photography was expensive and commercial outlets were few and almost entirely based in the major metropolises. This therefore restricted the medium in terms of it audiences.

Royalty and the nobility form a significant type of collector during this period and beyond. Prince Albert (1819–1861), the Prince Consort of Queen Victoria, seems to have been the primary catalyst in the formation of the extensive Royal Collection of photographs. Indeed, royalty are underresearched since their photographic collections were built through a matrix of commissioning, commercial acquisition and donation. In France, the collection of Emperor Napoléon III (1808–1873), formed during his reign between 1852 and 1870, reflects commercial and artistic photography during the most dynamic phase of 19th century photography. Across Europe and beyond, the nobility formed photographic collections, frequently as adjuncts to their print collections. However, there has to date been comparatively little study of these collections and their provenance.

Contemporary artists began to exploit photography during the 1840s. Jean-Auguste-Dominique Ingres (1780–1867) used the daguerreotype to record his paintings as early as 1842 and photographs from his collection, including daguerreotypes, survive. During the 1840s, John Ruskin accumulated a large collection of over 100 daguerreotypes some of which he used to help create illustrations for his book publications. These have survived as has the collection of 159 daguerreotypes of architecture in Italy assembled in 1840 and 1841 by Dr Alexander John Ellis (1814–1890) while travelling around the country. In both these instances the collector bought commercially available images and took, or commissioned, their own photographs. Ruskin exploited his daguerreotypes by using them as the basis for illustrations to his publications. Ellis had also intended to publish engraving after his daguerreotypes but the project never materialised.

Private art collectors began photographically documenting their collections during the 1840s. The Antwerp publisher Joseph-Ernest Buschmann (1814–1853) published his personal experiments on daguerreotyping his own art collection in 1847. The collecting of photographic portraits also began during the 1840s and the album of Salt prints assembled by the author and historian Thomas Carlyle (1795–1881) forms a prominent example the latter part of the decade.

Leading architects such as George Gilbert Scott (1811–1878) and Eugène Emmanuel Viollet-le-Duc (1814–1879) formed their own collections of photographs and the collections of photographs within architects' offices became integral parts of professional practice. Photographic publishers targeted this market produced an increasingly wide range of 'reference' photographs. In 1851 Gilbert Scott became one of the founders of Royal Architectural Museum that soon after began to collect photographs. By 1853 the Museum was publicising its intention 'to collect photographs of objects too large to be moulded.'

From the early 1850s the South Kensington Museum formed a large collection of architectural photographs. The professional institutions involved in architecture also collected photography. The Royal Institute of British Architects began to form its own collection and published at catalogue to its collection in 1871. In

1885 the *Königlich Preußische Meßbildanstalt* (Royal Prussian Photogrammetric Institute), the first photogrammetric institution in the world, was established by Albrecht Meydenbauer (1834–1921). Between 1885 and 1909, Meydenbauer and his staff took about 11,000 survey photographs of around 1,200 Prussian monuments. A further 1,600 photographs of 100 buildings in Germany outside Prussia were also acquired and some 800 photographs were taken of buildings outside of Germany, including in Athens, Baalbek and Istanbul. Meydenbauer's photographic archive survives to this day and is now under the control of the *Brandenburgisches Landesamt für Denkmalpflege* (Office for the Preservation of Monuments of Culture of the Federal County of Brandenburg).

In parallel, civil engineers also began to use photography as a professional tool and form collections. In France the l'Ecole des ponts et chausses commissioned photography from the late 1850s and formed a record of civil engineering work. The British Institution of Civil Engineers began its collection of photographs in the mid 1860s, by which time evidence suggests that all major civil engineering projects were being photographically documented.

The use of photography by government and state departments is also noteworthy. The military extensively used photography to document fortifications, equipment, maneuvers and battlefields. The British Royal Engineers began forming collections of photographs during the 1850s and also recorded art and architecture on behalf of other public institutions. The military also formed collections for related activities such as the thousands of photographs taken to produce *The Medical and Surgical History of the War of the Rebellion* published in Washington, D.C., between 1870 and 1888.

The criminal justice system began to form archives of photographs as early as the 1840s. In 1843 daguerreotypes were being taken of prisoners in the prison in Brussels and kept by the Sûreté Publique (Criminal Investigation Department). By the 1860s many European states were employing photography to create documentary records of prisoners. Scene of crime photographs were also being widely taken from this time.

The systematic use of photography within cultural and heritage institutions began in the 1840s. The Minutoli Institut in Liegnitz in Silesia was particularly influential and formative on British attitudes. The institute had been created by Alexander Freiherr von Minutoli (1806–1887) and had opened to the public in 1845. By 1848 the photographer Louis Birkes had taken at least 25 daguerreotypes of pieces from the collection. These were mounted in a frame and sent to various members of the Institut's society (*Gewerbevereine*). Some of Birkes' Daguerreotypes were exhibited at the 1851 Great Exhibition in London. Minutoli also exhibited Daguerreotypes from his collection at the Allegemeine Deutsche Industrie-Ausstellung in Munich in 1854 and in the following year exhibited three albums at the Exposition universelle in Paris. In 1856 he exhibited Salt paper photographs of his collection at the Industrial Arts Exhibition in Brussels At the 1862 International Exhibition in London, he advertised, and perhaps even exhibited, a seven-volume, twenty-four section set containing some 4,000 'works of antiquity, photographed from the originals and intended as models for manufacture, and artisans' Priced at £120 (800 thaler).

By the early 1850s a number of major museums and galleries began to build collections of photographs, sometimes exploiting a dedicated photographer such as Charles Thurston Thompson at the South Kensington Museum and Roger Fenton at the British Museum. Other institutions such as the British Library, the Bibliotheque National in Paris and the Library of Congress represent some other pertinent examples. The South Kensington Museum began its collection of photographs around 1853. Some 139 were listed as being held in the museum by the following year, almost entirely represented by 125 photographs of Maxime du Camp's views of Egypt, Nubia, Palestine and Syria. By 1880 there were some 50,000 photographs in the collection. Each photographic image—including those illustrating books and other publications—were individually logged in museum's the Photograph Register and allocated a unique number. The register not only recorded the date of acquisition but also the provenance and cost. It thus forms a rich source of information about a number of key aspects of mid 19th century photography.

Other key aspects of the photographic collections at the South Kensington Museum were the commercial sale of copies of the photographs taken on behalf of the museum—both of its collections and temporary exhibitions—and also aspects of outreach. The South Kensington Museum formed a 'Circulation Collection' for the provincial schools of art and photographic publications, such as the *Art Workmanship* volumes published during the late 1860s and early 1870s, played a prominent role.

Universities and research institutes also began to form collections of photographs from the middle of the 19th century. In the 1850s, Harvard University received a gift from Francis Calley Gray (1790–1856) of some 4,000 photographic reproductions of European paintings. The Deutsches Archäologisches Institut founded in 1829, which became a Prussian State Institute in 1871 and an Imperial institute in 1874, also formed collections of photographs. However, during the 20th century many universities and scholarly institutions disposed of their 19th century photographic holdings.

Photographic societies themselves began to form collections, primarily through donations. The Royal

Photographic Society, founded in 1853, and the Société française de photographie, founded in the following year, are two of the most prominent examples. The collections of local, rather than national, 19th century photographic clubs and societies, though significant, have largely been lost. However, the scale and scope of the evaluation of such institutional collecting is in its infancy and the history of the photographic collections in countries formerly part of the Soviet Union awaits fuller analysis.

The role of copyright law also played a crucial role in the forming of collections of photographs. In Great Britain the 1836 Copyright Act reduced the number of libraries entitled to receive legal deposit copies of published works from eleven to five, The British Museum Library (since 1972 the British Library), the Bodleian Library of the University of Oxford, Cambridge University Library, the Faculty of Advocates in Edinburgh and Trinity College Dublin. These institutions therefore began to acquire photographically illustrated publications through deposit and purchase. In the case of the British Library these holdings are international in scope.

State intervention to document national cultural heritage began in the early 1850s. In 1851 the French Government through the Commission des Monuments historiques selects five leading photographers, Édouard Baldus, Hippolyte Bayard, Gustave Le Gray, Henri Le Secq and O. Mestrel to document the medieval architecture of France. Some 258 prints and their corresponding negatives were acquired from this Mission héliographique though their contemporary impact was very limited. In 1874 Séraphin Médéric Mieusement (1840–1905) became the official photographer of the the Commission des Monuments historiques and took more than 6,000 negatives. Mieusement's work was complimented by another Commission photographer, Jean-Eugène Durand (active between 1876 and 1917)

In 1852 French copyright law was extended to include photographs. This meant that copies of all photographs on public sale be registered and deposited with the Ministery of the Interior or a local prefectural clerk. In Paris, over 9,000 photographs were registered at the dépôt légal during 1864, a peak largely reflecting the craze for *carte de visite* celebrity portraits.

After much lobbying and great debate, the 1862 Fine Arts Copyright Act was passed in Great Britain. For the fist time copyright legislation in Great Britain included the rights of photographers as 'authors.' Photographers could register their works at Stationers Hall using standard template registration forms (the originals now held in The National Archives, Kew) onto which copies of the image could be attached. However, photographs were also used to illustrate other works ranging from graphic designs, paintings and even designs for the specific use of chicken wire enclosures on poultry farms. The information on these forms, together with the photographs pasted on them, give a broad view of the state and application of photography during the second half of the 19th century. Hitherto they have been largely unresearched.

Artists, art schools and designers were early collectors of photography and a number of photographers created photographs specifically for this market. This seems to been particularly active in France where from 1854 Adolphe Braun of Dornach produced a series of flower studies (*Fleurs photographiée*s) to enable designers to work from natural models. In Paris from the mid 1860s Charles Hippolyte Aubry (1811–1877) created photographs of still lives of flowers that were sold to art schools. Similarly From the late 1860s the Italian Gaudenzio Marconi (1841–1885) created a wide variety of nude academic studies for artists.

The Royal Academy of Arts in London systematically collected the large format photographic portfolios of the collections of major European galleries issued by the firm of Adolphe Braun & Cie from the late 1860s. Other holdings include early portraits by William Lake Price (1810–1895) dating from the 1850's, portraits by David Wilkie Wynfield (1837–1887) dating to the 1860s and *Animal Locomotion* by Eadweard Muybridge (1830–1904).

Curiously, given the innovatory application of photography in France during the 1850s, the Ecole des Beaux-Arts in Paris began collecting photographs in 1866, some 14 years after the South Kensington Museum, though it to was to form a substantial collection by the end of the century.

The collecting of photographs by local history, antiquary, and archaeological societies forms another key component. From around 1850 there was a very dramatic increase in the number of these societies. This was on an international scale. Evidence suggests that most adopted photography to help fulfill their aims and objectives. It was noted that in 1856 the Architectural Society of the Archdeaconry of Northampton linked in 'union' with the local photographic society with the intention of members of the photographic society promising to enrich the architectural societies 'sketch book' with photographs of 'local architectural subjects.'

In 1858 Alexander James Beresford Hope (1820–1887), who was instrumental in the founding of the instrumental in the founding of the Architectural Museum in London implored those attending the inaugural meeting of the Kent Archæological Society that 'Photography is the honest friend who always comes out with the whole truth' and concluded that the Society should adopt photography for 'it would be a shame and disgrace to it not to do.'

The local history and archaeological societies also give insights into the collecting habits of their members.

In England each society held an annual conference at which a 'temporary museum' would be set up. Members regularly exhibited photographs from their collections.

The historiography of collections is of key significance in the evaluation of the long-term influence of 19th century photographic collections. The pathway from private collections to institutional collections began comparatively early. On his death Chauncey Hare Townsend (1798–1868) bequeathed his collection of photographs to the South Kensington Museum and these now form some of the most important works held at the Victoria and Albert Museum. Lord Martin Conway (1856–1937) and Sir Robert Witt (1872–1952) both started their respective collections of photographs in the late 19th century. While Conway's interests were primarily in architecture and sculpture, Witt specialized in the art of the Italian Renaissance and through donation, in 1932 and 1952 respectively; their photo archives became the core of one of the largest photographic collections of art and architecture held at the Courtauld Institute of Art of the University of London.

The 19th century saw the foundation of very significant numbers of professional bodies societies together with 'scholarly' societies and related organizations. Some professionals were involved in the vast construction campaigns undertaken during the period; architecture, civil engineering, railways and shipbuilding. Conversely, the fascination of the past spawned large numbers of societies dedicated to the understanding and preservation of the past. Architectural, archaeological and local history societies proliferated. All of these groups were to form collections of photographs to achieve their aims and objectives.

The study of ethnography and anthropology developed rapidly from the middle of the 19th century. In Great Britain the Royal Anthropological Institute (founded in 1871 from the merger between Ethnological Society of London and the Anthropological Society) began its collection of photographs that remains one of the pre-eminent example.

Another ethnographic photographic collection, that of the Smithsonian Institution, encompasses a number of aspects of photographic collecting. In 1867 the English financier William Blackmore (1827–1878) loaned his personal collection of photographs of "North American Indians" to Joseph Henry (1797–1878), the Director of the Smithsonian in Washington D.C., and hired the artist and photographer Antonio Zeno Shindler to make copies of them to help prepare the catalogue for an exhibition—*Photographic Portraits of North American Indians in the Gallery of the Smithsonian Institution*—that was mounted in 1869. This was the Smithsonian's first photographic exhibit and the copies of Blackmore's collection helped form the basis of the institution's own collection of ethnographic photographs. In 1872 the Smithsonian established a relationship with Blackmore to assist his project of building a photographic archive.

From the early 1860s Blackmore had formed a collection of some 2,000 photographs of North American Indians that dated from 1850–1875. This included his commissioning photographers. Blackmore had built a museum in his hometown of Salisbury to house his extensive collection of early archaeological artefacts and intended to place his photographic archive there. In addition, Blackmore planned to publish a series of photographs from his collections. His untimely death in 1878 scuppered these projects.

The British Empire provided fertile ground for photographic campaigns aimed at building associated collections. From 1868 onwards the British Museum Library and the India Office Library (the successor to the East India Company Library) both enjoyed the privilege of legal deposit of printed books, periodicals and newspapers from undivided India. Photography was extensively used by the 'Archaeological Survey of India,' established in 1861. Many of these photographs are now held in the India Office Collections of the British Library.

In London, the Royal Geographical Society was fortunate to have John Thompson (1837–1921), as instructor of photography, and both fellows and members were encouraged to take pictures, and give the Society any photographs they had taken or collected. Certainly in the 1860's and 70's a large number of photographs were donated which form the basis of the Society's extensive collection today.

Societies related to geographical and historical study included the Palestine Exploration Fund, founded in 1865. The Fund extensively exploited photography to document biblical and post-biblical archaeological sites. It formed a relationship with the British Royal Engineers whose photographers created numerous views, some published by the Palestine Exploration Fund .

Medical photography was well-established by the 1880s and some hospitals were creating albums of clinical photographs. By this time most hospitals in France had photographic departments though in England and the USA medical photography remained in the hands of individual photographers. By the mid 1890s X-ray photography was in use in German hospitals for orthopaedic surgery. Lantern slides created for teaching formed another aspect of such medical collections. Many such collections survived well into the 20th century but were eventually displaced by the 35mm transparency format.

By the 1860s many commercial manufacturers were using photography as a core business tool and forming photographic records of their productions. By the

early 1860s photos replaced drawings in the china manufacturer Minton company pattern books. Railway companies soon began to employ photographers to capture images of their newly completed locomotives, and some companies, such as British Beyer Peacock, gave them to their salesmen to show their potential customers.

Collections of photographs evolved during the 19th century to cover all aspects of human endeavour and were to have a significant effect on progress in perhaps the most dynamic phase of the 'industrial revolution.' However, the scale, scope and impact of such collections is largely an untold story that awaits to be told.

ARCTIC AND ANTARCTIC

As a result of being in partial or complete darkness for a significant period of the year. Polar regions present a shorter window of opportunity for the successful application of photography. Due to the expansive areas of snow and ice, there are challenges in lighting during periods of full or partial daylight which give rise to poor contrast and loss of detail due to overexposure.

The first objective interpretation of the, often romantically depicted, harsh and unusual polar landscape was undertaken by staff of scientific and exploring expeditions as an aside to primary duties. It would be more than twenty years after the introduction of photography, in the early 1840s, that a dedicated photographer would be appointed to an expedition to ensure that a new and fickle medium would become a reliable means of recording the opposite ends of the world.

Constraints in storage space made smaller glass plates a logical choice but potentially compromising quality of reproductions while shortage of water restricted processing and printing usually waited till return to civilisation.

Details of the technical challenges of photography, such as "keeping excited collodion plates sensitive" and "a remedy for cracking in negatives," are well recorded at the time in journals such as the British Journal of Photography. Similar discussion on the unique challenges relating to capturing images in the Polar Regions was limited and often left to others observing the process. Veteran Arctic explorer Dr. Isaac Hayes on board William Bradford's 1869 cruise to western Greenland recounted one such event observing that the "insects got into the instrument and ruined the plates."

Away from the ship photography was severely limited on account of low light and harsh, sub-zero conditions, as low as –30˚F, and technical difficulties posed by the wet plate process. Sledging journeys were gruelling and only essential equipment was carried and photographic equipment would account for about 5% of the load. Preservation of images was a significant challenge and they were often lost prior to return to civilisation.

Daguerreotype apparatus was uncommon but it was taken on the 1853–54 United States Franklin Search expedition, led by Elisha Kent Kane. Reportedly the apparatus was used but all images were lost on an ice floe.

Some of the earliest surviving images were from the collotype process, used by Surgeon of HMS *Resolute* William Thomas Domville while on Sir Edward Belcher's Franklin search expedition of 1852–54. Commander E. A. Inglefield used Glass plates while participating in a Franklin search expedition in 1852–53. Both groups of images are held by the National Maritime Museum, Greenwich. Until the advent of the dry plate process and its commercial patient in 1881 the wet plate process was most commonly used on polar expeditions.

George Simpson McTavish in the 1860s and Edward W. Nelson in 1877 were just two of the land-based expeditions who also used photography in the Arctic.

The *Challenger* expedition of 1872–1876 utilised photography and images from this expedition are the earliest known of Antarctic icebergs and sub-Antarctic islands. George Strong Nares was commander of *Challenger* and would later command of the British Arctic Expedition of 1875–1876. This expedition equipped and trained, through the Royal Engineers, Thomas Mitchell and George White in photographic processes. Their efforts gave rise to the 108 images produced as a boxed set and were also used as illustrations in accounts of the expedition.

In the 1880s scientific enquiry became increasingly coordinated on an international level giving rise to increased opportunities for photography. One example of this was the first International Polar Year in 1882–1883, which involved twelve countries with activities in both Polar Regions. Science and exploration were not alone in attempts to utilise photography to document human endeavour in a harsh, remote, unexplored region of the globe.

Pleasure voyages to the Arctic financed by independently wealthy individuals also provided a platform for

Bourne, Samuel. The Manirung Pass.

photography. Some undertook scientific observations, for example Benjamin Leigh Smith's voyages to Svalblad and Zemlya Frantsa-Iosifa in 1873 and 1880. William J A Grant participated on at least seven private or scientific voyages as photographer, including one of *Pandora* in 1876 and *Willem Barents* in 1881 and 1883.

William Bradford (1827–1892) privately financed six expeditions to the low Arctic between 1861–1869. He employed Boston-based photographers, John L Dunmore and George Critcherson from the studio of James Wallace Black to record images that would provide "accurate and instantaneous images which could later be used to create paintings." The results were highly successful as the photographers had a dedicated darkroom onboard, that Bradford had installed for their sole use. Aspects of these voyages are recorded in the impressive volume *The Arctic Regions*.

The more stable and transportable dry plate process increased flexibility for photographing Polar Regions as commercial and scientific expeditions increasingly focused on the Antarctic after 1880. By this time photography had proven itself as an ideal means of recording and broadcasting images that suited both scientific, sponsorship and commercial aspirations of expeditions.

Commander Adrien de Gerlache de Gomery and his compatriots in *Belgica* (1897–1899) were the first to over winter in the Antarctic and produced the first photographic images of the continent. Carsten Borchgrevinik and his privately financed British Antarctic Expedition (1898–1900) were the first scientific expedition to over winter on the Antarctic Continent and used photography.

Despite the abundance of opportunity, the medium had limited success when compared to other extreme environments, such as images of Kashmir, India from 1864 and 1866 by Samuel Bourne. Importantly, photography provided a means to convey to a wider audience

a sense of visual truth from a region previously often represented by exaggerated and fanciful images. With significant investment in skills and equipment reliable results and useful images could be achieved but results and how the images were utilised varied widely.

By the end of the nineteenth century photography was well placed to serve what became known as the *Heroic Age* of Antarctic exploration and the advances in science and technology that would follow in the first two decades of the twentieth century.

ARGENTINA

The daguerreotype

To understand the spread of photography in the whole country it is necessary to keep in mind that Buenos Aires was the main city and the only harbor devoted to international commerce. Moreover, the nation was involved in several internal conflicts.

Daguerreotypes were referred to for the first time in a Buenos Aires newspaper, the *Gaceta Mercantil*, on March 11th, 1840. It merely reproduced an article published in France. The demonstrations that took place at Montevideo (Uruguay) in March 1840, conducted by the Abbot Comte, were not commented in Buenos Aires due to political reasons. Three years elapsed before the arrival of the daguerreotype to Buenos Aires, this delay being caused by the French naval blockade to Buenos Aires harbor.

On June 1843 advertisements began to be published in the *Gaceta Mercantil*, *The British Packett,* and the *Diario de la tarde*, in which a North American, John Elliot, announced his studio at 56, Recova Nueva street. At the same time, the Litografía Argentina, at 28 Potosí Street, owned by a Spanish citizen, Gregorio Ibarra, informed the customers about the arrival from Paris of two cameras. In Buenos Aires the daguerreotype did not the same popular interest as in Paris or New York. It was still a small town and preserved many of its old colonial habits.

Another North American, John Amstrong Bennet, opened the second gallery of Buenos Aires in 1845, at 121 Piedad Street. He arrived from Mobile, Alabama, and worked as a daguerreotypist in Montevideo (Uruguay) during 1842 and 1843; by the end of 1845,he had left Buenos Aires for Bogotá (Colombia). In 1846, Thomas Columbus Helsby, who owned the Galería Montevideana in Uruguay, with his brother William, made frequent trips to Buenos Aires and worked as itinerant portraitist. In 1853 he settled with his brother in Chile, where they established renowned galleries, in Santiago as well as in Valparaiso.

Charles DeForest Fredricks (1823–1894), the most important photographer among those active in Argentina in the mid-nineteenth century, came to Rio de la Plata after travelling with his camera through Venezuela, Brazil and Uruguay. Although the first itinerant daguerreotypists worked in Buenos Aires, an Italian citizen, Aristide Stephani (1820–1865), opened the first provincial gallery as early as in 1846, in the city of Corrientes, where Anselmo Fleurquin and Joaquín Olarán became active soon afterwards. In 1855, a German, Adolfo Alexander (1822–1881), crossed the Andes coming from Chile to Argentina and worked in San Juan and Mendoza. A year later Amadeo Jacques—the future director of the most renowned high school in Buenos Aires—earned his living as a daguerreotypist in Santa Fe and Tucuman. At nearly the same time, Desiderio Aguiar—born in the Province of San Juan—an Englishman, Fergusson, and a North American, Bradley, made succesful careers taking photographs of the principal cattle-owners' families at the pampas.

Between 1855 and 1858, the names of Federico Artigue (1826–1871), Antonio Aldanondo (1831–1891), Bartolomé Bossi (1817–1890), Walter Bradley, Pedro Gartland, Emilio Lahore (1825–1889), Francis Meeks, Arthur Terry and Antonio Pozzo (1830–1910) were among those devoted to the new craft. The only woman daguerreotypist we know about was formerly a painter, Antonia Annat de Brunet.

In 1852, Juan Camaña (1795–1877) brought to Buenos Aires the stereoscopic daguerreotype. Stereoscopic daguerreotypes were not very popular because of their high cost.

As only a few daguerreotypists signed their work, most of them remain anonymous. Between the few artists that signed their works are Amadeo Gras (1805–1871), Saturnino Masoni (1826–1892), Juan Portal and Anselmo Fleurquin.

Daguerreotype Views

Nowadays, the only extant nine daguerreotype views are those preserved at the Museo Histórico Nacional (Buenos Aires), five of them signed by Charles De Forrest Fredricks and the rest attributed to Antonio Pozzo.

Ambrotype, Tintype, and *Carte-de-Visite*

These one-image procedures were common, in particular the ferrotype or tintype, but the albumen paper became popular in the *carte-de-visite* format and soon afterwards it was used in all the photographic size styles, including views for albums, that began to be produced in the midst of the 1860s. Some salt paper prints reached Argentina but they are very scarce.

Albums of Views

In the sixties, the first albums of views appeared. Some of the pioneers were Esteban Gonnet (1830–1868), Benito Panunzi (1819–1894) [Many albumen prints of outdoors scenery or popular types were wrongly attributed to Panunzi. A recent study clarifies the mistake and shows that Gonnet was the author of many of them. (Alexander & Priamo, 2000)], Adolfo Alexander, Georg Alfeld (in Rosario), and Ángel Paganelli (in Tucumán). In the following decades other authors were Antonio Pozzo, Christiano Junior, Desiderio Aguiar, Saturnino Masoni, Carlos Feltscher, Samuel Boote, Francisco Rimathé and Walter Bradley.

Portraitists

An English citizen, Alejandro Samuel Witcomb (1835–1905), was probably the most renowned portraitist of the 19th century [His archive—that included part of Christiano Jr. and Loudet' archives—is kept in the Archivo General de la Nación, Buenos Aires]. He arrived very young from England, and settled in Rosario; several years later he established in Buenos Aires, were he became a famous artist. Other outstanding masters were Antonio Aldanondo, Luigi Bartoli, Emile Mangel du Mesnil, F. Meeks, W. Bate & Co., Emilio Lahore (1825–1889), Bartolomé Loudet (1823–1887), Juan Ansaldi, Carlos Chute, Alfonso Fermepin, Arturo Mathile, Arquímedes Imazio, Francisco Monzón, Roberto Offer, and Juan Portal.

Photo Illustrated Books

William Fox Talbot rapidly realized that the photograph had a wide terrain to expand itself: the printing press products and as early as 1839 introduced an album with mounted photographs. In Argentina, as in other countries in the region, the photo illustrated book can be traced to the 1860s. Initially, the usual image was the author´s portrait but soon in the 1870s it was common to illustrate a book or a brochure with different kinds of images: city views, anthropological portraits and any kind of objects.

Photomechanical Processes

In early times different varieties of photomechanical systems were employed, mostly illustrating books, brochures and magazines. The first practitioners included Christiano Junior and Emilio Halitzky, who used mostly the phototype. In 1885 the Museo de La Plata brought from Europe modern photomechanical printing equipment, the best for the time being, for phototypes. As far as we know, woodburytypes were never made in Argentina.

Scientific and Technical Uses of Photography

During the 1860s the first medical uses of photography appeared. In the early 1870s Schultz-Sellack succeded in taking astronomical photographs, and the growing community of scientists left anthropological, paleontological and natural science testimonies by means of photography.

Engineering activities such as dam building, bridge construction, industrial facilities, railroad construction and mining activities were recorded.

The phototeodolite was briefly used, according to universitary registers.

Photomicrography was first tried by Roberto Wernicke, who made early experiments between 1884 and 1887.

Early experiments with X rays were conducted at the Faculty of Sciences of Buenos Aires, two months after the publication of Roentgen's paper.

The Argentine Society of Amateur Photographers

As in many other countries, a select group of the high society showed interest in photography and founded this Society in 1889. This Society was instrumental during several decades in publishing albums, as well as in organizing contests and printing a Bulletin.

ARNOLD, CHARLES DUDLEY (1844–1927)

Charles Dudley Arnold was born in Port Stanley, Ontario, Canada, moving to America at the age of twenty and working as a salesman. It is not clear when he took up photography, but by 1886 he was listed as a photographer in New York. His obituary mentions that he travelled with his camera in Europe—probably in the early 1880s—and architectural photographs by him survive of locations in England and France. Many of these photographs were published in 1896 in the book *Country Architecture in France and England XV. And XVI*. Centuries, and yet more, as late as 1924 in *French Farm Houses, Small Chateaux and Country Churches in France* by Antonio Di Nardo.

Arnold's first book of photographs, *Studies in Architecture at Home and Abroad*, was published in New York in 1888. Three years later, his reputation growing, he moved to Chicago to document the construction of the exhibition site for the 1893 Columbian Exhibition at Jackson Park.

He later went on to take photographs of the Cotton States Exhibition in Atlanta in 1895, and became official photographer for the 1901 Pan American Exposition which was held in his adopted home town of Buffalo — where he erected a large studio on the exhibition site.

He continued in business until the early 1920s, and died in 1927.

JOHN HANNAVY

ARNOUX, HIPPOLYTE (active 1869–c. 1890)

Hippoltye Arnoux was one of a group of photographers who entered the market catering for the growing number of visitors to the Nile Valley from the mid 1860s.

His place and date of birth are unknown, but he is known to have been French, based in Port Said, and his national origin may have played some part in his decision to produce an extensive photographic coverage of the Suez Canal.

His studio was located in the Place des Consuls, and later in Place Ferdinand de Lesseps in Port Said, and his premises, and the sailing boat which served both as a floating darkroom and to transport his equipment, advertised his specialism, being emblazoned with the legend 'Photographie du Canal.'

The earliest of his photographs—which are all undated except one—was taken shortly after the canal's opening in 1869, and he continued to expand his catalogue until c.1890. The one dated photograph comes from 1885.

In addition to images taken on the canal, studies of Egyptian types, probably taken in his Port Said studio, date from the later 1870s onwards.

It has been suggested that the Greek born Geogiladakis, perhaps a former assistant, may have continued to market Arnoux's images after c.1895, as several known Arnoux images bear an overprinted 'Georgiladakis' signature.

JOHN HANNAVY

ART PHOTOGRAPHY

In 1867, a decade before his election to the papacy as Leo XIII (1878-1903), Cardinal Gioacchino Pecci composed a Latin poem entitled "Ars Photographica." The poem proclaims that photography surpasses even the achievement of the ancient Greek painter Apelles, portraitist of Alexander the Great:

Drawn by the sun's bright pencil,
How well, O glistening stencil,
You express the brow's fine grace,
Eyes' sparkle, and beauty of face.
O marvellous might of mind,
New prodigy! A design
Beyond the contrival
Of Apelles, Nature's rival.
(Translated by Robert M. Adams)

Some years after becoming Pope, Leo XIII commissioned a fresco celebrating the new art of photography. Situated in the vault of the Galleria dei Candelabri, the mural depicts personifications of Painting, Sculpture and Architecture paying homage to Ecclesia; Photography is depicted in a lower realm, accompanied by Weaving. Despite being sanctioned by the pope, photography continued to occupy an ambiguous position in the hierarchy of art, science and craft during the second half of the nineteenth century.

In 1860, in a paper read to the South London Photographic Society, the Victorian portrait photographer Cornelius Jabez Hughes proposed to divide photography into three classes: "Mechanical [or literal] photography, Art-photography, and, for want of a better term, High-Art photography." In the first category, he suggested, the photographer aims at "a simple representation of the objects to which the camera is pointed … where all the parts are to be equally sharp and perfect." Art Photography, by contrast, "embrace[s] all pictures where the artist, not content with taking things as they may naturally occur, determines to diffuse his mind into them by arranging, modifying, or otherwise disposing them, so that they may appear in a more appropriate or beautiful manner than they would have been without such interference." For Jabez Hughes High-Art Photography was a discrete category of Art Photography limited to "pictures which aim at higher purposes than the majority of art-photographs, and whose aim is not merely to amuse, but to instruct, to purify, and ennoble."

Some years earlier, in a paper presented at the Royal Society of Arts in 1852, Roger Fenton had already acknowledged the difficulties facing the photographer when he or she attempted to represent the ideal by photographing the particular. Fenton recommended, as a partial solution, that practitioners should always select the best and most appropriate models. This recommendation echoes classical notions of ideal beauty, exemplified most famously by Zeuxis when he undertook to execute a painting of Helen of Troy for the citizens of Croton. It will be remembered that Zeuxis selected as his models the five most beautiful virgins in Croton and combined in his painting the best features of each woman. Zeuxis's emphasis upon selection prefigured Fenton's recommendation that photographers should choose the best models, but his practice of combining the best features of his models was incompatible with the literal nature of photography. Fenton's still-lifes and game-pieces confirm that he chose his models carefully. In addition, they link the practice of photography to venerable pictorial traditions, most particularly those of seventeenth- and eighteenth-century Italian, Netherlandish and Spanish painting. Fenton's still-lifes also link photography to ancient mimetic traditions, exemplified most famously by two paintings executed by Zeuxis and Parrhasios. Zeuxis's *trompe l'oeil* of grapes appeared so real that birds came to peck at it, but Parrhasios's painting of a curtain deceived Zeuxis himself. Similar to Fenton's artistic still-lifes and hunting pictures are photographs made contemporaneously in France by Charles Aubry, Adolphe Bilordeaux and Adolphe Braun.

William Henry Fox Talbot in the first years of photography created pictures that prefigured Fenton's and Jabez Hughes's definitions of art photography. In particular, Talbot's *Fruit Piece*, in *The Pencil of Nature*, anticipated Fenton's still-lifes by more than a decade. Talbot selected, arranged and composed his subjects, while also exploring various effects of light and shade. In some notable instances he produced alternative versions of the same composition, and in other cases he returned again and again to the same subject. Between 1843 and 1848, in Edinburgh, David Octavius Hill and Robert Adamson also produced architectural views, conversation pieces, portraits and *tableaux vivants* that transcended literal recording. Hill approached the practice of photography with a painter's training and eye and worked with composition, pose, light and shade to create pictures that were, in some respects, equivalents in the new medium to portraits by Henry Raeburn, for instance, or to etchings by Rembrandt. Hill and Adamson, like Talbot, were evidently more concerned with mood and effect than with the literal recording of their subjects. A photograph such as that entitled *The Fairy Tree at Colinton* demonstrates that Hill and Adamson could be as much concerned with magic and imagination as with the transcription of nature.

In 1868 in a review published in the *Art Journal* the anonymous author observed on seeing an album of photographs by the so-called father of Art Photography, Oscar Gustave Rejlander, "If, a few years ago, we had been asked the question, 'Has Photography produced anything worthy of being called a work of Art?' we

should have hesitated to give an answer in the affirmative." In the meantime, however, some photographers had shown that "more can be done than we at one time thought possible, and that results are obtainable from lens and camera, which are not merely imitations and copies from nature, but productions of mind and thoughtful study." "Of Mr. Rejlander's pictures (for such we may justly call them)," the reviewer concluded, "we have no hesitation in saying that they are full of beauty and full of mind." It is evident from this that photography, if it was to achieve the status of art, was expected to combine beauty, intellect and study; conversely, photography that merely transcribed the ordinary world could not aspire to be art.

Rejlander linked art and photography in various ways. This is evident from writings such as "An Apology for Art-Photography," a paper he read in February 1863 at a meeting of the South London Photographic Society, and from his photographs. Rejlander produced a large number of art studies based on figures in paintings by Raphael, Titian and others in the belief that they would prove useful to artists. In addition, he created photographs in the manner of Renaissance and Baroque painting and antique sculpture. In keeping with Fenton's and Hughes's ideas, Rejlander selected the most appropriate models for his subject pictures and arranged his sitters to create compositions that were not necessarily present in nature. On one famous occasion, reported by Rejlander himself, the photographer magically transformed a model drawn from the streets into an entirely plausible decapitated head of John the Baptist. It might reasonably be argued that Rejlander adapted the classical practice of selection and synthesis to photography, creating pictures that combined nature with beauty and intelligence. To achieve this goal Rejlander developed a practice that sometimes required the production of several negatives, which he would then combine harmoniously to create pictures that had no prior existence in nature or in the studio. Rejlander's most notable combination print is his great allegorical picture *The Two Ways of Life*, the most complex and controversial of his photographs. The didactic, moralising and uplifting nature of *The Two Ways of Life* situates it and other similar photographs by Rejlander firmly in Jabez Hughes's third category, that of High-Art Photography.

Julia Margaret Cameron**,** who may have received instruction in photographic technique from Rejlander when he visited the Isle of Wight in 1863 to photograph Alfred Lord Tennyson, consciously subverted the literal characteristics of photography in order to create pictures that sometimes concealed as much as they revealed. Like her predecessors in the 1840s, Cameron also created pictures that reflected her positive familiarity with earlier traditions in painting and sculpture, from the Elgin Marbles to Renaissance masters such as Pietro Perugino, Raphael and others. Among Cameron's contemporaries, Clementina, Vicountess Hawarden, and Charles Lutwidge Dodgson also produced photographs in which composition, light and visual intelligence outweighed the mechanical transcription of quotidian reality. Cameron, Carroll and Lady Hawarden, like Talbot and Hill, also created pictures that were themselves fictions, *tableaux vivants* inspired by works of art or literature, ranging from the Bible to the novels of Sir Walter Scott and the poetry of Alfred Lord Tennyson.

Among Rejlander's professional contemporaries, the painter–photographers William Lake Price and Henry Peach Robinson also employed the combination printing process to create *tableaux vivants* in the manner of Victorian paintings and to invent pictures that were often literary and elevating in nature. In fact, Robinson affirmed in *Picture Making by Photography* (1886) that his goal was "to induce photographers to think for themselves as artists and to learn to express their artistic thoughts *in the grammar of art* [my italics]." Robinson's *The Lady of Shalott* and *Bringing Home the May* are linked closely to the contemporaneous tradition of Pre-Raphaelite painting, echoing pictures by John Everett Millais. Although it was heavily criticised when

it first appeared, Robinson's composite photograph, *Fading Away*, is acknowledged now to be one of the most poignant visual evocations of death in Victorian society. Peach Robinson's *Pictorial Effect in Photography* (1869), in which he first articulated his theory of a photographic art, continued to be influential into the twentieth century.

At the end of the nineteenth century and the beginning of the twentieth, art photography developed in various forms in Europe and in North America. Peter Henry Emerson in his treatise *Naturalistic Photography for Students of the Art* (1889) articulated a vision of photography as an independent art, only to repudiate this position a year later in *The Death of Naturalistic Photography* (1890). Pictorialism evolved contemporaneously in Europe and in North America as an international movement. Pictorialists aimed to produce photographs that were painterly in nature, mirroring the ambiguous, amorphous qualitities of etchings and paintings by James Abbott McNeill Whistler, for instance. Their practice of lavishing great attention on individual prints was also in keeping with the cultivated rarity of the contemporaneous tradition in fine prints, illustrated particularly by the etchings and drypoints of Whistler, David Young Cameron and others. In England the ideals of Pictorialism were promoted by the Linked Ring Brotherhood, which included photographers such as James Craig Annan, Fred Holland Day, Frederick Evans and many others. In 1902, in New York, Alfred Stieglitz established the Photo-Secession, an association intended to promote photography as a fine art, and the following year he inaugurated *Camera Work*, which he produced and edited from 1903 to 1917. Stieglitz published the work of many of the American and European Pictorialists in *Camera Work*.

ART PHOTOGRAPHY AND AESTHETICS

Photography's productions are descriptive and relatively literal; their integrity as works of art depends on transformative processes that are material, experiential, and analytical. Aesthetic theory considers how works of art are perceived or experienced and how the artistic is understood and translated into visual characteristics. Accordingly, photographic art requires consequential aesthetics founded on formal attributes: composition, focus and distinctness, and relations of light and shadow; material characteristics, such as image colour and surface finish; and choice of subject matter. These elements might be couched in the terms of other visual arts, or simply borrowed, as George Davison observed in 1891: "Photography has come late in the day. It would be difficult for it to avoid likeness to something that had preceded it" (Davison 1891, 721). This was more than a defence of photography's nascent status as an art form; it was also a way of understanding photographs as pictures. Indeed, photography, like painting and drawing, is a transposition of mechanical and material realities to a two-dimensional picture plane, so an analogy with graphic art is appropriate.

The mere recording of surface facts is not sufficient to the wider consequence of art, and in photography, a more formal consideration of pictorial modes was derived from academic art, which endorsed invented, synthetic picture-making, founded on classical, Renaissance, and Enlightenment notions of ideal beauty. Art theory was codified in the late eighteenth and early nineteenth centuries by Sir Joshua Reynolds at London's Royal Academy and Antoine Quatremère de Quincy at the Institute des Beaux-Arts in Paris. Both distinguished between the raw content of art—a direct observation of nature—and the intellectual and picto-

rial exposition necessary to raise the picture beyond its utilitarian, descriptive function and into the realm of intellect and invention. Reynolds's theory of a "liberal art" appealed to the practitioners of a medium whose access to the status of fine art was thwarted by its association with popular, applied art and commerce, and his *Discourses*, like later works by John Burnet and Sir Charles Eastlake, would be central to early texts on photographic art, such as those by William Lake Price and Henry Peach Robinson.

In *Pictorial Effect in Photography* (1869), Robinson counselled photographers to look to established fine arts for aesthetic principles and compositional modes. This was consistent with the notion of art as a synthetic activity, inspired by but only tangentially concerned with nature. But photographic imaging was more consistent with materialism, predicated on the observation of readily defined and distinguished facts. In 1857, Elizabeth, Lady Eastlake noted a prevalent belief in photographic circles that "art had hitherto been but a blundering groper after that truth which the cleanest and precisest photography [...] was now destined to reveal" (Eastlake 1857, 461). In pictorial terms, this type of truth might be understood as 'imitation,' or superficial resemblance to the original referent. Yet pictures might also incorporate 'natural' truth, concurrent with physiological sensation, and 'artistic' truth, pertinent to the conventions of representation. All of this produced conflicting expectations of photographic art, illustrated by the reception of combination printing. The method synthesized a single image from multiple negatives in the service of a technical purpose: lenses did not have the covering power to resolve a large group of figures, nor could a practicable exposure time be achieved for a format that might exceed seventy centimetres. Combination-printed tableaux, notably by Oscar Gustav Rejlander and Henry Peach Robinson, were elaborate fabrications inspired by popular history painting. Yet what was unexceptional in painterly invention was contentious in a photograph. Combination prints deceived the viewer's expectation of photographic truth; particularly, the presumption that a photograph would necessarily depict a single material referent as it appeared at the moment of exposure.

Straight, unmanipulated photographs also produce "untruths" such as apparent distortions in tonal relations, perspective, and scale. Manipulation was a necessary corrective of those ostensible inaccuracies, however truthful in optical terms. It could also make the photograph more than an image "taken" directly from nature without mediation or interpretation. A photograph could be "made"; expected to function as a picture, with its own visual qualities and expressive modes. For Robinson, nature needed to be disciplined and dignified, and transformed into a "picture" through the use of selection and composition (as well as several negatives). His photographs showed a disposition of elements—figures, foreground interest, peripheral framing, and background closure—that marked such work as 'pictorial' rather than a spontaneous or serendipitous transcription. Robinson's subject matter of genre scenes and literary themes owed much to Pre-Raphaelitism, but that school was a problematic model for photographic art, as its concern with detail and disdain for pictorial convention was popularly thought to be inspired by an uninflected, 'mechanical,' photographic vision.

The nineteenth century saw a shift in art from the academic studio and its conventions, towards the inspirations of the natural world. There was an increased interest in individual experience, influenced by changing social and economic structures and reflected in the Romantic movement in literature. A Romantic resistance to urbanization and industrialization fed the interest in *plein-air* painting, whose attentions to a naturalistic diversity of light was detailed in effects of weather, foliage, and geological form, as discussed by Pierre-Henri de Valenciennes and John Constable and more widely couched in the theoretical vocabulary of the picturesque and the sublime. Photographers cited the same pictorial modes and locations: in France, Gustave Le Gray and Eugène Cuvelier shadowed Barbizon painters such as Théodore Rousseau at Fontainebleau, while in Britain's Lake District, Roger Fenton and George Washington Wilson traced the literary paths of Samuel Taylor Coleridge and William Wordsworth. Press reviews made an explicit correlation between Fenton and Wilson's exhibition photographs and John Ruskin's recasting of naturalism into cogent formalism, detailing atmospheric perspective and powerful luminosity as productive of a transcendent sense of infinity.

Academic art was largely based on the traditions of the past, and in this respect, American artists and photographers were at a disadvantage in developing an indigenous art within a national history scarcely a century old. Naturalism was a tremendous opportunity. In 1836, the painter Thomas Cole argued that American artists should attend to the "wildness" of unspoiled nature, and in the same year, Ralph Waldo Emerson proclaimed 'natural' truth as a liberating, spiritual force. Transcendentalist theory connected sight and insight; closely attentive seeing produced a more profound spiritual perception, and, with respect to John Ruskin's idea of the "innocence of the eye," contravened academic convention. Such theories supported luminist painting and Cole's Hudson River School, echoes of which appear in photographs by William H. Rau**,** Carleton Watkins, and Eadweard Muybridge. William J. Stillman presented a synthesis of Ruskin's naturalism and Emerson's transcendentalism in photographs and editorials for his weekly art journal, *The Crayon*.

The connections between naturalistic art and optical devices such as the camera obscura has been widely discussed in modern times, but in the nineteenth century the pictorial relationships were not seen as deterministic. Optical instruments were not the dominant basis for works of visual art; they were designed to replicate established visual conventions, and were valued more as teaching aids and auxiliary help for specific problems of perspective. Their productions only latterly validated artistic training; the lens's field of view coincided with the established awareness of a delineated frame, and its focal planes recreated, but did not inspire, the artist's emphasis or selection of certain planes of the picture. Optical aids predated the photographic camera, though not by much; problems with focus and lens aberrations meant that they were actually practicable for less than a century before photography's invention. Still, photographic cameras incorporated earlier designs and corresponding representational systems, even as the latter shifted from a unified, Cartesian space to one more fragmentary, subjective, and modern.

Relationships between vision and art were of great interest in the nineteenth century, and French 'realist' and British 'naturalistic' painters aimed to represent direct visual sensation as a means of rethinking representation beyond imposed ways of seeing and the pictorial devices of academic painting. One might imagine that photography had no such conventions and that the camera simply recorded material reality. But there was a similar argument to be pursued; does a photograph convincingly represent what we *think* we see in the natural world? While it might be assumed that a transcription of the visible world required the most precise resolution, it was recognised that the human eye had a very partial view of nature, circumscribed by distance, atmosphere, luminance, and field of view. If these limitations were true to the essential nature of human vision, then perhaps distinctness was not the most appropriate or truthful optical mode. Indeed, critics such as Charles Baudela**ire** ('The Salon of 1859') and Charles Blanc (*The Grammar of Painting and Engraving* 1867) criticized photography for its detailed and inexpressive literalness, reflecting concerns, in art, with the validity of verisimilitude and its rejection by those interested in more subjective or expressive schema.

An aesthetic justification for indistinctness emphasized its role in subduing disparities in tonal relations, equating this with the production of "breadth," a term in fine art generally taken to mean the suppression of complex detail in favour of broad, harmonious tonalities. In 1853, Sir William Newton argued that the effect of breadth in photography was determined by tonal rendition and image resolution or focus. He believed these attributes to be best represented by the calotype process, used by photographers such as Henri Le Secq and Benjamin Brecknell Turner (see under landscape) well into the 1850s. Glass plate negatives produced a higher resolution and better tonal separation, but these attributes undermined breadth. In 1860, Thomas Sutton made the same association with the glossy finish of albumen paper: "the real charm of a fine subject consists in a sort of mysterious impression of depth and space; and a varnished surface injures this effect by rendering the subject represented more intelligible in its details, flat, little, and vulgar" (Sutton 1860, 13). Sutton equated sharp detail with literalness and banality, and these failings were often identified as characteristic of photographic images.

Diffusion might counter these faults. In 1864, John Traill Taylor recalled that Talbot had recommended the interposition of translucent paper between the negative and positive to reduce sharpness, especially in portraits. (Taylor 1864, 27). Vignetting was used to a similar end; a graduated fading at the image periphery was originally produced by curvature of field and inadequate coverage in single lenses, but the effect had an antecedent in painted portrait miniatures and from the 1850s was purposely replicated in photographs, usually through the interposition of a mask.

Soft focus could be introduced by opening up the lens aperture, as recommended by Noël Marie Lerebours (see under Lemercier, Lerebours and Bareswill), or by moving the lens relative to the negative plane during exposure, proposed by Antoine Claudet and Joseph Bancroft Reade. The camera could be vibrated during the exposure, while the "vibrotype" used a spirit lamp, lit in front of the camera to create a current of denser air that veiled the object. From the 1860s, diffusion was produced through the reintroduction of lens aberrations such as astigmatism and spherical aberration. A number of lenses were designed to that end, most notably John Dallmeyer's 'Patent Portrait' lens (1865) and the Dallmeyer-Bergheim lens (1897).

Without a serious rationale, diffusion might simply be the abuse of a good lens or technical incompetence. But soft focus was believed to have a physiological basis, in being more true to human sight. In 1889, Peter Henry Emerson adopted theories on vision and representation from Hermann von Helmholtz and British "naturalistic" painters such as Francis Bate and Thomas Goodall. Emerson argued that the optical characteristics most in keeping with natural vision were represented by a simplified, centralized composition incorporating selective focus (see naturalistic photography). In the 1850s, similar debates concerned 'natural' binocular vision versus the unnaturally flattened picture space produced by the monocular eye of the lens. The issue shadowed the evolution of lens technologies; the original single, meniscus lenses had a relatively shallow focal plane, but newer combination lenses gave a more

consistent focus across the depth of field. Such equivalence across picture planes made the photographed subject appear more two-dimensional. To some, this looked inartistic and untrue to natural human vision, an argument partly inspired by contemporaneous critiques of Pre-Raphaelite painting as having forsaken volumetric devices such as atmospheric perspective, resulting in flattened pictorial planes. But the issue was an older one; one-point perspective presupposed static, monocular vision, and seventeenth century French discussions on geometrical optics noted its inadequacy in representing a mobile eye. In the early 1890s, these arguments were updated with the advent of properly instantaneous photographs, when the multi-second exposure times and expressive diffusion of Julia Margaret Cameron's portraits were discussed in terms of a more truthful duration of time representing the real experience of seeing a human face, rather than a frozen, static image produced in a split-second, faster than—and thus inaccessible to—normal human perception.

There were many ways of defining truth in vision; as physiological sensation, as a combination of sensation and mental synthesis, as observation enhanced by experience, not to mention the multiplicities of artistic truth. Critics of naturalistic painting and photography assumed that visual sensation—unaffected by the eye's mobility, by habit, convention, and experience—precluded the mind's participation. Without consciousness, sight was a simple reflex, shared by those of widely differing intellectual and imaginative capabilities. If photography was proposed as an imaginative art, then it too depended on mediated perception. In 1860, the art critic P. G. Hamerton explained the difference between artistic and photographic sight in just these terms: "What we artists see is a vision of Nature through the lenses that *she* has given us, our own human eyes brightened or dimmed […] with human joys and sorrows [... we do] not see her at second hand by the intervention of a glass lens and a mahogany camera" (Hamerton 1860, 128). The vagaries of individual perception did not bolster the notion of some ultimate truth to nature. Instead, they suggested that representation could be diverse because the seeing that it communicated was also varied, partial, and even idiosyncratic. Such ideas

would be pertinent to impressionism; the relationship between psychology and aesthetic experience, and an awareness of the power of individual temperament to affect the reception of sensation were argued by James Sully and Émile Zola, among others.

The emphasis on art as dependent on individual, subjective inspirations extended Romanticism and heralded the symbolist movement in literature and art. Symbolism was oriented towards mysticism and metaphysics; it correlated sensory and spiritual resonances between different art forms, and embraced allegorical subjects and simplified, organic motifs. In the 1890s, photographers such as Alfred Horsley Hinton and the critic Sadakichi Hartmann discussed these ideas in relation to photography. Symbolism recast traditional subjects in the Swedenborgian elements of Frederick H. Evans's architectural views, the close intimacy of seeing in Carine Cadby's still-lifes (Brotherhood of the Linked Ring) and Eva Watson-Schütze's portraits (Philadelphia Photographic Salon and Linked Ring). Many of these works used diffusion and grain to isolate the object from its material context, paring down detail to describe the essence rather than the facts of a subject; rather than mirroring exterior reality, the photographs suggested an interior world. Compositional devices included asymmetrical framing and flattening of pictorial planes, elements in modern painting that were seen as inspired by Japanese art (Richard Muther 1896), while in art photography, they were identified with contemporary art and snapshot photography (Gleeson White 1893). The snapshot camera used a short-focus lens whose wide depth of field compensated for the lack of focusing adjustments, but tended to flatten the picture planes. Equally, the box camera's absence of a viewfinder made framing a matter of guesswork, which could result in unconventional framing. The effect was appreciated as evocative of the lively jumble of modern life, already found in stereoscopic views of the 1860s and seen also in impressionist painting.

The Arts and Crafts movement held that a valid aesthetic experience could be realized through the making of a work of art. Photographers were receptive to such possibilities; photographic materials were already discussed in terms of taste and sensibility, and formal, aesthetic, and even moral values were ascribed to characteristics such as colour and surface finish. For example, the neutral image colour and matt finish of developed-out silver calotype positives and platinum prints were compared with engravings and drawings, and seen as more elegant than albumen prints, whose more brilliant finish and brown hues were by now ubiquitous. Tonal rendition was also compared: the platinum process produced a longer tonal range as compared with silver printing, and gave a superior rendition of detail in shadow areas. This was in keeping with the increasing interest in the faithful replication of natural luminance through the broadest range of tonal values, which developed out of the tenets of naturalism in painting and was taken up by photographers in the 1880s.

The monochrome subtlety of platinum prints was set against hand-tinted photographs. Restraint in the treatment of colour was an established issue in academic painting, and carried some urgency at a time when bright, aniline dyes were widely used, and glaringly visible, in mass-produced commercial goods. The same prejudices applied to the characteristics of surface finish; glossiness was associated with vulgar commercialism, and the sheen of albumen prints compared with varnished academic paintings, both described as showy and common. In fine art, there was a movement towards flatness in treatment and finish, a tendency in impressionist painting equated with a refusal of the artifice and conventions of the Salon. Likewise, at a time when the most typical, commercially acceptable photograph was glossy, a matt surface would look unconventional and uncommercial, and hence, artistic. Many wished for photographs with a rough surface like that of drawing or watercolour paper, but contact papers like platinotype and silver printing-out paper needed a relatively smooth finish to provide a good contact with the negative and a reasonable resolution in the resulting print. Not until the 1890s were more highly textured surfaces made for the new enlarging papers.

A rough surface also communicated a certain tactile animation. This was particularly advantageous with regard to photography, for in contrast to the marked surfaces of hand-made artefacts—paintings, drawings, intaglio prints—the photograph had a very consistent, uninflected surface, especially from the later 1880s, when manufactured printing papers were more uniform.

Photography also coopted, from etching, an idea of artistic intent in print-making, especially in terms of the printer's control over differences between successive proofs of the image. In 1889, Peter Henry Emerson described photogravure as "the final end and method of expression in monochrome photography," and imagined a time when "every artist who expresses himself by photography will also bite his own plates and make his own blocks, and the prints will be published by print-dealers as etchings are now" (Emerson 1889, 207, 212). From 1888, Emerson's portfolios and books were illustrated with photogravures, which appeared first in the *Photographic Journal* (1886-88). By the 1890s, the process accounted for almost one-third of printed illustrations, and even half-tone plates imitated the tipped-in presentation of gravures, complete with a tissue cover paper.

A similar impulse towards the crafted object contributed to a revival of hand-made photographic papers,

including salted paper (Lyonel Clark. Linked Ring), gum prints (Robert Demachy) and brush-developed platinum prints (Joseph T. Keiley). In the late 1880s and 1890s, home-made recipes were used for both new and old processes: the photographic press printed formulas for gelatin silver papers some years before manufacturers had perfected them, while calotypes and salted silver papers were championed in opposition to mass-produced materials. In photography, as in the decorative arts, there was a reaction against mechanization and industrialization, and a concurrent interest in a pre-industrial, artisanal tradition. Pinhole apertures and single lenses appealed to a similar nostalgia; in the 1890s, periodicals carried fond reminiscences of photographing with a spectacle lens set into a coffee canister or a tea tin.

Yet there was also a belief that the material qualities of a photograph were overemphasized. In 1891, Alfred Maskell argued for intentionality: "We are told that the photographer uses an unintelligent machine. Well—the brush and the palette, are they intelligent? Of course, in both cases, the intelligence is, or should be, in the user" (Maskell 1891, 142). This defended photography against accusations that it was the automatic product of a machine, a criticism that cut more deeply with the advent of snapshot photography. Small, hand-held 'detective' cameras and new, ready-sensitized dry plate negatives required little training or premeditation and photographs were popularly seen as both instantaneous and unmediated. While some technical skill was credited to the photographer, there was no recognition of the more subtle effects of picture-making: composition, management of light and shade, tonal control, and diffusion were all assumed to be inherent to the photograph, captured by a happy combination of luck and timing.

Maskell's argument also derived from a notion of art as founded on idea—intelligence or thought—over medium and materials, and he paraphrased the painter James McNeill Whistler's proposition that the finished work of art should not be dominated by the material properties of its production, because these distracted the beholder and undermined a full engagement with the work. This perspective also contributed to the debate about manipulated photographs and truthfulness. While 'hand-work' was key to the complicated pictorialist techniques that refuted photography's reproducibility, it was also associated with the extensive retouching practised by commercial portrait photographers, and condemned on principle by many, including Peter Henry Emerson and Alfred Stieglitz.

Some believed that, in order to establish photography's claim to art, it was necessary to withdraw from the practices that served the medium's commercial viability and professional base. In the 1890s, this encouraged a rejection of the old exhibition classifications that grouped pictures according to technical characteristics, irrespective of their pictorial intent. The pricing of photographs was less concerned with process than presentation, size, and uniqueness: at the 1898 Crystal Palace Exhibition of the Royal Photographic Society, silver, platinum, carbon, and gum prints by photographers such as Frederick Hollyer, Charles Job, and Charles Constant Puyo were valued within the same range. There was considerable attention to presentation: the traditional light-coloured mounts and gilt frames of mid-century were replaced by materials largely inspired by the Arts and Crafts emphasis on simplicity and unobtrusiveness. Frame shapes were simple and, like window mounts, often quite deep, setting the photograph off from its surroundings. This was a useful device, for until the early twentieth century, exhibition walls were crowded. Muted tones had a more 'harmonious' appearance in the exhibition hall, a prerequisite for taste and sensibility. Frames were made of stained wood or lightly gilded to a matt finish, and incised ornamentation was recommended for a greater unity of decorative effect between picture and frame. In keeping with Art Nouveau and the *Jugendstil* of the Vienna Sezession, the motivation was towards the *gesamtkunstwerk*—the total work of art, integrating tangible effects with immaterial concerns.

By the turn-of-the-century, pictorialism emphasized craft and the unique consequence of additive effort in producing a photographic work of art, individual over conventional modes of expression, and expressive rather than mimetic representation. This last aspect looked ahead to abstraction, for it presupposed substantial imaginative powers in the photographer and the viewer. It also addressed the fundamental relationship between photography and pictures; if the medium simply reproduces reality, then photographic images are distinguished only in terms of differences in the subject reproduced and the technical competence of the reproduction. Pictures, on the other hand, develop out of representational systems that transcend the common experience of reality through a material vocabulary and a perceptual interaction between the photographer, the object photographed, and the audience for the resulting photograph as a work of art.

ART UNION

The *Art Union* was a monthly periodical that began publication on 15 February 1839, priced at 8d. It was the first journal to be specifically devoted to the fine arts, and held a pre-eminent position for most of the century. Only 750 copies of the first issue were printed, but for most of the 1840s circulation was around 7,000 an issue. In 1849, the periodical changed its name to the *Art Journal*.

The advent of the *Art Union* was keyed into an increasing public interest in both Old Masters and contemporary British art. Its success also reflects the enormous growth in the market for prints that were sought after by an expanding and affluent middle class. Indeed, the origins of the journal stem from a meeting between Samuel Carter Hall, its editor between 1839 and 1880, and the well known London printseller, Thomas Hodgson. The preface to the first volume declared that journal's aim was to "communicate to Artists, from every available source, intelligence in which they are interested, and, at the same time, contain such professional information as might be supplied by persons of matured experience." Notable contributors included William Rosseti, John Ruskin, George Bernard Shaw and Sir Charles Eastlake.

An important characteristic of the *Art Union* was its interest in decorative, ornamental and industrial art. As such, during the 1840s and 1850s, the *Art Union* regularly reported on the progress of photography and enthusiastically reviewed of the annual exhibition of the Photographic Society of London. Its accounts do not contain the same scientific details as the *Athenaeum* or *Notes and Queries*, but they do express the changing aesthetic status of the medium.

The most significant photographic event involving the *Art Union* took place in June 1846, when every issue included a specimen calotype by Henry Fox Talbot. The accompanying editorial declared that "This will be a great boon to our readers, many of whom, although they have heard much of the wonderful process, have

not yet been enabled to examine an actual specimen." Engravings of daguerreotypes had previously been reproduced in periodicals like the *Illustrated London News*, but the reproduction of 7,000 photographs was a major and original achievement.

The principal writer on photography for the *Art Journal* during the 1850s was Robert Hunt, author of *A Manual of Photography* and founding member of the Photographic club, sometimes referred to as the Calotype Club. Hunt's contributions included long articles on the fading of photographs and the useful application of photography to the fine arts. One of the first descriptions of the making a collodion positive was published in the *Art Journal* in July 1851 in a communication from Fallon Horne to Robert Hunt. Other writers on photography included Ronald Campbell and Francis Frith.

In the late 1850s, the aesthetic agenda of the *Art Journal* became increasingly at odds with the commercial status of photography. Subsequently, although the *Art Journal* used photography to reproduce illustrations from the late 1880s, it rarely extended its coverage beyond a review of the annual photographic exhibition. The *Art Journal* finally ceased publication in February 1912.

ARTARIA, FERDINANDO (1781-1843)
Italian photographer

Among the first commercially available photographic views of Italy were aquatints done from daguerreotypes commissioned by the Milanese publisher Ferdinando Artaria. These plates, which were executed by Louis Cherbuin and Johann Jakob Falkeisen, were issued between 1840 and 1847 under the title *Vues d'Italie d'après le daguerreotype*. The first fifteen plates, which were registered in 1840 and 1841, are views of Milan. Of the 32 plates published in 1842, four depict Pisa and twelve are views of Florence, including two panoramas, scenes showing the Arno and its bridges and views of the principal piazzas and churches. Later plates, issued between 1843 and 1847, range from Como, Genoa, Venice, Padua and Verona, in the north of Italy, to Rome and Naples, in the south. Artaria's *Vues d'Italie* was contemporaneous with and similar in conception to Noël-Marie-Paymal Lerebours's *Excursions daguerriennes,* published in Paris between 1841 and 1843, and to Alexander John Ellis's unrealized *Italy Daguerreotyped.*

GRAHAM SMITH

ARTIFICIAL LIGHTING

During photography's early days artificial lighting was of limited use in the studio as emulsions speeds were slow: daylight was the only practical means of lighting a studio. There were experiments with flash photography as early as 14 June1851 when William Fox Talbot photographed a moving paper, claimed to be *The Times,* using an electric spark, at the Royal Institution. He took out a British patent (number 13661 of 1851) for this method. However, studio flash photography was not a truly viable and widespread until the first commercial flashbulb was made from 1929 and electronic flash became more fully developed in the later 1930s.

Artificial lighting using a high-powered illuminant was made use of as early as 1839 when Captain Levett Ibbetson used limelight to shorten exposure times when making daguerreotypes of microscopic objects. Similar light sources would be seen in the photographic studio later in the century. It was magnesium that was mainly used for lighting photographic subjects, usually away from the photographic studio, during the nineteenth century.

Magnesium was first discovered by Humphrey Davy in 1808 and William Crookes, the editor of the *Photographic News* attempted to make pictures using it in 1859, but it was not until the early 1860s that magnesium was able to be prepared in large quantities in a ribbon form. Alfred Brothers of Manchester produced the first portraits using magnesium lighting in February 1864 and in 1865 Charles Piazzi Smyth took photographs inside the Great Pyramid. Brothers took the first cave photographs, including stereoscopic pairs, in January 1865 in the Blue John Caverns in Derbyshire. With magnesium giving a powerful and controlled light, photographic

manufacturers began making special lamps from 1864 that would dispense magnesium ribbon using a clockwork mechanism. This style of burner remained popular throughout the century and simple hand-held manual versions were used for amateur photography into the 1920s.

It took more sensitive photographic emulsions from the 1880s and a significant reduction in the cost of magnesium ribbon around 1886/87 to further encourage the development of magnesium illuminants. Magnesium flash powders were introduced in the late 1880s. The powder was mixed with an oxidising agent to promote combustion and this allowed the development of holders that required no naked flame, although some devices made use of magnesium powder which was blown into a flame and ignited. Other methods included ignition using a percussion cap, a struck match head, electric fuse or spark from a flint. Portable and hand-held devices were produced, although there were significant risks associated with the handling of such an explosive mixture. In 1890 Robert Slingsby a photographer from Lincoln patented a device to synchronise a flash lamp with a camera shutter. By the 1890s patents were being issued for battery operated flash devices that could be synchronised to a camera shutter.

Magnesium was never widely adopted for professional portraiture in a studio. It was unreliable, it generated significant amounts of smoke and ash and it was potentially hazardous especially when used large quantities. The development of the magnesium wire flashbulb from 1925 which was successfully made commercially available from 1929 brought magnesium into the studio with the popular Vacublitz and Sashalite bulbs sold from 1929 and 1930 respectively.

In December 1841 Antoine Claudet patented (no. 9193 of 128 December) various methods of illuminating the studio including burning coal in oxygen in conjunction with a concave mirror to direct the light and in 1852 Pierre Bernardet de Lucenay described (patent no. 575 of 30 October) using a battery or 'pyrotechnic combustions' to provide a light for the photographic studio using a reflector and blue glass. Other methods of lighting were also trialled by photographers keen to extend the time available to make studio pictures. Gas illumination which was widely available from the 1840s was one source, although the light was of limited use for photography and generated heat. The development of the gas mantle in 1885 eased these problems. Limelight which was measured as eighty-three times brighter than oil lamps was another, but it required constant attention to keep the calcium carbonate trimmed.

The most popular of the early studio illuminants was the blue-flamed Bengal light. This was patented in France for portrait photography in 1854 and John Moule promoted its use for photography through his 1857 British patent (number 478 of 18 February). It was adopted by portrait studios as it was strong in 'actinic light' which collodion plates were most sensitive too. During the winter of 1860 an estimated 30,000 portraits were made in London. However, Bengal light was harsh and it produced noxious fumes.

The topic of artificial lighting for studios was regularly covered in the *Photographic News* in the 1870s and 1880s. In February 1879 one writer described using phosphorus and saltpetre which gave an 'exceedingly bright' light but was 'exceedingly hazardous.' The Brock firework company supplied that writer with other mixtures which, when combined with reflectors and a shade, were suitable for studio work, albeit with excessive smoke.

Electricity offered more potential to illuminate the studio in a safe, convenient and controllable way. Gaspard Félix Tournachon in Paris began experimenting with electric lighting in his studio from 1858 with limited success. He later used battery operated arc lighting to photograph below Paris in 1861 and 1862 where, despite great technical problems, he produced seventy-three images from the catacombs and twenty-three in the sewers.

Compared to other methods electric arc-lamps offered great potential for studio lighting and the introduction of the dynamo assisted this. The first studio to be illuminated by electric light was claimed to be Henry van der Weyde's Regent Street studio in 1877 although there is evidence that he was using electric lighting before this at special demonstrations and he took out a British patent for electric studio lighting in 1876. Van der Weyde's lighting in 1877 was powered by a gas dynamo and it reduced exposure times for carte-de-visite to two to three seconds. Other photographers quickly adopted electric lighting which was proudly noted in their advertisements.

By the end of the nineteenth century electric lighting was a firm part of the photographic studio and the use of the magnesium flash part of the outdoor photographer's skills.

ARTISTS' STUDIES

In a paper read in London in 1863, Oscar Rejlander touched on his practice of photographing models in the poses of figures in paintings by Raphael, Titian, Rubens and others." "I believe photography will make painters better artists and more careful draughtsmen," he affirmed. Five years later, a contributor to the *Art Journal* commented: "We hear that Mr Rejlander's avowed object and intention is to produce what may prove useful as studies to younger artists." "There may sometimes … be instances (e.g. the folds of drapery) where such assistance … might prove of great help," he continued, "but we are far from recommending any who would hereafter produce works that shall live, to lean for assistance in any way upon photographic studies, or upon aught else than originals." Julia Margaret Cameron**'s** contemporaneous photographs "after the manner of" Francia, Perugino and Raphael evoke paintings by those artists, rather being literal studies. On the other hand, Cameron's images of Mary and the infant Jesus and of Beatrice Cenci have the character of artists' studies, for the heavy garments worn by the models recall sculptural drapery studies made by artists of the Renaissance. Cameron's photographs of models posed like two of the British Museum Parthenon sculptures fall directly into the category of artists' studies; indeed, one of the photographs is entitled *Teachings from the Elgin Marbles*. Clementina Hawarden**'s** "studies from life" of her daughters likewise appear to be as much concerned with pose and dress as with portraiture or narrative. The foregoing observations point to the existence of two overlapping categories of artists' studies: photographs intended to replicate painted models or to emulate an artist's style; and photographs made to be used by artists in their training and practice. It is also important to distinguish between photographs made expressly for artists' use and photographs that were appropriated and used in ways that the photographer had not anticipated.

The practice of making studies to assist artists is almost as old as photography itself. The partnership between David Octavius Hill and Robert Adamson was initiated with a view to producing portrait studies of the Free Church ministers for Hill to use when he came to execute his historical painting *The Signing of the Deed of Demission*. Hill also used photographs to assist him with the execution of other paintings. For *Edinburgh from the Castle*, he relied on a calotype for the architecture in the central area of the view; in addition, the foreground of the picture is filled with numerous figures—Gordon Highlanders, Newhaven fishwives etc.—based on well known photographs by the partners. The painter David Roberts also used Hill and Adamson's photographs of Newhaven fisherwomen for his contemporaneous panorama of Edinburgh from the Castle. Other photographs by Hill and Adamson, such as one showing Lady Ruthven from behind, are drapery or costume studies as much as portraits. The partners also produced at least one nude study of a model holding a studio pose. In "The Calotype," an article published in July 1843, Hugh Miller wrote specifically about the potential usefulness of the Hill and Adamson calotypes for the visual arts, discussing particularly a portrait of Thomas Chalmers and a view of George Street, Edinburgh, with the church of St Andrew and St George, where the Disruption of the Church of Scotland began in May 1843.

Nadar, Gustave Dore.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

John Ruskin recognised the usefulness of photographs for the study of architecture. On a visit to Tuscany in 1846 he supplemented his own drawings by purchasing daguerreotypes, which he called "glorious things." "It is very nearly the same thing as carrying off the palace itself," he wrote to his father, "every chip of stone & stain is there—and, of course, there is no mistake about proportions." On his return to England Ruskin executed a watercolour from a daguerreotype of Santa Maria della Spina in Pisa in order to compensate for the difficulty of viewing the mirror-like plate.

Drawing from the nude model was central to the practice of artists trained in the academic tradition in Europe and North America during the nineteenth century. It is, therefore, not surprising that photographers worked from the nude and produced nude studies for the use of artists. In France Eugène Durieu produced

such studies in the 1850s in collaboration with the painter Eugène Delacroix. During the Second Empire, professional photographers made large numbers of *académies* (academic studies of nude models) specifically, if not exclusively, for artists. In England, Rejlander likewise made academic studies to be used by artists. Photographic composition studies for subjects such as the Crucifixion (Gaudenzio Marconi) and the Lamentation (Louis Bonnard) were also made, but those were much less common than individual *academies*. There are even instances in which photographs were squared for enlargement (Jean Nicholas Truchelut). Related to the *academies* were photographs reproducing ancient and modern statuary from the *Apollo Belvedere* and the *Belvedere Torso* to Michelangelo's *Moses* and Canova's *Hercules and Lichas*. These were published by photographic establishments such as the Alinari in Florence, Anderson in Rome, Naya in Venice and Braun in Paris. Such photographs were acquired largely by travellers, but they were also valuable reference works for artists. Such photographs did not supplant plaster casts, but they did provide alternatives to them.

Beginning with Gustave Courbet and Theodore Rousseau in the 1850s, French painters employed photographs as aids in their search for new forms of realism. Édouard Manet appropriated photographs as studies for contemporary history paintings such as the *Execution of the Emperor Maximilian*. Edgar Degas and Pierre Bonnard were themselves photographers and used their pictures in their work as painters. Thomas Eakins in Philadelphia made hundreds of photographs of his pupils and drew on these studies for major paintings such as *The Swimming Hole*. In Berlin in the 1890s Edvard Munch was influenced by the photographs of August Strindberg. At the turn of the century in Paris, Pablo Picasso made extensive use of ethnographic photographs for paintings leading up to and including the *Demoiselles d'Avignon*.

ASSER, EDUARD ISAAC (1809–1894)

Dutch photographer and advocate

Eduard Isaac Asser was one of the first representatives of early photography in the Netherlands. An advocate by profession and bred in one of the most prominent Amsterdam Jewish families of jurists and lawyers he experimented with photography at a very early stage. Eduard Isaac Asser and his sister Netje Asser were already known to the Dutch public because of their enchanting childhood memories of life in Amsterdam just after the Napoleonic period, written between 1814 and 1833, and published in 1964. In 1994 the Asser Family Foundation bequeathed the photographic legacy of Eduard Isaac to the State of the Netherlands. The photographs are now held in the Print Room of the Rijksmuseum in Amsterdam. These incunabula consist of four albums compiled by the photographer himself with c. 200 examples of early calotype photography (c. 1845), actually the earliest known photographs of Amsterdam, and from the beginning of the 1850s on until 1857 wet collodion photography. There is a group of 20 daguerreotypes from the 1840s, as well as proof prints of photolithography which he made in the late 1850s. Asser was active as an amateur artist as well. He received lessons from the Amsterdam painter Jan Adam Kruseman (1804–1862) and regularly sent his paintings to the so called Exhibitions of the Works of Living Artists. As all young men from well-to-do circles Eduard Isaac owned a large collection of scientific instruments.

It is presumed Asser bought his equipment and plates around 1842 in Paris, where the Fould family lived, they were related to his wife who descended from the Cologne banking family Oppenheim. From that moment on Asser learned to make the laborious daguerreotypes, mainly portraits of the members of his family. The first examples of paper photography date from 1845: small paper negatives with views from his house on the canal het Singel, which we can date fairly exactly. He also used this same process for portraits done around 1846–1847. Particularly of interest is a set of self-portraits starting on the title page of the first album, written in French, from which we can draw the conclusion that he somehow started this album as a photographic autobiographical notebook. The self-portrait on the title page is followed by others stating his various moods—'a morbid state' explains one of the adjoining written remarks. During his short career as an amateur photographer Asser kept making self-portraits of which especially the ones done

against a dark ground are intriguing. Asser is seen in a crumpled jacket with the black stains of the chemicals on his fingers sitting on the kitchen chair contemplating, the next moment probably running on to one of his many meetings in the as many distinguished councils he formed part of.

Self-portraits, portraits (groups and double portraits), still lifes and views of the city of Amsterdam were to be the main subjects of his oeuvre which is very similar to that of the British and French amateur photographers from the early period. They all made portraits of their wives and children or compositions with glasses, vases and small statuettes close to hand. Asser photographed from the window of his house, the obvious experiment with a new medium. A special category are his still lifes of photographic paraphernalia: a lens, a camera, a statuette, a stereoscope, a portfolio of photographic paper and a copy of the *Revue Photographique*. With the self-portraits they show his contemplating over the form and content of images done in a new medium of which the canon wasn't at all established yet.

Asser worked together with Marie Eugène Bour (1814–after 1884) a Frenchman and the managing director of the garancine factory in Amsterdam, a chemical factory which produced the red paint for the uniforms of the French army. It is very probable that at the beginning of the 1850s they experimented with glass negatives and new emulsions. In 1855 they submitted their photographs to the International Exhibition of Photography in Amsterdam where the Dutch public surely got a treat. There the Asser and Bour photographs were for the first and last time seen in public, and hung next to the works done by many distinguished photographers, among them Edouard Baldus, Charles Marville and Charles Nègre.

From 1857 on Asser experimented with photolithography and submitted his results of transferring photographs to the lithographic stone to the contest written out by the Duc de Luynes in France. He didn't come very far and the prize was eventually won by Alphonse Poitevin. Later Asser sold the patent for his process to the Bruxelles firm Simonau & Toovey who used it for various publications. In the Netherlands this process was now and then applied for a small group of users. For instance collectors of old prints obtained facsimile photolithographs of scarce material. Throughout his life Asser kept working with his own invention, supporting print firms in Amsterdam and printing from the stone himself.

During his long life that lasted nearly the whole of the 19th century Asser not only was a curious spectator at the discovery of photography. He lived through many a decisive development in the history of photography and photomechanical printing throughout the second half of the 19th century. But and that is even more interesting he also knew the world of arts and visual culture of the pre-photographic period. When in 1830 he visited his grandparents in Berlin he brought with him as a gift drawn portraits of the members of his family and he bought lots of lithographs of the interesting sites in the Prussian capital. Twenty years later it surely would have been his own photographic prints and instead of lithographs photographs of streets, monuments and places! In Berlin he also visited the sculptor Christian Rauch and bought a collection of plaster casts which he first draught and later used in photography as well. He followed lectures by Friedrich Hegel, and in Weimar caught a glimpse of the writer and philosopher Goethe whose likenesses he knew from the prints at home. Thus he gives us many clues as to how form and function of the new medium of photography was firmly rooted in the art practices of the pre-photographic world. In his albums we see photography naturally—and gradually—develop from it.

MATTIE BOOM

Biography

Eduard Isaac Asser was born on 19 October1809 in Amsterdam. He studied law in Leiden and became an advocate in the law firm of his father in Amsterdam. In 1850 he became the first Jewish member of the Provincial Assembly of the States of North Holland and held a number of public functions. He was an amateur artist and took up photography in the early1840s. He became a member of the Société Française de Photographie in 1854. Asser was active as a photographer between 1842 and 1857, when he put away his cameras for good. From that moment on until the end of his life in 1894 he found a new pastime in photolithography. In 1860 he sold his photolithography process to the Simonau & Toovey printing firm in Brussels. In the Netherlands this process of photomechanical printing was occasionnally applied to map making in the army and for book illustration. In 1892 he was the founder of a printing house Maatschappij voor Photolitho- and Zincographie. On 21 september1894 he died in Amsterdam at the age of eighty five. His photographic legacy stayed in the Asser family for a hundred years. In 1994 it was bequeathed to the State of the Netherlands and added to the National Photo Collection in the Print Room of the Rijksmuseum.

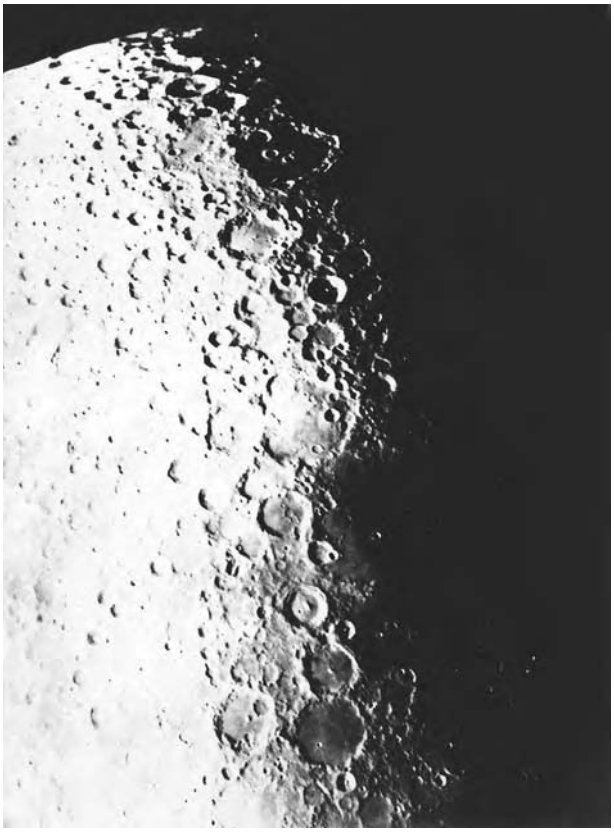
ASTRONOMY

The development of astronomy in the 19th century was in part due to the progress of science, specifically concerning optics, physics, and chemistry which consequently, became a part of photography as well. In terms of its invention, the new techniques accompanied deep rooted, scientifically based disciplines of calculation with the advent of astrophysics.

On January 7, 1839, Jean-Baptist Biot, demonstrated a "retina artificial" boundary in front of the Academy of Science with the daguerreotype. Arago, in the report on the daguerreotype made before the House of Commons on July 3, 1839 insisted, particularly, on the possible applications of photography in the field of science and the other services the technique could provide. Arago suggested in the two principal branches of astronomy and photometry, or the measured intensity of light and the observation of it, that it was now a possibility to create photographic charts of the Moon allowing thus to create "in a few seconds (...) one of the longest, most meticulous and delicate work in astronomy." On this date, Daguerre too collected "the print of the weak light of the Moon" on a plate, however the image appeared "fuzzy and low in details." Continuing Daguerre's work, the American astronomer John William Todrape, realized on March 23, 1840, in his observatory in New York, that several daguerreotypes of the Moon (which are lost today) 2,5 cm in diameter, with an installation ranging from 20 to 30 minutes, showed "the principal mountains of the star." Noting this difficult process, it was necessary to take precautions in the exposure of the plates, as the low sensitivity of the daguerreotype, combined with the very weak luminosity of the photographed object still constituted major obstacles.

It is important to note that astronomers and physicists were primarily the first to be interested in new photographic techniques. The latter were concerned with questions pertaining to the analysis of light and the settings of optics. Often these astronomers were also opticians and manufacturers of glass who expressed a natural interest in the connection between light and optical lenses. In fact, the word photography was "invented" during the first months of 1839 by two astronomers. The first was a Berliner, Johann Heinrich Mädler, who in 1830 created a drawn chart of the Moon, and later employed the recently forged term, which appeared in the columns of Vossische Zeitung on February 25, 1839. The other, John Herschel, was an inventor of his own process of paper developed photography, and during February and March in 1839, he used the term photography on several occasions in his notebooks which documented his experiments during these months. That same year he conducted experiments in which he took photographs in the light of the moon, in Talbot's company. Scientists, attracted by the prospect of reliable, objective documents and photographers were collectively interested by the new possibilities of the medium. The beginning of 1840 saw the flourishing of several experiments with daguerreotype as the base. The great majority of these plates like the eclipse of 1842, was photographed in Milan by Majocchi (2mn), and in Venice by Malacarne. At the observatory in Paris, under Arago, several research experiments were conducted around the photography of the Sun, as it is an object of strong luminosity, which seemed to be more accessible at the time and were conducted in collaboration with, Lerebours, Hippolyte Fizeau, Leon Foucault and Gustave le Gray between 1842 and 1847. Of this collaboration, the only daguerreotype to survive was taken by Fizeau and Foucault on April 2, 1845, which illustrated the sun. In 1848 in Dresden, Herman Krone succeeded in photographing two shooting stars, and in New York, Samuel D. Humphrey, developed two plates of the moon, which were widely celebrated and the accompanying notes appeared in the Daguerreian Journal on November 1, 1850.

In America, the observatory at Harvard had been studying astronomy since 1847, and experimented mostly in the field of the daguerreotype. The professional photographer, John Adams Whipple, obtained the first daguerreotype of a star Véga (July 17, 1850), in the company of George Philips Jump the director of the observatory, and then after many failures, captured a daguerreotype of the moon on March 14, 1851. A few days later, they took a daguerreotype of Jupiter. Of this production of the beginning of the 1850s were an estimated 70 plates, of which the location of only ten of the images is currently known. Exhibited at the Great Exhibition in London, 1851, these daguerreotypes of the moon by Whipple and Bond aroused a lot of interest in the scientific community. The comparison with the engraved and drawn charts of the time, in particular with that of Bee and Madler of 1837, made it possible however to reinforce statements made by their authors, according to whom these images offered



Henry, Paul. Photographie Lunaire, Come Sud, 29 Mars 1890. *The Metropolitan Museum of Art, Gift of Rolf Mayer, 1995 (1995, 125). Image © The Metropolitan Museum of Art.*

a "better representation of the surface of the Moon than any drawing." These results were considered modest to doubters. Even though it was used for ten years until 1850, as the only technique and device on which capable of capturing images of the Moon and Sun, one is forced admit that the daguerreotype rendered little service to Astronomy. The success of the images of Whipple and Bond, like the advent of the albumen-on-glass negative (experiments of Niépce de Saint-Victor in France in 51, or of Whipple and Bond in Harvard in 53) and later the collodion, contributed nevertheless to the rebirth of developments in the field of astronomical photography. The numerous experiments, actually, were conducted around the time of the total eclipse of July 28, 1851, and subsequently, the technology existed to capture it. Important for England and John Herschel in particular, a committee was created especially for this occasion, and at Harvard and in Italy around Père Secchi, the astronomers of these colleges were abound. In the British Isles photographs thus far remained exclusively created from the daguerreotype technique, and the advent of collodion marked the beginning period of great activity, and observatories multiplied. Among the numerous astronomers of the period, like Airy, Struve, Hartnupp Lord Rosse, J.B Reade, the principal figure was that of the amateur astronomer and director of printing works, Warren De La Rue, who, since 1851, used photography to document the skies at the end of his observation. Built and installed since 1858 at the observatory of Royal Astronomical Society, in Kew, an instrument called the photohéliographe, which had 1.50 meter long focal glasses, a clock, and a diaphragm or sliding apparatus, which controlled the maximum duration of light, allowed astronomers from day to day, the ability to take photographs of the sun, up to 10 centimetres in diameter. Giving the position and the solar size of the tasks, the first step towards this "history of the Sun" was headed by John Herschel. During the 1860s, nearly 3000 stereotypes of the sun were taken.

It was on the same principle and also using a photohéliographe that Warren de la Rue, photographer of the Royal Astronomical Society in Spain, obtained his images of the solar protuberance at the time of the total eclipse of the sun of July 18, 1860. The comparison of the stereotypes he took on this occasion with those taken at the same time some 400 kilometers away by the father Angelo Secchi of the observatory of the Romain College, made it possible to prove for the first time with certainty, not only the existence, but the origin of these solar phenomena. The photographs taken in Spain on this occasion, undoubtedly seemed the first true success of astronomical photography, and thus closed a chapter opened in 1842 by Alessandro Majocchi in Milan and a decade punctuated by unfruitful attempts in this field.

Another uncontested Master of lunar photography and the sky since 1856, was the amateur New Yorker, Lewis Morris Rutherfurd. Like Warren De La Rue, Rutherfurd was concerned with publishing his work in the United States as well as in Europe. His work, in fact, went well beyond the scientific community and was published in various formats such large mounted prints, cartes-de-visite, stereoscopic views, and albums like *Le Soleil* de Secchi. Presented regularly at the World Fairs, his images of the Sun and especially of the Moon, taken using achromatic lenses of his own design, were often spectacular and greeted with public success. The scientific community remained divided on their actual value for in spite of the undeniable progress achieved in twenty years, much of these stereoscopic views remained indeed less detailed than a number of likenesses drawn by hand, although these images were much less detailed than the photographs of the lunar surfaces, illustrating the work of James Nasmyth and James Carpenter. However, these images were published because of their detail, but were actually achieved by photographing plaster models of the moon.

During the years 1850–70, the astronomer, with the use of the telescope, was able to explore the stellar universe. This sphere of activity for the photographer, in spite of technical difficulties, remained limited to

a negligible part of the solar system, like the Moon, Sun, and at certain times, eclipses. In 1865 Rutherfurd was forced to recognize that "the results obtained by photography" were far from "able to compete with the human vision." Problems varied according to objects being photographed. For objects with weak luminosity like the Moon and stars, the length of the exposure times always constituted the principal difficulty, often forcing the photographer "to compensate" manually the rotational movement of the ground, which left the image at the mercy of atmospheric variations. For taking images of the Sun, the principal obstacle resided in the very strong luminosity, forcing the photographer to opt for less sensitive materials, like albumen-on-glass, daguerreotype, screens to reduce the power of the actinic rays or to reduce the durations considerably, which led to the development of mechanical shutters. The limits of photography were obvious at the time of the transit of Venus, 1874. The scarcity of the phenomenon, since the last passage had taken place in 1769, like the importance at stake, the goal of which was to determine the precise moment Venus appeared to make contact with the Sun, and to precisely calculate the distance from the Sun to the Earth, explained the extent to which photographer went to capture this. Sixty two photographers, equipped with numerous cameras were sent to the four corners of the world, disseminated in two hemispheres, and to eighty different sites of observation. They represented the only international effort ever made to observe "a simple" astronomical phenomenon. On this occasion, Frenchman, Jules Janssen, took his photographs repeating camera which enabled him to take 48 images in 72 seconds on the same plate. During the simple passage of 1874, several hundreds of stereotypes were taken on the various sites. Often of very good quality, however not all were successful. After long years spent analyzing them, in France and abroad, it was necessary to confront the obvious; photography was not better than visual observations and that the distribution of cameras to capture the measurements between Venus and the sun had made it impossible to achieve the precise measurements needed. During the international conference which occurred in Paris in October 1881 to discuss the observations the passage of 1882, the decision was made to return to traditional observation methods for the next year's images. These results did not prevent the astronomer Jules Janssen from proclaiming, based on an expression of Biot's in 1839, that at the end of 1870, photography had become the "true retina of the scientist."

The beginning of the 1880s brought the generalized use of gelatine-bromide, a more sensitive process than collodion, and with it, a type of photography that made it possible to photograph the visible universe. In January 1883, Andrew Ainslee Common, took the first images of stars one night in January in the suburbs of London. Additionally, during the same period, the most powerful telescopes made it possible to see stars as well. Photography had acquired the status of an instrument of discovery, making it possible to capture phenomena that had before then, not been photographable, such as Barnard's with work comets. Photography also facilitated interest in the Milky Way for photographers like Wolff, Barnard, Russell, Roberts, and Gould, all of whom were interested in new planets as well. Owing to Lowell's initiative, an observatory dedicated entirely to the study of Mars was created in Flagstaff, Arizona where photography played an integral part.

The process of developing celestial charts, which was previously done meticulously by hand, was replaced by the favored alternative of the photographic plate. In fact, several observatories launched companies that reproduced these charts. Vis-a-vis with these disordered initiatives, the need for a harmonization was profiled, and in 1887 was held at the observatory of Paris, where the first astrophotographic Congress International met "for the lifting of the sky chart." With this occasion, its director, the admiral Mouchez, summarized the intended ambitions of the project, that "the inventory [be] exact and as complete as possible of the perceptible Universe at the end of the 19th century" allowing these photographers to draw up a sky chart up to stars of the 14th size." Eighteen observatories throughout the world promised participation in this international project.

The company however was large and complex and relied upon a too new technique, which became quickly obsolete. The amalgamation, throughout the 1890s, required harmonization in terms of materials and methods used. Finally established out of this though was the equatorial method developed at one point by the Henry brothers at the Observatory of Paris. In spite of the importance of the company, and the means put into it, the exorbitant cost of the operation mellowed the enthusiasm of some. In the day before of the First World War only the observatories in Paris, of Toulouse and Algiers had partially completed work. Three-quarters of a century after its launching, in 1970, the project was definitively abandoned. In the last quarter of the century however, other atlas companies experimented with photography as well.

At the physical observatory of astronomy of Meudon, the celestial service of photography created by Jules Janssen in 1876 undertook a systematic study of the solar surface. Those principal results were published, between 1896 and 1905, in the astonishing *Atlas de photographies solaires* 1903, which illustrated the precise granulations of the surface of the star. In the field of lunar cartography, it was at the observatory of Paris, 1890, that *L'Atlas photographique de la Lune* was started. Composed of 71 boards from 6,000 stereotypes, published in volumes from 1896 to 1910, the unit still

remains, fifty years after its publication, as a reference tool. During the same time, Lick created his own *Atlas of the Moon* (1903), with a more modest inventory.

The use of photography in the field of Astronomy became accessible and provided useful information to astronomers regarding the physical nature of space. Drawn one time by hand, the detailed spectrum of stars was a work that was long, tiresome, and often required hundreds of hours of observations. Pioneers of the discipline like Draper in 1842, and later Secchi, Vogel, and Huggins all understood that drawings from the photographic plates would lead to the birth of the discipline "spectrography." From the 1880s on, these scientists created lists of characteristics of chemicals observed in space that were isolated and later observed in the laboratory. Those chemicals provided more information about the spectrum of the stars. Lists of these chemicals accompanied photographic atlases such those made by Pickering (1885), Rowland (1888) or Higgs (1891). Later, with the turn of the century, came the spectrohéliogrammes of the solar chromosphere discovered by Deslandres in Meudon and Hale in Chicago, which appears to have been the last photographic contribution of the 19th century to the advent of physical astronomy.

ATGET, JEAN-EUGÈNE-AUGUSTE (1857–1927)

Although two thirds of Eugène Atget's photographic career fell into the twentieth century, more than half of his life was lived in the nineteenth century and his esthetic roots were firmly grounded in the earlier period.

An orphan by the age of five, Eugène Atget, after insubstantial schooling in Bordeaux, was briefly a sailor before moving to Paris in1878 in order to attend acting school, which he fitfully did while completing compulsory military service. Dismissed from the school, nevertheless he toured the provinces in minor roles until 1887 when he gave up acting in order to take up painting. This too proved unrewarding and by 1888 he had established himself as a photographer in Clermont. In 1890 in Paris, to which he had again moved, he hung up a sign outside his apartment that read, "documents for artists." These photographs were at first plant and animal studies and landscapes, but he soon embarked on what became an obsessive quest to visually capture the city of Paris, with particular attention to those aspects of its past that were vanishing. For this there was clear precedent in Charles Marville's work in the 1860s, but Marville had imperial patronage while Atget operated wholly on his own with only one important commission.

Gradually he built up a roster of clients, including public institutions like the Musée Carnavalet (the museum of the history of Paris), for the inventory of images he painstakingly assembled of the city's architecture, ancient streets, shop signs and storefront displays, street furniture like lamp posts, itinerant vendors, street fairs, and public markets. One group of photographs represents domestic interiors at various economic levels; another records the remnants of the city's fortifications. He carried out a very extensive series of pictures in public gardens in the city, like those of the Tuilleries and the Luxembourg, and in the old royal parks around the city, like those at Versailles, Fontainebleau, St. Cloud, and Sceaux. These systematically depict garden sculpture, fountains, pavilions, parterres, *allées* of shaped greenery, and individual venerable trees and only rarely are studies of the palaces in these parks.

In the notebooks in which he tracked his ever-expanding encyclopedia of the city and its surrounds, he placed the images in categories of his own invention, like "The Art of Old Paris" and "Picturesque Paris" and "The Environs of Paris." Further, he noted likely buyers for various subjects and the hours at which his clients might likely be found at home. He intended the pictures to serve as references for artisans, illustrators, decorators, publishers, designers for textiles and the building trades, including workers in *boiserie* and wrought iron, and amateur and professional historians of the city. It is noteworthy that he did not photograph nineteenth-century constructions like Charles Garnier's Opera House or the Eiffel Tower, nor the grand boulevards that Haussmann had laid out, nor the elaborate mansions that had been constructed in the fashionable neighborhoods near the Arc de Triomphe. Atget's Paris is not a tourist's Paris. He was far more concerned with the city as experienced in everyday life, from the point of view of the pedestrian, moving around as he did, on foot, during countless solitary photographic rounds, often in less than ideal weather. It is characteristic of his outlook that when he made photographs of shop window displays, they were of unpretentious establishments instead of expensive boutiques. Streetside displays of vegetable vendors and the racks of second hand clothing stores were apt to figure in his works, with the occasional inclusion of a dozing shop attendant, an

observant waiter, or a sleeping cat, all of which although inessential for his purposes augment the sense of the specific texture of ordinary Parisian life. Sideshow attractions at annual neighborhood street fairs were part of a long, but declining tradition, and were of as much interest to him as old structures currently housing modern enterprises like automobile repair shops. Junkyards and squatters' shacks on the outskirts of the city were as appropriate subjects as garden prospects lined with eighteenth-century statues.

The photographs themselves were invariably contact prints, made from seven by nine inch glass negatives, which necessitated a satchel to carry them, and a tripod-mounted camera in which to place them for exposure. The negatives, of which there were eventually about 8500, were usually rendered as albumen prints, until albumen paper became unavailable about 1920 and he was forced to utilize gelatin silver paper. Occasionally, by rephotography, he enlarged portions of his negatives to produce pictures that showed at closer range the intricacies of decorative details in plaster, wood, or iron. He processed his negatives and produced his prints in his modest apartment without the help of assistants, except perhaps the actress, (aptly-named) Valentine Compagnon, whom he met in 1886, and who lived with him until her death shortly before his own in 1923. On the backs of his prints Atget invariably identified the places shown by inscribing street addresses or structure or site names and the number of the arrondissement. His knowledge of and interest in the history of Paris is confirmed by occasional supplemental inscriptions that provide information about a building's former use or the time of its construction.

Atget's importance lies not only in the trove of haunting but apparently straight-forward and objective images of nearly deserted streets of Paris that he produced, but also in the influence of the humble nature of his subject matter and his apparent objectivity on twentieth-century photographers like Walker Evans and Lee Friedlander. He provides an essential bridge between photography in the nineteenth and twentieth centuries. When toward the end of his life he was taken up by Man Ray and the Surrealists, who found inadvertent juxtapositions in his work that were unsettling and intriguing, Atget insisted that he did not have artistic aspirations, that the pictures were, as his sign said, simply meant as documents that could be useful to artists.

ATHENAEUM

The *Athenaeum* was the leading journal for literary and artistic reviews during the mid nineteenth century. It was launched by James Silk Buckingham as a 9d publication on 2 January 1828. After struggling for the first two years of its existence against its main competitors, the *Literary Gazette* and the *London Weekly Review*, the *Athenaeum* was made into a financial and cultural success when Charles Wentworth Dilke took over the editorship in June 1830. Dilke, whose editorship lasted until 1846, declared war on the puffery that dominated literary reviewing. He also reduced the price of the *Athenaeum* from 8d to 4d, dramatically increasing its circulation to average sales of around 18,000 copies a week.

One of the most distinctive features of the *Athenaeum* was the extensive attention it devoted to popular science. It chronicled in detail the meetings of the most important societies such as the Royal Society, Royal Geographical Society, Royal Asiatic Society, Society of Antiquaries, and British Association for the Advancement for Science. Prior to the publication of the *British Journal of Photography* and the *Photographic News*, the *Athenaeum* is thereby one of the most important indexes to the development of photography. In Jan 1839, its Parisian correspondent described a personal interview with Louis Daguerre that included a demonstration of his new process. During the 1840s and early 1850s, papers on photography read at the Royal Society and the *Academie des Sciences* were enthusiastically published by the *Athenaeum*. These often included precise accounts of the latest chemical processes aimed at improving the quality of photographs. Henry Fox Talbot, Sir John Herschel, and John Jabez Edwin Mayall were amongst those notable figures who had letters or papers printed.

Debates on photography were often played out in the pages of the *Athenaeum*. In May and June 1847, for example, Antoine Claudet and Robert Hunt were involved in a spat over the value of colouring photographs. Similarly, its reviews of the annual exhibition

of the Photographic Society also encouraged the status of photography. They treated the medium as an art by critiquing the pictures as if they were paintings being shown at the Royal Academy. The *Athenaeum* did more than simply report on the latest inventions and exhibitions: it was an important space in which photography was disseminated and debated.

The *Athenaeum's* coverage of photography declined markedly after the early 1860s. Partly, this was due to the increasingly literary and artistic bent of the journal: scientific meetings were no longer reported to the same degree as they were in the previous decades. The decrease in the number of articles also reflects the changing status of the medium itself. As photography became an increasingly commercial medium in the late 1850s and early 1860s, the *Athenaeum* lost interest in both its aesthetic or scientific value. Its review of the 1864 exhibition of the Photographic Society disappointedly noted that it was "the smallest and least interesting of the series." The *Athenaeum* came to an end in June 1911 when it was merged with the *Nation*. However, any serious engagement with photography had ceased several decades earlier.

ATKINS, ANNA CHILDREN (1799–1871)
British amateur botanist and photographer

Atkins was born Anna Children in Tonbridge, Kent, on 16 March 1799. The only child of John George Children and Hester Anne Holwell, she shared close familial and working relationships with her father after her mother's death in 1800. John Children was a scientist who held positions as Assistant Librarian and Keeper in the developing British Museum and as Fellow and Secretary of The Royal Society. He served as Vice President of the Botanical Society of London, to which Atkins was elected a member in 1839. Children's and Atkins's affiliations helped expose them to the newest in scientific discoveries and facilitated her experiments with photography beginning in the early 1840s.

Before undertaking these experiments, however, Atkins demonstrated her skill as a draftsman of scientific specimens. In 1823 she illustrated Children's translation of Lamarck's *Genera of Shells,* making 256 drawings. These images and the lithographed views of Wooton Church, Warwickshire (published by Charles Hullmandel), and Halstead Church and Halstead Place, Kent, which she produced after her marriage to John Pelly Atkins in 1825, reveal an attention to detail and artistic ability later exhibited in her photographic work with botanical specimens and other objects. When Children retired to the Atkins's home at Halstead Place in 1840, he and Anna Atkins tried their hand at producing photogenic drawings and calotypes—works in two new photographic processes announced by Henry Fox Talbot in 1839 and 1841, respectively—and she adopted Sir John Herschel's 1842 method of the cyanotype.

Children was privy to the groundbreaking results of Talbot's experiments in photogenic drawing almost from their first announcement at the Royal Institution on 25 January 1839. He was a member of the Committee of Papers that met to consider the publication of Talbot's "Some Account of the Art of Photogenic Drawing" and he chaired The Royal Society's meeting at which Talbot delivered the details of his invention. In correspondence, the two men discussed Talbot's process and, receiving samples of Talbot's calotypes in 1841, Children reported that he and Atkins would soon try out the new paper negative photography. That year Children purchased a camera for Atkins from Andrew Ross, but both his and Atkins's success with the instrument is uncertain. No known calotype prints by Children or Atkins survive.

It is likely that father and daughter found a more fruitful source for their scientific experimentation with Talbot's use of plants in his photogenic drawings. Reflecting Talbot's botanical example and possibly his desire to produce such a volume, Anna Atkins recorded specimens of seaweed with photograms in her serially-published work entitled *British Algae: Cyanotype Impressions* (1843–1853)—what many scholars have acknowledged as the first photographically-illustrated book. Rather than using Talbot's technical methods, however, she employed Sir John Herschel's cheaper and more permanent photographic procedure of the cyanotype.

Atkins quickly took up the cyanotype process in 1842 after Herschel, a wide-ranging scientific researcher and family friend, sent to Children his recently published paper containing the blueprint procedure. Coating her paper with a mixture of ferric ammonium citrate and potassium ferricyanide and exposing the dried paper to light for a brief period of minutes, Atkins could utilize fine specimens of "Ptilota sericea" and "Himanthalia lorea" as negatives which, when contact printed under the pressure of glass (or between sheets of mica?), would produce photograms of striking white images against a rich ground of Prussian blue. Intent on the information of size, shape, structure, and degree of transparency conveyed by each labeled example, she would have found the blueprint medium an appropriate and effective one for delineating the delicate "flowers of the sea." Additionally, the photographic process was conducive for producing multiple prints of the same specimen. With it, Atkins assembled more than a dozen copies of *British Algae* which she presented to scientific colleagues and institutions throughout Great Britain.

Atkins loosely based the organization and classification of *British Algae* upon that of William Harvey's 1841 *Manual of British Algae*, announcing in her preface that "I have intentionally departed from the systematic arrangement that I might give specimens of very various characters as a sample." The three-volume work—originally issued serially in 13 parts between 1843 and 1851—was to contain 14 pages of text and 389 pages of captioned plates. These parts, when rearranged into volumes between 1851 and 1853, included title pages, indexes, and an appendix that the books' recipients could order according to Atkins's inserted instructions.

With few references to the locations of collection for her specimens and no indication of the species' status in Harvey's color-coding system of red, green, and olive-green groups, *British Algae* did not present an entirely scientific case study. As Carol Armstrong has argued, however, although Atkins's project lacked in rigorous method, it demonstrated that she enjoyed the freedom to work "at the outer limits of the patriarchal conduct of normal science" in a way that might be seen to problematize "the system of positivist classification and the apparatus of the illustration" that would dominate much of the scientific literature of the 19th century (See Further Reading). The beauty and uniqueness of her publication continued to impress photographic practitioners and students of botany despite the fact that, by the 1850s, other books using drawn specimens, dried and mounted specimens, or images produced by Alois Auer's nature printing technique had rendered Atkins's work obsolete.

Halting publication for a year upon her father's death in 1852, Atkins authored a *Memoir of John George Children, Esq*., and then finished the final volume of *British Algae* in October 1853. With the decade-long project completed, she continued to make cyanotype photograms in collaboration with her close friend, Anne Dixon. Between 1852 and Dixon's death in 1864, the two women produced three presentation albums: *Cyanotypes of British and Foreign Ferns*, *Cyanotypes of British and Foreign Flowering Plants and Ferns*, and an unnamed third album (with the possible assistance of Herschel's daughter, Isabella Herschel) featuring photograms of botanical specimens, feathers, and lace such as "Peacock," "Emu," and "Papaver rhoes".

Atkins died at Halstead Place on 9 June 1871.

MEREDITH KEY SOLES

Biography

Anna Atkins was born Anna Children on 16 March 1799 in Tonbridge, Kent. Although her mother, Hester Anne Holwell, died of lingering complications from childbirth in 1800, Atkins shared a close bond with her father, John George Children. She married John Pelly Atkins, a county sheriff, railroad promoter, and Jamaican coffee plantation owner, in 1825. Atkins published *British Algae: Cyanotype Impressions* between 1843 and 1853. Interrupting this project for a year after her father's death, she produced a *Memoir of John George Children, Esq*. (1853). In collaboration with her childhood friend,

Anne Dixon [?–1864], she completed three presentation albums of cyanotype photograms: *Cyanotypes of British and Foreign Ferns* (*c*.1853), *Cyanotypes of British and Foreign Flowering Plants and Ferns* (*c*.1854), and an unnamed third album of botanical species, feathers, and lace (*c*.1861). Her photographic work was not included in exhibitions during her lifetime but was referenced in publications by Talbot ["On photography without the use of silver," in *The British Journal of Photography*, XI (9 December 1864), 495] and by historian Robert Hunt ["On the applications of science to the fine and useful arts. Photography—second part," in *The Art-Union*, (1848), 237–38]. Atkins died at Halstead Place on 9 June 1871.

AUBERT, FRANÇOIS (1829–1906)

French, photographer, active Mexico 1864–1867

Born in France, Aubert trained as a painter at the *Ecole des Beaux Arts* in Lyon and exhibited at the 1851 Salon. In 1864 he left for Mexico and the court of the newly-installed Emperor Maximilian which seemed a likely source of patronage. Shortly after his arrival in Mexico City, the young painter learned photography and either purchased or assumed the lease for a photographic studio previously occupied by Jules Amiel. Aubert established himself with official portraits of the Emperor and Empress, as well as portraits of officials, ladies of the court and military officers. He produced portraits in full size and carte-de-visite formats. Work from the studio bears the stamp Aubert et Cie and it is presumed that the work of the studio was performed by Aubert and some number of employee/operators. He (or his studio) is best known

Auber, Francios. The Shirt of the Emperor, Worn During His Execution.

for photographs of the participants and relics associated with the execution of Maximilian by firing squad in 1867. The series includes a group portrait of the firing squad, Maximilian's torn and bloody clothing, the sites of his execution and grave, and a portrait of Maximilian in his coffin. Aubert offered these "historical views" by prepaid subscription as full size prints or in carte-de-visite sets. In 1867, Aubert left Mexico. It does not appear that he practiced photography in Europe.

KATHLEEN HOWE

AUCTION HOUSES AND DEALERS

By the mid-1850s several dealers in London were offering photographs for sale, mainly by British and French photographers. Their premises were not devoted exclusively to the new art: Murray & Heath, the prominent dealers at 43 Piccadilly advertised as Photographic Instrument Makers, while Hogarth, Hering, Gladwell and Spooner were primarily print-sellers. They sold individual photographs; albums and photographs published in portfolios or books and lent works for sale to

exhibitions of the leading photographic societies. These events provided another opportunity for photographers to sell examples of their work. In 1859 the organisers of the sixth annual exhibition of the Photographic Society of London even allowed the inclusion of prices in the exhibition catalogue. Significant sales were handled by early agents, e.g. in 1865, the London art dealers, Colnaghi, sold eighty photographs by Julia Margaret Cameron to Henry Cole for the South Kensington Museum.

In Paris, the other early centre for photography, sales of the new medium were also handled by painting dealers such as Durand-Ruel or Legrand, print dealers or booksellers. The gallery or shop-owner usually took a share of the profits from a sale rather than owning the works outright. Throughout the 19th century, photographers and publishers such as Goupil, Blanquart-Evrard, Mansell**,** Agnew or Frith sold works direct as well as through more general print dealers and booksellers.

Seminal galleries in America, such as Stieglitz's "291" rarely showed historical works, although New York art dealer, Julien Levy, opened his gallery in 1931 with a retrospective of *American Photography*, organised in collaboration with Stieglitz. Levy went on to exhibit works by contemporary American and European photographers, but also included shows of Atget and Nadar. He quickly realised photography could not support the gallery financially and introduced a greater proportion of painting and sculpture. Nevertheless, many photographers shown by Levy in the early 1930s went on to become recognised and promoted by the Museum of Modern Art, when Beaumont Newhall introduced photography there in 1937.

Other galleries in Paris and New York were showing exhibitions of photographs, but again, the emphasis was on contemporary material and none could survive on photography shows alone. In 1954, Helen Gee opened her *Limelight* gallery and coffee bar in New York. She struggled too, surviving only until 1961, even with the income from the café subsidising the photography gallery. However, among her few buyers were those capable of influencing many: her last sale, of Julia Margaret Cameron's portrait of Julia Duckworth, was to Beaumont Newhall.

In post World War I Europe, where there were already a few active collectors of historical photographs, the sources for old photographs were antiquarian booksellers, general antique shops and markets, especially the flea markets of Paris.

There were no regular auctions of photographs until the early 1970s, but sporadic bursts of activity during earlier periods injected notable caches of material into the market place. Probably the earliest and most significant of these were the auctions of works by Roger Fenton. The commercial failure of his Crimean photographs prompted the publishers, T. & R. Agnew & Sons, to dispose of "all remaining copies of Fenton's Photo Pictures of the War In The Crimea" through the auctioneers Southgate & Barrett on November 29, 1856, "and five following evenings." The art dealers, Colnaghi, advertised Fenton's negatives for sale in January 1857, possibly having acquired them from this auction and in 1862, when Fenton quit photography, auctioneers J. C. Stevens sold "instruments, cameras and photo views of England & Wales by Roger Fenton."

Occasional dealer catalogues including old photographs had appeared since an important example compiled by E. Weil and published by London bookseller, E. P. Goldschmidt in 1939. Others followed this practice in the early 1970s such as the American dealer, George Rinhart, offering "Americana, Photographic Images and Rare Books."

Lee Witkin is considered the first successful modern dealer in photographs, his New York gallery opening in 1968 and establishing a precedent that was to be followed by others. Witkin maintained a stock of 19th century photographs, but like most other galleries in America, modern and contemporary photography predominated. With an occasional exception, such as the influential Galerie Texbraun in Paris, it was left to a handful of private dealers to nurture a still embryonic secondary market for historical photographs. Led again by American interest, a small network of dealers became established in the late 1960s and early 1970s, mostly in the USA but including prominent figures in England and France.

The auction houses now took the decision to enter what could reasonably be perceived as an emerging market. The specialist book auctioneers, Swann Galleries had been responsible for the first photograph auction in the United States with the Marshall sale in 1952 and Sotheby Parke Bernet held two successful sales from the estates of Will Weissberg and Sidney Strober in 1967 and 1970, but the first of the regular auctions was held at Sotheby's Belgravia saleroom in London in 1971. Christie's followed with auctions in London, and soon after both houses introduced sales in New York, as did Swann Galleries.

From the beginning London auctions were the focus for 19th-century material while 20th-century works dominated in New York. London quickly became the primary source for 19th century photographs fresh to the market; the publicity generated by early sales attracting important private consignments of archives and collections, many of which had long languished in dusty basements or attics. By the 1980s, when the Getty Museum made the decision to collect photographs they were able to acquire several ready-made collections including that of Sam Wagstaff, a key figure in the London auctions. Other notable collections including those of

the Canadian Center for Architecture and the Howard Gilman Foundation include rare treasures, which emanated directly from Christie's South Kensington or Sotheby's Belgravia. There can be few collections of 19th century photographs established since the 1970s that do not include auction purchases made either directly or acquired later through dealers.

Like other markets there has been gradual evolution and during the 1990s, the lure of regular auctions in Paris attracted international dealers and collectors. Again, examples have made their way into such famed collections as those of the Metropolitan Museum of Art in New York.

The complex relationship between museum curators, collectors, dealers and auctioneers is both competitive and supportive and has played a major part in the rescue and recognition of works by many photographers. Through such discoveries our knowledge of photography's history has been enhanced. The role of auction houses and dealers has contributed to the gradual acceptance of the historical and aesthetic importance of 19th century photographs.

AUSTRALIA

When the French barque *Justine* arrived in Sydney from Valparaiso, Chile, via New Zealand on 29 March 1841, Gallic Captain, Augustin Lucas (1804–54?) brought with him a daguerreotype camera and plates. His arrival was only a few days after Richard Beard (1801–85) opened London's first studio in Regent Street on 23 March 1841. The *Australasian Chronicle* of 13 April reported Lucas's intention to "dispose of the instrument at prime cost. The purchaser will be fully instructed in the method of taking views." A demonstration by a number of "gentlemen" took place a month later on 13 May. "At the stores of Messrs Joubert and Murphy, an interesting trial of the advantages of the Daguerreotype was made on Thursday, at which we were present, and received the politest attention at the hands of the gentlemen who conducted the experiment...an astonishingly minute and beautiful sketch was taken of Bridge-street and part of George-street, as it appeared from the Fountain in Macquarie-place" (*Australian,* 15 May 1841). No trace of the first photograph made in Australia has been found since its announcement over 164 years ago.

Captain Lucas returned to France in the *Justine* on 3 June 1841 (*Sydney Morning Herald,* 4 June 1841).The equipment may have been sold to one of the reported witnesses, Didier Numa Jourbert (1816–81), a French wine and spirit merchant and partner of Irishman Jeremiah Murphy. In 1843 Jourbert sold "a very superior daguerreotype [camera], complete, with all the apparatus, and a great number of plates" along with the contents of his Macquarie place household before leaving for Europe (*Sydney Morning Herald,* 21 March 1843).

No further mention of photography by the media is known until the arrival of George Baron Goodman (w. 1842–48, died 1851) the first professional photographer in Australia. Goodman was a Beard licensee who arrived in the *Eden* at Sydney on 5 November 1842 (*Sydney Morning Herald*). Goodman made around seventy miniature portraits in his "laboratory," a blue glass conservatory designed to capture the sun on the roof of the Royal Hotel in George Street. A week prior to the public opening, he showed them to the press. "The likenesses are indeed exact, and the sitter is only kept in suspense about half a minute…The charge is extremely moderate—a portrait, frame and case being less than the cost of a new hat, or a box at the theatre" (*Sydney Morning Herald*, 13 December 1842).

Goodman advertised to provide sitters with "highly finished reflections of themselves" (*Hobart Town Crier and Van Diemen's Land Gazette*, 6 October 1843), but it seems his daguerreotypes disappointed many sitters with their likenesses. A common complaint was the blue-grey deathly pallor. Extant daguerreotypes by Goodman verify the inadequacies of his technique, but with virtually no competition from any other photographers, he had a monopoly during the four and half years he was in business.

With the economic depression depleting customers in

Sydney, Goodman became an itinerant photographer. He travelled to Hobart Town, Van Diemen's Land in August 1843. He soon discovered he had a competitor, the portrait painter Thomas Bock (1790–1855) who advertised his intention to "take photographic likenesses in the first style of the art" (*Hobart Town Advertiser*, 29 September 1843). As a Beard licensee, Goodman threatened Bock with legal action. Bock withdrew, deferring professional daguerreotyping until Goodman had retired in Sydney in 1847. Before Goodman's departure from Hobart in February 1844, he displayed daguerreotype views of the city which were bought by Colonial Secretary, J.E. Bicheno, but these do not survive.

While Goodman was in Tasmania, two English professional photographers, C. and J. Trood, (w.1843–44) late of Claudet's Royal Adelaide Gallery of Arts and Sciences, swooped into Sydney in December 1843 and advertised coloured daguerreotype portraits for one guinea to £1.10s each, including morocco case. By the time Goodman returned to Sydney in March the Trood's had moved on, thus avoiding the litigious Goodman. Joubert and Murphy (their partnership resumed) must have recognised that Goodman's hold over the British colonies was collapsing with the sale of his business in April 1847 to his brother-in-law, Isaac Polack (w. 1845–51). At the end of the month they advertised "four complete Daguerreotype apparatus, with all the latest improvements, and a number of plates" (*Sydney Morning Herald*, 30 April 1847).

The first resident Hobart photographer, stationer and lithographer, Thomas Browne (1816–70) began taking daguerreotype portraits in September 1846. By 1847 his portraits could be taken without the aid of direct sunlight, Browne advertising that his portraits "are always taken in the shade, in which persons can better preserve a natural and pleasing expression of countenance. The early hours of the day are generally more favourable" (Moore's *Hobart Town Directory*, 1847).

While Goodman's 1844 Hobart views remain elusive, Australia's earliest extant view daguerreotype survives in the Tasmanian Museum and Art Gallery. This full plate of Murray Street, Hobart was taken in December 1848 by British itinerant daguerreotypist, J.W. Newland (w. 1848–49, died 1857) (*Hobart Town Courier*, 9 December 1848). It is a remarkable image for not only does it record the principal buildings, harbour and distant mountains, but people going about their daily business in the main street. Newland's stock portraits and views were exhibited at his Daguerrean Gallery in Murray Street, including 200 portraits of exotic people such as the King and Queen of Otaheite (Tahiti) made on stops during his journey across the Pacific ocean.

Australia's indigenous population was also photographed in the 1840s, but few images survive. Douglas T. Kilburn (1811–71), brother of William E. Kilburn (w. 1847–64), the London society photographer, established the first professional photographic studio in Little Collins Street, Melbourne, Victoria in 1847. In October, only two months after setting up, he paid local Aborigines, Koories from the Yarra Yarra tribe to sit for him. Kilburn recounted that the sitters were "superstitious" and fearful of "some misfortune" in having their portraits made (*Illustrated London News*, 26 January 1850: 53). It appears that not one of the men and women sat twice, despite his inducements, "…as upon seeing their likenesses so suddenly fixed, they took him for nothing less than a sorcerer." (*Papers and Proceedings*..., vol. 2, 1850–53: 504). Several of the portraits (thought to number as many as ten) were copied for engravings in 1848, 1849 and 1850. These have been identified with three daguerreotypes in the collection of the National Gallery of Victoria.

Another ten years passed before anyone again showed interest in photographing indigenous people. Aborigines were photographed in Western Australia in February 1858 by Royal Navy Lieutenant and amateur photographer, Arthur Onslow (1809–79) of the *HMS Herald* during his visit to King George Sound, Albany. Like Douglas Kilburn, he paid the frightened men to pose: "At first, I had great trouble getting them to sit, as they were afraid we w[oul]d. cause their death." Onslow added, "by giving them 6d. they plucked up courage enough to let me bring the lens to bear on them but they are bad sitters" (Arthur Onslow Journal 1857–61, 7 February 1858).

It was widely thought that the Aboriginal people were a "dying race" soon to become extinct through warfare with the European colonists. To "save" them, George Augustus Robinson, the Methodist 'protector' of the Aborigines in Van Diemen's Land removed them to Flinders Island in 1834. By 1847 only 44 people had survived due to their lack of immunity to European diseases. They were moved to a reserve at Oyster Cove, near Hobart.

The Bishop of Van Diemen's Land, Francis Russell Nixon (1803–79) an amateur photographer, made photographs of nine members of the Oyster Cove Coal Tribe in March 1858. These early photographs of Tasmanian Aborigines remained little known until the professional photographer, John Watt Beattie (1859–1930) made copies for sale to the tourist trade under his own name in the 1890s. Beattie also copied professional carte-de-visite portraits made by Charles Woolley (1834–1922) of the remaining five Oyster Cove Aborigines then alive in August 1866. The most well known are portraits of Truganini (Lallah Rookh), (Bessy Clarke), and King Billy (William Lanne).

Two years earlier in late 1864, Henry A. Frith (w. 1854–67) photographed the same three people, as well as another woman called "Mary-Ann" (also called "Pat-

sy"). Marketed as *The Last of the Tasmanian Natives*, Mary Ann, Truganini and Pinnanbothac were dressed in crinolines and William Lanne in a three piece suit. The women wore head-dresses of Oyster Cove shells to signify their Tasmanian origin. The publication of this photograph as an engraving in the *Illustrated Sydney News* (November 1864) and the *Illustrated London Journal* (January 1865) achieved international notoriety.

German born photographers appear to have had an anthropological predilection for photographing Aboriginals in all corners of Australia. Charles Walter (1831–1907) made view stereographs of Aborigines at prayer in European clothing at Lake Tyers Mission Station, Gippsland and ethnographic portraits of people at Coranderkk in 1867–68. Frederick Kruger (1831–88) visited Coranderrk in 1877 to take portraits of Aboriginals for the Victorian Board for the Protection of Aborigines. Copies were sold in albums. John William Lindt (1845–1926) made a tableau vivant portfolio of "Australian Aboriginals" in his studio at Grafton, New South Wales in 1873–74. Semi-naked for white people's gaze, the anonymous people with their traditional clothing and weapons are uncomfortably displaced against painted backdrops, dried flora and dead native fauna. These images were widely published in the 1880s as engravings in encyclopaedias. In the far north, Police Inspector, Paul Foelsche (1831–1914) made forty-eight portraits of Port Darwin and Port Essington Aboriginals which were displayed by the South Australian government in the Sydney International Exhibition of 1879.

The first commercial portfolio to contain views of Melbourne, the Victorian goldfields and Aborigines was *Sun Pictures of Victoria* by Frenchman Antoine Fauchery (1823–61) and Richard Daintree (1832–78). Produced in ten monthly instalments, from November 1857 to early 1859, each part had five albumen photographs mounted on card (La Trobe Library, State Library of Victoria). Before leaving Melbourne in February 1859, Fauchery summed the series up in a letter accompanying an album to the French Minister of Public Instruction and Worship: "There are some of great men, some of towns, some of the mines, some of the savages. There is a little of everything."

Fauchery became an official war correspondent and photographer for the French expeditionary force in China. Daintree, a trained geologist made hundreds of photographs of Queensland in his capacity as the Geological Surveyor of North Queensland. After taking an exhibition of his pictures and mineral specimens to London in 1871, he was appointed the London Agent-General for Queensland from 1872–76. His landscape views were scientific and as well as documentary, inspiring others to take their photographic vans into the country for the views trade.

Paper photographs became the choice of amateurs and professionals alike as soon as the collodion wet plate process arrived in Australia in 1854. Prints made from the calotype had a brief flush of popularity in the 1850s with amateurs, but because of the long exposures involved was little used by professionals. Daguerreotypes were more durable in their cases, and although in decline after 1860, were still available until the late 1860s. Cased ambrotypes were popular from 1855 until 1865. The American trained photographer, Thomas Skelton Glaister (1824–1904) and the Freeman Brothers (w. 1853–95) from England specialised in the collodion ambrotype. Joseph Lyne Brown (w. 1854–80) introduced the process to Sydney in 1854 and J. S. Scarlett (w. 1854) to Melbourne the same year. William Blackwood (1824–97) and James Freeman (1814–90) saw the advantage of using the collodion glass negative to make limitless albumen paper copies before the ambrotype completely fell out of favour.

The *carte-de-visite* (cdv) was patented by A.A.E. Disdéri on 27 November 1854 and introduced to Britain by the French firm A. Marion and Company, but received little notice there or in Australia until some years later.

William Blackwood announced the Australian launch of the cdv on 12 May 1859. This "Novelty in the Fine Arts" a new style of miniature visiting card portrait was available for 12 shillings a dozen. The *Sydney Morning Herald* prophesised: "Truly this *is* producing portraits for the million." Although meant metaphorically, it would be some time before the population approached this figure as only 350,000 people lived in the colony of New South Wales in 1859. Indeed, the whole of Australia's population did not exceed one million until 1861.

Blackwood's announcement met with total public indifference. He re-advertised "portraits on visiting cards" on 18 May, but not again. In fact this indifference extended to the whole Sydney profession as no one else advertised "visiting cards" in the *Sydney Morning Herald* until 9 November 1860. Why? An important accessory was missing—the photograph album.

John Jabez Edwin Mayall's (1810–1901) portraits of the British Royal family taken at Buckingham Palace on 10 May and I July 1860 launched the cdv in the British Empire and the United States of America. Copies of Mayall's portraits housed in the *Royal Album* arrived in Sydney by 18 October 1860 ("Per Overland Mail," *Sydney Morning Herald*).

Sydney photographer William Hetzer (w. 1850–67) can be credited with the successful introduction of the cdv to Australia in 1860. In 1858, noticing the popularity of imported stereographs, he created a market for stereographic views of Sydney and its surrounds. Eighteen months later he created the market for the carte-de-visite album portrait in Australia.

Hetzer seemed to have an instinct for predicting new photographic fads. On 10 November 1860 he advertised in the *Sydney Morning Herald* that he had imported a camera "expressly adapted for the new style of Portraits aux Cartes." Hetzer's order for camera and supplies was timely, enabling him to be the first to market the new process in Sydney. Blackwood, the original proponent in 1859, did not advertise cdvs again until December 1861.

Mayall's *Royal Album* with its portraits of the Royal family provided the impetus for people to have their own *family album*. Next to the Bible, the photographic album was a family's most treasured possession. It was a compact and portable memory bank designed for cdvs and later for tintypes. It approached the size of a Bible when it was upsized for cabinet cards and views. Its shape changed for Kodak prints and postcards at the turn of the century. The album became the principal repository for all kinds of photographic images, and remained so until the widespread use of digital imaging and computer storage in recent years. However, the album never lost its usefulness or popularity.

As a result of the success of the cdv and negative photography, the number of photographers leapt in the 1860s. Before the gold rush of 1851 there were less than six daguerreotypists in Australia. There were 249 professional, amateur and travelling photographers working across the country from 1850 to 1859. Between 1860 and 1870, the number of photographers in Australia rose to 367. Of these, only about 43 were travelling photographers. From 1866, following the Melbourne Intercolonial Exhibition, many photographers advertised their awards on the back of their cdv cards and on view cards sold in portfolios or individually for framing.

Many photographers stayed in the trade only a few months when they found that profits could not be sustained. Some, perhaps uncertain whether the boom would last, retained two professions. John Sharp (1823–99) of Hobart Town was Governor Young's dentist, as well as a photographer, photographic supplier and retailer in stereo-views of Tasmanian scenery from 1856–62. Together with Frederick Frith he made a five part panorama of Hobart from the Domain in January 1856. This panorama is seen as the beginning of the views trade in Australia.

News of the Tasmanian panorama spread to Sydney and Melbourne, where photographers quickly followed suit by making larger panoramas. In Melbourne, Walter Woodbury (1834–85) (inventor of the *Woodburytype*) made an eight part panorama of the streets of Melbourne in circa 1857. Ten part panoramas of Sydney were made in 1858 by the Freeman Brothers and William Blackwood.

Panoramas were expensive and sales were low compared with the small and ubiquitous cdv. The cdv was perfect for portraits of people posed in their "Sunday Best," however there were rigid conventions and a narrow catalogue of orthodox poses for studio portraiture. Exceptions to the "house-style" were made by itinerant photographers who seemed as interested in real estate as much as portraiture. Men, women and children responded enthusiastically to requests by itinerant photographers to pose outdoors in front of their residences, modest or grand. Shop owners stood with their staff and customers in front of their shops free from the constricting apparatus of the studio.

Street photography had been tried by Charles Dicker (w. 1861) who exhibited twenty four ambrotypes at the Victorian Exhibition "illustrative of the buildings and places around Dunolly" (*Argus*, 8 October 1861). These outdoor portrait-views were a precursor to cdv itinerant photography, but it seems Dicker met with little commercial success. Only twenty two plates survive and are now part of the La Trobe Library, State Library of Victoria.

The finest exponents of itinerant street photography were Henry Beaufoy Merlin (c. 1830–73) and his assistant, Charles Bayliss (1850–97). In September 1870 the Englishman and Australasian Photographic Company said it would "photograph every public building, shop, and private residence in Sydney." They claimed to have created a "revolution…in street photography…within the last 2 years they have photographed almost every house in Melbourne, and the other towns of Victoria" (*Sydney Morning Herald*, 21 September 1870). In 1873 Merlin and Bayliss arrived at Hill End, New South Wales, where they documented the burgeoning gold mining town and nearby Gulgong. Their studio was built on land owned by their future patron, German emigrant Bernard Otto Holtermann (1838–85).

Holtermann hoped to play a vital role in introducing photographs of Australian urban life and scenery to the world. He came into serious wealth as a major shareholder and mining manager of the *Star of Hope* Gold Mining Company which in 1872 uncovered the world's largest specimen of reef gold, standing 144 centimetres high. It was valued at over 50,000 pounds, a fortune at the time. Seeing the excellence of his tenant's photographs, he engaged Merlin to help him with his vision to promote migration to Australia through photography. Using Daintree's example for the *London Exhibition of Art and Industry* of 1871, he proposed that New South Wales should do the same with "Holtermann's International Travelling Exposition" of panoramic photographs, minerals, models of machinery, raw materials, zoological specimens and natural produce.

When Merlin died of pneumonia in September 1873, Bayliss took over Holtermann's project. He travelled to Ballarat, Victoria in 1874 where he made a nine part 360 degree panorama of the mining city from the tower in the Town Hall. In 1875 he positioned himself in the

tower of Holtermann's mansion in North Sydney to make a 22 part panorama of Sydney Harbour and suburbs. The glass plates were each 55.8 × 45.7 centimetres and when the prints were joined together they formed a view almost ten metres long. The "Holtermann Panorama" was exhibited in the USA and Europe winning competition medals at the Philadelphia Centennial of 1876 and the Paris Exposition Universelle Internationale in 1878.

Daintree's and Holtermann's promotion of their colonies' virtues led to the commissioning of photographers by the Government Printing Office's in other Australian colonies. Some of the most interesting views were made for exhibition in inter-colonial and overseas exhibitions, and for presentation to politicians and foreign dignitaries. None of the government photographs were for sale to the public so as not to interfere with the commercial views trade.

Photographically illustrated books were produced from the early 1860s on diverse scientific topics such as medicine, astronomy, geology, natural history, anthropology and expeditions, replacing the publishing norm of intaglio and lithographic plates with real photographs. The most outstanding book of its kind is the *Narrative of the Expedition of the Australian Squadron to the South–East Coast of New Guinea, October to December, 1884*, published by Thomas Richards, NSW Government Printer in 1885. The 35 photographs recording the proclamation of the British Protectorate on 6 November 1884 were taken by Augustine Dyer (w. 1873–1923) and John Paine (w. 1873–91).

Charles Nettleton (1826–1902), a regular exhibitor at colonial exhibitions from 1868 specialised in view photographs which he sold in albums. Nettleton was also an official penal photographer from the 1870s. He made full length cdv portraits of the bushrangers Harry Power in 1870 and ten years later of outlaw Edward "Ned" Kelly. On the day prior to his execution at Pentridge Goal on 11 November 1880, Kelly asked that "his photograph [be] taken by a departmental operator and copies [will] be given to his friends" (*Argus*, 11 November 1880).

An Australian icon then and now, following his capture at Glenrowan on 28 June 1880, Ned Kelly had been tried and sentenced to death by hanging. His 'gang'—three young men aged in their twenties—died in "The Glenrowan Inn," after it was set on fire by the police. The next day, the scorched and smoke blackened corpse of Joe Byrne, which had been dragged clear of the fire, was brought to Benalla and strung up on the door of the police lock-up for photography. J. W. Lindt photographed his colleague Arthur W. Burman (w. 1878–96) at his grisly work.

Live-action photographs of the fire at the hotel, its smoky progress and aftermath were taken by the unknown Oswald Thomas Madeley (w. 1880) who set his tripod up in the midst of the police siege. A set of nineteen photographs is held in the Copyright Collection, La Trobe Library, State Library of Victoria. It seems Madeley sold the rights to some of these dramatic images to James E. Bray (w. 1865–91) of Beechworth and to Burman who together made cdvs from Madeley's negatives selling them under each other's imprint.

Introduced in 1880, the dry plate provided greater freedom and flexibility for portraiture, enabling preparation of plates in advance, as well as a lighter load when travelling outdoors.

Victorian Nicholas Caire (1837–1918) was a specialist landscape photographer "in search of the picturesque." Always scouting for sites within striking distance of Melbourne, he specialised in fern gully scenes around Healesville sparking a new interest by the public in recreational tourism and the outdoors. J. W. Lindt also specialised in views of the fern-tree gullies and bush around Fernshaw. In 1887 landscape photographs by Bayliss, Lindt and Caire were lithographically reproduced in colour from original negatives by the Sydney printers Phillip-Stephan (1887–1910).

A new nationalism in photography and landscape painting arose from the late 1880s. By the end of the century, souvenir photographs, photolithographs and postcards could be bought of the new tourist routes opened up by railways.

Amateur photographic societies were founded in 1885 in South Australia and Queensland allowing a new group of amateurs to exhibit their work in local and inter-colonial competitions. Photographic magazines like the *Australian Photographic Journal* founded in 1886, and others, greatly increased the interest in photography.

Around 1890 silver bromide gelatine coated papers were introduced allowing prints to be developed more quickly. Pictorial photographers such as John Kauffmann (1864–1942) used bromide paper for soft-focus photographs which were "mistaken for works of art." (*South Australian Register*, 19 October 1901) Kauffman had witnessed the Pictorial movement in Europe and was an early convert. He operated a successful business in Melbourne until the mid 1930s.

The Kodak pocket camera was released in Australia in 1896. It was aimed at the snapshot photographer, rather than the true amateurs who were used to darkroom developing, printing and toning their work. Women were encouraged to take up snap-shot photography to provide "an outlet for the dormant artistic tendencies locked up in the minds of so many women" (*Australian Photographic Journal*, 20 April 1897). The earliest known female amateur was Louisa Elizabeth How (1821–93) who made an album of salted paper prints from 1857–59. Only twelve women are recorded as working as professionals during the late 1850s and 1860s. Some operated

independently, others were the wives of commercial photographers.

The Federation of the colonial States into the Commonwealth of Australia in 1901 was a cause for celebration. Also celebrated was Australia's pastoral prosperity as "the land of the Golden Fleece." "Rose's Stereoscopic Views" of triumphal arches, illuminations and buntings on light poles and bridges are perhaps the most well known images of an otherwise forgotten photographic moment. Yet the new millennium was distinguished by a national enthusiasm for Australia's natural assets—gum trees, sun and light which became the mainstay in pictorial photography, painting, printmaking and decorative arts until the Great War.

AUTOTYPE FINE ART COMPANY

The Autotype Fine Art Company began life in 1868 as the Autotype Printing and Publishing Company, with a factory in Brixton and offices at 5 Haymarket in London. From its inception to the present day the company has been involved in a variety of methods of producing images and imaging materials. For almost a hundred years, however, it was best known for its exploitation of Joseph Wilson Swan's Carbon Process, a method of producing prints in permanent pigments.

Swan patented his process in England in 1864 (No 503) and originally worked the process commercially himself. In 1868 he sold the English rights to a chemist, John Richard Johnson, and a photographer, Ernest Edwards, both of London. The same year, the rights were in turn acquired by the newly formed Autotype Printing and Publishing Company, with Johnson and Edwards becoming major shareholders. The name Autotype had been devised before the company existed, possibly as early as 1864. It was proposed by art critic and one time editor of Punch, Tom Taylor, and derived from two Greek words, 'autos' meaning self, and 'tupos' meaning stamp, as in the impress of a seal.

The merits of the carbon process, rich tonal range and, particularly, its permanence soon commended itself to other photographic entrepreneurs. Almost immediately, rivals announced a series of doubtful 'improvements' to the process and the company was forced to assert its patent rights. The company successfully defended its position, either in court or by buying out the opposition. Under the company's umbrella, Johnson was also working on improvements to Swan's original process and new patents were filed in February 1869 and January 1870.

Despite its early problems, the company successfully developed the business of supplying carbon printing materials as well as making carbon prints for the photographic trade and to sell directly to the public. In 1870, the London office was transferred to 36 Rathbone Place, next door to the artists' suppliers, Windsor & Newton. The factory was also moved from the original site in Brixton to new premises in what was then a rural location at Ealing. In order to raise further capital, the company was refloated and now called the Autotype Fine Art Company Limited.

During the next few years, the company underwent a period of rapid expansion and diversification. In 1871 a photo-collographic printing department was added to the Ealing factory under the management of J.R.M. Sawyer and W.S. Bird. It also acquired the expertise of J.A. Spencer by amalgamating with his independent carbon printing business. Other rival concerns were acquired in similar fashion, A further reorganisation took place in 1873 when Spencer, Sawyer and Bird, purchased all patents, property and stock to form a new firm, Spencer, Sawyer, Bird and Co. The Autotype Fine Art Company continued as a separate concern dealing with the fine art business until the end of 1875 when it was purchased by Spencer, Sawyer, Bird and Co. The new joint concern now became simply The Autotype Company.

By the latter half of the 1870s, the Autotype Fine Art Company had become a prosperous and thriving concern with world wide interests. It was rapidly gaining a reputation for high quality carbon print reproductions of fine art and photographs. In the sixth edition of his manual, *The Autotype Process* (1877), Sawyer claims that the publication forms the basis of manuals in five languages and that galleries throughout Europe as well as "…our own splendid collections at the British and South Kensington Museums have yielded copies of their pictures." Advertisements at the back of the book give further insights into the market for Autotype reproductions. The company's catalogue included copies of works by Reynolds, Turner and Michael Angelo. Also listed is "A Splendid Series of Mrs Julia Cameron's Art Photographs." The body of the manual contains detailed instructions for working the Autotype process. There is also a note stating that instructions " will be given at the Autotype Works by previous appointment only, Tuesdays, Wednesdays and Thursdays in each week."

Towards the end of the century, Autotype broadened its interests further. It moved into the general photographic supply market, selling collodion for wet plates and later its own brand of gelatine dry plates. More importantly, it found a new market for the pigment paper. This was an essential component of photogravure, a new means of producing book and periodical illustrations that was being perfected and commercially exploited. The Autotype Fine Art Company was one of the first firms to experiment with the process and called their version 'autogravure.' They provided illustrations for books, including plates for Peter Henry Emerson's *Pictures of East Anglian Life*, but soon found it more profitable to concentrate on supplying pigment paper to what was a rapidly growing branch of the printing industry. By 1930, production of photogravure pigment paper represented about 75% of the company's manufacture.

In 1919 Autotype purchased the rights to H.E. Farmer's Carbro process, carbon prints made directly from bromide prints. Autotype simplified the process and began promoting it commercially in 1921. It became popular during the 1920s and 1930s, particularly in the form of trichrome carbro printing, a means of producing fine colour prints. Autotype supplied materials and instructions for the process until it was displaced by tri-pack colour film.

The 1950s saw Autotype finally abandoning carbon printing. The company's main business now centred around supplying materials to the thriving photogravure companies and also the rapidly growing market of screen printing. Autotype had entered the latter business in the 1920s, manufacturing a special pigment paper for the trade. From1958 to 1963 it also successfully marketed its own carbon based photo-stencil process. By 1976 the company had outgrown the Ealing factory and moved to a new site at Wantage, Oxfordshire. The company underwent another minor title change and became Autotype International Limited. At the beginning of the 21st century, Autotype International is a global company. It has moved into digital printing applications and now provides materials for touch screens, LCD displays and control panels.

B

BABBITT, PLATT D. (1823–1879)
American photographer

Equal parts artist and entrepreneur, Platt Babbitt made memorable photographs in a frontier region of young America. For several years, he worked a commanding vantage, selling to tourists daguerreotypes he made of them as they experienced brink of Niagara Falls. Information about Babbitt—and a good bit of his legendary appeal—was influenced by accounts written more than 30 years after the facts by John Werge, a traveling photographer and teacher from Scotland, who sold accoutrements for the early photographic processes and later wrote about his exploits in a book copiously entitled, *The Evolution of Photography with a Chronological Record of Discoveries, Inventions, Etc., Contributions to Photographic Literature and Personal Reminiscences Extending over Forty Years.* Werge may have overstated Babbitt's "monopoly" over photographs of the Falls, where he was said to have taken daguerrean exposures of visitors "without their knowledge," but he was fully accurate in identifying Babbitt as a "speciman of American character."

Born and raised in Lanesboro, Massachusetts in a Berkshire farming family, Babbitt caught the national impulse for westward migration, and followed the Mohawk Trail toward the great Niagara, the giant cascade that had captured the imagination of a young American republic with its power and subliminity. The Erie Canal, which paralleled the age-old byway of native people, had opened in 1825, facilitating travel and tourism, and Niagara Falls was a commanding destination. The small village at the Falls became a far larger, as all sorts of cash opportunities opened along the banks of the Niagara. Vendors hawked access to special points of view from which to consider the Falls, guidebooks, and trinkets, including daguerreotype likenesses, displayed in cases and in jewelry. Platt Babbitt's name first appear in Niagara regional press advertisements in 1850, first on the Canadian side, in partnership with photographer and concessionaire Saul Davis, who was known for his aggressive sales tactics, and later, by 1853, on the American side, sometimes in partnership with a store owners, such as with Thomas Tugby, owner of Tugby's Mammoth Bazaar, located several hundred feet from the location that Babbitt used to make his images.

By 1853, Babbitt had leased property to create a pagoda to hold his camera set up, established with a view toward the lip of the American Falls. It was a dramatic site, where visitors could feel the huge roar of the falls and enjoy the gentle mist that filled the air. Babbitt set up his daguerreotype apparatus such that it also allowed exposure of scenic Goat Island, Terrapin Tower and the Canadian Horseshoe Falls in the background, along with the likeness of tourists in the near ground, standing on the rocks at the edge of the river. Babbitt then is among the first to make a photograph to enhance a tourist's experience, and he is among the first to work the taking of photographs within the landscape.

The likelihood that tourists were unaware that Babbitt was exposing a daguerreotype plate of them is remote, however, given the prominence of Babbitt's pagoda and the advertising of his studio, located in the second floor of the building that provided entrance to an incline car, also at Prospect Point. The incline elevator permitted passage down the precipice to the ferry at the base of the falls. All of this attention should have attacted even the most awe-filled visitor, who would unlikely maintain the pose and stillness that Babbitt's images evidence. Indeed, Babbitt was an intrepid business man, using every device to attract business, shifting into different media as it was called for by the advances of the period. He also was a skilled image-maker; his full plate daguerreotypes (6½ × 8½ inches) are uniformly well

exposed, with remarkable depth of field and tonal range. His compositions of the various sites from which to view the Falls display creative points of view and framing. Thus, it seems particularly unlikely that he would leave the arrangement of his visitors at Prospect Point, and the expense of his exposures, to chance.

Babbitt was a versatile photographer, a man who seized opportunity to make a saleable image. His work as a documentarian—as an early photojournalist, even —rarely receives notice today. But in 1853, Babbitt created one of the most gripping of any early photographs. In that year, a man named Joseph Avery was boating above the Falls with a friend, when their boat was overtaken by the current, and capsized. Avery clung to a log that had lodged against a rock in the rapids. His friend was swept over the brink to his death. It was a bright day, and Babbitt had the time to move his camera to water's edge, where he made an image of the helpless Avery clinging to the log in the water, moments before his death. Attempts to save the man failed, and he, too, was carried across the brink. Niagara was a place for disasters, and for daredevils, and during his career, Babbitt documented these events, as well as those who came to visit.

Babbitt was not the first to document the Falls and its visitors. M.H.L. Pattinson, an English daguerreotypist who documented Niagara in 1841 for Noel Marie Paymal Lerebours, publisher of *Excursions Daguerriennes vues et monuments les plus remarqualles du globe*, was the first, followed by several others in the 1840s, notably including Frederick and William Langenheim of Philadelphia. But Babbitt was the first resident photographer on the American side, and he knew the Falls in its changing, annual faces, most spectacularly in the winter, when few tourists braved the challenging Western New York weather. His views all along the banks of the river, and his views from the base of the falls and the Cave of the Winds behind the falls, are spectacular, technically skilled and artfully handled, at first as daguerreotypes in full, half and quarter plates, later in dagurrean stereo views and glass plate colloidon stereo, window transparencies, and paper stereo prints.

Babbitt led a hard-scramble life in what amounted to a frontier town. His photography attracted attention through the 1850s, but late in that decade, the public record shows, his work became more of a struggle. He felt called on to defend his territory on Prospect Point from encroachment by other photographers, and he would disrupt their exposures with men waving open umbrellas in front of their cameras. And he fought with his landlord in a public brawl that attracted newspaper attention. During the 1860s, he dropped away from public view.

In 1873, a story in the local paper announces his return from "several years of retirement," with an offering a new glass transparency views of Niagara. And then in 1879, another story in the local press, reports his suicide, after a period of poor health, suffering from weakness and fainting spells. His death is marked by irony, for a man as skilled as he in negotiating the dangerous shores of Niagara, was found with a rock tied around his neck, face down in a creek of three-feet of water in a small town south of Buffalo.

Chiefly remembered for his setup exposures of tourists at the edge of the Falls, Babbitt is represented principally by this image in most museum collections and histories of photography. His work as a landscape photographer and documentarian is equally fine, and increasing attention has been given to this work, notably in Frank Henry Goodyear's *Constructing a National Landscape: Photography and Tourism in Nineteenth Century America,* a dissertation for doctor of philosophy at the University of Texas at Austin, 1998, and the author's *The Taking of Niagara: A History of the Falls in Photography,* 1982, Media Study/Buffalo.

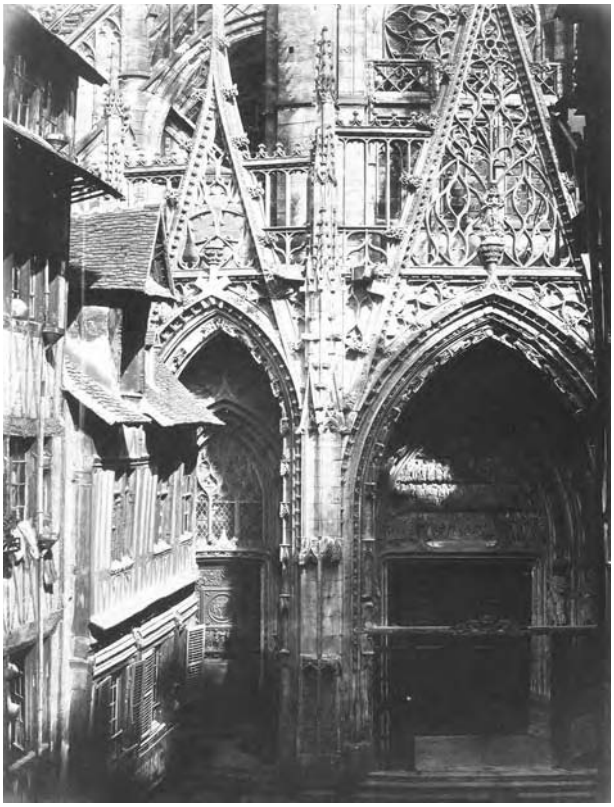
BACOT, EDMOND (1814–1875)

A painting student of Paul Delaroche, Edmond Auguste Alfred Bacot took up daguerreotypye by 1846 (although no examples survive) and paper photography by 1850. His largest and most impressive photographs, made with glass negatives between 1852 and 1854, depict historic monuments in his hometown, Caen, and in Rouen, Bayeux, and other sites in Normandy. With their focus on Gothic architecture and deep swaths of shadow, photographs such as *Saint Maclou, Rouen* rival the work of Bacot's Parisian counterparts and evoke the romantic spirit of Victor Hugo's writings and drawings. A Republican sympathizer and supporter, Bacot visited Hugo in exile on nearby Jersey in December 1852 and provided photographic instruction to his son Charles Hugo in Caen in March 1853. An album of 28 lavishly presented photographs by Bacot (Metropolitan Museum of Art, New York) likely consists of the prints sent to Hugo and much admired by the writer and his son. Six architectural photographs also appear in an album assembled by Bacot's fellow Norman gentleman-amateur, Louis Alphonse de Bisson (Musée d'Orsay, Paris). More widely distributed were Bacot's formal portraits of Vic-



Bacot, Edmond. Saint-Maclou, Rouen.

tor Hugo taken in 1862, on which occasion Bacot also executed a series of stereoscopic views of the exiled writer's Guernsey residence, Hauteville House.

MALCOLM DANIEL

BAKER AND CO, F. W. (active 1850s–1860s)

A prolific commercial photographer in Northern India from the mid-1850s until the end of the 1860s, Baker appears to have arrived in Calcutta in around 1855, as an employee of the millinery firm of Appleton and Co. He was also, however, concurrently managing the daguerreotype studio of James William Newland and in August 1857, on his return from a photographic tour of the North West Provinces, he established his own business in Calcutta under the title of Baker's Daguerrean Rooms. The studio flourished throughout the 1860s, in due course changing its name to the Calcutta Photographic Company. While Baker produced the standard commercial fare of portraits and topographical views for the European market, the studio's most historically significant work remains its extensive documentation of the devastating cyclone which struck Calcutta in 1864. Baker appears to have abandoned photography completely in 1869, when his negative stock was sold to the firm of Saché and Westfield, returning to his early trade as a milliner in the partnership of Baker and Catliff. Between 1887 and 1896 he was resident in Rangoon and although his date of death or departure from India has not been established, he appears to have still been living in Calcutta as late as 1908.

JOHN FALCONER

BALDI, GREGOR (1814–1878) AND WÜRTHLE, KARL FRIEDRICH (1820–1902)

Born in Telve, South-Tirol, Austria, Gregor Baldi started work as an arts and crafts dealer in his brothers shop in Linz, Upper-Austria at the age of 15. From c. 1842–1861 he had his own successful art-shop in Salzburg. He edited nine albums with steel-engravings of topographic studies, some made by Karl Friedrich Würthle, born Konstanz, Germany.

In January 1862 they established Baldi & Würthle in a purpose-built studio in Riedenburg Nr. 17, a suburb of Salzburg.

In 1866 the studio was moved to Schwarzstraße near the theatre. They made studio-portraits and groups in albumen and later gelatine. But the most numerous subjects were hundreds of location photographs of Salzburg-town and landscape and mountain-photos of country areas in Salzburg and his neighbourhood, now housed in the Salzburger Museum Carolino Augusteum. These photos were produced in a range of sizes from carte-de-visite to 370 × 570 mm, and, from 1866, panoramas (230 × 530 mm).

From 1874 they operated separate studios, with Würthle moving to Schwarzstraße 11. From 1875 to 1880 Würthle alone was the owner of the studio of which the name remained 'Baldi & Würthle.' From 1881 to 1892 the atelier 'Würthle & Spinnhirn' belonged to Würthle and his brother-in-law Hermann Spinnhirn, a chemist.

From 1892 to 1904 the studio name was 'Würthle & Son,' out of which they photographed and published images.

'Baldi & Würthle' and their successors were the first fully professional, important and well known photographers in the capital town of Salzburg and other western countries of the Austrian empire and remained so until about 1900.

ERHARD KOPPENSTEINER

BALDUS, ÉDOUARD (1813–1889)

French photographer

Édouard Baldus arrived in Paris to study painting in 1838 at the age of twenty-five, shortly before the first public announcement of photography's invention. He

was a native of the small German town of Grünebach, forty-five miles east of Cologne, and, according to some reports, had first embarked on a career as an artillery officer in the Prussian army before becoming a painter in the early 1830s. He is said to have exhibited his paintings with some success in Antwerp and to have traveled throughout America as an itinerant portrait painter, but neither statement can be confirmed by surviving evidence. In Paris, Baldus worked outside the École des Beaux-Arts and atelier system; he submitted work to each of the annual *salons* from 1841 to 1851 but achieved little success and received no critical mention as a painter. In the decade that followed, Baldus abandoned the easel and took up the camera, rose to the top of his new profession, won international critical acclaim, secured commissions from governmental ministries and captains of industry, and created photographs now considered masterpieces of art.

Baldus first experimented with photography in the late 1840s, although no surviving prints can be definitively dated prior to 1851, the year in which he, Gustave Le Gray, Henri Le Secq, Hippolyte Bayard, and O. Mestral were awarded *missions héliographiques*, photographic surveys of the nation's architectural patrimony carried out at the behest of the Commission des Monuments Historiques, a government agency. Baldus's *mission* took him to Fontainebleau, through Burgundy, the Dauphiné, Lyonnais, Provence, and a small section of Languedoc. According to an account published the following year (Baldus, Édouard, *Concours de Photographie,* Paris: Victor Masson, 1852), Baldus utilized his own variation of the paper negative process, which included a layer of gelatin to provide a smoother surface and finer rendition of detail. Although prints from the *mission héliographique* are rare, the majority of negatives from this campaign survive in the collection of the Musée d'Orsay, Paris. Extant prints and negatives show that Baldus occasionally overcame the limitations of scale, depth of field, and varying light conditions by piecing together a jigsaw puzzle of individual negatives to form a single large composition.

So impressive were Baldus *mission* pictures for their clarity, beauty, and size that he quickly won government support for a project entitled *Villes de France Photographées,* a series of architectural views of Paris and provincial cities that fed a resurgent interest in France's Roman and medieval past. After photographing the chief monuments of the capital in 1852, Baldus returned to the south of France in the autumn of 1853, accompanied by a student, Wilhelm von Herford (German, 1814–1866) and an assistant. There he photographed, for the *Villes de France* series and for his stock, many of the same monuments he had recorded in 1851 on negatives that he had subsequently been obliged to turn over to the government. His large-format (35 × 45 cm) negatives of 1853, however, show the Roman theater and triumphal arch at Orange, the church of St. Trophîme at Arles, the Tour Magne and Maison Carrée at Nîmes, and other monuments of Provence with an unprecedented directness that would establish the standard for architectural photography. Gone were the picturesque elements, figures, and anecdotal details present in his earlier photographs and traditionally considered necessary to animate topographic prints of the period.

The following summer Baldus coursed the dirt roads of the countryside by horse-drawn cart in the company of Fortuné-Joseph Petiot-Groffier (French, 1788–1855), moving from ruined castle to thatched hut, from pilgrimage church to paper mill, from town square to wooded chasm, through the fertile lowlands and rugged mountains of the Auvergne, in central France. In a departure from his earlier work, perhaps owing to the different physical character of this region, Baldus photographed not only medieval pilgrimage churches such as Brioude and Issoire, but also vernacular architecture and unpopulated landscape, adding a poetic force to the graphic power and documentary value of his earlier photographs.

By 1855, Baldus had established a reputation as the leading architectural photographer in France, and his pictures drew much public attention and critical notice at the 1855 Exposition Universelle in Paris. In August of that year Baron James de Rothschild—banker, industrialist, and president of the Northern Railway—commissioned Baldus to produce an album showing views along the rail route from Paris to Boulogne-sur-Mer. The lavish album, presented to Queen Victoria as a souvenir of her passage on the line during her state visit to Paris and still housed in the Royal Library at Windsor Castle, contains 50 beautifully composed and richly printed photographs of cathedrals, towns, railroad installations, and ports that are among Baldus's finest images.

Also in 1855, Baldus began photographing on the worksite of the New Louvre, documenting for the architect Hector Lefuel every piece of statuary and ornamentation made for the vast complex linking the Louvre and Tuileries palaces. As individual records these photographs served a practical function on the bustling worksite, keeping track of the many hundreds of plaster models and carved stones sculpted for the project. As a collected whole, however, they formed a new means of comprehending and communicating a complex subject, bit by bit, to be reconstituted by the mind. Only photography—precise, omnivorous, prolific, and rapid—and then only in the hands of an artist both sensitive and rigorous, could produce an archive as a new form of art. Of the several thousand images made at the Louvre during the period 1855–57, however, it is the large-format photographs of the principal pavilions

Baldus, Èdouard. Entrance to the Donzera Pass. *The Metropolitan Museum of Art, Gilman Collection, Gift of the Howard Gilman Foundation, 2005 (2005.100.364.20) Image © The Metropolitan Museum of Art.*

that are his most carefully crafted and clearly articulated demonstrations of photography's unparalleled capacity to represent architecture, fully exploiting the medium's ability to render the play of light, the volume of architectural forms, and the most intricate details. Baldus's photographs of the New Louvre were assembled in albums (four volumes in each set) and presented by the emperor to government ministers, the imperial family, and the reigning monarchs of Europe as New Year's gifts in 1858.

In June 1856, in the midst of his work at the Louvre, Baldus set out on a brief assignment, equally without precedent in photography, that was in many ways its opposite: to photograph the destruction caused by torrential rains and overflowing rivers in Lyon, Avignon, and Tarascon. From a world of magnificent man-made construction, he set out for territory devastated by natural disaster; from the task of recreating the whole of a building in a catalogue of its thousand parts, he turned to the challenge of evoking a thousand individual stories in a handful of transcendent images. Baldus created, in the words of Ernest Lacan, a "painfully eloquent" record of the flood without explicitly depicting the human suffering left in its wake. The "poor people, tears in their eyes, scavenging to find the objects most indispensable to their daily needs," described by the local *Courier de Lyon*, are all but absent from his photographs of the hard-hit Brotteaux quarter of Lyon, as if the destruction had been of biblical proportion, leaving behind only remnants of a destroyed civilization. In Avignon Baldus stood on the cathedral terrace from which, a few days earlier, Napoleon III had surveyed the floods, and pivoted his camera to compose a sweeping six-part panorama that encompasses the entire Rhône valley—the inundated island of Barthelasse, the town of Villeneuve-les-Avignon, and the river, slowly returning to the confines of its banks.

In the late 1850s, Baldus expanded his highly successful series of large-format views of historic monuments in both Paris and the provinces, and around 1860 he photographed the rough alpine regions of southeastern France. At the height of his success, he employed a dozen assistants and sold his work through a dozen merchants in Paris and through print and book dealers in Nîmes, Hamburg, Florence, Venice, Turin, Milan, Vienna, and London.

In the second of his two railway albums, commissioned in July 1861 by the Chemins de fer de Paris à Lyon et à la Méditerranée (PLM), Baldus again pioneered new aesthetic ground and drew from a decade's work to speak forcefully and eloquently about the relationship of history and progress. The album is a masterfully composed sequence of sixty-nine photographs of the landscape, towns, principal sites of interest, and railroad structures along the line from Lyon to Marseilles and Toulon. By interspersing boldly geometric images of the railroad tracks, stations, tunnels, and viaducts with his classic views of historic architecture—the ramparts of Avignon, the Maison Carrée, Saint-Trophîme, the Pont du Gard—Baldus presented Second Empire engineers

as the natural heirs to a great tradition of building that stretched back to Roman and medieval times. The final section of the album presents the natural beauty of the Côte d'Azur, including the majestic rock formations at La Ciotat. The concluding pair of images—the barren, rocky Ollioules Gorge and the iron and glass railroad station of Toulon—restates the album's central theme of progress, contrasting wilderness and civilization, nature and man. A dozen examples of the PLM album are currently known (three in an abridged form).

While the PLM album is a triumphal climax to the most fruitful period of Baldus's artistic career, more than half his professional life still lay ahead. During the next two decades, he increasingly shifted his energy from the production of ambitious and carefully crafted works of photographic art to the commercial and industrial applications of the medium. In part, personal factors account for this shift. In the years following the death of Baldus's wife Élisabeth in March 1858, her mother probably helped care for the couple's children; after his mother-in-law's death in April 1862, the responsibilities of fatherhood may have kept Baldus closer to home and his three teenage children, and prompted him to focus on Parisian views and on the publication of his work in gravure form. By 1869, when his daughters were married and his son had reached majority, Baldus was approaching sixty, and the labor and hardship that characterized the extended photographic excursions of his younger days may have seemed less appealing, less necessary, or less possible. External factors, however, were also at work: social and economic forces increasingly pushed photography toward ever-cheaper and more widely distributed images. In the early 1850s, few outside scientific, artistic, and aristocratic circles collected photographs, but by 1860 the carte-de-visite portrait and the stereo card, produced by the thousands and available at extremely low cost, had brought photography into the homes of a much broader public. It was surely in an attempt to market his work to the souvenir-seeking tourist and public that Baldus produced a series of 95 small-format views of Paris (approximately 20 × 30 cm) in the early-1860s, and even tried his hand at stereographic photography. In contrast to his large-format work of the previous decade, his smaller, glass-negative photographs of Paris and the provinces appear indifferently composed and printed.

Beginning in the mid-1860s and lasting until the early 1880s—in other words, for more than half his career as a photographer—Baldus's primary commercial activity centered on the production of photogravures, a process that he had first explored as early as 1854. Baldus's photogravure process (or "héliogravure," as he called it) triumphed equally as a photographic method of producing facsimile gravures and as a gravure method of printing photographic images. His first major publications in gravure form, issued from 1866 to 1869, all reproduced ornamental engravings by past masters—Heinrich Aldegrever, Hans Sebald Beham, Jacques Androuet Ducerceau, Albrecht Dürer, Hans Holbein, and Marcantonio Raimondi.

Baldus first published his own photographs in photogravure form in a three-volume publication on the architecture and ornamentation of the Louvre and Tuileries palaces that parallels his earlier photographic albums. *Palais du Louvre et des Tuileries: Motifs de Décorations… must have seemed ironically timely, for while it was still being issued the Tuileries Palace and parts of the Louvre were burned down in the destruction of the 1871 Commune.* Although he did not reveal the details of his process, nor enter the Duc de Luynes's competition, Baldus achieved results in photogravure that were unrivaled in their detail, smoothness of gradation, and richness.

Encouraged by the success of his volumes on the Louvre, he published a portfolio of one hundred photogravures reproducing elements of interior and exterior decoration of the Château de Versailles and of the Grand and Petit Trianons—garden vases, statuary, fountains, paneling, moldings, consoles, tables, and so forth, as well as six exterior architectural views. With his photogravure publication *Principaux Monuments de la France* in the early 1870s, Baldus came full circle, issuing in gravure form a series of architectural photographs much like his *Villes de France photographiées* of the early 1850s, and, in a few cases, utilizing the same negatives. Baldus's last known photographic activity was a publication in the same vein as his Louvre and Versailles volumes—a collection of one hundred photogravures of the architectural and sculptural decoration of the new Hôtel de Ville of Paris, built from 1882 to 1884 to replace the building burned down by the Commune a decade earlier.

Baldus's extensive publishing activity did not necessarily signal financial success. Perhaps having overextended himself in the production of *Hôtel de Ville* or perhaps the victim of other circumstances, Baldus transferred to his son-in-law more than seven hundred copper printing plates for the Louvre, Versailles, Hôtel de Ville, and Ducerceau gravures, and thousands of unsold prints from those publications as collateral for a small loan in October 1885, probably to protect the means of his livelihood from creditors; only fifteen months later, in January 1887, he filed for bankruptcy. Édouard Baldus died December 22, 1889, in Arcueil-Cachan, a suburb south of Paris.

The first major exhibition devoted to the photograph of Baldus was presented at The Metropolitan Museum of Art, New York, the Canadian Centre for Architecture, Montreal, and the Musée national des monuments français, Paris, in 1994 and 1995.

Although photographs by Baldus—especially the small-format albumen prints of the 1860s—are relatively common, richly printed, well preserved salted paper prints of his best work of the 1850s are indeed rare. Newly discovered prints—some of previously unknown images—have appeared steadily throughout the late 1980s, 1990s, and 2000s as the market for nineteenth-century photographs has matured. An important cache of exceptionally beautiful, unmounted salted paper prints from the mid-1850s was discovered in 1988-89 by the descendents of Léon Bourquelot, Baldus's contact in the office of the Architect of the Louvre.

The Musée d'Orsay, Paris, holds the most important collection of Baldus photographs including the negatives from his *mission héliographique* and 1856 flood series as well as many fine salted paper prints of his work from the 1850s. Other significant Baldus holdings in public institutions include: Médiathèque du Patrimoine, Paris, notably for *mission héliographique* prints; École des Beaux-Arts, Paris, and École Nationale des Ponts et Chaussées, Paris, both of which collected Baldus's work in the nineteenth century for their students' edification; Canadian Centre for Architecture, Montreal; J. Paul Getty Museum, Los Angeles, including two copies of the PLM album; The Metropolitan Museum of Art, New York; and Gilman Paper Company Collection, New York.

MALCOLM DANIEL

Biography

The second of eight children and the eldest son of Johann Peter Baldus and Elisabeth Weber, Eduard was born in Grünebach, Prussia, on June 5, 1813. Little is known about the first twenty-five years of his life. He moved to Paris in 1838 to study painting and changed the spelling of his name to "Édouard" (he has often been referred to erroneously as "Édouard-Denis"). In September 1845 he married a French woman ten years his junior, Élisabeth-Caroline Étienne, and within four years was the father of two daughters and a son. He was naturalized a French citizen in June 1856 and was awarded the Legion d'honneur in August 1860.

Baldus began photographing in 1848, and was a founding member of the Société héliographique in 1851, the year in which he received a *mission héliographique* to photograph historic monuments, principally in Provence. The following year he began a critically acclaimed and commercially successful series of large-format photographs that continued for more than a decade; his principal subjects included architectural monuments of Paris and the French provinces, particularly Provence (1852–61); landscapes of the Auvergne (1854) and southeastern France (1860–61); railroad and civil engineering works, particularly along the routes of the Northern and Paris-Lyon-Méditerranée lines (1855–62); the construction of the New Louvre (1855–58); and the Rhône River floods (1856). From 1866 to 1884 the majority of his efforts were devoted to the publication of photogravures. He filed for bankruptcy in January 1887 and died December 22, 1889, in Arcueil-Cachan, a suburb south of Paris, where he is buried in the local cemetery.

Baldus's work was sold by at least two dozen book and/or print sellers in Paris and throughout Europe. He participated in many exhibitions, including the following: Photographic Society of London, 1854; Tentoonstelling van Photographie en Heliographie gehouden door de Vereeniging voor Volksvlijt, Amsterdam, 1855; Exposition Universelle, Paris, 1855; 1st Annual Exhibition of the Photographic Society of Scotland, Edinburgh, 1856; Photographic Society of London, 1856; Manchester Photographic Society, Exhibition of Photographs at the Mechanics' Institution, 1856; Exposition Instituté par l'Association pour l'Encouragement et le Développement des Arts Industriels en Belgique, Brussells, 1856; Deuxième Exposition Annuelle, Société Française de Photographie, 1857; Exposition Instituté par l'Association pour l'Encouragement et le Développement des Arts Industriels en Belgique, Brussells, 1857; Architectural Photographic Association, London, 1858; Photographic Society of London, Fifth Year, 1858; Architectural Photographic Association, Second Annual Exhibition, London, 1858–59; Troisième Exposition de la Société Française de Photographie, 1859; Exhibition of photographs, Aberdeen, 1859; Architectural Photographic Association, Third Annual Exhibition, London, 1860; Exposition Photographique d'Amsterdam, 1860; Architectural Photographic Association, Fourth Annual Exhibition of English and Foreign Photographs, London, 1861; Quatrième Exposition de la Société Française de Photographie, 1861; Exposition de la Société Photographique de Marseille, 1861; Universal Exhibition, London, 1862; Exposition Universelle, Paris, 1867; Huitième Exposition de la Société Française de Photographie, 1869; Exposition de la Société Photographique de Marseille, 1871; Welt-Ausstellung, Vienna, 1873; Dixième Exposition de la Société Française de Photographie, 1874.

Baldus's publications included: *Concours de Photographie* (1852); *Vitraux de l'Église Sainte-Clotilde* (1853); *Réunion des Tuileries au Louvre* (1857); *Recueil d'Ornements* (1866); *Oeuvre de Marc-Antoine Raimondi* (1867); *Oeuvre de Jacques Androuet dit Du Cerceau* (ca. 1969); *Palais du Louvre et des Tuileries* (1869–71); *Palais de Versailles* (early 1870s); *Les Principaux Monuments de la France* (early 1870s); *Reconstruction de l'Hôtel de Ville de Paris* (1884).

BALL, JAMES PRESLEY (1825–1905)

One of the country's first African American photographers, James Presley Ball learned his craft in 1844–5 from fellow African American John B Bailey, before opening his first studio in Cincinnati in 1845.

Ball was born in Virginia, a free man, and went on to become a significant figure in both photography and the abolitionist movement in America.

A brief move to Richmond, Virginia, in 1846 brought some success and, but he was back in Cincinnati from 1847 and "Ball's Great Daguerrean Gallery of the West" was established at 28 West 4th Street. With his brother Thomas running the studio, Ball became an itinerant photographer for a period travelling in both America and Europe. Alexander Thomas joined him in Cincinnati from 1852, becoming his partner before 1859, and by 1854 he was recorded as employing nine people.

With his studio established and his reputation and wealth growing, Ball turned his attention to the plight of slaves, publishing a pamphlet on the subject in 1855, and mounting panoramic exhibitions in his gallery to highlight the evils of slavery.

A tornado destroyed the gallery in May 1860, but it was rebuilt, and his partnership with Thomas continued the 1870s, by which time his son, James Presley Ball Jr. also a photographer, had been taken into partnership with him as well.

The studio moved to Minneapolis and St Paul (mid 1870s) and Helena, Montanta (1887), and eventually Seattle (1900) followed—where he operated as the Globe Photographic Studio, and where he died in 1905.

JOHN HANNAVY

BAMBRIDGE, WILLIAM (1819–1879)

British photographer

As a young man William Bambridge travelled with the 1841 mission of Bishop Selwyn to New Zealand, which had recently come under British sovereignty. There Bambridge was employed as a teacher and clerical assistant. He became an accomplished colonial artist and made many drawings of native Maoris and Europeans. Bambridge returned to his home town of Windsor in 1848 and is known to have been working for the Royal Family at Windsor Castle from 1854.

Bambridge appears to have started work in the Royal Household with the role of photographic manager; printing and cataloging negatives from the many commissioned 'Royal' photographers, including Roger Fenton.

In 1857 he printed Fenton's large negatives, taken at Balmoral (the Queen's Scottish estate). That same year he was kept busy printing many of the Queen's other negatives; just between July and September 1857 he made nearly 2000 prints and that year's bill for his photographic services was the then large sum of £640.

As well as printing other photographers' work Bambridge took many pictures himself. Living locally he was on hand to record the royal pets and farm animals and to make informal family portraits. He exhibited his pictures of animals, including cattle, dogs and deer at the Photographic Society between 1855–57. He also was involved in copying many of the Royal Collection's art works, including the Raphael Cartoons.

In the early 1860's Bambridge collaborated with the keen amateur photographer James Sinclair, fourteenth Earl of Caithness (1821–1881), to produce a book of tree studies, taken in the nearby Royal Parks. *The History of Windsor Great Park and Windsor Forest.* Longman, Roberts, Green and Co. (1865) comprised 20 studies of ancient trees. The photographs were probably taken by Caithness, with the assistance of Bambridge, who also made the 10 × 12 inch albumen prints.

Bambridge retired from photography in 1874 and was granted a Royal Pension for his 20 years' service.

IAN SUMNER

BARKANOV, V.V.

Professional photographer

V.V. Barkanov was one of the first Georgian photographers. His full name, date of birth and death are unknown. He began working as a professional photographer in 1869 in the town of Kutaisi, later moving to Tiflis (today Tbilisi) to work there. He made studio portraits but it was his collection of "Views and Types"

that made him famous. His photographs illustrate folk musicians, noble ladies of the Caucasus in national costumes, coal-sellers and numerous other types of people.

Barkanov also made trips to various regions of the Caucasus with his mobile studio often photographing individuals that interested him. His contemporaries praised his work for the scientific techniques, and today, the high artistic quality of his work is also discussed.

Barkanov's works were awarded medals at the Polytechnic exhibition in Moscow in 1872, the World exhibition in Vienna in 1873 and in Paris in 1874. Barkanov was also awarded the title of "Court Photographer of His Highness, Prince Mikchail Nikolajevich." In 1877 and 1878, Barkanov worked as photographer in the army during the Russian-Turkish war. In the 1880s he sold his photo-studio, and in 1881 he received a diploma at an exhibition in Toulouse.

Throughout his career, Barkanov made huge contributions to the development of ethnographic photography in Russia.

ALEXEI LOGINOV

BARKER, ALFRED CHARLES (1819–1873)

English photographer

Dr. Alfred Charles Barker (1819–1873) arrived in New Zealand in 1850 as part of a successful venture which saw the establish of a new English immigration scheme establish in the South Island. His role as a doctor in Christchurch was cut short by a fall from a horse. He then turned his attention to land purchases and other investments which helped to found his family¹s fortunes. In 1858 he took lessons in photography from the architect Benjamin Mountfort and became proficient in the collodion process. For subject matter, he photographed his family in their environment on the Canterbury Plains, producing prints from his negatives which he distributed to friends and relations both at at home and abroad. Today these are treasured because of their significance in documenting the life and times an Englishman in a new land. Most of these historically important social statements were made in his Œgarden studio. As well he also distinguished himself with forays into stereoscopy and recording important civic events. In comparison to other colonial amateurs, Barker seemed to care little for formalities when it came to obeying the rules of pictorial composition and formal portraiture. Despite his apparent disregard for photographic protocol, his work displays a directness and vitality all of its own.

BARKER, GEORGE (1844–1894)

The Canadian photographer George Barker was born in London, Ontario, in 1844, opening a photographic studio in that city at the age of eighteen. He is believed to have been trained in photography in the late 1850s by James Egan.

By 1863 Barker had moved to Niagara Falls, New York, where he worked for Platt D. Babbitt, who had operated a studio there since 1853.

Barker later established studios in both Niagara and London, Ontario, and by the late 1860s his catalogue of views—both large format and stereographs—was extensive. A fire destroyed his premises on 7th February 1870, but as the *Philadelphia Photographer* reported, his unique catalogue of stereoscopic negatives was rescued. By the late 1880s, his stereo views of the Falls were mounted on cards bearing the legend 'George Barker, Photographer, Eleven First Prize Medals, Stichmeyer & Wyman Publishers,' and the titles were printed on the reverse side in six languages.

Barker's work was used—as tipped-in heliotypes—to illustrate James T. Gardner's *Special Report of the New York State Survey of the preservation of the Scenery of Niagara Falls, and Fourth Annual Report of the Triangulation of the State* published in 1880, and in reporting his death in 1894 the photographic press described him as 'the eminent photographer of Niagara Falls.'

After his death his negatives were acquired by Underwood & Underwood.

JOHN HANNAVY

BARNARD, EDWARD EMERSON (1857–1923)

American astronomer, celestial photography pioneer, and a prolific writer and publisher of over nine hundred scientific papers

Barnard only received two months schooling in his early years, as his mother taught him from home. His father died before he was born, so at the age of nine, he started work in a photography gallery. He was put in charge of a solar enlarger, which was used to track the sun and make photographic prints. Barnard went on to privately study, photograph and discover comets, nebulae and planets. His photographic atlas of the Milky Way is of such accurate detail and quality, that it is still used to date. His drive to discover new comets was rewarded by a wealthy patron of astronomy, Mr H.H.Warner, who rewarded each comet's discovery with $200. In 1883 he received a Fellowship to Vanderbilt and graduated in Mathematics in 1887. From 1887–1895 he worked as an astronomer at Lick Observatory in California. In 1892 he discovered the first comet photographically and discovered the fifth moon of Jupiter, Amalthea. As the first four moons had been discovered by Galileo in 1610, and none since, this catapulted him into being an astronomy celebrity. From 1895 onwards he was a Professor of Practical Astronomy at Chicago's University and an astronomer at Yerkes Observatory. His work received distinguished recognition by the Royal Astronomical Society in Great Britain and a Gold Medal in 1897. He was also recognised by the Academy of Sciences in France.

JO HALLINGTON

BARNARD, GEORGE N. (1819–1902)

Born in Connecticut, American photographer George N. Barnard is best known for his views of the American Civil War, published in Alexander Gardner's *Gardner's Photographic Sketchbook of the War* (1866), in Barnard's own *Photographic Views of Sherman's Campaign* (1866), and widely-circulated in engraved form in *Harper's Weekly*. Barnard's photographs are an indispensable chronicle of the destruction wrecked and losses suffered in the Civil War.

Barnard appears to have made his first photographs around 1842. The following year, at the age of twenty-four, he opened a daguerreotype studio in Oswego, New York. Among Barnard's earliest surviving works are two views of a fire at the Ames Mills in Oswego ("Burning Mills at Oswego, NY," 5 July 1853). They stand as remarkably early examples of daguerreotype reportage. In the same year, Barnard became secretary of the New York Daguerrean Association. After purchasing Clark's Gallery in Syracuse, he began making ambrotypes. At some point in the late 1850s, he studied and adopted the wet-collodion negative process, then rapidly increasing in popularity.

In the years before the American Civil War, Barnard

Barnard, George. Ruins in Columbia, S.C. No 2. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

appears to have ventured widely while pursuing his craft, even making photographs in Cuba in 1860. Unfortunately, none of these works have been located. Shortly before the outbreak of the Civil War, Barnard was either employed directly by Matthew Brady or working as an independent contractor for him in New York, and, possibly, in Washington, D.C. During this period, Barnard made photographs of President Abraham Lincoln's inauguration.

With the advent of hostilities, Barnard entered into a partnership with photographer John Gibson. Together, they made and copyrighted photographs of Centerville and the Bull Run Battlefield (the site of the first major land battle of the Civil War) in March of 1862. These images were published by Matthew Brady as "Incidences of War," and later published by Andrew Gardner in his *Sketchbook* (see, for example "Ruins of Stone Bridge, Bull Run," 1862, published in *Sketchbook*, vol. 1, pl. 7). In 1862 Barnard briefly returned to his native New York, and made portrait photographs at Gray's Gallery in Oswego.

In 1864 and 1865 Barnard worked as an independent photographer for Orlando Poe, Chief Engineer of the Military Division of the Mississippi in Nashville, Tennessee. indwas official Army photographer in the Chief Engineer's Office, Division of Mississippi. Barnard does not seem to have received a received a military commission, unlike his contemporary, photographer A. J. Russell, who was a captain in the U.S. Army and official photographer for the United States Military Railroad. Barnard's photographs of Civil War battlefields in the Deep South and his coverage of Union General William Tecumpseh Sherman's western campaign were published to wide attention in *Harper's Weekly*.

After the conclusion of the war, Alexander Gardner credited to Barnard 8 of the 100 wet-collodion negatives (singly or jointly) printed for his two-volume *Gardner's Photographic Sketchbook of the War* (1866). Many of Barnard's negatives were wrongly credited to Brady. Perhaps in response to the wide circulation of his images under his Brady and Gardner's names, in the same year, Barnard published to wide notice his own *Photographic Views of Sherman's Campaign*, though circulations was limited, owing in no small part to the expense of the folio ($100).

After the war, Barnard returned to his native upstate New York, settling in Syracuse around 1866. He is also known to have operated a photographic studio in Charleston, SC. While there, he produced and published a series of stereographs of African American street vendors. Between 1869 and 1871 Barnard ran a studio in Chicago and photographed the aftermath of the Great Fire (1871). In 1883, he returned to New York and promoted the gelatin dry plate for George Eastman of Rochester. Barnard operated his last studio in Plainsville, Ohio (1884-86), after which, at the age of sixty-seven, he appears to have retired from the business of making photographs. Barnard died in 1902 at the age of eighty-three.

BARNARDO, THOMAS JOHN (1845–1905)

Irish patron and businessman

Thomas John Barnardo was born in Dublin on 4 July 1845. In 1866 he studied at the London Hospital, preparing to become a medical missionary in China. He began mission work among the poor of Stepney, east London, and started his own Ragged School to teach homeless children. Barnardo opened his first boarding home in Stepney in 1871. By the time he died in London in 1905 almost 8,000 children were in residential care, over 4,000 were boarded out, and 18,000 had been sent to Canada and Australia.

From 1870 Barnardo used various commercial firms to take 'before' and 'after' photographs showing how wretched the children looked on arrival and how they looked after they had been trained to work in the home's workshops. In 1874 Barnardo opened his own Photographic Department to help record the personal history of every child. Most of the photographs were taken by

commercial photographers Thomas Barnes and his son (up to about 1888) and Roderick Johnstone from 1883. Barnardo also sold photographs on cards, reproduced them in pamphlets and in his house journal, *Night and Day*. By 1905, the Department had taken over 55,000 pictures, many of which still survive at Barnardo's.

JOHN TAYLOR

BARNETT, WALTER H. (1862–1934)

Australian portrait photographer

Henry Walter Barnett was born in Melbourne, Australia, on 25th January 1862, his parents having moved there from London probably in the late 1840s. In 1875, only 13 years old, he left school and joined the most successful photographic studio in Melbourne, Stewart and Co. This business had started some 12 years before and had grown very rapidly. The business was clearly a gold mine, but the resulting product was standardised, lacking distinction. "I have never seen a print of Stewart's worth a second glance," wrote one of Barnett's later protégé's, Jack Cato (Cato, *Story*, 88).

It was here that Barnett first met the young Australian artist, Tom Roberts, who joined the firm in 1877. This was the start of an artistic relationship that was to extend over fifty years. Roberts was to become recognised as "the father of Australian landscape painting."

In 1880, Barnett moved to Hobart, Tasmania, to set up his first commercial venture, a studio he owned together with Harold Riise. He stayed for two years, and then, recognising that he needed wider experience and new ideas if he was to make his mark, he took the bold step of travelling around the world, working as he went for leading photographers of the day: in San Francisco (I. W. Taber), then Chicago (Joseph W. Gehrig), then New York, and finally London, where he was on the staff of the court photographer, W. and D. Downey. Barnett was operator at sittings of the Prince of Wales (later Edward VII), "and dukes and duchesses and titles galore," according to Cato. (Cato, *Story*, 90).

By this time, Barnett had wider skills than any portrait photographer in Australia, and in 1885 he returned home, to Sydney, and opened Falk Studios, which quickly gained a reputation as the best of its kind in the city. Barnett's rise to the top was driven by two main factors: he pioneered in Australia a new look in portrait photography, and he displayed masterly skills in marketing and public relations.

His new look enabled him to present his sitters with a paradoxical mix of glamour and realism. Before his arrival on the scene, Australian photographers had gone for a bright, flat lighting system, giving the sitters a white, shell-like appearance. Barnett introduced dramatic side-lights, emphasising bone structure and enabling his sitters' individual personalities to shine through. As Jack Cato noted: "Walter Barnett in Sydney was discarding retouching altogether for men. He was the first to deliberately photograph the course, deep-toned texture of the skin; to show the bone structure of the skull, to get the sculpturesque modelling of the human head" (Cato, *Story*, 91). Other studios usually took just one position of each sitter, sometimes two. Barnett used up to a dozen different positions, and for a really major celebrity he might take fifty.

Barnett's relationships with an extended group of Australian artists were formed around this time, amongst them Arthur Streeton. Streeton was impressed by the photographer and his work: "He is and very artistic and has good appreciation for the beautiful" (Streeton to Roberts, April 1890).

A major strand of his work at this time was actors and actresses. With major visiting celebrities, Barnett typically negotiated exclusive rights to photograph them and to market their pictures to an eager public. Amongst these was the great French actress, Sarah Bernhardt (1891). So successful was his work for her that for many years she continued to order copies from whatever part of the world she happened to be performing in.

High society in Sydney flocked to Barnett's studio, including leading politicians. His 1892 portrait of the premier of New South Wales, Sir Henry Parkes, is one of his most memorable images. Other important sitters included the writers Robert Louis Stevenson (1893), Mark Twain (1896) and Banjo Patterson (c 1895)—who wrote the original poem, "Waltzing Matilda."

In 1895, Barnett opened a new studio in Melbourne, but it was around this time that he conceived the notion of returning to try his luck in London. On a return trip from there in 1896, he met in Bombay a young Frenchman, Marius Sestier. A cameraman for the pioneering movie film company, Lumiere, Sestier's Indian film had not developed properly. Barnett proposed that he come to Sydney—and this he did, leading to the first movie film to be shot and developed in Australia.

Moving decisively to London in 1897, Barnett opened a studio in Knightsbridge, quickly establishing himself as one of the leading portrait photographers. In 1899, he was invited to join the influential photo-secessionist group, The Linked Ring. Two years later he became a founder member of the Professional Photographers Association, becoming a vice president shortly thereafter, and by 1903 he had become the only professional to be elected to the council of the Royal Photographic Society. Barnett's artistic goals in his early days in London were clear: "I have long been conscious of the deficiencies of portrait photography. Being an enthusiastic admirer of English mezzotint... it seemed to me that it might not be impossible to make photography a humble follower" (*Photography*, 22nd June 1899). A collection of his early

London work, mixed in with the best from Sydney, was to win an important prize in his first year there.

In London over the next two decades, Barnett continued to photograph high-society, writers, artists and musicians. The French sculptor, Auguste Rodin, sat for him in 1903, the great opera singer, Dame Nellie Melba, the year before.

During the First World War, Barnett changed towards a more modern style. In 1920, he sold his London studio, moving to France. In Dieppe, he put on an exhibition of his latest work—of working men around the town. There he also photographed the English post-impressionist, Walter Sickert and the ageing French composer, Camille Saint-Saens. He died at Nice in the south of France on 16th January 1934.

ROGER NEILL

See Also: Australia.

Biography

Born in Melbourne, Australia, on 25th January 1862, Walter Barnett became Australia's first world-class portrait photographer. His Falk Studios was established in Sydney in 1885 and in Melbourne ten years later. In Australia, the main focus of his business was stars of the stage—local and imported—together with his circle of artist friends, politicians and high-society. Through Barnett, the first movie film was shot and developed in Australia. Moving to London in 1897, he established a studio in Knightsbridge, operated under his own name, which attracted celebrities of all kinds—royalty, artistic, governmental etc. He died at Nice, France, on 6th January 1934.

BARTHOLDI, AUGUSTE (1834–1904)

Born in the little city Colmar, the famous sculptor of the statue of Liberty also practiced photography. He had an interest for the new medium both as a creative image and as a commercial image designated to document his work. After studying in the studio of Ary Scheffer and of the sculptors J.-F. Soitoux and A. Etex, the young Bartholdi was commissioned in 1855 to go to Greece, Egypt and North Africa with his friend, the painter J.-L. Gérôme. Initiated the year before the trip to the calotype technique, he returned with a hundred photographs which have been arousing a justified interest for several years now. With a high sense of composition, Bartholdi recorded the picturesque aspects of Egypt: houses, minarets, bazaars, cafés, shops and landscapes. He only reserved one-fifth of his production for great monuments. The graphism of forms and the harmony of strong contrasts of light and shape reveal his personal way of seeing. Their aesthetic power is obvious even though the technique hesitates a bit. After a trip to Yemen in 1856, Bartholdi abandoned this practice, but kept on using photography, as other artists, as an advertising support and document of his sculptural work.

LAURE BOYER

BASSANO, ALEXANDER (1829–1913)

Between 1870 and 1900, Alexander Bassano ran one of the most successful London High Society photographic studios. Bassano enjoyed a fashionable status comparable to that enjoyed by Camille Silvy and John Jabez Edwin Mayall during the 1860s. His pictures were frequently sold as celebrity photographs or reproduced by the illustrated press. Bassano's most famous photograph is undoubtedly the portrait of Lord Kitchener used for the iconic World War One poster "Your Country Needs You." Many other distinguished sitters also patronised the studio, ranging from Queen Victoria and Lillie Langtry to Cecil Rhodes and the Zulu King Cetewayo.

Alessandro Bassano was born in 1829 and was a direct descendant of Duc de Bassano, secretary to Napoleon. In April 1850, he married an Englishwoman, Adelaide Lancaster, by whom he had three children, a son and two daughters. By 1889, he had anglicised his first name to Alexander.

Bassano spent his early days receiving artistic training in the studio of Augustus Egg, and from the water colourist and scene painter, William Beverley. The reception room at his Old Bond Street Studio contained busts of Duke of Connaught and Prince Imperial that had been sculpted by Bassano. His first studio was at 122 Regent St West (1862–76), and subsequent premises were at 72 Piccadilly West (1870–81); 25 Old Bond Street West (1878–03); 182 Oxford Street (1889); 42 Pall Mall (1891–92); 18 Alphoa Road, London (1892–96).

The Prince of Wales reputedly started off Bassano's run of fashionable sitters when he visited Regent Street studio. Bassano later wrote that when he received the

news of the Prince's visit, as well as having "a feeling of sacredness at the prospect . . . I was a little timid of whether I should be able to rise to the occasion." He went on to photograph most members of the British royal family, including Queen Victoria Princess Helena and the Princess of Wales. Benjamin Constant's late portrait of Victoria, exhibited at the Royal Academy after her death in 1901, was based on a Bassano photograph. In recognition of his royal work, Bassano was appointed Photographer to Her Majesty on 24 November 1890.

Baden Pritchard's visit to Bassano's Old Bond Street Studio sums up the enviable reputation he enjoyed by the early 1880s:

> A handsome suite of rooms on the first floor of fashionable area, a *clientele* that only troubles you only in the season, and sitters who do not object to pay well for the attention they receive. Listen to this, good friends, who believe that photographic portraiture is no longer worthily compensated. (Baden Pritchard, *Photographic Studios of Europe*, 81)

Bassano's Old Bond Street studio was limited to photographs by appointment, while his second establishment at Piccadilly was for more impromptu work. Sittings usually lasted for thirty minutes, although more time was allowed for full or three-quarter length portraits. Each visit cost two guineas, for which the sitter received either twelve cabinet or twenty *carte-de-visite* photographs.

The Old Bond Street studio had several dressing rooms in which Ladies could prepare themselves for their sitting, such as through changing into Court dress. It was one of the first studios to be electrified and, on days when Court levees were taking place, was often open all night long. The principal studio was 26 ft in length and contained a single background that measured no less than 80 ft. It was mounted on perpendicular rollers like a panorama. As it was unrolled, the scene could be changed from outdoor to indoor, from the sublime to the picturesque. Many of Bassano's pictures use elaborate props, inherited from the *carte-de-visite*, such as strips of turf to create rural settings.

In his Old Bond Street, Bassano had a staff of three artists constantly employed as retouchers. Many of the studio's negatives of aristocratic sitters show evidence of skilful and extensive retouching, suggesting Bassano's success stemmed not simply from his artistic proficiency. Bassano also operated a large printing establishment at Kilburn, where his photographs were taken after being retouched and approved.

Bassano's personal view of photography was that it could not idealise but should be "nature apprehended in its most intellectual phrase." In a short article in *The Sketch* in 1903, he put the success of his portraits down to that fact that "I am one of the very few photographers who can show that they enjoyed artistic training and association in early life." Bassano believed that this gave him particular advantages in his understanding of composition and illumination, the two qualities he claimed were most important for taking an artistic picture. His cabinet portraits are usually half or quarter-length portraits, and are notable for the skilful lighting of the sitter. Bassano's article in *The Sketch* claimed that photographic portraiture at the present time was lamentably deficient in these qualities.

Although Bassano enjoyed a hugely successful professional career, unlike some other photographers, he does not seem to have been at the forefront of any technical advances. His only recorded innovation was the attempted introduction of a new size of portrait format in the early 1880s called the Holbein, which measured 7½ × 5 in.

Bassano was claimed to have made £60,000 from his portraits studios. When asked what the secret of his success was, he replied:

> Secrets? Lord Bless you! I have none . . .I have met with some success, but the only secret which has tended to it has been that I have bought to bear upon my work whatever art cultivation, inclination and circumstance have fostered. (Baden Pritchard, *Photographic Studios of Europe*, 82)

Bassano died in 1913 and is buried in Kensal Green Cemetery in West London. The studio underwent extensive refurbishment in 1903, when it was renamed Bassano Ltd, Royal Photographers. The company became Bassano and VanDyck Studio in 1964, Bassano and VanDyck Studio (Incorporating Elliot and Fry) 1965-76, and Industrial Photographic from 1977. The National Portrait Gallery now owns more than 50,000 of the firm's original glass negatives.

BAUDELAIRE, CHARLES (1821–1867)

French poet and art critic

Baudelaire wrote one of the most famous essays on photography in the nineteenth century. Known as "The Salon of 1859," it is a review of a Parisian art exhibition, the first Salon show to include photographs. Although his literary importance rests with his verse and prose poems, Baudelaire began his writing career as an art critic. To understand better the context of Baudelaire's statements about photography in "The Salon of 1859," it is useful to trace his aesthetic development through his art reviews.

Baudelaire's first published work was a review of the Salon of 1845. Informing his career as art critic was a tradition in French letters that began with La Font de Saint-Yenne in 1747 and Diderot in 1759. The painter Eugène Delacroix and Stendhal's writings on art complete the major influences on Baudelaire's thoughts on the subject of painting and the visual arts in general. Many key phases and concepts that recur in Baudelaire's art criticism appear first in "The Salon of 1845." They include "originality," "reality" or "the real," "the new," "naivete," and "the heroism of modern life." It is noteworthy that in 1845 Baudelaire is impressed with Jean-Auguste-Dominique Ingres, "who is so much in love with detail" (Baudelaire, "The Salon of 1845," *Art in Paris: 1845–1862*, Ithaca: Cornell University Press, 1981, 5).

In announcing his view of criticism in "The Salon of 1846," Baudelaire contends that it "should be partial, passionate and political (Baudelaire, "The Salon of 1846," *Art in Paris: 1845–1862*, Ithaca: Cornell University Press, 1981, 44). Contemporary art, on the other hand, should "contain an element of the eternal and an element of the transitory—of the absolute and of the particular" (Baudelaire, "The Salon of 1846," *Art in Paris: 1845–1862*, Ithaca: Cornell University Press, 1981, 117). With this doctrine he seeks to root the artist's subject in his or her own time and experience. Yet one of the greatest faults that an artist may possess, according to Baudelaire, is to believe that beauty resides in the exact rendering of nature in all her detail. Baudelaire expounds a theory of art derived in part from Delacroix's own theories: nature is a vast dictionary to be consulted yet ultimately transformed by the memory of the artist. "Exact imitation spoils a memory" (Baudelaire, "The Salon of 1846," *Art in Paris: 1845–1862*, Ithaca: Cornell University Press, 1981, 80).

In 1846 Baudelaire has yet to reject photography—specifically daguerreotypy—as a negative, mechanistic medium, but by 1855 in his review of the Exposition Universelle, he solidifies his views concerning the visual arts. Ingres is pilloried by Baudelaire, who on entering a room devoted to the artist's works experiences nothing but boredom commingled with fear. For Baudelaire Ingres's work is now devoid of imagination; he considers it a product of a conscious aesthetic of the "real" devoid of sentiment or the supernatural. This lack of sentiment and the supernatural has already been linked by Baudelaire to the insufferable fashion for "progress," "this gloomy beacon, invention of present-day philosophizing, licensed without guarantee of Nature or of God—this modern lantern throws a stream of darkness upon all objects of knowledge; liberty melts away, discipline vanishes" (Baudelaire, "The Exposition Universelle, 1855," *Art in Paris: 1845–1862*, Ithaca: Cornell University Press, 1981, 125–126).

In "The Exposition Universelle, 1855" Baudelaire unequivocally separates his aesthetics from the "realist" school of painting and "realist" art in general. His concept of the correspondence between the spiritual and the natural and of the underlying unity of all art keeps him at odds philosophically with the perception or representation of nature as an end unto itself. A work that merely describes is not art, according to Baudelaire, because a work of art must transport ideas from the natural world to the supernatural and/or spiritual realm.

Baudelaire's derision of daguerreotypy as expressed in "The Salon of 1859" is what is generally understood to be his absolute and exclusive opinion on the medium. Sociological and cultural factors, as well as the development of Baudelaire's unique artistic vision, seem to support the finality of expression offered in the Salon review. By 1859 Baudelaire has separated "Truth," at least as he believes the public to understand it, from "Beauty." He contends that nature is the only thing in which the public believes and, therefore, the public believes that only the exact reproduction of nature is what art should be. Former graphic artists dominated the photographic "industry" of mid-nineteenth-century France: Daguerre epitomized this world. Baudelaire's diatribe against photography in "The Salon of 1859" is a political tract that appears to attack Daguerre as "Messiah" of this new industry but remains more completely a denunciation of the public. Although daguerreotypists are co-conspirators with the public, it is the public's unquestioning belief in nature that offends Baudelaire. He rails against the failure of the public to doubt, to think, and to challenge the world in which it lives and links this failure with the ascendancy of the belief in progress that specifically partakes of science and mechanistic inventions and discoveries.

Baudelaire may not have even attended the Salon of 1859. In one letter to his friend Nadar, he claims first that he is currently writing on the Salon show without having seen it and then retrenches somewhat in a second letter by stating that he had lied a little and had made one—and only one—visit. Baudelaire professes to rely on a "livret" describing the exhibition for his analysis.

The image has taken second place behind writing for Baudelaire: what there is to know about this exhibition and its contents exists in the political, social, or aesthetic philosophizing that Baudelaire wishes to make. "The Salon of 1859" is a work on the philosophy of art and therein lies its greatness. Baudelaire's denunciation of photography is a convenience to introduce the more important concept of the imagination in relation to art. It does not provide a complete picture of his relation to photography. Photographers, most specifically Nadar, were among Baudelaire's close friends, and Baudelaire was quite willing to sit for his own photographic portrait, e.g. with Étienne Carjat, Charles Neyt, Nadar, as well as the son Paul. He even contributed one of his poems, "Le Reniement de Saint Pierre," to Nadar's album for guests/clients who visited his photographic studio.

Baudelaire's letters reveal his conflicted emotions regarding the relatively new medium of photography. In an 1861 letter he claims that "photography can produce only hideous results" (Baudelaire, *The Letters of Charles Baudelaire to His Mother, 1833–1866*, New York: Haskell House, 1971, 187)—a comment prompted by activities relating to the illustrations for the *fine* edition of *Les Fleurs du mal* [The Flowers of Evil].

In a letter from December 1865, however, he requests that his mother provide him with her photographic portrait:

> I would very much like to have a photograph of you. It is an idea *which now obsesses me*. There is an excellent photographer in Havre ... [but] *I must be there*. You know *nothing about them*, and all photographers, even the best, have ridiculous mannerisms. They think it is a good photograph if warts, wrinkles, and every defect and triviality of the face are made visible and exaggerated; and the HARDER the image is, the more they are pleased. (Baudelaire, *The Letters of Charles Baudelaire to His Mother, 1833–1866*, New York: Haskell House, 1971, 275–276)

Baudelaire represents the conflicting sentiments among many nineteenth-century aestheticians regarding the upstart field of photography. Is it a mechanical trade or an artistic medium? Few published writers indulged in the discussion that it could be both: most took a side either for or against the consideration of photography as art.

NANCY M. SHAWCROSS

Biography

Charles-Pierre Baudelaire was born in Paris, France on 9 April 1821 to Joseph-François Baudelaire and Caroline Dufays. His father died in February 1827; 18 months later his mother married Jacques Aupick, a general in the army who later become the French ambassador to the Ottoman Empire and Spain and then a senator. Initially schooled in Lyons, Baudelaire completed his education in Paris but was expelled from college in 1839, after which he briefly studied law. Around 1840 he contracted syphilis, from which he would ultimately die. Living the life of a dandy in Paris, Baudelaire exhausted half of his inheritance within two years of turning 21. He wrote his first art reviews in 1845 concerning that year's Salon exhibition, followed by reviews of the Salons of 1846 and 1859, as well as the Exposition Universelle of 1855. His first published literary works were the short story *La Fanfarlo* [The Fanfarlo] in 1847 and a translation of Edgar Allan Poe in 1848; his first poem was published in 1851. In the 1850s Baudelaire continued to translate works by Poe and published his poetry in earnest, culminating with *Les Fleurs du mal* [The Flowers of Evil] (1857) and *Les Paradis artificiels* [Artificial Paradises] (1860). An expanded second edition of *Les Fleurs du mal* was published in 1861. In the 1860s, Baudelaire suffered from failing health and continued to be plagued with financial troubles. A debilitating stroke in 1866 forced him into a nursing home where he died on 31 August 1867.

BAUER, FRANZ ANDREAS (1758–1840)

Austrian Artist

The botanical illustrator Franz Bauer was born in Feldsberg, Austria. After persuasion by Sir Joseph Banks (1743–1820), who remained his patron, he took up a position as a resident draughtsman at Kew in 1790 and he received a life annuity of £300 after Banks' death on condition he remained at Kew. Bauer took an active role in wider discussions on science, botany and medical matters forming acquaintances with many of the leading scientists and figures of the day. He became a Fellow of the Linnean Society in 1804 and the Royal Society in 1821.

In mid-September 1827 Joseph Nicéphore Niépce (1765–1833) arrived in Britain to visit his seriously ill brother Claude. He also used the opportunity to explore

the possibility of commercial exploitation of his heliograph process which produced etchings on metal and had been developed in 1826–27. On the recommendation of William Towsend Aiton (1766–1849), he met Bauer on 20 November who asked him to submit to the Royal Society an account of his heliogravure process. Niépce wrote a longer four-page account *Notice sur l'héliographie* dated 8 December 1827 in which he referred to fixing the image of objects by the action of light. Despite introductions to Dr William Hyde Wollaston and Sir Everard Home both Vice Presidents the paper was never published by the Society and no lecture was given because Niépce would not disclose the detail of his process. Niépce brought with him experimental plates with images made using light-sensitive bitumen of judea, a type of asphaltum, which were to be shown at the proposed lecture; these and the account were left with Bauer on Niépce's departure.

Niépce's plates that had been given to Bauer were eventually exhibited at a Royal Society soiree on 9 March 1839 alongside photogenic drawings of Talbot and Herschel. Three heliographs showing copies of engravings of *Cardinal d'Amboise*, *Christ Carrying the Cross* and *Elodie, a stage design* eventually ended up in the collection of the Royal Photographic Society. The only picture from life *View from the Window at Le Gras* circa 1826 was rediscovered by Helmut Gernsheim in 1952 and now resides at the University of Texas and is considered the world's first photograph.

Niépce returned to France probably in early February 1828 disappointed at the lack of interest in his work and his brother died at on 10 February. Bauer died on 11 December 1840. Both were buried in St Anne's Churchyard, Kew Green.

MICHAEL PRITCHARD

BAUSCH AND LOMB

The origins of Bausch and Lomb date to 1853 when John Jacob Bausch (1830–1926) established an opticians shop in Rochester where he sold spectacles imported from Germany. He was supported financially by a Rochester-based German cabinet maker Henry Lomb (1828–1908) and on Lomb's return from the Civil War the two began a formal partnership in 1863 as Bausch & Lomb. Lomb later moved to New York as the company's representative from 1866 to 1880. From 1866 until 1876 the company was known as the Vulcanite Optical Instrument Company, reverting back to the Bausch and Lomb Optical Company in 1876. The firm expanded rapidly establishing factories in Rochester and in 1874 they moved to St Paul Street where they were to remain until 1975.

In 1874 Bausch's eldest son, Edward, began the expand the firm's manufacturing activities to optical instruments and Ernst Gundlach was hired. Gundlach had worked in various European optical firms before emigrating to the United States. He left Bausch and Lomb in 1878 and established his own optical and photographic business. A microscope was the first successful product and by 1903, 44,000 had been sold. Edward Busch (1854–1944) was the driving force behind the firm's photographic optical activities and patented an iris diaphragm shutter in 1888 and the Plastigmat lens in 1900. He became president of the company on his father's death and was a major benefactor in Rochester.

In 1883 the company began to make photographic lenses and in 1888 they began making photographic shutters. By 1903, 500,000 photographic lenses and 550,000 shutters had been made. The firm's lenses and shutters were used almost exclusively by Eastman Kodak from the introduction of the original Kodak of 1888 and the two companies enjoyed a long mutually beneficial relationship. Bausch and Lomb's high profit margins, even after negotiations to reduce these, finally encouraged George Eastman to establish his own lens making works from 1911 after which Kodak's orders quickly declined.

The firm was licensed by Carl Zeiss in 1892 to make Zeiss Anastigmat and other lenses for the American market and they also made Compound and Compur shutters for Deckel.

The first world war ended these licensing arrangements and as the supply of optical glass ceased in 1915 Bausch and Lomb became the first American manufacturer of optical glass in the United States building on experiments it had been conducting since 1912. By 1917 the company was producing upwards of 40,000 pounds of barium crown glass per month, fulfilling more than two-thirds of the government's wartime requirements for glass for munitions. In 1919 it offered twenty-five different types of glass. Manufacture ceased in 1986.

The firm's photographic lenses were used on television cameras on the 1964 Ranger 7 spacecraft, but it was increasingly moving into contact lenses and consumer eye care products with approval in 1971 from the Federal Drugs Administration to market soft contact lenses. The firm remains in Rochester.

BAYARD, HIPPOLYTE (1801–1887)
French photographer

Hippolyte Bayard, one of the pioneers of early French photography, discovered a process for making direct positive photographs on paper in 1839. Although his invention was eclipsed by the brilliant success of fellow Frenchman Louis Jacques Mandé Daguerre, Bayard nevertheless deserves greater recognition for his role as an independent inventor of photography than he has generally been accorded.

Bayard was born on 20 January, 1801 in Breteuil sur Noye, a small down located in the department of the Oise. The son of a justice of the peace, Bayard worked as a clerk in a notary office before moving to Paris where he obtained a position as a civil servant in the ministry of Finance. According to an early biographer, Bayard's father, who was an avid gardener, experimented with the chemical actions of sunlight on the skin of ripening fruit. Cutting out letters or numbers from a dark piece of paper and wrapping it around a peach as it ripened on the tree, Bayard senior effectively created a "signed" piece of fruit, for the skin of the peach remained light where it had been masked by the paper and darkened in the areas that had received exposure to sunlight.

Whether or not Hippolyte Bayard's interest in photography can be traced back to his father's experiments with photographic writing on peaches, it is clear that he became interested in the chemical actions of light sometime in the 1830s. Although he worked as a government functionary, Bayard's social sphere in Paris included painters, printmakers, stage designers, writers, and actors, many of whom he met through his childhood friend Edmond Geffroy, an actor at the Comédie Française. Through Geffroy, Bayard met the painter Amaury-Duval and seems to have frequented his studio in the 1830s. In this milieu of intellectual discourse and artistic experimentation, Bayard would likely been aware of attempts by Niepce, Daguerre and others to fix the image produced by a camera obscura by means of chemical manipulation.

The official announcement on 7 January, 1839 by scientist and politician François Arago of Daguerre's discovery of a method for capturing the image from a camera obscura seems to have spurred Bayard into action. By 20 January of that year, Bayard had begun experimenting with the light-sensitive properties of silver chloride. By 5 February, two weeks after William Henry Fox Talbot showed his "photogenic drawings" to the Royal Institute, Bayard invited the physicist and member of the French Academy of Sciences César Despretz to view his first photographs. These appear to have been similar to Talbot's "photogenic drawings," that is, negative images made by soaking paper in silver chloride, covering one side with a layer of silver nitrate, placing an object on the paper and exposing it to light.

Seemingly unaware of the value of a negative image that could yield positive prints, Bayard continued to search for a way to produce direct positive images. His progress was rapid, for, according to according to a notebook preserved at the *Société Française de Photographie*, on 20 March, 1839 he showed to friends his first direct positives on paper.

In February 1840, Bayard described his process for making a direct positive on paper. A sheet of paper was "salted" writing paper by soaking it in a solution of sodium chloride. After the paper dried, it was sensitized by floating it in a silver nitrate bath to create light-sensitive silver chloride. The paper was then exposed to light until it turned black (due to the action of light which converts the silver chloride into silver metal), washed, dried, and kept in a portfolio until use. Immediately before use, the paper was soaked in an potassium iodide solution, placed in the camera, and exposed to light. The areas of the paper that received light were bleached in proportion to the intensity of light exposure, while areas that did not receive light remained dark. The paper was then fixed in sodium thiosulfate and washed in water and ammonia.. The resulting image was a unique, laterally reversed, positive photograph. The slight orange tint typical of many of Bayard's direct positives on paper is the result of his use of potassium iodide.

Bayard continued to improve his process and by the end of May had shortened the exposure time from one hour to approximately fifteen minutes, depending on light conditions. On May 20, he showed his direct positive prints to Arago, Daguerre's champion. According to Bayard, Arago convinced Bayard not to reveal his discovery immediately. Bayard, who later concluded that Arago's advice was designed to stall him until Daguerre's experiments were published, would come to feel that his rightful place as inventor of photography had been usurped.

Whatever the truth of this claim, Bayard did in fact exhibit direct positive prints on paper in July 1839, several weeks before the public unveiling of Daguerre's process at the French Academy of Sciences. The occasion was an exhibition of art benefiting the victims of a recent earthquake in Martinique. The first known public exhibition of photography, Bayard's direct positive prints (among them a number of still lifes) roused great interest and were praised for their artistic merit by several major Parisian newspapers, including *Le Moniteur universel* and *Le Constitutionnel.* The latter enthused over Bayard's photographs, writing that "we are not competent to discuss the intrinsic merits of Mr. Bayard's process, nor compare it to that of Daguerre. But the results obtained by Mr. Bayard are of an exquisite fineness, a harmonious softness of light that painting

Bayard, Hippolyte. In the Studio of Bayard. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

will never attain. Nothing could be more charming that these little forms bathed in elusive half-light, like the chiaroscuro of nature. Art must resign itself in comparisons such as these to remain ever inferior to reality" (Gautrand, 1986, 24).

Despite the great interest these photographs provoked, Bayard did not officially present his invention in an institutional setting until several months after the publication of Daguerre's process for making direct positives on metal. On November 2, the architect Désiré Raoul-Rochette presented a report on Bayard's invention to the Académie des Beaux-Arts praising Bayard's invention on both practical and artistic grounds. Rochette noted that unlike the daguerreotype, Bayard's process enabled the papers to be prepared up to a month ahead of time, thus reducing the equipment needed to make an exposure. More significantly, the report found that Bayard's process possessed artistic advantages over the daguerreotype, for the paper support yielded a vagueness of contour and rich harmony of warm tones that suggested an artistic sensibility and recalled the *sfumato* of old master drawings. Writing in 1851, the critic Francis Wey would reiterate Rochette's praise, recalling that when he first saw the photographs in 1839 "they resembled nothing I had seen.…One contemplates these direct positives as if through a fine curtain of mist. Very finished and accomplished, they unite the impressionism of reality with the fantasy of dreams: light grazes and shadow caresses them" (Gautrand, 1986, 24–5).

Despite the acclaim surrounding the exhibition and the support of the Academy of Fine Arts, Bayard failed to receive recognition he desired for his inventions, nor did he achieve the level of state support that was awarded to Daguerre. As a reaction to the injustices he felt he had suffered, Bayard created witty, enigmatic photograph of an inert man entitled *Self Portrait as a Drowned Man*. Bayard inscribed the back of this self-portrait with the following narrative

> *"The corpse which you see here is that of M. Bayard, inventor of the process that has just been shown to you. As far as I know, this indefatigable experimenter has been occupied for about three years with perfecting his discovery.… All those who have seen his pictures admired them as you do at this very moment, although he considers*

them still imperfect. This has brought him honor, but not a single penny. The Government, which has been only too generous to Monsieur Daguerre, says it can do nothing for Monsieur Bayard, and the unhappy wretch has drowned himself in despair.

Oh human fickleness! For some time, artists, scientists and the press took an interest in him, but now that he has been at the morgue for several days, nobody has recognized him. Ladies and gentlemen, let us discuss something else so as not to offend your sense of smell, for as you can see, the face and hands of the gentleman are already beginning to decay." (Gautrand, 1986, 221)

In fact, Bayard's hands and face appear darker in tone than the rest of his body because they were sunburned when this photograph was made.

In spite of his failure to achieve the recognition he craved, Bayard remained an important and productive member of the French photographic community for the rest of his life. He continued to explore photographic chemistry, including methods for developing the latent image on paper. Invented by Bayard in 1839, but not presented at the French Academy of Sciences until Feburary 8, 1841—the timing no doubt spurred in part by Talbot's announcement of his discovery of the latent image phenomenon in early January —Bayard's process entailed preparing a sheet of paper with potassium bromide and silver nitrate, exposing it while still wet in the camera, and then exposing the paper to mercury vapors (as in Daguerre's process) to reveal the latent image. Bayard also described a second method for developing the latent image which entailed soaking paper in a sodium chloride solution, allowing it to dry and then covering it with a silver nitrate solution. Once dry, the sheet was exposed to the vapor of iodine crystals (to form silver iodide), exposed in the camera, then exposed to mercury vapor, and finally fixed in a hyposulfate solution. In both cases, the final images were negative.

By 1842, Bayard was using the paper negative (calotype) process only recently introduced by Talbot to create a series of photographs of Montmartre. The two may have met when Talbot visited Paris in 1843; certainly they were aware of each other's work, as the presence of several salted paper prints by Talbot in one of Bayard's albums suggests. By 1846, Bayard seems to have fully abadoned his direct positive paper process in favor of a modified version of Talbot's paper negative process, which he employed with great skill to make portraits, self-portrait, still-life studies, genre scenes, and photographs of Paris and its environs. Bayard's city views, among the first photographic records of the changing urban texture of Paris in the 1840s, include a series on Bayard's own neighborhood, the Batignolles (1845), the Seine and other aspects of Paris (1847–8), and the barricades erected during the Revolution of 1848. Bayard's skill with the paper negative process is also evident in the series of portraits he made in the 1840s. Likely made for personal rather than commercial purposes, many of these salted paper prints reveal a simple yet strong composition that concentrate attention on the nuances of his sitters' personalities.

An inveterate explorer, in the early 1840s Bayard also used the daguerreotype process, and beginning in 1849–50 produced highly accomplished prints from albumen on glass negatives. After 1851, Bayard also employed the collodion wet plate process. Although he began his photographic career as an amateur, by 1846, he was actively selling photographs through print shops (including English dealer F. Sinnett's shop at 10 Rue Vivienne). In 1855, he opened his own studio at 14, Port-Mahon and in 1861, he founded a portrait studio with Bertall (Charles Albert d'Arnoux), where he made portraits, landscapes, reproductions of art, and *cartes de visite* and was among the first photographers to exploit the possibilities of mass production of photographic prints.

Bayard also played an important role in the institutional development of French photography. He was commissioned in 1843 to make daguerreotypes of the Chateau de Blois, which were later used by the architect Felix Jacqued Duban for his restoration project. In 1851, Bayard was hired by the Commission des Monuments Historique, a wing of the French Government, as one of the founding photographers of the Mission Héliographique, an initiative to document the historic sites and monuments of France by means of photography. The only one of the five to employ glass negatives, Bayard photographed numerous architectural sites in Brittany and Normandy, some of which were published in 1853 by Blanquart-Evrard in the latter's album *Souvenirs Photographiques.*

Throughout his photographic career, Bayard enjoyed significant critical and commercial success, particularly from the early 1850s onward, when the paper negative and the negative–positive process definitively triomphed over the daguerreotype in France. In 1849, Bayard won a silver metal for prints made using glass negatives at the Paris industrial exhibition. In 1851, he garnered another medal at the Cyrstal Palace exhibition in London. In 1854 he became a founding member of the Societé Française de Photographie, and served as its secretary from 1865 until 1881. He participated in the Société's exhibitions in 1855, 1857, and, with Bertall, in 1863, 1864, and 1865. In 1862, the pair received a medal at the Universal Exhibition in London. In 1863, The French government awarded him the medal of the Legion of Honor for his contributions to photography. He retired to Nemours in 1869 and died there on May 14, 1887.

The bulk of Bayard's oeuvre is conserved at the Societé Francaise de Photographie, Paris, which holds some 600 prints as well as notebooks and other archival

materials. Other significant institutional holdings of Bayard's work include The George Eastman House, Rochester, The J.Paul Getty Museum, Malibu; Harry Ransom Humanties Research Center, Austin; The Art Institute of Chicago.

SARAH KENNEL

Biography

Hippolyte Bayard was born January 20, 1801, in Breteuil sur Noye, in the Oise district of France. Son of a justice of the peace, Bayard worked as a notary before moving to Paris in the late 1820s, where he was employed by the Ministry of Finance. Bayard began to experiment with photographic chemistry in January 1839; by March 1839 had invented a process for making direct positives on paper. Over the next three decades, he made portraits, landscapes, still lifes, and architectural images using a variety of processes, including daguerreotype, paper negative, albumen, and wet plate collodion. A founding member of the *Sociéte Héliographique* (1851) and the *Société Française de Photographie* (1854), Bayard opened a commercial studio in 1855 at 14, Port-Mahon. In 1861, he and Bertall opened a commercial portrait studio that specialized in *cartes de visites.* He exhibited at the *Société Française de Photographie* (1855, 1857, 1863–65), and won medals at the Paris Industry exhibition in 1849, the London Crystal Palace exhibition (1851), and the London Universal Exhibition (1862). He died in Nemours, France, on May 14, 1887.

BAYLISS, CHARLES (1850–1897)

English born photographer

Bayliss was born in 1850 in Hadleigh, Suffolk, the son of Charles Baylis (sic) a sadler and Elizabeth Gardiner. The family immigrated to Melbourne in 1852 aboard the *Moselle.* In 1866, aged 16 Bayliss joined Henry Beaufoy Merlin in the American & Australian (sometimes Australasian) Photographic Company in 1866, spending four years touring Victoria and New South Wales, visiting towns and photographing every dwelling then offering these for sale to the locals. Merlin set up a studio in Sydney in 1870 then he and Bayliss continued there endeavour to visit as many towns as possible, which included the gold mining towns of Hill End and Gulgong during 1872. Following Merlin's death in 1873, Bayliss returned to Victoria taking views including a 9 panel 360º panorama of Ballarat in 1874. Under the patronage of Bernard Hotlermann, Bayliss made a panorama of Sydney in 1875 and then from 1876 he is listed with a studio at a succession of addresses in George St., Sydney. He produced further panoramas including another of Sydney in 1879 and these were entered in various exhibitions in America, Europe and Australia. During March 1880 Bayliss travelled to Queensland, and took mammoth plate views around Maryborough. In 1886 Bayliss was appointed official photographer to the Royal Commission on Water Conservation and in this capacity photographed extensively along the Darling River. Bayliss was one of Australia's most accomplished landscape photographers. He died 4 June 1897.

BEALS, JESSIE TARBOX (1870–1942)

Canadian-born American photojournalist

One of the first American photojournalists. Beals was a teacher from the age of 18, whose interest in photography was sparked by winning a camera in a competition. She resigned from teaching after realising she could make more money as a professional photographer. In 1897 she married Alfred Beals. She selected paying clients for her portraits, and instructed her husband on how

to operate the darkroom. In 1900, Beals' photographs were published in the Windham newspaper; the resulting credit line establishes her as the first published female photojournalist. She was then awarded the post of first female staff photographer in the USA, for the Buffalo Courier, in 1902.

In 1904, she was the first female to obtain an official press pass to photograph the Louisiana Purchase Exposition. Her most famous photograph of the fair was an aerial photograph taken nine hundred feet in the air, for which she was awarded a gold medal by the Exposition. Beals' tenacity was further illustrated when she stopped President Roosevelt at the fair and asked if she could photograph him. Beals diversified so that her work ranged from portraits of literary and entertainment figures to urban, interior and garden photography. She photographed the slums of New York in an attempt to assist the Community Service Society and even did some writing and illustrating of books of poetry. Beals divorced in 1924, and moved with her daughter to Greenwich Village; where her photos of the people, the haunts and the studios, earned her the title of 'official photographer of Greenwich Village.'

Jo Hallington

BEARD, RICHARD (1801–1885)

British inventor, entrepreneur, patent-holder, and photographer

In a remarkably short period of time, Richard Beard progressed from being a wealthy coal merchant, to being one of the most influential figures in the development and promotion of photography in England.

His interest in the commercial potential of photography, and in the daguerreotype which was to dominate several years of his life, can be traced back to mid-1839. By that time, the daguerreotype process was known in England through Miles Berry's British Patent No.8194, which had been filed in August 1839 on behalf of Louis Jacques Mandé Daguerre. By the following year Beard had been introduced to the innovative mirror camera design of Alexander S. Wolcott. His first personal involvement in a photographic patent came in mid-1840 (British Patent 8546) when he patented Wolcott's camera design on behalf of himself and John Johnson, an American photographer who was also Wolcott's business partner. Included in that patent were several significant improvements upon Daguerre's original formulation for the process.

Beard later bought Johnson's interests in the camera, and made it available only to his patentees. Thus daguerreotypes produced using his system were not laterally reversed, while those taken with cameras using lenses were. While Beard never publicly stated how much he eventually paid to acquire all interests in the Wolcott camera in England and Wales, Johnson later claimed that £7000 had changed hands.

By summer 1840, Beard had completed negotiations with Daguerre and Joseph Nicéphore Niepce—through their patent agent Miles Berry—and acquired exclusive rights in the daguerreotype in England, Wales, Berwick-upon-Tweed, and the 'Colonies and plantations abroad.' Uniquely missing from these patent rights were Scotland and Ireland, each with its own legal system and separate patent laws. Apparently Berry had seen no merit in paying for such patent protection, a decision which considerably encouraged the development of photography in Scotland. Of significant interest here is the fact that Beard patented both the Wolcott camera and his "improvements" in the process in both these countries. Two Scottish Patents were filed, No.144 in December 1840 and No.148 in November 1841, and one Irish Patent, No. 229, in April 1841. Thus photographers in Scotland and Ireland were free use Daguerre's original process without fear of patent infringements, but not Beard's improvements.

While negotiating with Berry et al., Richard Beard had been working to improve the sensitiveness of the daguerreotype plate. Through the expertise of the chemist John Frederick Goddard, sensitivity was increased substantially—sufficient to make studio portraiture practicable—and with John Johnson, Beard opened England's first professional photographic portrait studio at the Royal Polytechnic Institution in Regent Street, London, in March 1841. Goddard's achievement was to replace the iodine in Daguerre's original formulation with bromide of iodine, and by so doing, he reduced exposures to between one and four minutes in bright light —which was sufficiently brief to make studio portraiture a practical proposition. Interestingly, the patents which embrace Goddard's improvements all claim to have been communicated to Beard "by a certain foreigner working abroad."

The Royal Polytechnic Institution was a unique and highly popular venture in the heart of London, a place where the latest inventions, innovations and ideas could be seen, explored and debated. Large numbers of visitors each paid a shilling to pass through its doors. It was appropriate that the first photographic studio should be established there, and despite the imposition of an admission charge in addition to his prices, Beard's financial return from the glasshouse studio was considerable.

Before opening his first studio, he had also conceived a bold idea to license the daguerreotype process on a strictly controlled regional basis, thus granting each licensee a clear monopoly.

The first such licensed operation opened in Plymouth in July 1841, and was followed by *Photographic Institu-*

tions in Bristol, Cheltenham, Liverpool, Nottingham, Brighton, Bath and Manchester. Two further studios were opened in London in 1842—one in King William Street, and the other in Parliament Street, the former being managed by Beard's eldest son, Richard Beard Jnr. from about 1846.

The granting of exclusive licenses permitted Beard to charge high prices to his licensees, and enabled them to extract high returns from their investment. As some photographers paid over £1000 for their licenses, a considerable return was essential. The lack of competition, however, considerably restricted the growth of photography in England. Beard aggressively prosecuted breaches of his patent rights through a number of celebrated court cases, but there can be no doubt that the exclusivity of his establishments worked against the public interest. Even some of those Londoners who could afford to have their likeness made, complained about the time involved in waiting to be photographed, and in 1846 he eventually agreed to license more studios.

Years ahead of his time in the thinking behind such franchise agreements, Beard controlled the manufacture sale and distribution of the equipment and materials which accompanied professional portrait photography —including cameras, frames, mats (overlays), preservers, and cases. Approved products were identified with the words "Beard Patentee"—embossed on the faces of frames or brass mats and on printed labels inside morocco cases. There is evidence that some of his cases and their fittings were made for him by Thomas Wharton, a Birmingham manufacturer whose involvement with case-making predated photography. A small number of the "Patentee" labels bear Beard's original signature in blue ink, perhaps identifying himself as the photographer. Beard's 1842 Patent No.9292 described a method of hand-tinting the daguerreotype—already within a year after the first studio opening, the absence of colour had been identified as a shortcoming of the new process. The procedure was based on proposals by Johann-Baptiste Isenring.

By 1845 he was entering into concession agreements with photographers who could use the process without buying a license, in return for a share in the profits, and by the 1849, he was legally bankrupt, although whether by business failure or business planning remains open to debate. Later studios in Manchester and Liverpool traded under the partnership name of Beard and Foard, and it remains uncertain whether this was Richard Beard or his son Richard Beard Jnr. He was also a partner in a London studio, Sharp & Beard, in the later 1850s.

He appears to have retired completely from photography by 1858, and applied himself to a range of other business opportunities until his death.

JOHN HANNAVY

Biography

Richard Beard was born in Devon in December 1801, the second of six children, four of whom did not survive beyond their mid-teens. He joined the family grocery business in Newton Abbott and while still in his early twenties, was effectively in charge. He moved to London in 1832 and went into partnership with a coal merchant, establishing Pope, Beard & Company, later to become Beard & Company. With his wife Elizabeth, he had six children, the first of whom, Richard Jnr, followed him into photography. After leaving photography, he lived for many years in Hampstead, London, where he died on June 7th 1885.

BEATO, ANTONIO (c. 1830–1903)

Itinerant photographer

For many years, historians believed that a photographer by the name of Felice Antonio Beato had photographed extensively throughout Japan, China, Egypt and the Holy Land. This error came about as a result of the two brothers Felice Beato and Antonio Beato signing some of their works with a composite name.

Antonio Beato worked with his brother for several years, opening a studio with him in Calcutta c.1858. By 1862 he had set up a studio in Cairo, with another studio in Luxor opening a decade later. His work was sold widely to those travellers who undertook the Grand Tour of Egypt from the 1870s until the end of the nineteenth century.

Beato's Egyptian images are distinctively different from those of Francis Frith. While Frith concentrated on the grandeur of the antiquities, in Beato's images people

going about their daily work are of at least equal importance to the grandeur of their architectural settings. His output embraced landscape, architecture and people, and many images bear the legend 'A Beato' handwritten onto the collodion negative. Some also have an additional ink signature on the print. Additionally, several of Beato's images exhibit a pink hue to the highlights, believed to have been introduced by dyeing the albumen to give a warmer alternative to the conventional albumen print.

JOHN HANNAVY

BEATO, FELICE (c. 1834–1906)

Corfu-born photographer and merchant of British nationality

Despite Felice Beato's reputation as a pioneer war and travel photographer, many aspects of his life and background remain unknown. At a meeting of the *London and Provincial Photographic Association*, he was described as "a Venetian by birth, but now a naturalised Englishman," however no firm evidence has emerged to substantiate this claim of 'Italian' birth. Current research indicates that he was born on the island of Corfu around 1834.

Like his brother Antonio Beato, Felice obtained his knowledge of photography in the mid-1850s from his brother-in-law James Robertson, chief engraver of the Imperial Mint in Constantinople. The correspondence of the French military artist Jean-Charles Langlois provides the earliest known reference of his photographic activities. In a letter from the Crimea, dated 30 April 1856, Langlois noted the presence of Robertson's assistant at work photographing the stationed troops: "We believed that the figure was not Robertson himself, but his first student, a replacement." A few days later Langlois confirmed the identity of this assistant with evident disdain for his work: "Certainly this M. Beato is no artist." While this judgment perhaps reflects Beato's inexperience in the field, his formative training in the Crimea enabled him to establish strong ties with the British officer class that would prove invaluable in his future career (see Gartlan).

> Over the next year Felice Beato continued to work as Robertson's able assistant in several Mediterranean locations as their professional relationship gradually transformed into a collaborative partnership. En route for London in September 1856, Robertson left an assistant in Malta to manage his operation, and once again, Beato was almost certainly delegated this task. On 3 March 1857, Robertson and his two brothers-in-law, Felice and Antonio Beato, registered their arrival in Jerusalem at the British Consulate. Given that the prints taken thereafter in Jerusalem, Athens, Constantinople and Egypt were signed either 'Robertson and Beato' or later 'Robertson, Beato & Co.' (unlike the former accreditation of prints to Robertson alone), Felice Beato appears to have gained some recognition from his elder mentor for his contribution to the enterprise's success.

Beato began his own independent photographic career on his embarkation for Calcutta in early 1858. He travelled widely through northern India, photographing the embattled buildings still evident months after the Sepoy Rebellion at Lucknow, Delhi, and Cawnpore (now Kanpur), and preparing a portfolio of architectural views of Agra, Benares, and Amritsar. His gruesome photographs of the Lucknow massacre, in which the exhumed remains of numerous Indian insurgents lie strewn on the city streets, established his penchant for battlefield scenes showing the dishevelled victims of British military action. Among the earliest photographs to portray corpses on the battlefield (although like Alexander Gardner, Beato certainly 'arranged' his war scenes), these images differed markedly from the earlier absence of corpses in the Crimean War photographs of Roger Fenton and James Robertson. In subsequent years, Beato accompanied military forces as a war photographer in China (1860), Japan (1864), Korea (1871), the Sudan (1885) and Burma (1886). From July 1858 to December 1859, Antonio Beato assisted his brother in the management of a studio in Calcutta until he returned to Egypt to eventually open his own studio at Luxor in 1862.

On 26 February 1860, Beato left Calcutta for Hong Kong to join the Anglo-French forces gathering in readiness for a retaliatory campaign to North China. Over the next eight months, he assembled a comprehensive record of the campaign, from the first encampment at Kowloon to the final destructive events in Beijing. Beato displayed his enthusiasm for battlefield scenery soon after the allied forces captured the strategic Dagu forts on 21 August 1860. The memoirs of the military surgeon, Dr. David Field Rennie, provide some insight into Beato's eagerness on the battlefront:

> I passed into the fort and a distressing scene of carnage disclosed itself; frightful mutilations and groups of dead and dying meeting the eye in every direction... Signor Beato was here in great excitement, characterising the group as "beautiful," and begging that it might not be interfered with until perpetuated by his photographic apparatus, which was done a few minutes afterwards. (Rennie, 112)

Gathered into albums in chronological order, these photographs were sold to numerous British officers and soldiers in the course of the campaign. Although the experienced photographer Antoine Fauchery also accompanied the French forces, Beato's portfolio constitutes the only substantive photographic record of the campaign and includes the earliest known photographs of Beijing.

Soon after his arrival in London in October 1861, Beato sold the rights to his India and China images to the commercial publisher Henry Herring. The following summer, Herring exhibited the portfolios at his Regent Street premises, though he planned to market the collection primarily by mail subscription. While the commercial success of this venture was probably modest, Herring's subscription list provides scholars with a valuable resource for the study of Beato's India and China portfolios (for reproduction see Harris, *Of Battle and Beauty,* 177–180).

During the Anglo-French campaign in China, Beato met the British artist and *Illustrated London News* correspondent Charles Wirgman. A resident of Yokohama since May 1861, it was probably at Wirgman's instigation that Beato decided to first visit Japan. By 13 July 1863, as Wirgman noted in one of his regular columns, Beato's photographs were already attracting attention in Yokohama: "my house is inundated with Japan officers, who come to see my sketches and my companion Signor B-'s photographs." (*ILN,* 26 September 1863, 303) Between 1864 and 1867, the two colleagues operated the influential firm of 'Beato and Wirgman, Artists and Photographers.' Beato was primarily responsible for popularising the practice that would become a hallmark of the Yokohama photographic industry: the hand-coloured albumen print. He travelled extensively throughout Japan, on occasion accompanying ambassadorial delegations in order to gain access to regions otherwise restricted to foreigners. Although he continued to serve as a war photographer, accompanying the punitive expedition to Shimonoseki in 1864, his topographical and studio genre work predominated in the 1860s.

On 26 November 1866, a devastating fire destroyed Beato's photographic studio and stock along with most of Yokohama. This disaster stymied Beato's desire to send the *Bengal Photographic Society* "a set of views, not only of scenery in Japan, but also of native portraits in *cartes-de-visite,* illustrative of the different dresses, customs, and habits of the people." (*Journal of the Bengal Photographic Society,* March 1867, 25) Despite this setback, Beato quickly rebuilt his portfolio and only five months after the fire, the *Bengal Photographic Society* received "an Album of Photographic views and costumes taken in China and Japan, chiefly by Cigni Bento of Yokoham[a]." (*JBPS*, March 1867, 5) Over the next year, Beato continued to rebuild an inventory of Japanese 'views' and 'costumes' published in various leather-bound album formats, often with the embossed cover title *Vues du Japon* or *Views of Japan* (Bibliothèque nationale, Paris). One superb example preserved in the Victoria and Albert Museum, London, and published in 1868 with the title *Photographic Views of Japan by Signor F. Beato, with Historical and Descriptive Notes, Compiled from Authentic Sources, and Personal Observations During a Residence of Several Years*, consists of two volumes containing respectively 101 untinted views and 100 hand-tinted genre subjects. As the title suggests, a lengthy printed caption accompanied each print, attesting to the album's instructive

function at a time of few first-hand, European-language accounts of Japan. Beato not only established the range of typical subjects and practices followed by his successors, but also trained several leading photographers of the next generation, most notably Kusakabe Kimbei and Baron Raimund von Stillfried. Although the studio of *F. Beato & Co.*, located at No. 17 on the Bund, continued to operate from 1869 until 1877, Beato's own photographic activities declined as he delegated further responsibility for the studio's operations to his assistants. Nonetheless, he accompanied the American naval expedition to Korea as official photographer in mid-1871, and, despite the meteoric rise of Baron von Stillfried and other competitors, continued to maintain a high professional reputation. The traveller Elizabeth Amy Cathcart Payne could still note in her diary on 8 November 1874: "We also had our photos taken by Beato, accounted the best photographer in Japan." (Connie Keat (editor), *Amy's Diaries: The Travel Notes of Elizabeth Amy Cathcart Payne, 1869–1875,* Morwell, Australia, 1995, 52.)

Yet aside from such occasional photographic activities, Beato was increasingly preoccupied after 1869 with other financial projects, culminating in the sale of his studio and inventory to *Stillfried & Andersen* in January 1877. A popular resident known for his eccentric personality, Beato enjoyed the local horse races, game shooting, and other social pastimes of treaty port life. During a brief visit to London, he continued to move in Yokohama circles, dining with "quite a Japanese party" of former residents on 5 November 1871 (Schmidt, p.200). He was one of several financiers responsible for establishing the Grand Hotel in Yokohama and was regularly caricatured in Wirgman's illustrated magazine the *Japan Punch.* In December 1875, Beato's ambitions expanded to the opening of a general store at No. 57, Yokohama. According to the *Japan Herald*, this venture epitomised his entrepreneurial spirit:

> Obedient to the command of the new lessee, Mr. F. Beato, a small army of carpenters took possession, and in a few weeks, some four in all, had raised a new edifice… and now, in all the glare of bright paint and paper, the new premises assert themselves to every passer-by as the depôt of the "Yokohama Trading Company," where everything, we are told by the enterprising proprietor, from a gimlet to a bedstead, from a bottle of gin to a hogshead of claret, can be had for about half nothing, or for even less, rather than lose a customer... [Mr. Beato's] wonderful energy, and his elasticity of spirit in these dull times, are calculated to ensure success. He deserves it. (*Japan Herald Mail Summary,* 30 December 1875, p.3)

Success, however, remained elusive. In the end, he lost all his money speculating on the Yokohama silver exchange, and left Japan on 29 November 1884 with his passage paid by friends. While such merchant activities deflected his attention from the studio, Beato made an enduring contribution to photography in Japan, establishing the benchmark in terms of production standards and themes for subsequent studios.

Five months after his departure from Japan, Beato was again employed as an expedition photographer accompanying General Wolseley's British campaign to the Sudan. Although he exhibited the photographs in February 1886 before members of the *London and Provincial Photographic Association,* these Sudan photographs have yet to be identified. At a subsequent meeting of this society on 4 March 1886, the secretary announced that "Signor Beatto ... had unexpectedly to leave England for Burmah on the first of this month." (*British Journal of Photography,* 12 March 1886, p. 167) While the exact date of Beato's arrival in Burma remains conjectural, his prompt departure and expressed destination suggests that he probably settled there before the end of the year. The travel account of George Bird supports this supposition, affirming that Beato "arrived in Mandalay in 1886." (Singer, p. 98) He soon established a successful studio marketing architectural views, genre subjects, and other Burmese subjects that furnished the illustrations for several turn-of-the-century travel accounts. From 1895, the Mandalay studio expanded into an emporium of Burmese curios, with a branch office at Rangoon offering ivory carvings, silverware, and other regional merchandise to tourists and an international 'mail-order' clientele. Beato's various enterprises in Rangoon and Mandalay continued to prosper into the early twentieth century, until his final documented listing in *Thacker's Indian Directory* in 1908. He is thought to have died in Burma about 1908.

Luke Gartlan

Biography

Despite extensive research in recent decades, the birth and death details of Felice Beato continue to elude scholars. Current research indicates he was born on Corfu about 1834 and first trained as an assistant photographer to his brother-in-law James Robertson in the mid-1850s in Constantinople (now Istanbul). From 1855, he was active at the Crimean War and thereafter visited Malta, Jerusalem, and Egypt, before embarking for Calcutta in early 1858. Closely associated with the British military class, he recorded several colonial conflicts including the aftermath of the Sepoy Rebellion in India (1858) and the Anglo-French campaign in Northern China (1860). In the following years, he returned to war photography joining the military campaigns to Shimonoseki, Japan (1864), Korea (1871), Sudan (1885) and Burma (1886). An accomplished topographical and architectural photographer, excelling in multi-part panoramas, Beato also had a formative role in establishing the scenic 'view,' as

well as the street and studio-based 'costumes' of early Japanese photography. In later life, he produced a similar portfolio of photographs during an equally lengthy residence in Burma, where he possibly died around 1908. For over fifty years into the early twentieth century, Beato's photographs of Asia constituted the standard imagery of travel diaries, illustrated newspapers, and other published accounts, and thus helped shape 'Western' notions of several Asian societies.

BÉCHARD, HENRI AND ÉMILE, AND DÉLIÉ, HIPPLOYTE (active 1869–1880s)

French, commercial photographers

Henri Béchard operated a photographic studio in Cairo in the Ezbekiah Garden district from which he sold rather standard tourist views, as well as a series of types and costume studies. In 1888 he published with A. Palmiere, a set of photogravures, "L'Égypte et la Nubie." Émile Bechard, assumed to be related to Henri, formed a studio with Hipployte Délié. Prior to coming to Cairo—no doubt attracted by the influx of visitors and potential customers at the time of the opening of the Suez Canal, which also coincided with the first package tourist trips to Egypt—Délié had worked supplying travel views for wood engravings for *Le Tour du Monde*. Délié et Bechard had the photographic concession at the Cairo antiquities museum and produced the handsome *Album du Musée Boulaq: Photographie par Délié et Béchard, avec texte explicatif par Auguste Marriette Bey* (Cairo, 1872). The partnership was dissolved sometime after publication and both continued to work in Egypt as commercial photographers. Both received medals at the 1878 Paris Universal Exposition.

KATHLEEN HOWE

BECQUEREL, ALEXANDRE EDMOND (1820–1891)

French scientist and physicist

Becquerel was born in 1820 and is known for his studies in light, photochemistry, and phosphorescence. In the field of photography his main contribution is in color recording experiments. Before describing his work in the field of photography, it is necessary to mention the research in color recording performed before Becquerel. After the invention of black-and-white photography a lot of research was devoted to the possibility of recording natural color images. Even before photography was invented, Johann Wolfgang von Goethe published a book on light and color (Zur Farbenlehre), in which light and color recordings were discussed. Experiments performed by Johann Thomas Seebeck (1770–1831) was included as an appendix in Goethe's book and is probably the first (about 1810) contribution to color photography. Seebeck made experiments in which solar spectra were projected onto silver-chloride impregnated paper. The recording which unfortunately could not be preserved (fixed) showed colors which were induced by the different colors of the solar spectrum. The philosophical explanation of this was: "light chose to impress itself on material objects in its own colours." Thus, it makes sense to describe such a process a *natural* color-recording technique. To some extent Becquerel's

color photography experiments were also based on Sir John Herschel's systematic investigation of solar spectra recorded in silver-chloride impregnated paper. This type of photographic recording technique is often referred to as *heliochromy* (sun-coloring) and the images as *heliochromes*.

Instead of using paper as the material substrate, Becquerel coated a silver subchloride (Ag_2Cl) emulsion on a polished silver plate. Actually, Becquerel preferred chlorination by a galvanic process. The silver plate was immersed as the positive pole in a weak (1:8) hydrochloric acid, the negative pole being a platinum sheet. Within a few minutes the process was completed. By timing the process, he could accurately control the thickness of the layer. The best colors were obtained when the galvanic process was stopped at the "fourth-order violet" which corresponded to a thickness of 1/588 mm. Employing such plates, the colors of the recorded solar spectrum were much brighter than previously recorded spectra. However, the same problem of fixing the images remained unsolved, and despite trying hard, Becquerel could not find a solution. The images faded rapidly under daylight illumination. They had to be stored in complete darkness. In addition to solar spectra recorded in 1848, Becquerel succeeded also in recording color photographs of objects. He recorded some colored engravings and brightly dressed dolls which all required between ten and twelve hours exposure in bright sunlight. For example, at the 1855 Exposition Universelle in Paris, such color photographs were on display in an almost dark tent to preserve the photographs as long as possible. The only light inside was a single candlelight.

Lord Rayleigh (1842–1919) suggested in 1887 that the images obtained in the Becquerel experiment could be explained in this way: "The various parts of the film of subchloride of silver with which the metal is coated may be conceived to be subjected, during exposure, to *stationary* luminous waves of nearly definite wavelength, the effect of which might be to impress upon the substance a periodic structure recurring at intervals equal to *half* the wave-length of the light." Then the recording technique is: "to produce just such a modification of the film as would cause it to reflect most copiously that particular kind of light." In 1889 Otto Wiener (1862–1927) investigated and explained the experiments by Seebeck and Becquerel as well as interferential color photography invented in 1891 by Gabriel Lippmann (1845–1921). The colors observed in the experiments are obtained in two ways: caused by *interference* or by *absorption and bleach-out* process. Becquerel's process may, to some extent, be based on interference, but is much more similar to color recordings on chloride paper. In this case a chemical bleaching process of pigments is behind the colors. The light-sensitive substances are bleached out only by those kinds of light which they absorb, while they are not destroyed by light of their own color. One of Becquerel's solar spectra recorded in 1848 has been preserved and belongs to the collection of the Musée national des techniques (Conservatoire national des arts and métiers) in Paris. It is stored in complete darkness in a box. It is very difficult to get permission to view the photograph. Only on a few occasions have researchers been able to view and investigate the recorded spectrum. However, ordinary photographic color prints exist of Becquerel's photograph; for example, a photo is reproduced on page 29 in *Histoire mondiale de la photographie en colours*, a book by Roger Bellone and Luc Fellot published in 1981.

Hans I. Bjelkhagen

Biography

Alexandre Edmond Becquerel was born in 1820, the son of Antoine César Becquerel who was a pioneer in electrochemical science. Alexandre Edmond's son Antoine Henri was the famous scientist who discovered radioactivity in 1896 for which he shared the Nobel Prize in Physics in 1903. Alexandre Edmond is known for his studies in light, photochemistry, and phosphorescence. For example, he is the inventor of the phosphoroscope. Alexandre Edmond discovered the photovoltaic effect in 1830. Doctor of Science in 1840 and professor of Physics at the Conservatoire national des arts and métiers (National Academy of Arts and Trade) in 1852. When his father died in 1878, he succeeded him as a professor at the Muséum d'Histoire naturelle (Museum of Natural History) in Paris. He is the author of the book: *La Lumière ses causes et ses effets,* published in 1868. In the field of photography he is known mainly for his work in color recording experiments. He died in 1891.

BEDE, CUTHBERT (1827–1889)

English writer and illustrator who satirized photography

Cuthbert Bede was the pseudonym of Edward Bradley, an English clergyman who, as a writer and illustrator, explored the comic possibilities of photography. It is known that in the 1850s he also took photographs although the extent of this activity is uncertain and no surviving photographs can be reliably authenticated as his. Unless more evidence comes to light, Bede's importance to the history of photography rests principally on his book *Photographic Pleasures: Popularly Portrayed with Pen and Pencil* published in January 1855 and his allusions to photography in *The Adventures of Mr Verdant Green, an Oxford Freshman* which dates from 1853, and which subsequently spawned two sequels.

Edward Bradley was born in Kidderminster in the County of Worcestershire, England, on 25th March 1827. The son of a surgeon, he was educated at Kidderminster Grammar School and at University College, Durham, Northumberland. He obtained his Licentiate in Theology and then went on to take holy orders. He invented his pseudonym by combining Saint Cuthbert and the Venerable Bede whilst still an undergraduate student. In common with many contemporary and near contemporary literary satirists such as Thomas Love Peacock, the youthful Bede began with poetry and prose writing for the periodical press, including *Bentley's Miscellany* and *Punch,* before turning to book publications. 'The Wanton Sunbeam' of 1847 is an example which indicates Bede's incipient interest in photography. It took Bede some time to realise that his talent lay in combining his comic prose with his own humorous illustrations. However before this point was reached, Bede had begun work on one of the first commercially produced Christmas cards, and on an early example of a double acrostic crossword, the later subsequently appearing in *The Illustrated London News* in 1856. He was later to return to verse again in, for example, *Funny Figures* of 1858, a book for children.

In terms of the development of his ideas, it is likely that Bede would have known William Makepeace Thackeray's character Michael Angelo Titmarsh, a parody of 'the artist connoisseur' which first appeared in *Fraser's Magazine* in 1838, which itself was modelled on Thomas Rowlandson's Doctor Syntax, an open parody of the champion of the picturesque, William Gilpin. Titmarsh is similar in many respects to the caricatured 'photographer' that Bede went on to create in *Photographic Pleasures*. Bede met George Cruickshank, the pre-eminent graphic satirist of the period in 1853 and the latter recommended that Bede produce something similar to his own *Adventures of Mr Lambkin: or the Batchelor's Own Book*. It is significant that following the publication of *Photographic Pleasures*, Bede was to be compared to Cruickshank as well as to Richard Doyle and John Leech. Bede also collaborated with Albert Smith of *Christopher Tadpole* fame and with Alfred Crowquill (Alfred Henry Forrester) who provided the illustrations to Bede's 1864 book *Fairy Fables*.

Bede soon found himself with two quite different professional lives, that of his religious calling and that of his work as an increasingly successful satirist. His first curacy was in Glatton-with-Holme in Huntingdonshire which commenced on 17th November 1850. A further curacy followed at Leigh, Worcestershire and he married Harriet Hancocks from nearby Wolverley in 1858. By this time he was vicar at Bobbington, Staffordshire and went on to become rector at Denton-with-Caldecote in Huntingdonshire (now part of Cambridgeshire) and rector of St Nicholas in Stretton in Rutland. After his death on 12th December 1889, he was buried in Stretton churchyard. He had two sons who grew to maturity, one of whom, Charles Bradley, wrote and illustrated mostly on sporting subjects. During his time at Stretton, Bede became heavily involved with antiquarianism and with congregational obligations including fundraising for church restoration and various educational projects. His gained his last living at Lenton in Lincolnshire in 1883.

The Adventures of Mr Verdant Green, An Oxford Freshman, a 'town and gown' story which appears to have been drawn from Bede's own experience at Durham and possibly from time residing in Oxford, was originally intended for serial publication in *Punch*. Nothing came of this and Bede suffered further disappointment when it was first accepted by the *Illustrated London News* and then dropped. By 1853 the story was completed and had been taken up by Nathaniel Cooke who marketed it as a railway novel. It employs photography in the narration, principally in the form of Miss Bouncer, a typical Bede play on words as she was much inclined to *embonpoin*t. Miss Bouncer, an exponent of the "fascinating art of photography" is depicted in one of Bede's illustrations calotyping Mr Verdant Green. Indifferent to Miss Bouncer, he preferred Miss Honeywood, in whose eyes he saw "little daguerreotypes of himself."

The first and second editions of this volume, though not subsequent editions, appeared with a portrait frontispiece of its author adapted from a photograph

taken by Oscar Gustav Rejlander and engraved by Sir John Gilbert. Bede met Rejlander in the early 1850s through a mutual friend William Parke, a Wolverhampton bookseller and printer. Rejlander was the unmistakeable model for the Swedish photographer in Bede's *Photographic Pleasures*. Other friends also found their way into the book including Hussey Pache, who inspired the creation of the young woman with chemically stained fingers in Bede's illustration 'A Photographic Positive.' Hussey Pache was the niece of John Moyer Heathcote, who was then living at Conington Castle, Huntingdonshire. Along with the amateur photographer Captain Grenville Wells, Heathcote became interested in photography in the early 1850s and Bede appears to have learnt how to take photographs in their company. Heathcote was satirised under a photographer's focusing cloth in Bede's 'The Present Attitude to Photography.' Bede may have produced his own photographs for *Glencreggan* of 1861 but by 1864 he had turned to John Thomson, a Scottish landscape photographer, to provide the plates for *Rosslyn and Hawthorden*.

Thomas McLean first published *Photographic Pleasures* in 1855 priced at 7s.6d. In 1859 it passed to John Camden Hotten and by 1863 Day & Son published it at a cover price of one shilling. An example of the book's topicality is its allusion to the Talbot v. Laroche patent infringement case. However not all of Bede's references are credible in that he misspelt Thomas Wedgwood's name and credited Daguerre with fixing his photographs on paper with nitrate of silver. Although Bede's familiarity with photography may have been relatively superficial, his sense of humour and comic timing were well judged. He left behind a body of work that satirised but never maligned what at the time were seen to be the manifest absurdities of photography.

Janice Hart

Biography

Cuthbert Bede was the pseudonym of Edward Bradley, born on 25th March 1827 in Kidderminster, Worcestershire, England. He created his pseudonym from the names Saint Cuthbert and the Venerable Bede. A comic writer and illustrator he pursued these interests alongside the obligations of his religious calling. He led a number of congregations, advancing from curate, to vicar to rector in small to medium sized, and often ancient and beautiful, orthodox churches. His best known works are *The Adventures of Mr Verdant Green, an Oxford Freshman* published in 1853 and *Photographic Pleasures: Popularly Portrayed with Pen and Pencil* which appeared in late January 1855. He was advised by George Cruickshank, collaborated with Alfred Smith and knew a great many of the literary men and illustrators of the period. He appears to have learnt photography with the amateur enthusiasts John Moyer Heathcote and Captain Grenville Wells and also met a number of professional photographers including John Thomson and Oscar Gustav Rejlander. *Photographic Pleasures*, his most sustained satire of photography, is a mixture of acute observations and unintended errors, the later indicating that Bede's grasp of photography was relatively slight. However Bede did bring humour to what were thought of at the time as photography's most absurd and therefore entertaining characteristics. He died on 12th December 1889.

BEDFORD, FRANCIS (1816–1894)

British photographer, artist, lithographer, and publisher

Francis Bedford was as accomplished with watercolours, lithography and architectural drawings as he was with photography. As an architectural and landscape photographer, his achievements rank alongside those of Roger Fenton and Francis Frith.

Throughout the 1840s, with a growing reputation for ecclesiastical architectural drawing and his established talent as a lithographer, he was commissioned to illustrate a number of projects, including *A Chart Illustrating the Architecture of Westminster Abbey* (1840), *A Chart of Anglican Church Architecture Arranged Chronologically with Examples of Different Styles* (1843) and *The Church of York* (1843).

In 1851 he produced 158 chromolithographs for Digby Wyatt's *Industrial Arts of the Nineteenth Century, at the Great Exhibition 1851* which was published over the following two years. Other lithographic commissions included 100 plates for Owen Jones' *The Grammar of Ornament* (1856), and *The Treasury of Ornamental Art* (1858). For the latter, and for *Art Treasures in the United Kingdom* (1858), the lithographs were "drawn on stone" from Bedford's own photographs.

Bedford, Francis. The Waterslide, Badgworthy. *The Metropolitan Museum of Art, The Elisha Whittelsy Collection, The Elisha Wittelsey Fund, 1973 (1973.502.6) Image © The Metropolitan Museum of Art.*

He likely entered professional photography in 1851 or 1852. In his obituary in *The Bookseller* in 1894, it was suggested that this change of direction was at the suggestion of his publishers Day & Son, who may have seen the value in having a foothold in the emerging photographic market.

In 1851 Bedford moved to 326 Camden Road, London, which would be the base for the photographic business until his death in 1894. By 1853 he had exhibited photographs for the first time—copies of Middle East lithographs by the artist, David Roberts. The photography of art objects occupied much of his early career—interiors of Marlborough House, and reproductions of work from the Royal Collection for Queen Victoria being significant early commissions.

Like many architectural and landscape photographers of his day, Bedford's early images were taken with a large format camera—his 12 × 10 prints attracting considerable praise in the photographic press. Later images were typically also produced in *carte-de-visite* and stereoscopic formats. Examples of his photography appeared in *The Photographic Album* of 1855, with views in North Wales appearing in the second volume the following year.

A further commission from the Queen—to take views of Coburg for her to present to Prince Albert—came in 1857, the year he joined the Photographic Society of London, and in the following year, his enthusiasm for architecture photography resulted in a set of his images becoming part of the collection of the Architectural Photography Association. Examples of his work were published in *The Sunbeam*, edited by Philip H. Delamotte—first published in six parts between 1857–59 and as a single volume in 1859—alongside such contemporaries as Delamotte, Fenton, and Joseph Cundall.

He was elected to the Council of the Photographic Society in 1858, and became Vice-President in 1861, before which time he had entered commercial photographic publishing, with his series of stereoscopic cards, *Chester and North Wales Illustrated*. Further series on Somerset, Devon, Stratford-on-Avon and other areas of central England, western England and Wales followed regularly over the following years, printed in his large printing works adjacent to 326 Camden Road, and published in Chester by Catherall & Pritchard.

While photographers like Roger Fenton and Francis Frith eschewed the low cost *carte-de-visite* print, the introduction of the carte era was enthusiastically embraced by Bedford, and saw many of the subjects which had already proved successful with both the large format camera and the stereoscope being republished as cartes. Extensive series of carte-de-visite prints, often from cropped-down stereoscopic images, were available throughout the 1860s, all bearing the legend "F. Bedford Photographer to H. R. H. The Prince of Wales" over the Prince's coat of arms.

By the mid 1860s, Bedford's catalogue ran to over 9000 images in a variety of formats, including multiple-view cartes-de-visite, copied from montages of large format views. Over 10% of his published output was of Welsh subjects, and the majority of his work was produced in Wales and the west of England—perhaps surprising for a photographer who was so firmly based in London. He had a virtual monopoly of stereoscopic views of Bath, Bristol, Warwickshire, North Wales and Cheshire, and series of *carte-de-visites* of the came

locations. The quality of the interior views available as cartes rivals the very best in large format views.

A significant boost to his reputation came with the commission to accompany the Prince of Wales, later King Edward VII, on a trip to Egypt and the Holy Land in the spring and early summer of 1862. The resulting images were exhibited in London in July 1862, and published in four volumes by Day & Son in 1863. Selections from Bedford's Middle Eastern views were included in *The Stones of Palestine* (1865) and *The Holy Land, Egypt, Constantinople, Athens &c* (1866).

Bedford was an accomplished manipulator of his images, and many of his surviving negatives show evidence of that manipulation. Skies painted out to be replaced by clouds printed from separate negatives, areas darkened in the negative by application of tissue paper to lighten the print, and extensive work with the pencil and the brush, are all devices Bedford used to ensure that perfect prints were produced from often imperfect negatives. In an essay on landscape photography published in the 1867 *Yearbook of Photography and Photographic News Almanac* he wrote of further tricks—including pruning foliage and tying plants back on windy days

> If, however, the wind, our greatest foe, proves too much for us, even then there is good work to be done. There are often magnificent cloud effects at such times, and if the photographer will set to work upon them, he may obtain a stock of such cloud negatives as will serve to convert comparatively uninteresting views into perfect pictures. (Bedford, "Landscape Photography and its Trials" in *The Philadelphia Photographer* v.XIII, No.148, 1876)

Prior to 1880, Francis Bedford retired from photography and passed the business to his son William who died in 1893. Bedford himself died the following year.

A major collection of Bedford's negatives and contemporary prints is held by the Central Library, Birmingham, England.

John Hannavy

Biography

Francis Bedford was born in London in 1816, the eldest son of the architect Francis Octavius Bedford. He studied art and architecture from an early age, and first exhibited at the Royal Academy in 1833 when he was only 17, and exhibited annually from 1844 until 1849.

He devoted the early part of his career to lithography and chromolithography, his work being published widely. Turning to photography in 1851 or 1852, he quickly earned a reputation as one of the finest architectural and landscape photographers of his day. An early and enthusiastic member of both the North London Photographic Association, and the Photographic Society of London, on the Council of which he served for many years, and as Vice President twice, being elected in 1861, and again in 1878. Little is known of his private life except that he had one son, William born 1846, who later joined him in the photographic business. After Francis's semi-retirement from professional photography in the 1870s, William ran the business until his death in 1893 at the age of 47. Francis Bedford died the following year, 1894.

BEERE, DANIEL MANDERS (1822–1909)

Professional photographer

Daniel Manders Beere (1822–1909) came to New Zealand in 1863 where he was employed as a surveyor for the Auckland Provincial Government. During the Maori Land Wars (1863–1872), he enlisted with the militia and served not only in his professional capacity but as a photographer, supplying photographic prints for his friends and colleagues in the field. Many of these survive today in family albums. It seems he arrived in New Zealand proficient in the use of the collodion method of photography. It is thought he acquired this knowledge in Canada where he took part in the Assiniboine and Saskatchewan Expedition of 1858. He used his photography to record the terrain of where a supply road was being put through heavily forested countryside to supply the colonial forces in the Waikato. This area was noted for frequent skirmishes and ambushes by the Maori forces. One of his most striking images from this period is a staged reenactment of the Maori War party advancing across an open piece of ground with clubs and hatches held at the ready! More common are his studies of settlers posed in front of their cottages. His

name is commemorated to this day with a suburb called Beerscourt in the city of Hamilton.

William Main

BEHLES, EDMUND (1841–1921)

Italian photographer and studio owner

Edmund Behles was born in Stuttgart on 21st July 1841. He was married to Luisa Fetzer. First he worked as a photographer in Rome with Giorgio Sommer from1859 to 1860, becoming the most brilliant and qualified photographer in Sommer's firm. Their association lasted until about 1866. During this period they often sold photographs under the name of either of them without distinction or with both their names together. This makes the attribution of these early photographs very difficult. During their collaboration, Behles and Sommer travelled all over Italy and became famous for their photographic views of important monuments and landscapes in enlarged and stereoscopic prints. When Sommer went to Naples, Behles remained in Rome and worked independently until 1878 in Via Mario de' Fiori, 28. He also had a shop in Via del Corso, 196. He became well known for portraits, while continuing to take photographs of landscapes and historical sites. He won prizes at international exhibitions with Sommer (Dublin 1865), with whom he was honoured by Vittorio Emanuele II as Royal Photographer (1865). He also won prizes on his own (Paris 1867; Vienna 1873), continued his activity as a photographer until about 1890. Edmund Behles died in Rome on 21 November 1921.

Silvia Paoli

BELGIUM

The creation of the Belgian state in 1830 and the invention of photography were virtually synchronous. The country's specific cultural and geographical context made it fertile ground for the new medium to take root. An initially politically fragile buffer state on France's northeastern flank, Belgium could only thrive by a policy of free trade and open borders, to achieve emancipation, both economically and culturally, from its larger southern neighbour. This factor contributed to making Belgian society relatively receptive to innovations such as photography, and ready to exploit its applications, for instance to the printing press. Furthermore, Belgium was the second European power after Great Britain to undergo the deep cultural change which is labelled the Industrial Revolution. The resultant consolidation of a large middle class fostered the diffusion of photography both as a leisure pursuit and as an autonomous economic activity.

The first phase in the socialisation of the new technology was the experimental or laboratory phase. This is the period in which the inventor or his representative hoped to market the invention, without fully meeting the two preconditions of viability and market need. In Belgium, the first phase of socialisation lasted from the announcement of the invention of photography in January 1839 until the spring of 1842.

The figure who best characterises this phase is the printer, lithographer, journalist and polemicist Jean Baptiste Jobard (1792–1861). While not exactly a representative of Daguerre, he had several meetings with him in Paris that year, and purchased a camera from Isidore Niépce, son of the inventor. On 17 September 1839, he announced in the columns of his own newspaper *Le Courrier belge* that he had succeeded in taking the first photograph in Belgium—a seven-minute exposure from the window of his Brussels town house. Jobard also informed his readers that he had set up a company, the Societe belge du Daguerrotype, and that "the firm will send on site artists versed in selecting the most suitable viewpoints for monuments, mansions or factories or machines to be copied, while awaiting [the possibility] of portraits from life" (*Le Courrier belge*, 12 September 1839). But Jobard's initiative was stillborn. It was not that he had failed to grasp the potential of the new technology; rather that it had not yet attained viability. Later on in the year, still possessed by the spirit of utopian ambition, Jobard foresaw the application of photography to the printing press: "We declare that before another six months have passed, daguerreotype plates will be engraved for print-runs of thousands," (*Le Courrier belge*, 25 September 1839). He was wrong of course, but it should be remembered that, in common with many of the pioneers of the new medium, he was a lithographer by training. His predilection for photography, like Nicéphore Niépce**'s** motivation for inventing it, sprang from a search for a technical aid to the graphic arts, a means of raising productivity by replicating handmade objects (lithographs and engravings) in block printing. The printing press would indeed provide a major application for photography—but not yet. Jobard's fate was typical of many such precursors in that he was defeated by a new and untried technology.

By the time the second phase of socialisation was initiated, the visionary had given way to the commercial. This second phase can be defined as a period when financial incentives and the assistance of entrepreneurs, willing to shoulder the risk of commercialisation, enabled the medium to become truly viable. In Belgium, the onset of this phase can be dated precisely to the second week of March 1842, when all of the financial and technological factors finally fell into place with the opening of the first two portrait studios in Brussels. In portraiture, photography found or created the well-defined consumer need prerequisite for its success. The

technical viability was secured to a great extent by British entrepreneur Richard Beard. While Beard could not patent photography per se, he acquired rights on a series of modifications and improvements which constituted a new production process. His agent took out the first Belgian patent in photography on 23 February 1841 for "an improved apparatus for transferring drawings and natural objects to metallic surfaces prepared by an improved process." The improved process consisted of the use of bromine and iodine in equal parts, combined with a description of the lay-out of a portrait studio employing a Wolcott mirror camera, referred to in the patent as "the reflecting apparatus."

A year after taking out his Belgian patent, Beard advertised the "Photographic portrait establishment of the Royal Polytechnic Institution of London, and at the Bazar Pantechnique, near the Park in Brussels. The photographic process for making portraits is an improvement of Monsieur Daguerre's method. Mr Richard Beard has just obtained a patent for Belgium. Portraits taken by this method require several seconds of exposure only and possess a softness and a delicacy which can only be obtained by the process of Monsieur Daguerre." *(Journal de Bruxelles*, 11 March 1842). Beard's operator, an Englishman by the name of Billing, immediately faced competition from the locally established firm of opticians, the Brand brothers, and from Vanmalderen in Liège. It is not known how long the Beard studio operated but the small format of the plate which the Wolcott mirror camera was capable of holding must have finally told against him. Beard never managed to institute in Belgium the franchising system which had been so successful in England. A risk-taker by nature, he was ultimately to bankrupt himself. At least Beard had demonstrated the commercial possibilities of the new technology, but it was left to other individuals, with firmer roots in the local marketplace, to see photography through the next phase.

This third phase in the timetable of photography's socialisation may be summed up as the period when invention becomes innovation. The technology was now being used more widely and demand for it began to grow. In Belgium, this phase lasted about fifteen years—from 1846 (when the first permanent portrait studios were operational in the major towns) until 1860. During this time, the practice of photography, concentrated almost exclusively in the hands of professionals, was characterised by two distinct methods of exploitation. In the larger centres of population—Brussels, Liège, Antwerp and Ghent—permanent portrait studios were erected. Outlying districts and smaller towns were served by short-stay itinerant photographers who would usually operate in a hotel courtyard or garden. The town of Tournai offers a typical case study. Travelling daguerreotypists were recorded as visiting the town in 1843 (Mr Guyard and one anonymous itinerant), 1844 (Messrs Guyard and Housselot), 1848 (Edouard) followed by a certain Dondez "Professeur de daguerréotype" periodically between 1852 and 1857. The first permanent professional photographers in Tournai, Lefebvre-Midavaine and Louis Duchâtel, began operating in 1853 and 1855 respectively.

In phase three of the photography's take-up, the medium cannot yet be considered as economically significant in Belgium. A handful of full-time practitioners, supplemented by their itinerant colleagues, had little economic impact. There was no great reservoir of well-heeled amateurs, eager to drive the innovation process, as in Great Britain and France, so that Chevalier Dubois de Nehaut and Edmond Fierlants had to look to Paris for intellectual stimulus. In the Belgian population census of 1856 (the first time that photography is mentioned), the term "photographer" is not autonomous but subsumed into a miscellaneous list allied to the printing trade, comprising "playing cards, cardboard, wax and signets, pencil manufacturers, illuminators, photographers, manufacturers of printers' ink, fount makers, type and other engravers." The concern of the Belgian authorities at the laggardly nature of take-up found concrete form in a willingness to support individual initiatives in the domain, by Guillaume Claine and Edmond Fierlants, especially when these initiatives could be linked to a reformulation of the new state's cultural heritage. A similar preoccupation underlay the organization of the first two photography exhibitions in Belgium in 1856 and 1857.

The small number of patents taken out in Belgium are an accurate indicator the negligible economic impact of photography until 1860. Thus in the 1840s only nine patents were issued in the domain, rising to 55 in the 1850s. There is a clear jump in the 1860s to a level of between 10 and 20 per year, a range which remained constant well into the 1880s. The origin of individual patents also reveals the position of Belgium in the matter of technology transfer. As might be expected, about 90 percent of patents are of foreign origin, typifying Belgium as a "consumer" rather than an "initiator" of technology, and dependent on other countries throughout 19th century. Furthermore, the diffusion of know-how can be inferred from the rate of transfer of patent rights to third parties, a central aspect in acquiring, managing and exploiting new technology. No such transfers were registered in Belgium in the 1840s and 1850s. Photographic technology began to be used by individuals other than the patentee in a modest way from 1860 onwards; the first such case being the transfer of Dutchman Eduard Asser**'s** patent for his photolithographic printing process to the Brussels printers and lithographers Simonau & Toovey, the first photomechanical printing process exploited in Belgium. Previous to this, the only photographic print-

Laurent, Juan and José Martinez Sánchez. Zaragoza à Pamplona y Barcelona—Puente de Zuera.

ing establishment to operate in Belgium was run by Gilbert Radoux (1820–?), a French "proscrit" [political refugee]. A total of five patent transfers were recorded in the 1860s, five in the 1870s, dropping to two in the 1880s before jumping to twenty-two in the final decade of the century.

Successive political upheavals in France enriched the photographic life of the Belgian capital, where refugees tended to congregate. Both Radoux and his successor Charles Neyt (1833–1908) kept up contacts with the exiles from the régime of Napoleon III, cultivating the company of artists and writers who passed through Brussels, such as Gustave Courbet, Victor Hugo, and Charles Baudelaire, all of whom had their portraits taken during their stay. Another frequent visitor to Belgium was Nadar, whose wide circle of friends included Louis Ghémar, his Brussels counterpart as caricaturist, portraitist, and showman. Following the events of the Commune, Gaudenz Marconi, photographer of "académies pour artistes" [nude studies for artists], relocated to Brussels in 1872, where he led a more obscure life. Diffusion of knowledge and technical know-how in the domain was promoted by the handbooks, written in Belgium but published in France, by the prolific researcher Désiré van Monckhoven.

The rise in the number of patents and of transfer rights heralds the onset of phase four of the socialisation process, as society began to accustom itself to the new technology. In Belgium, this sustained take-off ran for some 30 years from 1860. There is enough quantitative as well as qualitative data to confirm the starting date. Quantitatively, we have the census returns: from an estimated 38 persons who exercised the profession of photographer in 1856, the number had risen in 1866 to 256—in other words, a jump of 670 percent. Qualitatively, we have the testimony of contemporary observers, such as this journalist reporting on the construction of a new portrait studio in Brussels in 1864: "Ten years ago, photography was scarcely known here, only Daguerre's system was in vogue and astonished many people. Today portraits on metal plates are quite out of fashion; men of progress have put their minds to it and, aided by chemistry, have managed to reproduce on paper portraits which can be preserved indefinitely. Progress has not

stopped there: to be convinced, you need only consider the number of photographic establishments founded in Brussels alone in the past few years; this is the best proof of vitality in this industrial branch." (*L'Etoile belge*, 16–17 May 1864). A monthly periodical, *Bulletin belge de la Photographie*, appeared from 1862 to 1880, until 1872 with the support of the photographic supply house of Léon Deltenre-Walker (1819–?) in Brussels.

The advent of the fourth phase was made possible by the huge and virtually instantaneous popularity of the carte-de-visite, introduced as a novelty in the autumn of 1859, which, only a year later, had achieved universal acceptance in portrait studios throughout the country. The card portrait, aimed at the middle-class consumer, proved to be an extraordinary marketing phenomenon in Belgium as elsewhere, the motor which would secure for photography its position as an autonomous economic activity. The bread-and-butter work of the portrait studio allowed a small number of firms, some with a strong regional identity, to expand their operations and sustain a reputation over several decades. They include Louis Ghémar in Brussels, Joseph Maes in Antwerp, and Armand Dandoy in Namur, young men dynamic enough to seize the opportunities which the new medium offered in other areas, and sufficiently affable to flatter and retain the bourgeois clientele of their bedrock portraiture business.

A phenomenon typical of professional photography during this phase in Belgium is geographic clustering. Brussels, as capital city, was the pole of attraction. During the period 1860 to 1890, about a third of all portrait photographers in Belgium were to be found in a relatively small area of Brussels. Data aggregated from trade directories emphasises the level of concentration. In 1860, Brussels had 23 out of 36 studios in the whole of Belgium. By 1868, this had risen to 49 out of 127. While there was a shake-out in the 1870s in Brussels, due to economic downturn, the major cities of Liège, Antwerp and Ghent came nowhere near to catching up. By 1888, Brussels still had three times as many studios as Antwerp—72 to 25. Seen per head of population, the position of Brussels is just as predominant: in 1866, there was one photographer for every 6000 inhabitants in the capital (the average for the country as a whole was 1 in 19,000). The density ratio of 1:6000 was not reached in Liège and Antwerp until the mid-1890s, and by the country as a whole only after the turn of the century. Brussels, with its concentration of wealth, was therefore the natural environment for what was still very much a luxury commodity.

Concerning the social and professional origins of 19th-century practitioners, professionals were the most diverse—a good minority claimed to be artists and painters, or had previous experience in an allied graphic trade such as lithography or engraving. Many of the daguerreotypists had a solid grounding in optics and mechanics. But the majority of men entering the profession during the period covered were artisans, skilled craftsmen with previous experience in a quite unrelated field. Their continued presence in the domain depended not just on their manual skill, but on an ability to run a small business. For many, photography was only one activity within a lifetime of varying activities, and the average life of a studio in Brussels up until 1900 was little more than five years. Success was also partly a function of geographic distribution: the best known and most successful establishments tended to be situated along the central and more fashionable streets in the main towns, while photographers in other locations lived a more precarious existence. The profession was overwhelmingly male, with some widows or single women (often daughters of photographers) active as studio head, while others worked as colourists and retouchers.

The fifth phase of photography's socialisation was a quantitative leap. The technology experienced a wide social and geographic dissemination, and was incorporated into everyday life. In Belgium, this point was reached around 1890, as professional photographers began to open studios in working-class suburbs and in country areas. The number of patents registered rose from 251 in the 1880s to 592 over the following decade. In parallel, the penetration of the medium as a leisure activity reached new levels, thanks to the successful marketing of Kodak cameras and film. The early 1890s saw the formation of local amateur groups, but also led to a fragmentation of attitudes. The last unified photographic exhibition in Belgium, covering equipment and images of all sorts, was organised by the Association belge de Photographie in 1891. Thereafter equipment could only be seen at industrial fairs, and exhibitions were either for all-comers or the pictorialist elite.

In fact, pictorialist trends developed rapidly in Belgium, as leading amateurs (and a few professionals) broke with artistic conformity, asserting a recognisably individual aesthetic vision in image-making. A prominent presence in the first wave of pictorialism, Léonard Misonne acquired a lasting reputation for landscapes, bucolic and timeless. His images are characterised by a masterly treatment of light and atmospheric conditions, as summed up in the credo "Le sujet n'est rien, la lumière est tout" [The subject is naught, light is all]. Also typical of the new movement was Gustave Marissiaux, whose images of mine workers in the Liège region express a social concern previously absent from Belgium photography.

A main characteristic of the fifth phase of the socialisation process was the broadening of applications, when photography began to be applied to completely fresh areas of human endeavour. When the two major inventions to incorporate photographic technology—

cinematography and Roentgen**'s** X-rays—emerged in the mid-1890s, Belgian photographers were quick to take advantage. The botanist and microphotographer Henri Van Heurck (1858-1909) experimented X-ray photography intensively from January 1896, while the versatile Alexandre [Drains] (1855–1925) exhibited his films of the Tervueren colonial exhibition in 1897. The take-up of both applications was much more rapid in Belgium than for photography itself, due in part to the transformation in infrastructure and economic power which had taken place in the previous 50 years.

Within the photographic branch itself, industrialisation meant the division of labour and a move away from artisan-dominated structures. By 1900 the main business of a number of photographic printers, notably Jean Malvaux of Brussels, was supplying halftone blocks for illustrated magazines, such as *L'Illustration européenne.* The man behind the camera was only one skilled operator on a long process line. The new century dawned with photography catering to a mass market and requiring large scale industrial production of cameras and continuous production of paper and plates. Despite facing stiff competition from foreign imports, some local firms benefited from this scaling-up. They included the Royal Photographic Manufactory of cameramaker Louis Van Neck (1853–1917) and the specialist emulsions and photographic paper plant founded by Lieven Gevaert (1868–1935).

BELITSKI, LUDWIG (1830–1902) AND VON MINUTOLI, BARON ALEXANDER (1806–1887)

Ludwig Belitski was born January 15, 1830, in Liegnitz / Silesia. From 1845 to 1847, he visited the city's school for arts and crafts, and in 1848 he was made apprentice to the mechanicus Haertel in Liegnitz. It was there that he started to work as a photographer to Minutoli. In 1854, Belitski moved to the neighbouring town Teplitz to open a photographic studio, and later moved in 1856 to St.Petersburg, and then in 1860, to Hamburg. From late 1862 on, Belitski operated his own studio in Nordhausen/Harz until his death on July 1, 1902. He died as one of the most recognised craft photographers in Germany, having published a large number of articles under his name and being a honory member to a great number of associations.

Alexander Baron von Minutoli was born December 26, 1806, in Berlin. He studied law and economics at the universities of Berlin, Bonn, and Goettingen where he was promoted in 1828. After several years of journeys where he became one of the most effective collectors of antique and historical items. In 1843 he bought the mosaics from the apsis of Santa Michele in Ravenna for the Prussian king. After, he took up state positions from 1835. In 1839 he was made officer for industrial politics in Liegnitz, a position he held until his retirement in 1865 onward. In 1863 he bought a former knight's farm at Friedersdorf on Queis where he lived until his death on December 17, 1887. His private collection of more than 7,200 items formed the basis for the Berlin Museum of Arts and Crafts.

On January 18, 1845, Alexander Baron von Minutoli, a Royal Prussian officer of the Liegnitz area, an industrial district in Lower Silesia, announced the foundation of "a collection of good pattern images for the education of taste" for all industrial branches. In the industrial area, arts and crafts had undergone radical changes towards poverty and only small textile, glass, ceramic, and metal industries survived. Minutoli, himself a noted collector and conoisseur of the arts, had no money to spend on buying quality products of the past years to show to these industries in the hopes that examples of good design for household goods would be helpful. His idea, apparently conceived as early as in 1842, was to collect daguerreotypes of well-known articles in arts and crafts, which he did until the late 1840s. The announcement of 1845 therefore provided an invitation for manufacturers to borrow these daguerreotypes from him.

By the early 1850s, most of the daguerreotypes Minutoli had used, became worn out or destroyed, and some of the original works collected were on the edge of destruction by the borrowers. Minutoli decided to print smaller catalogues after having heard of similar examples by the imprimery of Blanquart-Évrard, and he looked for help with a local mechanic who encouraged his young apprentice, Ludwig Belitski, to take up photography to help with the planned albums. Between 1853 and 1855, no less than 150 photographs were taken and published in large albums, the whole process receiving numerous reviews and wide acclaim. By 1862, Minutoli published another 663 photographs showing no less than 4,000 items but this work was not as successful. Minutoli sold his collections to the Prussian government, and Belitski who had already withdrawn from the project by 1856, never gained copyright for his participation in this first virtual museum of arts and crafts.

ROLF SACHSSE

BELL, WILLIAM (1830–1910)

English-born American photographer

William Bell's extraordinary, sixty-year career as a photographer began in the daguerreotype era and ended well after dry plates and film had transformed the making of photographs, but he is remembered primarily for the work he did as chief photographer for the U.S. Army Medical Museum, 1865–1867, as Timothy O'Sullivan's replacement on the Wheeler Survey in 1872, and as an accomplished practitioner of the dry collodion process. His role as photographer for the U.S. government sponsored 1882 Transit of Venus Expedition to Patagonia is also noteworthy, but is little known, and photographs he made for the Kentucky State Geological Survey in 1884 have never been identified.

William Bell of Philadelphia's life and career differentiate him decisively from Dr. William Abraham Bell, with whom he is often confused and conflated, even in major references, because of the similarity of their names, because they were contemporaries, and because they both photographed in the American West.

William Bell was born in Liverpool, England, and brought to the United States as a young child by his immigrant parents. Orphaned in a cholera epidemic, he was adopted and raised by a Quaker family living outside Philadelphia. Notwithstanding this pacifist upbringing, the 16-year old-Bell enlisted in the Army to fight in the Mexican War. He became a photographer when he returned to Philadelphia from Mexico in 1848 and went to work for his brother-in-law, who owned a daguerreotype studio. Over the next half century Bell was associated with a string of portrait and commercial studios in Philadelphia, either as sole proprietor or as a partner. The relatively few images from any of these studios that are known are notably conventional: Bell's significant work was done in non-commercial arenas.

In 1865, after three year's service as an infantryman in the United States Army during the American Civil War, Bell joined the staff of US Army Medical Museum as its chief photographer, with the rank of Hospital Steward. Founded in 1862, the Army Medical Museum was mandated to advance the study of military medicine and to produce a medical and surgical history of the on-going "War of the Rebellion." The Museum's staff included Dr. Joseph J. Woodward, one of the leading photomicrographists of the era, and photography was considered a vital tool of this mission. From the beginning, the Museum had acquired photographs of war injuries and the results of unusual operations and amputations; during his two years of service with the Museum Bell contributed hundreds of photographs of to its collections, including images of specimens as medical portraits of servicemen who had survived diseases, horrendous wounds, and operations or amputations, which are among the most poignant of American Civil images. Many of these photographs were used as illustrations in the monumental, groundbreaking *Medical and Surgical History of the War of the Rebellion* (1870–1883) and other Army Medical Museum publications—either as tipped-in original albumen prints, sometimes as woodburytypes, collotypes, or photolithographs or other forms of reproduction. In addition to this medical work, Bell took portraits of dignitaries visiting the Army Medical Museum, as well as landscape views of Civil war battlefields, and in April 1865, he and his staff printed some 1500 copies of portraits of the conspirators involved in President Lincoln's assassination for use on wanted posters.

In 1867, Bell returned to Philadelphia and opened his own studio, but in 1872 joined George M. Wheeler's

survey of the territories west of the 100th meridian as a replacement for Timothy O'Sullivan, who had joined a U.S. Navy expedition exploring the Darien Peninsula in Panama. During his single season with the Wheeler Survey, Bell photographed along the Colorado River and the upper reaches of the Grand Canyon in southwestern Utah and northwestern Arizona—well to the west and north of where William Abraham Bell took photographs in 1867. Bell used both the wet and dry collodion processes in the field, and employed two cameras, an 8 × 11 for large views and a 5 × 8 for stereos. In composing his images Bell utilized a distinctive compositional formula that emphasized both the overwhelming scale and the vast spaces of the landscape he encountered. While he made horizontal views (including several multi-plate panoramas), Bell's characteristic Western images are vertical compositions with a strong, dark visual element that parallels the picture plane and dominates the foreground, while the middle ground recedes into the distance in a series of increasingly lighter toned parallel planes. This compositional formula typifies stereoscopic photography, and it yields dramatic and evocative results in Bell's images, while it serves to distinguish them from the work his contemporaries. After the Wheeler Survey, Bell returned to Philadelphia, and in 1875 went into partnership with William Rau, his future son-in-law, who was a noted professional photographer in his own right. Except for his brief stints with the Transit of Venus Expedition in 1882, the Kentucky State Geological Survey in 1884, and a commission from the organizers of the Columbia World's Fair in 1892 to travel around Europe to photograph the paintings being borrowed for exhibition at the Fair in 1893, Bell spent the remainder of his career in Philadelphia, where he was active in the photographic societies and contributed technical articles on the dry plate processes (on which he was considered an expert), as well as memoirs of his experiences to, professional publications, notably *Philadelphia Photographer* and *Photographic Mosiacs*.

William Bell has been overshadowed by his contemporaries, overlooked in most of the influential histories of photography, and confused with William Abraham Bell by many historians. His photographs were included in the albums published by the Wheeler Survey, and they were exhibited in the Vienna Universal Exposition (1873), the Louisville Industrial Exposition in Kentucky (1873), and at the Centennial Exhibition in Philadelphia (1876), but they received little attention. After his death his obituaries noted his military service, his work with the Army Medical Museum and the Wheeler Survey, and his expertise in the dry-plate processes, but only within the past three decades has William Bell begun to receive the recognition due him.

BELL, WILLIAM ABRAHAM (1841–1921)

Dr. William Abraham Bell, an English physician who came to the United States in 1867, is significant because of his brief but unsuccessful career as one of the first survey photographers of the American West and because he been conflated with two other William Bells who were his contemporaries: William Bell from Philadelphia (c. 1830–1910), who had a long, varied, and important career as a photographer, and William C. Bell, a minor Washington, DC (later Baltimore, MD) studio photographer (active c. 1860–c. 1880). Dr. William Abraham Bell was active less than six months and was not prolific. His work is extremely rare and seldom seen or reproduced, with the exception of one image. His photograph of the mutilated corpse of Sergeant Wyllyams, a cavalryman killed by Cheyenne Indians near Ft. Wallace, Kansas, is one of the most vivid documents of the horrific nature of the Indian Wars.

William Abraham Bell was the son of a London physician. He was born in Ireland, earned his medical degree from Cambridge University, and practiced at St. George's Hospital in London before leaving for the United States in 1867 to study homeopathic medicine in St. Louis, Missouri. Upon arriving in Philadelphia, however, Bell decided instead to join an expedition organized by the Union Pacific Roadway, Eastern Division (soon renamed the Kansas-Pacific) to determine the best southern rail route from Kansas to California. Through the influence of friends in Philadelphia and the personal recommendation of John Lawrence LeConte (1825–1883), the expedition's geologist, Bell was appointed the expedition's photographer, even though he knew nothing about making photographs. He spent two weeks learning the rudiments of the wet plate process from John C. Browne, editor of *Philadelphia*

Bell, William Abraham. Private George Ruoss.

Photographer, before leaving for Kansas, and Browne put together Bell's photographic outfit—camera equipment, chemicals, plates, darkroom tent, etc.—and shipped it after him.

Bell joined the expedition at its jumping off point, Ft. Wallace, near the Colorado border, in the heart of Indian country, and the focal point of the Indian Wars. Sgt. Wyllyams was killed shortly after Bell's arrival and he photographed the body as it was found. Perhaps because Bell was a physician and unsentimental about death, the image is straightforward and unflinchingly gruesome—Wyllyams' corpse had been stripped, horrifically mutilated, and shot full of arrows. When the photograph was reproduced soon afterwards in *Harper's Weekly* as a sanitized wood-engraving, surprised and dismayed Kansas-Pacific officials saw it as negative publicity and suspected that Bell intended to profit personally from the photographs. They were already dissatisfied with the quality of Bell's work and had hired Alexander Gardner as Chief Photographer for the expedition.

Before Gardner could reach the expedition, however, it left Ft. Wallace, traveled southwest across desert country to New Fort Lyon in southeast Colorado (close to the mouth of the Purgatoire River and near present day Las Animas), where it split into two parties. The northern party to explored south central Colorado, then followed the Rio Grande south to the rendezvous at Ft. Craig in southern New Mexico. The southern party, which included Bell, explored north central New Mexico west to the Rio Grande, then went down the Rio Grande south through Albuquerque to the rendezvous at Ft. Craig.

Alexander Gardner joined the survey at Ft. Craig, where the expedition was reorganized and again split into northern and southern parties. Gardner joined the northern party, which followed the 35th parallel to California. Bell went with the southern party, which traveled west along the 32nd parallel. However, Bell left the expedition when it reached Camp Grant in south central Arizona. Taking only what he could carry on his horse, and leaving his equipment and negatives behind, Bell rode across Mexico to the coast, caught a ship to San Francisco to return overland to the East Coast and on to England. Bell had been with the expedition about six months and had made perhaps 100 usable negatives, all taken in Kansas, southeast Colorado, and New Mexico. Kansas-Pacific officials complained that Bell's negatives were "not of much account. Most of them are too dim or not well finished and the photographer here complains much of the negatives and says the result is caused by carelessness."

William Abraham Bell's photographs proved useless for the purposes of the railroad, but his experience with the expedition benefited him personally. He wrote a best-seller account of his experiences, *New Tracks in North America* (1869), which proved so popular in both Great Britain and the United States that it went through two editions in two years. Moreover, while he was with the survey Bell had become close friends with it's leader, William J. Palmer, and when Bell returned to the United States in 1871, they became business partners and played a significant role in the development of Colorado. They founded the town of Colorado Springs, as well as the Denver & Rio Grande Railroad, and created a business empire that brought investments and settlers to the state

and made both men very rich. Bell himself founded the town of Manitou, which became an internationally famous health resort, and he lived there until 1890, when he retired to England, where he died in 1921. Briarhurst, the estate Bell built in Manitou, remains one of the town's major landmarks and tourist attractions.

Although William Abraham Bell one of the first to photograph in the difficult conditions of the American West, it cannot be said that he had a significant impact as a photographer. He never mastered the wet-plate process, and in the six months or so he was active as a photographer, made only a limited number of images, most of which were imperfect and virtually none of which were seen by the contemporary public, at least not as original prints. Only two Bell photographs—the one of the body of Sgt. Wyllyams and one of an agave plant—were included in the portfolio of 127 photographs entitled *Across the Continent on the Kansas-Pacific Railroad (Route of the 35th Parallel)* that Gardner produced for the Kansas-Pacific Railroad (and of the four largely complete examples of this very rare portfolio known, all but one is missing the Wyllyams photograph). *New Tracks in North America* is therefore the major reference to Bell's photographs, since its two volumes are illustrated with lithographs and wood engravings copied from photographs, many of them after Bell's photographs (and so credited), some after Alexander Gardner's (but not credited).

New Tracks is the most extensive contemporary account of Western exploration written by a survey photographer, but it is primarily an illustrated travel book that provides disappointingly little information about the trials and tribulations of photographing in the field that would have been useful to a contemporary or insightful to a modern photographic historian. Bell, however, took pains to acknowledge John C. Browne's tutelage, and he included Browne's formulas for coating and developing plates and for sensitizing papers in an appendix because they "did me good service all through my trip," blaming the West's exceptionally dry climate and alkaline water for the poor quality of his negatives.

Very little of Bell's work survives. In addition to the five prints made by Gardner in the extant copies of *Across the Continent*, the thirty-seven vintage albumen prints in the collection of the Colorado Historical Society (Bell's own set), the few vintage albumen prints in the collection of the U.S. Geological Survey, and the several prints (including vintage enlargements) formerly in the collection of Arnold Crane and now at the J.Paul Getty Museum constitute the only known examples of William Abraham Bell's original photographs. The prints at the Colorado Historical Society are all trimmed to an oval, measure approximately 5 ½ × 3 3/8 inches (13.5 × 86 cm), and are the work of a photographer interested primarily in recording visual information without any attempt to achieve dramatic visual effect. Bell was clearly uninterested in exploring the aesthetic potential of photography, and when he abandoned the expedition in he also abandoned whatever personal commitment to the medium he may have had.

BELL, WILLIAM H. (1833–after 1880)

American photographer

William H. Bell was born near Fredericksburg Virginia, into a family of photographers—his father and his four brother brothers were all in the business. The Bells moved to Washington, DC, in the early 1860s and opened a studio, F.H. Bell & Brothers, which employed all the sons at one time or another. Charles Milton Bell (1848–1893), the youngest son, took over Bell & Brothers in 1874, and within a short time the C.M. Bell studio became one of Washington's leading photographic firms. By 1870, however, William H. Bell had left Bell & Bros and relocated to Baltimore, where he opened his own studio. He remained in business there as a local photographer until at least 1880, when he is listed in the Federal Census. Nothing further is known of his life or career.

William H. Bell is a very minor figure in the history of photography, worth noting only because the similarity of their names and the fact that they were both in Washington, D.C., at the end of the American Civil War have led some modern historians to confuse and conflate him with the British-born Philadelphia photographer William Bell (1830–1910), a major figure because of his work for the Army Medical Museum (1865–1867) and the Wheeler survey (1872).

WILLIAM STAPP

BELLOC, JOSEPH AUGUSTE (c. 1800–c. 1868)

French photographer

Joseph Auguste Belloc was born in the beginning of the 19th century, in Montrabe, located in the Southwest of France (Haute-Garonne).

He began his career as a painter of miniatures and watercolors. Belloc's first photographic studio was mentioned in 1851. Practicing daguerreotype, he became involved in wet collodion development and improved the wax coating process, helping the pictures to keep their wet-like luster.

But the most important research he led was about color stereoscopy (3 dimensional photography). Known for his nudes and portraits, he looked for the best way to express the reality and found a new method. This practice considered erotic photography and was declared illegal by the police in 1856 and 1860.

However, he was aware of the new discoveries and tried to facilitate the technique. In 1856, he even registered a patent for a framework and presented his invention at the Société française de photographie of which he was member since 1854.

From the very beginning, he was implied in the photographic democratization, gave photographic lessons and wrote about ten treatises concerning the photographic processes, the way to use them, and some of practical advice.

"Les Quatre branches de la photographie," edited in 1855, was so successful that it was republished three years later.

When he disappeared in 1868, his studio was acquired by Gaudenzio Marconi.

MARION PERCEVAL

BEMIS, SAMUEL (1789–1881)

Dr. Samuel Bemis, a Boston dentist, made his first daguerreotype on April 19, 1840, using a whole plate camera he purchased from Jean-Baptiste François Fauvel-Gouraud of New York four days earlier for the considerable sum of $51. That camera is believed to have been the first sold in America by Gouraud, the American agent for Parisian camera maker Giroux et Cie, and the camera, along with the bill of sale, is preserved in George Eastman House, Rochester, New York, along with several of his early images. The twelve plates Bemis purchased at the same time cost him a further $24, with an additional dollar for carriage.

His first image, of King's Chapel Burial Ground in Boston, showing the small cemetery hemmed in by tall buildings, is also in the George Eastman House collection, which holds the only twelve identified images by him, several of which are variations on the same subject. On the reverse of the plate, Bemis recounted every stage of the process—"Boston, April 19 1840.—S. A Bemis's first daguerreotype experiment.—Iodizing process 25 mts. (apparatus new), camera process 40 mts.—Wind N.W., sky clear, air dry and very cold for the season. —Lens meniscus Daguerr's (sic) apparatus.—Time 4.50 to 5.30 p.m.; N.Y. plate, ordinary."

Bemis took his camera to the White Mountains in summer 1840, but, dissatisfied by the unpredictability of his results, within a year had lost interest in photography completely.

JOHN HANNAVY

BENECKE, ERNEST (1817–1894)

French photographer

Although Benecke's importance as an early traveler/photographer in the Near East has long been recognized, few of his works were identified until recently. Preceded in his voyage to Egypt by a number off well-known photographers including Maxime Du Champ and Felix Teynard, Benecke differed from them in largely ignoring Pharaonic and other ancient monuments in favor of ethnographic studies. When depicting buildings or landscape, he preferred views of unfamiliar scenes or monuments seen from unusual angles.

Though Benecke can no longer be regarded as the first photographer of everyday life in the Near East, his work remains the most comprehensive body of ethnographic views known from the region during the early years of photography.

A well-to-do amateur, Benecke made no effort to exhibit his work or to join photographic societies, and his biography remains among the most obscure of important mid-nineteenth century photographers. Benecke (1817–1894) belonged to an English mercantile family of German origin that was involved in textile manufacturing. The family firm, Benecke Brothers, had branches at various times in London, Manchester, Leeds, Lille and Alexandria. When the firm was dissolved in 1850, Ernest Benecke remained in Lille. It is not known when and where Benecke learned photography. By the time of his "grand tour" of Egypt, Nubia [modern northern Sudan], Syria, Lebanon, the Holy Land, Greece and Italy in 1852 he was active as a photographer, utilizing the paper negative process to produce salted paper prints. After his return, four of Benecke's studies appeared, some more than once, in albums produced in 1853 and 1854 by Louis-Desire Blanquart-Evrard of Lille, the leading European photographic publisher of the period. This publication of Benecke's work, the only one in his lifetime, may be assumed to be the result of a personal acquaintance in Lille between photographer and publisher.

The rare Blanquart-Evrard albums remained one of the few sources for Benecke's work until recent years. The appearance of an unbound portfolio of 143 signed and captioned prints or images by Benecke at auction in Germany in 1992 has lead to it great increase in knowledge about the artist's Work. Following the dispersal of this album, a second album with more than eighty photographs by Benecke was on the New York art market in 2003 (now Wilson Centre for Photography; London). Although fewer than forty of his images have appeared in widely scattered publications since 1853, a clearer understanding of his style is now emerging.

The largest number of Benecke's known photographs were taken in Egypt and Nubia. Often captioned in French, signed and dated in the negative, the images were made in Cairo, on the Nile, in the Sinai, various villages of Upper Egypt, and the Sudan. Little-known locations and even individuals are identified precisely in the captions. He also recorded ancient monuments in Upper Egypt (February–March 1852), including the temples of Kalabashie and Dakkeh and the Temple of Amenophis ill at El Kab near Edfou, often adopting steep raking angles or other unusual formats. Identifiable locations in Palestine include panoramic views of Jerusalem and Hebron; Benecke's broad, atmospheric technique is particularly well adapted to landscapes or cityscapes of this kind. On the return journey through southern Europe Benecke photographed at a number of well-known sites; including the Acropolis in Athens (August 1852) and the Ponte Vecchio in Florence. Benecke does not appear to have returned to the Near East. An isolated View of Nazareth published by Perez reportedly is dated 1858 in the negative; if this reading of the date is correct, the image was probably dated and printed belatedly.

Benecke's warm, brown-toned prints are technically imperfect, appearing slightly blurred when his human subjects have moved during the exposure. In his most successful portraits the subjects adopt a steadying pose and lower or close their eyes during the exposure, as in *Zofia, Woman of Cairo, in Harem Dress* of 1852. This image appeared in Blanquart-Evrard's album *Etudes photographiques, 1re seire* of 1853; it may be the earliest published photograph of an "Oriental," a genre that was to prove as popular in photography as it already had been for some decades in painting.

The most frequest subjects of Benecke's portrait studies are women, some heavily robed, others in showy "harem" attire (possibly professional dancers) or seminude. He also, however, depicted musicians, a slave dealer, a Bedouin chieftain with his retinue, and groups of children. Scenes of everyday life show a peasant pumping water from the Nile, a potter in his workshop, and the autopsy of a crocodile on ship board. He also made very fine studies of trees (two published by Blanquart-Evrard) and of vernacular architecture in Egypt and Palestine.

Several signed prints by Benecke bear the stamp of the well-known photographer Charles Marville on the verso, indicating that some or all prints from Benecke's paper negatives were not produced by the photographer himself. Prints of all Benecke images are rare, and many are unique; the negatives are not known to have survived. Despite Benecke's lack of interest in marketing his work, groups of his ethnographic studies were acquired by travelers to Egypt or the Mediterranean, including the art historian Emile Prisse d'Avesnes, the well-known sculptor Frederic-Auguste Bartholdi, and the English academic painter Sir Laurence Alma-Tadema. Some of the prints are numbered in the negative; these notations, which run well above the number three hundred, may indicate Benecke's intention to produce a large portfolio, either of his own work or in collaboration with other photographers, that has not been identified.

It is now known that Joseph-Philibert Girault de Prangey, not Benecke was the first to photograph everyday life in the Near East. de Prangey made nearly a thousand daguerreotypes during a voyage in 1844–45, including perhaps a dozen portraits of Egyptians and Turks. A handful of portrait studies, contemporary with Benecke, survive from elsewhere in the Near East, but Benecke's work, nevertheless, remains the earliest important body of Near Eastern ethnographic studies.

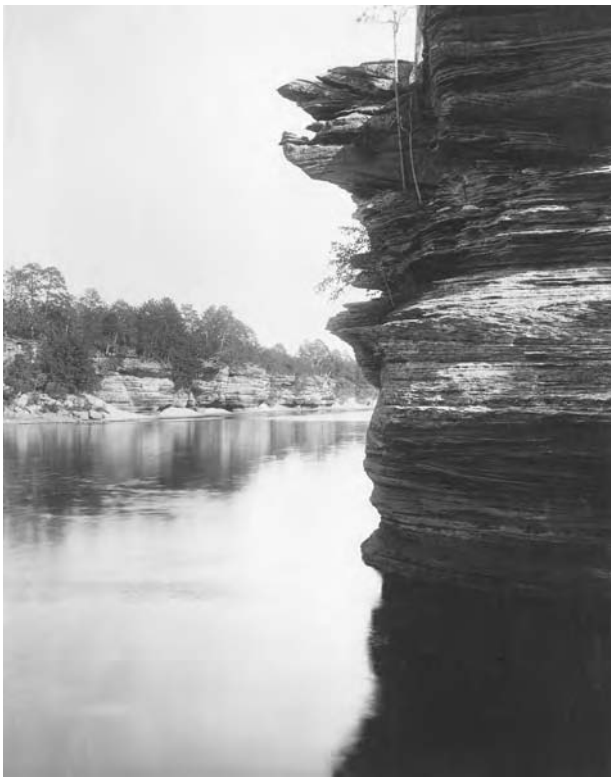
BENNETT, HENRY HAMILTON (1843–1908)

American photographer and inventor

Originally a carpenter, Bennett injured his hand with his own gun in the American Civil War. In 1875 he opened a portrait photography studio in Wisconsin Dells (then Kilbourn City), which is now a museum open to the public. Bennett quickly realised that he could not support himself and his wife just from taking studio portraits and turned his attention to his local landscape. In particular, the unusual sandstone geological formations



Bennett, Henry Hamilton. Wisconsin Dells.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

that ran for six miles along the Wisconsin river. By naming and photographing over 90 local features and other local history sites, he turned the Wisconsin Dells into a desirable, 'must-see' tourist destination. The prosperity he generated led him to market many stereographs for a growing tourist market. In the early 1880s he produced an entire stereo catalogue. Although financially satisfied, he wanted to produce exhibition quality photographs. He did this by using a mammoth plate camera and an eight-by-ten-inch view camera. Using his early carpentry experience, Bennett designed robust camera boxes, printing equipment and tripods that could cope with being used outside in the harsh natural landscape. He also designed a rotating print house, which enabled him to utilise all available natural sunlight to print images throughout the day. Bennett also developed an instantaneous shutter that aided photographing a moving person. This type of shutter allowed him to be able to freeze action and he produced one of his most famous photographs, 'Leaping the Chasm at Stand Rock'.

JO HALLINGTON

BENTLEY, WILSON ALWYN (1865–1931)

A pioneer in photomicrography and meteorology, Bentley spent his life on the family farm in Jericho, Vermont. Bentley never married and obsessively studied and recorded snowflakes, rain, fog, and dew. Bentley's formative years were influenced by his mother; a former school teacher, who was fascinated by all knowledge and possessed an early microscope. Bentley used the microscope to observe snowflakes and attempted to draw them until he convinced his parents to buy a bellows camera and microscope objective. In January 15, 1885, he became the first person to photograph a single snow flake and discovered that each snowflake is unique and individual. Working in relative isolation and without peer recognition for most of his life, Bentley was encouraged by a local professor to share his findings with the world outside of Vermont. In 1898 his first article was published in Appleton's Popular Scientific Monthly. He continued his research and published numerous articles in relative obscurity, until in 1924 he was awarded the first ever grant from the American Meterological Society for his lifetime's work. Bentley never copyrighted his work or did it for monetary gain as he considered his photographs to be 'illustrations of God's work in all its beauty.' His life's work was published in collaboration with Dr. William J Humphreys in 1931, and entitled 'Snow Crystals.' His work was carried out outside, in order to keep the snowflake frozen and intact, which may have resulted in his death from pneumonia in 1931.

JO HALLINGTON

BERGGREN, GUILLAUME (WILHELM) (1835–1920)

Swedish photographer

Berggren was born in Stockholm and in 1850 was apprenticed to a carpenter. In 1855 he traveled to Berlin, where he worked in a photographic studio. Later he traveled to other European cities, and in 1866 set sail from Odessa on the Black Sea to travel around the world.

> When Berggren reached Istanbul and toured the city he was so fascinated that he decided to settle there. He worked for a shipping company until the early 1870s, when he opened a photographic studio on Grand' Rue de Péra. His niece Hilda Ullin (1861–1953) arrived from Sweden and began to work with him.

Berggren was a master of technique and composition, and produced some of the finest scenes of Istanbul and the Bosphorus, and photographs of local people. During construction of the Baghdad railway he photographed many of the cities on the route.

When the Swedish King Gustaf V (1858–1950) visited Istanbul in 1885, he presented Berggren with a decoration. Berggren was also awarded an Ottoman decoration by Sultan Abdülhamid II (r. 1876–1909). When he died his niece Hilda Ullin buried all his photographic equipment with him in the Swedish cemetery in the Feriköy district of Istanbul.

ENGIN ÖZENDES

BERNOUD, ALPHONSE (1820–1889)

French photographer

Jean Baptiste Bernoud, known as Alphonse, was born at Meximieux, Lyon on 4th February 1820. He started his activity as a photographer by doing daguerreotypes on the Ligurian Riviera. In 1850 he worked with Lossier in Genoa at Palazzo Pallavicini, strada Scurreria. In the 1850s he moved to Florence, Santa Maria in Campo, 434, but he also opened branches at Siena, piazza S. Petronilla, and Livorno, via Ferdinanda 71. He became well-known for his photographic portraits, often touched up in watercolours. In 1854 he showed some daguerreotypes of animals at the Esposizione Industriale Toscana in Florence. In 1856 he moved to Naples, via del Boschetto della Villa Reale and then in Palazzo Berio, via Toledo 256. He continued to work in Florence until 1878, in via dei Balestrieri, 434, via dell'Oriolo, 51 and in via del Proconsolo. He took part in the Paris Exhibitions of 1855, 1857, 1867. At the Italian Exhibition in 1861 he won a prize for his "cartes de visite" and his stereoscopic views. He photographed important events: the earthquake of December 1857 in Naples, the fall of the Regno delle Due Sicilie in 1860–1861 and the eruption of Vesuvius in 1872 (P. Becchetti collection,

Rome). He published famous albums such as *L'Italia contemporanea* (1864), with portraits of historical figures. After 1872 he sold all his Italian studios and returned to France. He settled in Lyon, in rue Camille and later in rue des Archers 2, devoting his activity mainly to portraits. Here he died on 24 November 1889.

SILVIA PAOLI

BERTALL, CHARLES ALBERT, VICOMTE D' ARNOUX (1820–1882)

French painter and photographer

Bertall was born Charles Albert, vicomte d' Arnoux, comte de Limoges-Saint-Saëns, the 18th of December 1820, in Paris, France. He studied drawing with neoclassical painter Michel Martin Drolling 1786–1851 and began his artistic career as a draftsman for popular novels—he illustrated Honoré de Balzac's, from 1843 —and newspapers.

At the same time, Albert d'Arnoux changed his complicated name for Bertal (an anagram of his first name), which became Bertall on Balzac's advice.

In the middle of the century, he met Hippolyte Bayard, one of the most active people in the photography realm, and became involved with photography. Together they opened a studio in 1862, place of Madeleine in Paris, specialized in portraits and art reproduction. They separated themselves in 1866—the same year he enrolled in the Société française de photographie Society—but Bertall continued this activity under the name Bertall and Cie and portrayed the artists and intellectuals of his time.

From the beginning of the 1860s, he wrote his own novels and illustrated them. He kept both occupations: writing and illustrating books, and taking photographs of his contemporaries.

He died in the South of France, in his retirement in Soyons, in February 1882.

BERTILLON, ALPHONSE (1853–1914)

French photographer

Alphonse Bertillon, who developed the first scientific prisoner identification system though the use of photography, was born on 24 April 1853 to Louis-Adolphe and Zoé Bertillon. After an academic career marked by his expulsion from countless schools, Bertillon earned a baccalauréat at the advanced age of 20. He then completed mandatory military service and perfected his English by working as a tutor in England.

Bertillon's poor academic qualifications and his lack of interest in any apparent career worried his father. The elder Bertillon used his connections to obtain an entry-level job for his son as a clerk with the Prefecture of Police of Paris in 1879. The job required Bertillon to file information on criminals but the filing system was so unwieldy as to be virtually useless. The French police had collected masses of information on criminals but no systematic organization system existed so the information could not be accessed. Folders simply piled up in the filing office. Bertillon immediately recognized the need for a more efficient system of management.

Criminal identification in France before Bertillon was based on photographs, personal recognition, and alphabetical registration. The French police had been taking daguerreotypes of prisoners as early as 1841 but neither the pose nor the lighting conditions were standardized. Additionally, a photograph became obsolete as soon as the shutter snapped. The picture did not age as did its subject. If a criminal was identified, no clear language existed to transmit the details of the photograph to police officers since the definition of "large" or "average" is not precise. The French police had no ability to positively identify a person, especially when criminals were in the habit of using disguises and aliases to conceal their true identities.

Bertillon believed that nature did not repeat itself. A mathematical system of identification would permit easy recording and retrieval of information. But when Bertillon submitted his proposal on 1 October 1879, he was advised by the chief of police to seek psychiatric

help. The French authorities did not appreciate the ideas of a mere clerk, especially one who had a reputation for being reserved and angry. Louis-Adolphe Bertillon, advised to investigate his son's mental stability, recognized the merits of the new system and promoted it to his politically well-connected friends. When the old chief retired, Bertillon received the chance to test his system. In February 1883, he identified his first repeat criminal. By the end of the first full year of testing, he had identified 241 recidivists. When France established the Department of Judicial Identity, Bertillon became its first chief on 1 February 1888.

Bertillon pioneered many techniques of legal photography, including the mug shot. He introduced a system whereby a full face and profile portrait appeared upon every identification card. The photograph included a prisoner's ears because Bertillon believed that they could aid in identification. He took sectional photographs of the forehead alone; forehead including eyes; ears; eyes alone; nose alone; and half the profile. The existence of special marks, such as scars or warts was noted. Bertillon claimed that if a study of these sectional photographs was made feature by feature, someone could recognize a criminal despite never having seen the suspect's face before.

Although Bertillon incorporated photography into his system, he had doubts about the objectivity of the camera. To create the ability to effectively search for a criminal, Bertillon used a mathematical identification process that relied upon human body measurements known as anthropometry. This "*portrait parlé"* or speaking likeness would allow police officers on a beat to apprehend a suspect based solely on a verbal description. Translating bodily features into a universal language also allowed the transmission of physical descriptions by telegraph.

To make a speaking portrait, a prisoner would undergo eleven similarly precise measurements: height, head length, head width, arm span, sitting height, left middle finger length, left little finger length, left foot length, left forearm length, right ear length, and cheek width. Bertillon selected these specific lengths because they were the proportions least likely to be affected by weight change or aging. Bone structure would remain constant. This data was supplemented by the additional details of eye color, hair color, and skin pigmentation so that fourteen total points of resemblance were needed for formal proof of identity. The measurements were filed according to small, medium, and large dimensions. After a Bertillon operator measured a prisoner, he took a new identification card into an archive to look for a card with matching anthropometric values. If he found a tentative match, he would confirm it by referring to the photographs.

Bertillon's system worked best with male prisoners. Anthropometric measurements relied on tightly applying calipers and rulers to body parts. This practice required more physical intimacy between the Bertillon operator and the prisoner's body than was deemed appropriate for male jailers and female prisoners in the Victorian era. Nevertheless, by 1899 the Bertillon system had been adopted by Germany, Belgium, the Netherlands, Spain, Italy, Russia, Sweden, Norway, Turkey, Monaco, Luxembourg, Romania, and Switzerland.

The Bertillon system had a fatal flaw. The measurements had to be taken exactly as Bertillon specified or else they could be inaccurate. While Parisian Bertillon operators took careful measurements, men further away from the supervision of Bertillon were less careful. In one famous American case, two prisoners had the exact same Bertillon measurements, probably because of operator error. The men, who may have been brothers, looked almost identical. Fingerprints were the only way of distinguishing them.

Bertillon was an outspoken opponent of fingerprinting, chiefly because he did not see how fingerprints could be cataloged. However, unlike Bertillonage, fingerprinting was a foolproof means of identification. By the early years of the twentieth century, Bertillon's system had gone into eclipse, as fingerprinting became the judicial identification system of choice. By the mid-twentieth century, it had stopped being used. Bertillon died in Paris on 13 February 1914 of pernicious anemia.

CARYN E. NEUMANN

Biography

Alphonse Bertillon was born on 24 April 1853 as the middle of three sons of Louis-Adolphe and Zoé Bertillon. After attending many grade schools, he graduated in 1873. He traveled to England to teach French and held a series of posts as a tutor. Bertillon returned to France and, during military service, rose to the rank of corporal. He became a clerk in the Prefecture of Police in Paris on 15 March 1879. He formally proposed the Bertillon system it to the French police on 1 October 1879. He married his secretary, Amélie Notar in 1883. The couple did not produce any children. On 1 February 1888, Bertillon became the head of the newly established Department of Judicial Identity. The Bertillon system spread to other nations and Bertillon received a number of honors as a reward. His first honor came in July 1893, when he received the Swedish Order of Wasa. France gave Bertillon the Blue Ribbon of the Legion in 1893. Holland awarded him the Order of Orange-Nassau in 1896. In August 1898, he became a Knight of the Order of Königlichen Kronen (Germany). In March 1902, he became a Knight of the Order of Dannebrog (Denmark). Bertillon's subsequent awards were: 1902, Officer of the Order of the Star of Romania;

1908, Knight of the Order of St. Maurice and St. Lazare of Italy; 1913, Commander of the Order of St. Maurice and St. Lazare of Italy; 1913, Commander of the Order of Isabella the Catholic of Spain. He also received the Drummond Castle medal. Following a long battle with pernicious anemia, Bertillon died on 13 February 1914. He was buried with national honors in the family vault in the cemetery at Père-Lachaise.

BERTSCH, AUGUSTE NICOLAS (1813–1870)

French amateur photographer and civil engineer

Auguste Bertsch became a well known figure in photography. Bertsch invested little time in the daguerreotype during the 1840s, but that interest became more focused in 1851 during the second era of his photographic career, which spanned nearly twenty years. A few months after the dissemination of Englishman Frederick Scott Archer's negative process on glass, Bertsch put on sale a more sensitive collodion, which attempted instantaneous photography. The columns in the newspaper *La Lumière* created enthusiasm and controversy which centered around Bertsch's process but it was not long before he published the instructions of his process. In 1852 he submitted a patent application for a clever, but still imperfect shutter. This shutter included a mechanical and rotary system which was improved during the 1880s.

Nadar made great use of Bertsch's collodion from 1856. At that time Bertsch's associate Camille d' Arnaud, former newspaper writer, artist and friend of Nadar's as well, tried photography. Both Bertsch and d' Arnaud presented some images at Société française de photographie (SFP) in 1857, those of which included a few of the actress Adélaïde Ristori and the zoologist Henri Milne-Edwards.

Appreciated for their general clarity, and their sharp and soft lighting, their images did not promise, a long career in the field. Their workshop, established in 1855 in a laboratory located above Bertsch's apartment, which was unfortunately close to Pigalle's, did not have the acclaim of the other studios on the grand boulevards which catered to the Parisian middle-class. From 1854 to 1857, Bertsch's collaboration with d' Arnaud was rather profitable with successes such as the portrait of the Félicité priest on Lamennais on his deathbed, in 1854 in the Historical Musée of the town of Paris; of their instantaneous photography, like the image of pedestrians infront of the Blanche place, 1855, SFP; and of reproduction of engravings, and scientific photography (SFP).

Additionally, they attempted twice to produce images of an eclipse. They used the new glasses of Porro to photograph the moon eclipse on October 13th, 1856. The moon eclipsed itself little by little, and proved to be another occasion which illustrated the great sensitivity of Bertsch's collodion. On July 18 1860 they tried to photograph the multiple phases of a total lunar eclipse in Paris.

In addition to their interest with lunar photography, the microscopic world too was often under their meticulous observation. Several images are stamped dating to their collaboration, however, photomicrography was Bertsch's field which from 1851 to 1870, he most favored. Focused on optics and natural science, his advanced techniques enabled him to acheive results which exceeded what had been currently attempted at the time. He used the wet collodion process on glass with great dexterity, and reached exposure times of a tenth of a second according to his records. Moreover, the transparency of the glass, which combined reproducibility and smoothness of the image, adapted better to the photography of the infinitely small than that of the single plate daguerreotype (Foucault) or the less distinct calotype (Talbot).

The clarity of his stereotypes was also due to the quality of his solar microscopes, which used achromatic lenses which reduced spherical aberration, and they were sometimes fitted with a polarizer. Bertsch built these between 1852 and 1861, in conjuction with professor Hartnack's knowledge and aid in1857. Capable of proving undeniable evidence in the microscopic field, these photographs were, for Bertsch, the means of improving the scientific community. Now photographic proof of observations under the microscope could support or discredit theories. Scientific discredits were often the result of exaggerated and whimsical conclusions of certain negligent scientists. Acarina, the apparatus causing the phosphorescent glow of the glow-worm, cuts of wood, red globules, diatoms, and crystals were many subjects which when maginified from 50 to 500 times, illuminated under direct, oblique, monochromatic or

polarized light provided truth and illustrated the many possibilities of this medium.

A text entitled Studies of Natural History Under the Microscope provided the gallery for the microscopic "portraits" taken. The boards were joined together in a portfolio and made available for ordering. Presented at the SFP (1855, 1857, 1859) and at the World Fairs (1855, 1856, 1867), these were greeted by the press with special interest because of their precision as images. Additionally, they served as advertisements of a renewed union between photography and science. After sending his illustrated atlas to the Ministry for the State of Education, Bertsch was decorated with the Legion of honor in 1858. However, in spite of this reward and the remifications of its results to the Academy of Science in 1853 and 1857, the scientific community could not adapt to this method and thus remained indifferent to the technique.

As a founder and member of the SFP in 1854, Bertsch became part of the Board of directors from 1858 to 1870, and was often named at boards of examiners of apparatuses because of his selection of exposures. He regularly presented to them his improved work, devices, and techniques. The majority of photographers were often encumbered by imposing darkrooms in order to achieve enlarged photographs so Bertsch developed a technique based on the image captured on small instantaneous stereotypes, which was then increased. Between 1860 and 1863, he invented a solar megascope, which was among the best of the recently produced enlargers. In spite of Bertsch's desire to popularize photography, his remarkable instruments attracted only some followers.

Biography

A skillful technician and rigorous inventor-manufacturer, Bertsch was an easy and modest photo hobbyist who defended, with enthusiasm, his interpretation of photography. In spite of some obvious failures, praises that testified to his work registered him in history. He is considered by all traditionalists of historiography and as a figure not to omit. According to his birth certificate, Auguste Nicolas Bertsch was born on December 6, 1813 in the old 2nd district in Paris, today known as the 9th and not far from the Garnier Opera. He was the first child of George Frederic Bertsch, a tailor, and of Anne Francoise Landry. Bertsch lost his father at 9 years old, and married later in life, on March 29, 1865, to Marie Emilie Pizzetta, 28 years his junior. As a civil engineer, Bertsch began his photographic activities in 1851. He had moved in 1848 to the 5th floor of the 27 street Fontaine Saint-Georges and joined in 1854 Camille d' Arnaud, a student of Nadar's. Together, they created a studio-laboratory in the small panelled space of the 6th stage, but their collaboration lasted only briefly. A founding member of the Société française de photographie in 1854, he presented his work to them and defended his idea of photography. He remained there until his death during the Franco-German war in 1870-1871. Forgotten mainly in connection with the process of negative-glass, wet collodion, he was remembered for his application for creating photographs for microscopic use and for his apparatuses heralding the photographic practice at the end of the 19th century.

BEY, MOHAMMED SADIC (1832–1902)

Photographer, military officer

Born in Cairo in 1832, Sadic was educated in Egypt and in Paris, where he trained as an engineer at the *Ecole Polytechnique.* As a Colonel in the Egyptian army, he was the first to photograph the two holiest cities of Islam—Medina and Mecca—in 1861, and to document the *Haj.* Although the survey account and his photographs were not published until 1877 (*Summary of the Exploration of the Wajh-Madinah Hijaz Route and its Military Cadastral Map*), his accomplishment was widely reported. In 1880 he was assigned as treasurer to the annual caravan bringing the *mahmal*, the embroidered covering for the *Kaaba*, from Cairo to Mecca. He photographed the pilgrims as they camped along the journey and in Mecca again made photographs of pilgrims circling the *Kaaba,* the al-Safa Gate, the tomb of the Prophet's parents, and Shaykh 'Umar al-Shaibi, the guardian of the key of the *Kaaba*. In Medina he photographed Sharif Shawkat Pasha, the guardian of the Prophet's Mosque, and made panoramic views of the city from the walls. Sadic's earliest photographs of Medina were exhibited in the Egyptian pavilion at the Philadelphia Exhibition of 1876. In 1881, he displayed a portfolio of photographs of the holy cities at the Third International Congress of Geographers in Venice where he was awarded a gold medal.

KATHLEEN HOWE

BEYER, KAROL ADOLF (1818–1877)

Karol Adolf Beyer is one of the most important Polish photographers of the 19th century, and is best remembered for his famous photo-panorama of the city of Warsaw. Born on February 10, 1818, in Warsaw, Poland, Beyer was a publisher, numismatist and political activist, and also played a significant role in introducing new technological developments in photography into Poland and popularizing the medium. In 1844 Beyer opened one of the first daguerreotype studios in Warsaw, having become familiar with the daguerreotype process during a trip in 1842 to Paris and parts of Germany. He introduced the collodion negative process to Warsaw in 1851, which he had learned during a trip to London that same year. Additionally, Beyer published a number of photographic albums on a wide range of themes, and created photographic reproductions of important Polish national treasures and artworks. Around this time he also produced an important ethnographic photographic series, for which he photographed Polish peasants in their national and local costume.

In 1857 Beyer produced a photo-panorama of the city of Warsaw. Shooting from the cupola of Warsaw's St. Trinity Lutheran Church and using the wet-plate collodion process, Beyer took twelve sequential photographs in order to produce a 360-degree view of the city. Beyer continued to promote and advance photography in Poland throughout his life, co-founding the illustrated magazine *Tygodnik Ilustrowany* ("Illustrated Weekly") in 1859 and in 1870 opening the first studio in Warsaw to produce photographs using the Albertotype process, which Beyer learned from Joseph Albert while in Munich some years earlier. Beyer died on November 8, 1877 in Warsaw, Poland.

MAXIM WEINTRAUB

BIBLIOTHEQUE NATIONALE DE FRANCE

Photography is displayed in all departments of the Bibliotheque Nationale de France, however it is mainly located in the department, Cartes et Plans (Charts and Plans), and especially in the department Estampes et de la Photographie (Prints and Photography).

In 1851, the first image donated to the Bibliotheque Nationale de France was by Louis-Désiré Blanquart-Evrard, editor-photographer and was copyrighted, which at that time was optional because the law did not impose it on photographers as judiciously as they did with engravers. At least 100,000 images became part of the Bibliotheque in this way until 1914. Later images were purchased or given as gifts to supplement the donations, which were needed and remain necessary today as the Bibliotheque Nationale de France depends on the goodwill of photographers and the photographic dealers in France for additions to the collectioin held in the Bibliotheque.

Prior to 1941 the Bibliotheque had no protocol for handling donations so a service for collecting photographs was created within the Cabinet of the Prints at Jean Laran's request, who was chief of the Cabinet from 1939 to 1942. Jean Prinet followed until 1954, and later, Jean Adhémar from1961 to 1977, were the first people in charge of this new program. This was the starting point of a policy for voluntary and organized donations to the Bibliotheque as nearly 500,000 images had been collected between 1949 and 1961, and useful and profitable contacts with professionals, and experts of photography had been established.

In 1949, 50,000 images were acquired from the workshop of Felix and Paul Nadar, and in1954, the Reutlinger studio donated 30,000 images of Léopold taken in 1853. One of the first private collectoions of nineteenth centruy photography, established by George Sirot, which contained 75,000 images, were obtained via purchase in 1955, with the rest donated in 1956. Many images, letters, and handwritten notebooks of Louis-Alphonse Poitevin's, who was considered a major contributor to photography after Nicéphore Niépce and William Henry F. Talbot, were donated in 1989.

The first exhibition in France was held at the Bibliotheque consisting of portraits du passé (1961), Atget (1964), Nadar (1965), and Niépce (1967).

In 1976, the Cabinet of the Prints became the Department of the Prints and Photography. In the prestigious Mansart Fallery of the Bibliotheque, expositions became "an invention of the 19th century, expression and technique of photography," which paid full homage to the Société française de Photographie. 346 pieces of work were donated (1854). These events, which were accompanied by a catalogue that reproduced all the images, inspired the Bibliotheque to hold exhibits and rotate out images with other to allow the public and historians access to various different images to study them.

This initiative with the support of Metropolitan Museum of Art, 1980, became the year of the "Regards sur la photographie en France au XIXe siècle" (Paris, Petit Palate and New York, with 192 images and 102 photographers). In 1983, it introduced "George Sirot 1898–1977" (Paris, bibl. nat., approximately 170 parts), however, unfortunately, the show was without a catalogue. Then "Le corps et son image" was shown in 1986 (Paris, palate of Tokyo, 89 photographers, 171 numbers). The first two exhibitions increased the anthology of work. More modest achievements although, which were just as instructive and appreciated as other major works, were held in the Galerie de Photographie at the national Bibliotheque, which opened its doors in 1971. This space accomodated and was devoted to more than 120 exposures, the majority of which belonged

to young contemporary authors, until it permanently closed in 1996.

The year 1989 marked the celebration of the 250th anniversary of photography and included five major expostions in Paris. The national Bibliotheque hosted two of them, one in conjunction with the Musée d'Orsay which displayed a wide selction of 19th century images under the title, "L'invention d'un regard" (Paris, Museum of Orsay, 281 images belonged to a majority of these institutions).

Other exposures followed which depicted personalities, and subjects of a current period, revealing important dimensions to the donated material. Included were "L'Art du nu au XIXe siècle" (Paris, bibl. nat. of France) in 1997, "Les frères Bisson photographes" (Paris, bibl. nat. of France) and "Degas photographe" (in conjunction with the Metropolitan Museum of New York and the J. Paul Getty Museum, presented in Paris, bibl. nat. of France, New York, Los Angeles) in 1999, and "Voyage en Orient, photographies 1840–1880" (Paris, bibl. nat. of France) in 2001.

The national Bibliotheque participated in raising awareness of photography to the extent of establishing it as having culturally recognized value. The Bibliotheque also supported the movement through frequently lending their collections to other French or foreign institutions like "Nadar, les années créatrices 1854–1860" which was organized in 1994 by the Musée d'Orsay and Metropolitan Museum of Art, New York, and "Eugène Atget, le pionnier" which was put together in 2000 for the photographic Inheritance (Paris, Hôtel of Sully).

All the great names of photography are represented at the Bibliotheque like: Antoine Samuel Adam-Solomon; Olympe Aguado; Eugene Atget, of whom's work 3,600 images were purchased between 1900 and 1927; Edouard Baldus; Louis Auguste et Auguste Rosalie Bisson; Adolphe Braun; Etienne Carjat; Hippolyte Auguste Collard; Louis Emile Durandelle; A. A. Eugène Disdéri; Gustave Le Gray; Henri Le Secq; Charles Marville; Félix Nadar; Charles Nègre; Pierre Petit; and Victor Regnault. The images of the following photographers however are unfortunately rare or completely absent in the collections of the other French or foreign institutions: Charles Aubry; Bruno Braquehais; Adalbert and Eugene Cuvelier; Constant Famin; Jacques Antoine Moulin; Camille of Olivier; Achilles Quinet; Adrien Tournachon; Julien Vallou of Villeneuve are all underrepresented internationally.

Albums though, of voyages and early reports are located at the Bibliotheque such as Edouard Delessert's Italy, Gustave de Beaucorps' Spain, Ambroise Richebourg's Russia, and Maxime Du Camp's Egypt. Auguste Salzmann's images of l'Orient, along with accounts from Louis De Clercq, Felix Bonfils, James Roberson are available for viewing also.

Examples of pictorialism can also be located at the Bibliotheque, with many images from Alfred-Louis Begoz, Maurice Bucquet, Jean Ferdinand Coste, Robert Demachy, Etienne Descargues, René Lédard, Constant Puyo and famous publications such as the *L'Epreuve photographique*, *L'Art photographique*, *Camera Work*. Further documents included in the collections are nearly 1,800 single documents of nature in ambrotypes, ferrotypes, autochrome plates, daguerreotypes (plates by Louis Fizeau, Leon Foucault, Joseph Philibert Girault de Prangey, of the baron Large Jean-Baptist-Louis...), calotypes, plates with collodion, flexible supports by George Balagny, and various other formats.

The technical progress of photography was advanced by the hard work of pioneers such as Louis Ducos du Hauron who researched and developed the three-colour processes, Abel Niépce de Saint-Victor who worked with photogravures, Joseph Lemercier's work on lithophotographies, Alphonse Poitevin's exploration with photolithographies and coals, and finally Etienne Jules Marey's motion-analyses. Their advances and other made to standardized production in 1855, contributed to the popularization of the photographic image. The collection at the Bibliotheque includes portrait-cartes or *carte-de-visites*, 50,000 images of which, not counting the 18,000 images from Disdéri's workshop, were purchased in 1995, as well as carte albums totaling 18,000 images, and 20,000 stereoscopes on paper. These artifacts of photography have become invaluable testimony to amateur practices, starting with the beginning of photography where the images were of sitters in long-held poses to years later when the images and position of the sitter gave the impression of an instantaneous photograph. These are priceless documents for the historian as these images capture people in their familiar and private environments throughout time.

Although tracking and maintaining whole collections is a main priority for the Bibliotheque, some collections are donated in many separate donations, or are donated unlabeled. The dislocated collections however that are then reunited, happen largely because of the people that research them or because they are required by occupation to know about this information. This data of 19th century photographers is kept organized in a methodical table ordered by subject to facilitate the location of any image searched for. The Bibliotheque has gone to great lengths to organize the catalogues and monographs on the authors and the history of photography, both old and recent. This documentation has been exhaustive for the French publications, and the department's new site (Bibliotheque François Mitterand) supplements this. There are numerous files and, in particular, an abundance of correspondence including what survived the closing of the Nadar and Poitevin's workshops.

The department conducted the examination of

specialized reviews of the most important content published in the 19th century (*Bulletin of the Company French of Photography*, *Bulletin of the Photo-Club of Paris*, the *Light*, the *Monitor of Photography*, the *Review of Photography*) and gathered a collection of articles relating to the old exposures. This was then filed and sorted to provide easy referencing.

BIEWEND, HERMANN CARL EDUARD (1814–1888)

German daguerreotypist

Biewend was born on 28 August 1814 in Rothehütte near Hanover. He was a scientist and amateur daguerreotypist. He studied sciences and gained his doctorate. After his studies he applied in 1843 for a job as treasurer in the Royal Bank of Hamburg in Clausthal and got the rights of an inhabitant of Hamburg. He published many scholarly articles on chemistry and may have collaborated with another scientist to test lenses and cameras. He began to photograph sometime between 1846 and 1849, and he was one of the few German daguerreotypists to make landscapes and architectural views as well as portraits.

Biewend participated for a long time only as an amateur daguerreotypist who enjoyed little interest. This was because the photo historians only knew two daguerreotypes by him. That changed with the discovery of a lot of his work in a private collection of the Hamburg-photographer Werner Bokelberg (1937–).

Thanks to this discovery we do know that Biewend not only photographed architecture but also his family and friends. His portraits show often himself, his wife and children, his sister and her family. The portraits were most of the time taken on location, often posed outside his house or his sister's home in Germany. Typical in Biewend's photographs, is the persons often are placed full-length within the setting. The setting is integral to the composition, and to our understanding of the portrait as an intimate and informal family gathering. While Biewend had to deal with changing light and weather conditions he conquered the challenge of complete control of his lighting. The fine detail and delicate surface of his daguerreotypes gave his images a quality that was quite different from others and unique. He was an artist of rare delicacy and used sunlight and shadow to great effect.

Much information concerning Biewend has been found in his notes of 25 September 1843, like the fact that he took over the function of treasurer from Schirven Knoph. He worked during 33 years as a treasurer for the bank, from 1843 to 1876. This has been unknown for a long time. Just after the discovery of the daguerreotypes in the private collection or Bokelberg, someone started to do research in the old town files of Hamburg. Between 1846 and 1849 Biewend started to do experiments with photography. He experimented in his laboratory with gold, silver and other metals, as well as with indigo, saltpeter and potassium, pyrolusite and other chemicals. It is rather strange that in those times it was accepted to combine a job as a treasurer with a free practice. Biewend could clean gold and other metal very well and introduced this in his sensitive solutions, supposedly by his experience in his state office. There he had, of course, experience with very fine and detailed work like with gold and silver on the currencies.

That had to be correct during the manufacturing of currencies. The many details on Biewend's daguerreotypes are very characterizing for his work. He left behind a treasure of information on his daguerreotypes such as the type of camera, data of the subject, place, and time. Both the contents and the technical aspects of the photograph are defined, also a habit from his profession in the bank. Since daguerreotypes are on polished silver and subject to tarnishing, daguerreotypes were put behind glass and sealed with paper tape so air could not tarnish the plate (there often is some tarnish around the edges of the picture). Daguerreotypes that have survived show Biewend's skilled use of painted backgrounds, of curtained dummy windows. Several of these examples were handcoloured. Coloring was applied very carefully with dry color mixed with finely powdered gum, for the daguerreotype image is very delicate. Breathing on the plate was sufficient to soften the gum and fix the color. His portraits were among the best ever done

by daguerreotype process; they display great sense of composition, awareness of background and props, and naturalness in pose and expression.

Later, in the collection of Voigtländer, two daguerreotypes of Biewend were found, on which were mentioned the technical data. The photos of Biewend have supposedly arrived in Voigtlander's collection because they were related. He stayed in Saint Georg, is now a part of Hamburg.

Unfortunately, during the years people destroyed more than one hundred of his daguerreotypes with themes as landscapes, architecture and portraits. In 1876, he retired from the bank. Biewend died at the age of seventy-four on 31 December 1888 in Hamburg.

BIGGS, THOMAS (1822–1905)
English photographer

Captain, later Colonel, Thomas Biggs produced a body of work in India in the mid 1850s using post-waxed paper negatives, long after most photographers had eschewed paper in favour of collodion on glass.

Born in Hertfordshire, England, Biggs joined the Indian Army in 1842, serving in the Bombay Artillery, before learning photography with the East India Company and being seconded for a few months—from February to December 1855—to the post of Government Photographer in the Bombay Presidency, then the name given to a large area of British India.

His assignment was to start to document the many historic architectural sites within the area of the Bombay Presidency.

With the task only partially completed, he returned to military duty in December 1855, being succeeded by Dr William Henry Pigou who continued his work.

Certain aspects of the work did not suit his tastes —in letters in the India Office records, he expressed his distaste at some of the sculptures he was required to photograph and wrote of their 'disgusting immorality' (see *India Through the Lens*, Prestel, 2000).

A second series of assignments in the 1860s resulted in further images, still apparently using paper negatives, which were widely published. There is no record of him continuing with his photography after returning to England.

JOHN HANNAVY

BINGHAM, ROBERT JEFFERSON (1824–1870)

On the backs of *carte-de-visite* photographs produced by British-born photographer Robert J. Bingham in his studio at 58 Rue de Larochefoucauld in Paris was printed the claims 'inventeur du procedé collodion' and 'Medailles de 1re Classe 1855–1862.' He was a resident in Paris by 1851, and operated a portrait studio at that address from 1861 until 1870.

He was one of several photographers who claimed to have successfully experimented with collodion before Archer published his account of the process in 1851. His claim was based on a note in the 7th edition of his manual *Photographic Manipulation* published in 1850, a note which largely reproduced a similar account published by le Gray in his *Traite Pratique de Photographie sur Papier et sur Verre* in 1850. The process had been predicted since 1847.

Born in Billesdon, Leicestershire, England, in 1825, as the son of a customs officer. He moved to Paris c.1850, and his studio initially specialised in the photography of works of art. He was certainly in Paris by the date in 1851 when the contract for printing the illustrations for the Reports of the Juries of the Great Exhibition was being assigned. The contract was initially offered to him through the London art dealer Richard Colls, but was withdrawn after Talbot was granted an injunction in January 1852.

JOHN HANNAVY

BIOT, JEAN-BAPTISTE (1774–1862)
French scientist

Jean-Baptiste Biot was born in Paris 21 April 1774, the son of Joseph Biot, an upwardly mobile government functionary originally from Lorraine. After a classical education at the respected Collège Louis-le-Grand in Paris, Biot began taking private lessons in mathematics. Hoping for a career in science, he resisted his father's wishes that he enter into commerce. Enlisting in the army in 1792 allowed him to evade his father's control while simultaneously earning the experience and record of government service that helped him gain entrance to the newly formed École polytechnique in 1794. Biot soon emerged as an exceptionally promising young scientist with widely related interests in astronomy, optics, mathematics, physics, and chemistry.

In 1801, Biot was elected to the Académie des sciences. Soon after, he was invited to join the Société

d'Arcueil, the most fertile scientific circle of its day. There, in 1809, he became better acquainted with François Arago, a younger colleague in astronomy, with whom he would have a long and stormy professional relationship. They traveled together for the Bureau des longitudes and collaborated on several projects and papers early in their careers but soon developed opposing scientific views. By 1815, they were engaged in a polemical rivalry over competing theories of light, with Biot taking a conservative neo-Newtonian position while Arago embraced the new and more radical wave theory of light. Twelve years Arago's senior, Biot was an Orléanist and a devout, regenerate Catholic, an eloquent and dignified academic whose productivity in research and publishing nevertheless failed to win him an 1822 bid for the Académie's highest post of *Secrétaire perpetuelle*. To Biot's disappointment, this coveted, permanent seat would go to his rival in 1830, which provided the radical constitutional liberal Arago with tremendous power and influence. Biot had to be satisfied with his election in 1835 to the Académie's temporary post of vice president.

Despite their differences, Arago and Biot would soon become pendant figures as the two main academic supporters of early photography. With their mutual expertise in optical science, they made natural technical consultants for emergent photographic science, and Jacques-Louis Mandé Daguerre sought them both out in the mid- to late 1830s. In 1838, together with Alexander von Humboldt, they officially examined Daguerre's process prior to the Académie's first public report on daguerreotypy in January, 1839. Biot's remarks to the Académie at the January 7 meeting echoed those of Arago in describing the process as a formidable tool for empirical science; he saw the process as a new means "to study the properties of natural agents" and to supply independent proof of scientific assumptions. Concluding that first official communication on photography, Biot credited Daguerre with having placed an "artificial retina" at the disposal of physicists.

By this time, Biot and Arago had set aside some of the bitterness of their rivalry. However, when the British photographic inventor William Henry Fox Talbot learned that Arago had brought Daguerre's work before the Académie, Talbot cannily approached Biot to present his claim of priority of invention to the Académie. Biot was famously supportive of younger colleagues, a respected elder who embraced the ideal of an international, politically disinterested realm of pure scientific dialogue. In the months to come, Biot served as Talbot's advocate before the Académie on numerous occasions. Still, there was no obvious conflict between Arago and Biot over the Daguerre/Talbot contest. For his part, Biot had no significant personal stake in Talbot, although the men were acquainted through British scientific circles. However, Biot did have an old and dear friendship with Talbot's main ally and scientific advisor, Sir John Herschel. In acting as Talbot's representative before the Académie, Biot may have been acting upon the friendship and courtesy he felt for their mutual friend, Herschel. While giving Talbot a window to the official proceedings, Biot was careful to maintain his neutrality. From 1839 to 1841, he corresponded with Talbot in a spirit of honesty and good faith, giving advice and reporting to the English inventor on the Académie's continuing discussion of his claims. He also thoroughly examined Talbot's methods, and personally presented each of Talbot's successive communications and his own findings to the Académie, but he would not enter the debate as a partisan. Yet Biot ultimately expressed his frustration over the rivalry between Daguerre and Talbot—and other photographic inventors, for that matter—and plainly felt that Talbot's reticence to reveal his methods was harmful to scientific progress, as well as to Talbot's own best interest. More than once he urged Talbot to quit stalling and publish explicit descriptions of his methods. By the end of almost three years of Talbot's protracted struggles with the Académie, Biot was perhaps weary of carrying out the service of intermediary. When Talbot sent Biot some photographic papers and instructions for their use in 1841, Biot declined to examine them himself, but instead passed them on to Victor Regnault, a colleague with fresh enthusiasm for the new art.

Biot was not known as a photographer himself, and it appears he did not belong to any of the early photographic societies. His role in early photography was thus essentially that of a technical authority. In addition to examining Daguerre's and Talbot's processes, he joined Regnault in assisting Louis Désiré Blanquart-Evrard when Blanquart brought his paper process before a joint committee of members of the French academies of science and beaux-arts in April of 1847. There, Biot also agreed to an impromptu sitting to test the suitability of the process for portraiture. Indeed, unlike Arago, of whom no photographic portrait is known, Biot posed for a number of portraits, including sitting for Regnault at least four times. As a gesture of respect, Regnault sent some of those portraits to members of the British scientific community as mementos of this esteemed French scientist.

Biot was a respected writer on historical subjects as well as science, and over his long life he published more than 300 articles and many textbooks. He died in 1862 at the age of 88.

Laurie Dahlberg

Biography

Jean-Baptiste Biot was born in Paris 21 April 1774. Although his father wanted him to enter commerce, Biot

was drawn to science and mathematics. After serving in the revolutionary army (1792–1793), Biot entered the newly formed École polytechnique in 1794. His wide researches in physics, chemistry, mathematics, and subfields like optics won him the recognition of the great scientific leaders Laplace and Berthollet, who welcomed him into the elite Société d'Arceuil around 1801. His research and breadth of knowledge made him one of the first technical consultants in the emerging field of photography and as a member of the Académie des sciences he was appointed to examine Daguerre's, Talbot's, and Blanquart-Evrard's photographic processes, among others. A close friend of Sir John Herschel, Biot also agreed to serve as the intermediary for Herschel's associate William Henry Fox Talbot when Talbot brought forward his claims of priority for a photographic process before the Académie in 1839. It is not thought that Biot made photographs except in an experimental capacity and no works have been attributed to him. He died in 1862.

BIOW, HERMANN (1804–1850)

German daguerreotypist

Hermann Biow was born in 1804, possibly in Hamburg. Initially working as a painter, lithographer and writer, he was one of the first German daguerreotypists and opened his studio in August 1841 in Hamburg, Altona. From 1842 to 1843 Biow worked with the photographer Carl Ferdinand Stelzner. He evolved into a specialist portrait photographer. Biow is also well known for making documentary daguerreotypes of the aftermath of the 1842 fire in Hamburg, although only three of the supposed forty-six made at the time survived, now preserved in Hamburg, (Historical Museum and Museum of Art and Design). In 1846 Biow began practising portrait photography in Dresden, Berlin and Frankfurt am Main, focussing on prominent politicians, artists and scientists, including the Prussian King Friedrich Wilhelm IV, Alexander von Humboldt and the Brothers Grimm (1847) which were later engraved and published as *Deutsche Zeitgenossen* [German Contemporaries]. Between 1848 and 1849 he daguerrotyped the Parliamentarians of the German National Assembly in Frankfurt am Main, later edited in an album of lithographs, Männer des deutschen Volks oder Deutsche National-Gallerie" [Men of the German Nation or German National Gallery]. Biow opened a new studio in 1849 in Dresden, but died soon after on 20 February 1850.

Stephanie Klamm

BÍRÓ, LAJOS (1856–1931)

Lajos Bíró was a Hungarian natural scientist and ethnographer, born in Tusnád, Zilah county, currently Tusnad, Romania, in 1856. As a recognized zoologist he travelled to New Guinea, where he stayed from January 1896 to December 1901. During his six years of zoological, ornithological and entomological research, he collected over 200,000 animals, mainly insects and more than 6,000 pieces of ethnographical objects. He brought back several thousand pages of notes and more than two hundred photographs to Hungary. And upon returning home, he worked as a natural scientist. In 1926 he was awarded as an honorary doctor of the University of Sciences of Szeged, Hungary. He died in 1931, and more than two hundred animal species and eighteen genera are named after him. In deed, he discovered six new species, which can be found in his collection of birds and one was even named after him.

During his travels, he took documentary photographs for scientific, anthropological, and ethnographical purposes. His recordings made it possible to learn about a mostly undiscovered society of the tropical island with documentation, notes and references that are still referenced today.

In the course of his travels, Lajos Bíró went to several places outside Europe, like India, Ceylon, South East Asia, Anatolia, and North Africa. He took scientific photographs in Singapore, Bombay, Tunis, and Tripoli, but the six years spent in New Guinea were what established international reputation amongst Hungarian scientist.

His first expedition for zoological research was on 7th November 1895 to the second biggest island of the world to continue the work begun by the Hungarian natural scientist Sámuel Fenichel. He worked in what was the German New Guinea when the landscape was almost unapproachable due to the tropical climate, impenetrable jungle, high mountains reaching into the heights of 40,000 meters, and deep valleys. Incurable diseases like malaria, dysentery, and smallpox afflicted not only Europeans but natives, too. Therefore, several tribes fearing epidemics, mainly in mountain areas, lived extraordinarily isolated from each other.

Communication with the external world was further hindered by seclusion because of the specific laws of bartering, via language barrier, and by the lack of geographical information. As a result, at the end of the 19th century natives lived there at a level of development of the Palaeolithic age. This way of life was recorded with a high degree of precision and scientific authenticity by the documentary photographs of Lajos Bíró.

His work was hampered by numerous circumstances, like the murderous climate, language differences, difficulties with travel, and with obtaining and replacing instruments. However, in spite of these hindrances, he collected and prepared insects and birds often using every moment to conduct microscopic studies and to make notes, drawings and photos.

His most valuable photographs were taken on the northern and northeastern coastal regions of the island which had been undiscovered from an ethnographical point. The land that makes up this area are the little islands in front of Aitape (Berlinhafen), Seleo, Ali, Angiel (Angel Island); Erima in the Bay of Astrolabe, around Staphansort and its villages (Bongu, Bogadjime); several sites of the Mountains Hansemann, Oertzen, and Constantine, Bilibi (Bilibili Island), Siar, and Gragat Island, in the region of the Huon Bay. He visited the whole peninsula setting off from Simbang (close to Fischhafen). He also stayed with the highlander Kaio's, with the Jabim's living at the coast and visited Tami Island, and the Bukawa's living on the northern coast of Huon Bay. His travels also extended to the New Ireland Islands, and the (Vitu) French group of islands.

Lajos Bíró's photographs can be divided into four major thematic groups:

- Landscape, natural plants, and their transformation;
- Anthropological photos of natives;
- Recording their way of life, their culture, and traditions;
- Way of life of European settlers, and their settlements.

Full-length, standing or sitting, photos of the inhabitants of various villages are mainly group photographs or portraits made in relaxed, natural postures. Ethnographers were, however, were primarily interested in photographing places, objects, or activities of everyday life like, family houses, the yam stores, a meeting house under construction, the fish barrage, people travelling, agriculture, fallow lands of one and two years, yam plantations, coconut germination beds, or even snail bracelets, potters at work, and also people cooking dinner, or preparing kava. Similarly, the rituals of the closed communities, which were hidden from certain members of the community itself, such as the ghost house in Seleo, and ritual accessories like musical instruments, or festive rituals like the funeral feast, ritual dances, and partaking people, which is the circumcision of the young, were also of interest to ethnographers.

Since Lajos Bíró could see the inevitable effects that people like him posed to the colonial people and their culture, he considered photographing extremely significant and thought of it as his obligation to make the records of their status and development as authentic as possible. This deep sympathy and understanding can be well sensed in the informal atmosphere of the pictures.

Another of Lajos Bíró's interests was to photograph the living quarters of the Europeans. In one photograph in particular, the official building of the German Government can be seen in the shadow of huge palm trees. The house stands on piles, and has a spacious veranda richly decorated with artworks of local hand craftsmen. Among other images that were photographed was a grocery, a study of the officials of the German administration in Friedrich-Wilhelmshafen, supervisors and workers on tobacco plantations, which were directed by the members of the Neu-Guinea Compagnie, and the flagged building of Club Astrolabe in Stephansort. These places were designed with careful landscaping, indicative of a European presence. Europeans in tropical helmets, traders arranging bartering, and a Catholic missionary and his helpers working on creating a new settlement were also depicted in Bíró's photos as well.

Bíró used glass plates of 12 × 16.5 cm in size to make photographs. He had a transportable, folding camera with wooden framework made by W. Watson & Sons in London, who manufactured optical & photographic instruments in London, but also distributed their products in Hungary via the Calderoni firm. According to his notes, he indicated that he also used "the photosensitive plate [that] has been on me for 5 years already, no wonder, it did not give a good picture."

Considering the tropical climate, successful laboratory work was extraordinarily circumstantial. The high temperature of the water, as it seldom cooled down to 22-26°C even at night, made development difficult. Drying the plates was also difficult because of the high humidity of the air, and anything that was not completely dried often became mouldy immediately. Therefore, in order to make successful photographs, Bíró made meteorological observations. He measured the temperature of air and water, air pressure, and the quantity of precipitation. He then developed his plates during cooler nights, which allowed him to be able to replace bad quality pictures or damaged plates, if necessary.

Money was always an obstacle for Lajos Bíró. He once made money by selling photo plates of anthropological pictures of Papuans for 3 Marks each to a Ger-

man businessman who was collecting pictures for the Berlin Museum. The value of the pictures was increased by the fact that making such pictures was not simple. Concerned about their souls, local people did not allow photographs, or anthropological measurements of their height, or of their head, etc. to be taken of them. They were afraid of "bewitchment," and frequently ran away from both the camera and ethnographer.

The authenticity of his scientific photos and records is confirmed by his incredibly accurate notes. He documented the exact names of the people, their places of residence, the tribes they belonged to, their social status, and offered references and explanations for the clothes, behaviour, changes in the gesture, such as posture, or even mimicry. Bíró mentioned once, "I did not tell them what to do" and that he "just let them be as they wished." From his scattered notes we can see his working method: he developed the picture, showed it to the models, and then recorded their reaction in writing. In cases of photographed objects and landscapes, the place of origin, the name of the manufacturer, way of manufacturing, and the different parts and types were listed in 3 to 4 native languages. The same procedure was applied concerning the technical details of photographing, for example he numbered his pictures, supplied the brand of the film used, and what time of day the photo was taken and under what kind of circumstances such as "cloudy but sunny" or "sunny." Additionally, he documented the time increments the film was exposed for such as "momentary" or if a "delayed action" occurred, what "iris opening" he was worked with, and he even referred to the photographer's position, like "taken from a speeding train," and also gave the name of the developer. He also supplied reasons for why a photograph would be of a particular quality and he makes references to his experiments, which were aimed at making more perfect pictures. One such instance can be found in the documentations in his notebook describing his series of developing trials. It seems thus obvious that the value of the photographs taken by Lajos Bíró is not merely attached to their subjects like the discovery of the inhabitants of New Guinea and their way of life, but attached as well to his chosen and modern scientific method and the visual notes that accompanied and complemented by detailed textual explanations. This detailed work was not a widely applied practice for etymological and anthropological research at the end of the 19th century.

The original New-Guinean glass plates by Lajos Bíró and the album compiled from their prints, his Diary and the Singapore photo album are preserved in the Budapest Museum of Ethnography. The original, archive pictures, and other pictures made on his later travels to Egypt, and to the caves in Hungary are preserved in the Budapest Natural History Museum.

BISSON, LOUIS-AUGUSTE (1814–1876) AND AUGUSTE-ROSALIE (1826–1900)

Photographic firm owners (1852–1863)

On September 1, 1856 a British visitor wrote in "The Photographic Record and amateur Guide" that the photographic undertaking of Louis Auguste Bisson (1814–1876) and Auguste Rosalie Bisson (1826–1900) employed about 200 people. Of those, more than 50 constantly travelled through many European Countries taking photographs of which the photographs from Venice were particularly inspiring. The surviving documents from the same year depict about 30 men and women, who worked in the studios and produced latent images. From 1850 to 1860, the Bisson brothers took most of their photographs during the Fall.

In 1841 François Bisson (1795–1865) began to work in his home studio often devoting himself to the daguerreotype. A year later his son, Louis Auguste improved the daguerreotype process in such a way that his portraits became unrivalled in Paris. In 1843 the father and the eldest son opened a photographic studio in the Rue Saint Germain l'Auxerrois, which was well-known throughout Paris. At about that time, Bisson was offered the job of photographing the 900 elected representatives of the National parliament, the Assemblée Nationale. These patrons were wealthy and provided Bisson with a table high advertisement in the likeness of an 1850s panoramic daguerreotype, which was posted over the studio and could be seen from the Seine bank. These patrons also expected a certain quality that forced Louis Auguste to rise to a higher level of professionalism and ingenuity. Both Louis Auguste and August Rosalie established and displayed a most distinct command of photography, which later served as educational parameters and has been disseminated, often having influence on public opinion.

The introduction of the wet collodion process in 1851 in France brought the brothers to the realization that this process, in addition to the others they utilized, would greatly improve their already superior photography. Previously, Louis Auguste had mostly worked with his father in their studio, while August Rosalie had established a studio on Boulevard des Italiens with his partner P.A. Guevin, until 1851. Even though many small studios at the time were becoming established, both Louis Auguste and August Rosalie independently maintained their clientele and popularity because they had unique talents, which transcended to their photography.

Louis Auguste was interested in the technical aspect and had established a better daguerreotype process. He

had also patented a new dip developing process that consisted of bronze or brass on metal. August Rosalie was rather artistically inclined, as seen in his photographs of architecture, and made some of the most beautiful photographs of the 1850s, for example "The Interieur of the cathedral of Rouen" (1858) or the large-sized photographs of Parisian Louvre (about 1854).

Soon, however, the brothers joined efforts because of the great competition amongst the various portrait-studios in the French capital and because although they were already partly paid, the portraits of the elected representatives were still unfinished. Unfortunately due to the revolution of 1848 and the tumultuous internal political disputes, many members left the Assemblée Nationale, and the capital all together. Another reason for forging this partnership was because of the success of Gustave Le Gray's work in the Exposition des Produits de l'Industrie, Paris 1849 in which the Bissons

participated as well, receiving a bronze medal for their photographic prints on paper. The relatively small world of participants of innovative photographic "amateurs" considered every photographic invention as an occasion to think over their own photographic process, to rationalise it, and to try to figure out how to make it better.

Shortly after, the Bisson brothers became the coveted firm for architectural photographs, and not just in France, but post 1854, in Spain and Italy as well. They enjoyed the freedom of independent contracting, but were also wary of working for themselves. Their freedom allowed them to choose the photographic themes and fields, who they worked for and what type of work they did. For instance Auguste Rosalie was employed by the Scientific museum in Paris (Musée d'histoire naturelle), and the Louvre (with Charles Blanc) to make reproductions for a publication on and of the etchings of Rembrandt. Their concern though lay in the fact that their choices and livelihoods were their own responsibility.

In 1854 the Bisson brothers became acquainted with the Alsatian industrial Daniel Dollfus-Ausset, who had been interested in the two photographers since 1849, and asked them to travel to the Alps to take photographs of the glaciers. Dollfus-Ausset researched how the glaciers developed and retreated. Unfortunately, his discovery was criticized in by the scientific community. Auguste Rosalie Bisson's first attempt to reach the summit of Mont Blanc, in August 1859, to photograph the Alps failed. A second expedition in July 1860 became prematurely terminated because of abrupt weather. On July 24, 1861, Auguste Rosalie reached the top and took three photographs. It was written by the photographic journal "La Lumière" that "two very good" and one was simply "good."

In June 1854, the Bissons presented the amazing "Panorama—copie de cour de Louvre," 105 × 45 cm. The panoramic view was created by three compounded negatives, and was used by Dollfus-Ausset to serve his academic purposes at the Academy of Sciences. In August 1855, August Rosalie spent nearly a month in the Alps taking photographs from the mountains and the glaciers. The "Panorama of the Aar-glacier," 182 × 50.5 cm, was one of the first photographic commentaries about a natural glacier. In August 1855, Auguste Rosalie photographed the landscape of an earthquake's aftermath. This first photographic report after an earthquake, depicted the Alps in a way that no one had ever seen and was a sensation in the Parisian photography and scientific circles.

At the end of 1855, the brothers set up a limited partnership with a large contribution from Dollfus-Ausset. Their new commercial address on Boulevard des Capucines was known to be the finest in Paris. The years 1856 to 1858 were the most successful of their historical enterprise. The fast expansion and popularity of the studio attracted even royalty, when in 1858 the emperor, Napoléon III and the empress Eugénie, visited. Participation in international exhibitions, where by their frequent mention by other photographers, perpetuated the idea that the "Bisson frères" were known as one of the most important photographers not only in France, but in Europe as well. The diversity of the Bisson brothers' talent, from reproductions of etchings of Rembrandt's, to the photography of Dürer's architecture, and especially the photographs from the Alps, drew not only artists and amateurs to the luxurious reception rooms on the Boulevards des Capucines, but also large audiences that often wanted their portraits taken. The Bisson brothers became wealthy from these profits and used them to cover all the costs of the photographic expeditions to the Alps.

In the end, both brothers generated little "profit" from those burdensome and life endangering expeditions. Not even one of the photographs from top of Mont Blanc or a composition of Napoléon III was included in the two family albums. In fact, it was rumoured that Auguste Rosalie's successful expedition to Mont Blanc contradicted the reports of his contemporaries, the expedition companions, as well as of the editor of "La Lumière," Ernst Lacan, whose authority remained typically unquestioned. Interestingly, no photographs exist of the failed climb up the Mer de Glace in September of 1860 by Napoléon, Eugénie, and the Parisian Court.

The extensive travels of the Bisson brothers in France, Belgium, the Netherlands, Germany, and Italy as well as the commercially disastrous expeditions in the Alps allowed Dollfus-Ausset to withdraw from the limited partnership "Bisson frères." "Bisson frères" was given 5 years to liquidate their debt, but failures in marketing, opportunities and stubborn independence marked the end of the firm in 1863. On December 29, 1863 the company declared bankruptcy and on January 1, 1864 their photographic studio closed forever.

Milan Chlumsky

Biography

Louis Auguste Bisson was born on April 21, 1814, and died on May 12, 1876 in Paris. Louis Auguste took drawing lessons at home, studied architecture, and later became an architect of the Parisian municipal administration in 1838. In 1841, Louis Auguste was most likely given instruction from Daguerre himself. Enthusiastic about chemistry, he opened a Daguerre studio for portraits with his father. He better developed the procedure by shortening the exposure time. Within three years he claimed six patents, and presented them to the Academy of sciences. In 1847 he established his own studio, and developed an interest in Galvanic plastic. The revolution of 1848 destroyed the basis of the industrial firm that he ran with Armand-Pierre Gaugain.

Between 1848 and 1849 he made the daguerretypes of the 900 members of the Assemblée Nationale. In 1851 Louis Auguste became a founding member of the "Société héliographique." The "photographic print shop" of the Bissons in the Rue Garancière, was next to the industrial area of Paris, which was where the brothers made prints from their own negatives as well as from other colleagues' negatives. In 1855 he expanded his studio up to 3 stories with 5 rooms in which to develop pictures. After he becomes bankrupt, the 59-years old Louis Auguste collaborated with Emile Placet, after which he ended his photographic career.

Auguste Rosalie Bisson, was born May 1, 1826 , and died on April 22, 1900 in Paris. He learned the daguerreotype process from his father and brother. He assisted his brother with the photographs of 900 members of the Assemblée Nationale. In April 1850 he was appointed to the Weight and Measure Office in Rambouillet . For a short time he maintained a photographic studio with Guevin in Paris, where he seldom worked because of his employment in Rambouillet. In 1852 he became a partner with his brother Louis Auguste but left in February of the same year, however he collaborated extensively with his brother before photographing the Alps and Italy. On July 24, 1861, he reached the summit of the Mont Blanc. After going bankrupt in 1863, he established an undertaking with the youngest Bisson, and specialized in architectural photography. In June of 1866 his firm failed, and so became an independent collaborator for other photo studios. In 1868 he again attempted to climb the Mont Blanc for the photographic firm "Léon & Lévy." He travelled to Egypt in 1869 with Edouard Welling. In 1873 he photographed the new halls of Le Louvre for the firm "Goupil," and in 1883 he provided services for "Adolphe Braun & Cie" in the Alsatian Dornach, and accompanied the son, Gaston Braun to Berlin. With this final travel, he ended his photographic career. Auguste Rosalie was also a member of the society of watercolour painters ("Société des Aquafortistes ") in Paris.

BLACK, JAMES WALLACE (1825–1896)

American photographer and inventor

The son of a carpenter, Black was born in Francestown, New Hampshire, on 10 February 1825. Apparently orphaned as a teenager, he worked in a Lowell, Massachusetts tannery and then in the town's Boott Cotton Mills from 1842 to 1844. In 1846 he learned daguerreotypy from John A. Lerow in Boston and then served as an itinerant photographer for several years before returning to Boston to work for L.H. Hale & Company where he operated the rotary buffing machine used to polish the silver-coated daguerreotype plates. Black partnered briefly with Loyal M. Ives and then began apprenticing with John Adams Whipple around 1850 at 96 Washington Street. He became a full partner in 1856 and until 1859 they operated under the name of Whipple & Black. At the height of its success, their studio rivaled that of the well-known firm of Southworth & Hawes with whom they maintained a healthy competition.

One of the mainstays of any photographic business in the nineteenth century was portraiture, and Black was well known for his ability to secure the best moods and expressions in his clients due to his "natural courtesy and gentlemanly attention." However, Black seems to have been more interested in composition than in capturing the psychology of his sitter, favoring pyramidal compositions and massing of figures that enabled him to play with positive and negative space.

This experimentation with composition is reflected in a project he undertook in 1854 to photograph the landscape of his native New Hampshire. Taken fifteen years before the great landscape photographs of the American West, Black's photographs represent some of the earliest views taken with the glass negative/paper positive wet plate process, in this case, the crystalotype process pioneered by Whipple and which Black was instrumental in improving. According to art historian Sally Pierce, while the resulting salted paper prints lack the sharpness, detail, and sense of depth that can be found in albumen prints, they have a textural quality that works well in capturing the rugged landscape of the New England countryside.

For unknown reasons Whipple and Black dissolved their partnership in 1859. After leaving Whipple, Black purchased the studio of J.B. Heywood at 173 Washington Street and in 1860 formed a partnership with itinerant daguerreotypist Perez M. Batchelder. The new firm was known for its high-quality cartes-de-visite and stereo views and was praised for the artistry of individual and group portraits.

In 1860 Black attempted to take aerial views of Providence, Rhode Island, but had difficulties developing the wet collodion plates in the makeshift darkroom he set up in the basket of the balloon. In October of the same year, he produced six successful negatives of Boston, including views of the downtown and waterfront, from a balloon tethered above the Boston Common. These were the first aerial views taken in America, a feat that was well publicized in the photographic journals and local papers.

In 1861 Black began experimenting with using porcelain as a photographic support. The process was praised for its softness, delicacy and resistance to fading, and taken up by other photographers in the area, including Whipple.

After his partnership with Batchelder dissolved in 1862 Black continued the business on his own for several years and was quite successful. He expanded his studio space into another building and, according to contemporary accounts, employed anywhere from three to sixty assistants. An 1863 advertisement from the Boston Directory describes the firm's services: cartes-de-visite and life size portraits in oil, pictures finished in India ink and watercolor, an operating room that could accommodate large groups, the copying of daguerreotypes, and cartes-de-visite "enlarged and finished in any style, and in the most perfect manner." Black was also known for his generosity in showing people, including other photographers and inventors, around his studio.

John G. Case was Black's partner from July 1864 through February 1867. During that period they did an extensive business at the Boston location and also operated a studio in Newport, Rhode Island. In 1864 there were about seventy photographers operating studios in Boston. One contemporary observer claimed that Black's was the largest, occupying a "wilderness of rooms" and employing as many as sixty people. There were 40,000 negatives, nearly twenty tons of glass according to this observer, stored throughout Black's establishment at 163 and 173 Washington Street.

Among Black's best-known photographs are views of the Great Boston Fire of 1872, which destroyed over one thousand buildings in the city's commercial district. His studio on the north side of Washington Street was saved, but all the buildings across the street were gutted. Black made over 150 large and small albumen prints of the destroyed "burnt district" that he sold for $3.00 and $1.50 respectively. He also made magic lantern slides of the ruins. Although many photographers took pictures of the fire's aftermath, those by Black were widely published both nationally and abroad and compiled by Black in *Ruins of the Great Fire in Boston. November 1872* (Boston, 1873). As Pierce has noted, the images are successful because of their unique point of view: rather than photographing large areas of damage, Black focused on architectural structures and unusual details such as piles of wet clothing and included people in his views to emphasize the devastation caused by the fire.

In 1874 the firm name was changed to Black & Co. and in 1876, Black's assistant John L. Dunmore became a partner. In the later years of his photographic practice, Black and his partners created large format images of a variety of subject matter, including military subjects, factories, public buildings and residences, special events, and works of art. Black began to experience financial difficulties in the second half of the 1870s, but continued working until his death from pneumonia on 5 January 1896. His son Otis Fisher Black took care of the studio's business affairs until its close in 1901. Selections of Black's work can be found in the following collections: *Boston Athenaeum, Boston Public Library, Bostonian Society, Massachusetts Historical Society, Society for the Preservation of New England Antiquities, and the International Museum of Photography, George Eastman House*.

MICHELLE LAMUNIÈRE

Biography

Black was born on 10 February 1825 in Francestown, New Hampshire. He first learned daguerreotypy from John A. Lerow in Boston in 1846, but his most important affiliation was with John Adams Whipple with whom he partnered from 1856 to 1859. Black married Frances Georgianna Sharp, the daughter of painter and lithographer William Sharp, on June 9, 1859. Their two surviving children, Olive P. Black and Otis Fisher Black, were born in 1861 and 1867 respectively. In addition to his portrait work, Black's noteworthy projects include New Hampshire landscapes, aerial views of Boston, and documents of the aftermath of Boston's Great Fire (1872). For nearly thirty years beginning in 1856 he contributed regularly to the exhibitions of the Massachusetts Charitable Mechanic Association, frequently receiving awards. He was also active in the National Photographic Association and a founding member of the Boston Photographic Union, later renamed the Boston Photographic Association. Black died in Cambridge, Massachusetts, on 5 January 1896.

BLACKMORE, WILLIAM (1827–1878)

William Blackmore was born in Salisbury, England in 1827. Having trained as a lawyer, he moved to Liverpool in 1848 and joined a firm of solicitors. He prospered and by the 1860s was one of the leading figures in the business of land grants in the American West, specifically in Colorado and New Mexico.

Blackmore had been interested in Native Americans since his teenage years and believed that photography was the best medium for recording the rapidly vanishing Native American communities and set about creating an archive of such images. He purchased photographs and commissioned photographers, both to copy photographs or to photograph Native Americans in their natural habitats or when their leaders visited Washington D.C. as part of delegations. Blackmore also published two sets of photographs of North American natives.

The work of some twenty-eight photographers were to be found in Blackmore's photographic collection. These included Antonio Zeno Shindler (d.1899), Alexander Gardner (1821–1882), William Henry Jackson (1843–1942), and Dr. William Abraham Bell (1841–1920).

In 1867 Blackmore's photographs were copied by Antonio Shindler to help prepare the catalogue for the Smithsonian Institutions first photographic exhibition in 1869, *Photographic Portraits of North American Indians in the Gallery of the Smithsonian Institution.* In 1872 the Smithsonian established a relationship with Blackmore to assist his project.

Blackmore's business ventures failed in the 1870s and he committed suicide in 1878. His collection, held in Salisbury after his death, was dispersed from the 1930s. The British Museum now holds Blackmore's core photographic albums of some 2000 images.

ANTHONY HAMBER

BLAIR, THOMAS HENRY (1855–1919)

Canadian photographer

Canadian-born Thomas Henry Blair arrived in America in 1873 from Nova Scotia, to earn his living as an itinerant tintype photographer.

He took up the already obsolescent wet collodion process, and filed a patent for the *Tourograph* camera in 1878, which folded into a box for carrying, and when assembled for use combined a camera with a small darktent for the preparation and processing of the plates. The camera was made for him by the American Optical Company, a division of the Scovill company.

The Blair Tourograph and Dry Plate Company, was established in 1881. With facilities in Boston, New York, Cincinnati and San Francisco, the company advertised that "Photography with Blair's Cameras becomes a Delightful Pastime." The *Boston Detective Camera* of 1884, and the *Lucidograph* of 1885 were just two of their successful designs.

Blair shortened the company name to the Blair Camera Company in 1886, but within a few years his interest in flexible film took him back into materials manufacture eventually becoming a major manufacturer of celluloid film in the 1890s, and also of roll-film holders and cameras—in direct competition to George Eastman. Blair's 100-exposure Kamaret camera was a direct rival to the Kodak, and the two companies were on a collision course.

Ousted from the management of his own company, Blair moved to Britain and established the European Blair Camera Company in London.

In America, the original Blair company was sold to Eastman in 1900, becoming the 'Blair Camera Division of Eastman Kodak.'

JOHN HANNAVY

BLANCHARD, VALENTINE (1831–1901)

Valentine Blanchard first exhibited at the Dublin International Exhibition of 1865, at which time he had a studio in London's Camden Town, having previously briefly been based in the Strand in the late 1850s.

By 1862, he had developed a technique for achieving very short exposures with his stereoscopic camera, producing popular instantaneous images of the bustle of London street life. Throughout the decade, his catalogue of stereoscopic cards was extended, covering every area of London.

An explosion at his Camden studio in 1870, probably caused by guncotton igniting, necessitated relocation, and he is listed at an address in Piccadilly from 1871 until 1875, thereafter at 289 Regent Street, the address on many of his surviving portraits.

Blanchard was a prolific writer on photography, contributing articles and opinions from 1860, and consolidating his reputation. In his book *The Silver Sunbeam*, published in 1863. John Towler refers to his formula for bromo-iodised collodion. By the 1870s, it was his portraiture rather than his urban landscapes which were being widely praised, with particular recognition being accorded to his control of diffuse lighting, and his use of a soft-focus lens.

After closing his London studios, he was elected a member of the Brotherhood of the Linked Ring's first meeting in 1892, and exhibited widely for much of the remainder of his life.

JOHN HANNAVY

BLANQUART-ÉVRARD, LOUIS-DÉSIRÉ (1802–1872)

French photo publisher, inventor, photographer, and essayist

Louis Désiré Blanquart-Évrard's name remains indelibly associated with the "imprimerie photographique" (photographic printing factory) he opened in 1851 in Loos-lès-Lille. This facility was the first of its kind in France, and the first in the world operating at such an industrial level. The printing workshop William Henry Fox Talbot established in Reading (England) in 1844 was not on the same level. Blanquart-Évrard was a photographer himself, as well as an inventor. On the basis of his important essay *La photographie, ses origines, ses progrès, ses transformations* (1869) he deserves also be considered a photo-historian.

Blanquart-Évrard was born in Lille on August 2nd 1802. Around 1826, he studied with an influential, young chemist, Frédéric Kuhlmann (1803–1881). Soon, he was an assistant in his teacher's laboratory. This background in chemistry became crucial to his future in photography. He also practiced painting, chiefly miniature painting on ivory or porcelain, earning a few awards in local exhibitions. It remains unclear when Blanquart-Évrard became interested in photography. Like many others involved in art and science, he seemingly reacted enthusiastically to the announcement of Daguerre's invention in 1839. Around 1844, he heard about Talbot's negative-positive process, and, from that moment on, devoted himself to perfecting this technique.

Blanquart-Évrard's first important results attracted public attention in December 1846, when he submitted several prints to the Académie des Sciences in Paris, and in January 1847, when he was invited to present his research. The academy warmly supported Blanquart-Évrard's work, summarized in a treatise he published the same year. Though he didn't explicitly acknowledge it, his process was very close to Talbot's, but he improved it in many respects. The main difference was that Blanquart-Évrard sensitized the paper by floating it into the silver solution instead of merely applying it superficially with a brush. Soaked with the solution, the sheet became more sensitive, and the proofs more accurate and stable than Talbot's. Later, in 1849, Blanquart-Évrard experimented with glass plate negatives prepared with albumen; one year later, he applied this process to paper negatives.

From the beginning, Blanquart-Évrard's work was aimed toward adapting photography to industrial production. His whole research was made in view of achieving this goal, and the creation of a photographic printing factory. There was a growing interest for this project in French photographic circles. The Société Héliographique (created January 1851, later Société française de photographie, SFP), was the locus of intense debate on the topic, as reported in their journal *La Lumière*. A photographic printing factory was envisaged as a major instrument for the progress of dissemination of photographs, making possible the publication of photographically illustrated albums, books and magazines—the dream of a future when photography would play a major role in visual communication. Not only focusing on technical features, Blanquart-Évrard also insisted on economical issues. According to his analysis, three conditions were necessary for such a factory to be profitable [*La Lumière*, April 13, 1851: 37–38]: ability to produce regardless of weather ("not to depend upon the vagaries of sun"); capability of supplying large quantities in a short time; and a price attractive to publishers. Blanquart-Évrard's motto was: "produce quickly, good quality, and cheap." He estimated that within one workday one could obtain 200 to 300 prints from a single negative, for 5 to 15 cents a piece, according to size. Moreover, provided the factory was well organized, 30 negatives could be treated in a single day, thus producing 5,000 to 6,000 prints. However, these estimates proved to be too optimistic.

From a technical standpoint, Blanquart-Évrard found the way "not to depend upon the vagaries of sun." Instead of a long exposure depending on weather conditions, he used the property of the latent image, which could be obtained in few minutes, then developed and fixed. The developing method represented a major advance. It provided more stable prints, too. Blanquart-Évrard submitted it to the Académie des Sciences in April 1851 and improved it constantly. He also presented it at the 1851 London exhibition, and explained in a new book, *Traité de photographie sur papier*. Once more, Blanquart-Évrard adapted Talbot's work, for Talbot had already used the latent image principle to obtain his negatives, but not positive prints.

Late in getting started, Blanquart-Évrard was overtaken by Eugène Piot, who released the first installment of his *Italie monumentale* portfolio in June 1851. Francis Wey praised Piot's success and blamed Blanquart-Évrard for being overly concerned with theory and too little with practice [*La Lumière*, August 17, 1851, 107 and 111]. Remarkably, Wey compared Piot's prints to "beautiful and large mezzotint engraving," thus emphasizing the nascent competition between photography and traditional printmaking for the market of illustrated publications. Eventually, Blanquart-Évrard's long-awaited *imprimerie photographique* officially opened in September 1851. As stated in an advertisement in *La Lumière* (September 28, 1851), its mission was "to propagate photography on paper by an abundant reproduction of prints."

Blanquart-Évrard's first publication bore the programmatic title *Album photographique de l'artiste et de l'amateur*. It was conceived as "a frame within which all the applications of the new discovery would gather," thus echoing the purpose of Talbot's *Pencil of Nature*. While many of the 36 plates remain unidentified, it comprised photographs by Baron Alexis De la Grange, Alphonse de Brébisson, Maxime du Camp, and Charles Marville. Architectural views (taken in France, Italy, Belgium, India, and Jerusalem) mingled with a Lebanese landscape by Ernest Benecke and reproductions of artworks. Art reproductions would be the subject of the second album, *L'art contemporain*, reproducing twelve paintings exhibited at the Salon in 1853, photographed by Hippolyte Bayard and F.A. Renard. In total, Blanquard-Évrard published 24 albums, of which Isabelle Jammes established a 555 entries catalogue raisonné (see "further reading"). They included masterpieces by Charles Marville—Blanquart-Évrard's principal photographer and the author of the most important monographs he published, *Les Bords du Rhin* (1853, 28 plates)—Henri-Victor Régnault, Henry Le Secq, Thomas Sutton, and Louis-Rémy Robert. It is most likely that some of the unsigned plates can be credited to Blanquart-Évrard himself (especially the three plates of *Paysages de Flandres*, 1853, according to Jammes); unfortunately, little information exists on his own photographic practice. The general publishing policy remained more or less the same as set by the *Album photographique de l'artiste et de l'amateur* (architectural views and reproductions of works of art, with some landscapes), with the exception of few genre scenes.

As anticipated, other publishers commissioned Blanquart-Évrard for the printing of negatives they wished to publish. This was especially the case with Gide & Baudry, a powerful publishing company specialized in travel accounts, archaeology, and scientific literature. Blanquart-Évrad executed the prints for two landmark photographic books they published, Du Camp's *Egypte, Nubie, Palestine et Syrie* (1852, 125 plates) and Auguste Salzman's Jerusalem (1856, 174 plates). Du Camp's album was a success, and about 200 copies were manufactured. A few of his photographs were also included in Blanquart-Évrard's own publications. Blanquart-Évrard also printed John B. Greene photographs on Egypt, gathered in *Le Nil*, a self-published album (1854, 94 plates).

Though groundbreaking and well planned, Blanquart-Évrard's venture was destined to fail. He underestimated the operating costs, and the photographic prints remained too expensive to produce, thus to sell. Instead of the few cents estimated in the Spring of 1851, he would ask 6 francs for the first 16x20 cm print, with the next from the same negative priced at 2 francs each. Consequently, *Album photographique de l'artiste et de l'amateur* plates (available individually, which was the case for all his publications) sold for 6 francs each. Moreover, even if Blanquart-Évrard's process was one of the best, salt paper prints were still not considered to be stable enough. The public was not ready to pay such prices for prints that might fade; a lithograph was much cheaper. Blanquart-Évrard cut prices down about 50% in 1854, but it was too late. The *imprimerie photographique* closed in 1855. By this time, other publishers like Goupil had stopped publishing photographs (mostly printed by H. de Fonteny, Blanquart-Évrard's most serious competitor)—though they would resume this activity in 1858, focusing on their own niche, reproduction of artworks, and using albumen prints, which were more stable than salt paper prints. In September 1855, Blanquart-Évrard formed a partnership with the English photographer Thomas Sutton. They opened the Establishment for Permanent Positive Printing in Jersey. It closed in 1857.

A major figure of the development of photography in the golden decade of the 1850's, Blanquart-Évrard devoted the rest of his life to new research (including color photography). In 1863, he published an important treatise, *Intervention de l'art dans la photographie*, in which he described the negative as raw material begging to be interpreted by the photographer, modulating shadows and highlights, in order to obtain a relevant and valid artwork. Such a conception predated the pictorialist aesthetic. But Blanquart-Évrard's main achievement after the Loos-lès-Lille factory closed was his major book, *La photographie, ses origines, ses progrès, ses transformations* (1869), in which he gave an accurate account of the first three decades of photography. Ironically, his book contained original silver prints, at a time when photo publishing as he had envisioned it was definitively threatened by the advent of photomechanical processes.

BOCK, THOMAS (1790/93–1855) AND ALFRED (1835–1920)

Australian photographers and studio owners

Thomas Bock, born 1790/1793 in Birmingham was trained as an engraver and miniature painter. He was transported as a convict to Van Diemen's Land in 1823. After being pardoned, he again pursued painting and engraving as well as lithography, teaching his stepson Alfred and son William the arts. While continuing to paint mostly portraits in 1847 Thomas opened Hobart's first established daguerreotype studio at 22 Campbell St. that he operated until his death on 18 March 1855. Alfred who had taken the only know photograph of his father in 1847 assumed control of the studio, helping to support his family. He moved the business not long afterward to 78 Liverpool St., taking over the premises vacated by Duryea and McDonald, then moved to 18 Macquarie St. in 1857, but he became insolvent the following year. Later during 1858 he reopened a studio at 140 Elizabeth St., called The City Photographic Establishment. Alfred offered ambrotypes, and later *carte-de-visite* and also sennotypes. He continued trading until 1865, before again declaring insolvency. In 1867 Alfred Bock moved to Gippsland, Victoria on account of his wife's health, opening a studio in Sale. In 1882 he moved to New Zealand and ran a studio in Auckland for six years, but he returned to Victoria in 1888, working there until 1899 when he went back to Tasmania where he worked until 1914. Alfred died in Wynyard in 1920. William Bock became a revered engraver working mostly in New Zealand where he was amongst other things heavily involved in postage stamp production.

BOGARDUS, ABRAHAM (1822–1908)

American photographer and gallery owner

Born 1822 in upstate New York, Bogardus learned daguerreotyping in the George Prosch Gallery in New York, in the mid-1840s. He opened his own gallery 1846 in lower Broadway, and later operated galleries in both New York and New Jersey.

Bogardus worked aggressively against patents limiting daguerreotype photography, & the 25 cent "cheap workers." He photographed in all of the various mediums over the years, including carte, wet plate, etc. He was the first President of the National Photographic Association, in 1869, and was re-elected seven times.

When he left photography in 1884, after four decades, a journal of the day said of Bogardus: "Everyone knows him well as one of the heartiest, jolliest, best-natured, whole-souled men in the trade. His success was great & he did an immense business….employing thirty assistants. During his experience he has taken the portraits of four Presidents and nearly all of the houses of Congress. He is a fine looking and large gentleman, with full grey beard; his after dinner speeches are much applauded."

After retirement he painted off-and-on and died in Brooklyn in 1908. Primary institutional holdings include The George Eastman House, and The National Museum of American History.

LARRY WEST

BOLAS, THOMAS (1848–1932)

Born in London in 1848, Bolas trained in chemistry at Charing Cross Hospital working under Professor Charles Heaton and with Dr. John Stenhouse. From 1872 he undertook private chemical work, lectured extensively, published his own research and worked

as a scientific journalist across several different fields. He coined the term 'detective camera,' demonstrating his own design in 1879 and edited several important photographic periodicals during the 1880s and 1890s and authored a number of popular photographic books. He died in Wimbledon on 1 March 1932.

Thomas Bolas was born in 1848 and in 1862 he entered the laboratory of the Medical School of Charing Cross Hospital working under Charles W Heaton who had just been appointed professor of chemistry. He remained at the hospital until 1876 becoming a member of the teaching staff and spending much of his time between 1865 and 1872 in the laboratory of Dr John Stenhouse FRS where he also worked alongside Raphael Meldola, a later photographic chemist and author.

From 1872 Bolas was primarily involved in private chemical practice and scientific journalism in particular in the fields of photography, printing, glues, rubber and railways. He was a regular contributor the *Journal of the Chemical Society*, *Chemical News*, the *Journal of the Photographic Society*, *Photographic News,* and other technical journals as well as a frequent lecturer across all these subjects. He delivered the Cantor Lectures to the Society of Arts on Photography in 1878, on India Rubber (1880), Industrial Uses of Calcium Compounds (1881), Photo-Mechanical Printing (1884) and Stereotyping (1890). He was a Fellow of both the Institute of Chemistry and Chemical Society. He was the author of an article on Indiarubber (*sic*) for the ninth edition of the *Encyclopaedia Britannica* and produced a handbook on glass blowing, an area in which he was particularly skilled, in 1898.

Photography seems to have been a particular interest to Bolas at a time when it was still possible for individuals to make contributions to photographic chemistry and theory outside of a formal academic or commercial laboratory. He joined the Photographic Society in 1875 and played a prominent role in the Society's activities for many years.

Bolas constructed and demonstrated a hand or 'detective' camera at the Photographic Society in late 1880 which he had designed to make use of the newly introduced and more sensitive gelatino-bromide plates. The design which was reported in the *Journal of the Photographic Society* on January 21 1881 described a camera with separate viewing and taking lenses (essentially a twin lens reflex camera) enclosed within a wood box with room for thirteen double dark slides. The camera measured 12 inches square by 5 inches deep and Bolas showed photographs of London street life taken with it. The camera's design ensured that it could be used without being detected by the subject and the design was taken up by the Criminal Investigation Department of Scotland Yard. The camera was further refined by Bolas who introduced a cylindrical shutter to the camera which was the subject of a provisional British patent number 4823 of 3 November 1881. The term 'detective camera' coined by Bolas was quickly adopted by other makers of box form hand cameras and was widely used until the late 1890s. Bolas's own design does not appear to have been produced commercially and other similar designs, notably the Schmidt Detective camera patented in the United States in 1883 and numerous British designs quickly achieved popularity.

Bolas experimented at an early date with using burning aluminium leaf metal in oxygen in 1893 although little was to come of this for widespread photographic flash lighting until 1925. In conjunction with a lecture-demonstration on 'The Physics and Chemistry of Development' given by him at the Cordwainer's Hall on 11 March 1895 to the Photographic Society and published in the *Journal* on 30 April1895 Bolas made the first Hertzian or wireless signal transmission in the City of London.

Bolas edited the *Photographic News* from 1884, after Henry Baden Pritchard's death until 1891 during which time he gave the journal a greater emphasis on the science of photography. He edited the associated *Year Book of Photography* from 1885 until 1893. He also published his own journal *The Photographic Review* from 6 July 1889 until 18 January 1890 to provide 'a weekly commentary on photographic progress.' Publication resumed from February 1890 with a new editor and publisher. He edited the seventh and eighth editions of *Wall's Dictionary of Photography* and wrote two popular books for the large photographic retailer and manufacturer Marion & Co.: *The Photographic Studio. A Guide to its construction, design and the Selection of a Locality* (1895) and *A Handbook of Photography in Colours* (1900). He also wrote other photographic books.

Bolas was described by the British *Journal Photographic Almanac* as 'a most original character with an immense fund of knowledge and whimsical humour' with an encyclopaedic knowledge of photographic and photo-mechanical work.

He ceased to be a member of the Royal Photographic Society several years before his death and made few contributions to photography in the twentieth century. He died in Wimbledon on 1 March 1932 aged 85 years.

MICHAEL PRITCHARD

BOLDYRJEV, IVAN VASILJEVICH (c. 1848–1898)

Amateur photographer, inventor

Ivan Vasiljevich Boldyrjev was born into the family of a Don kazak. In the sources one can find various dates of birth, from 1848 to 1850. When he was 18 years old he moved to Novocherkssk and became apprentice photographer at a studio.

In 1872 he moved to St. Petersburg. During this time, only low depth lenses were used in photography studios. Boldyrjev, with no special knowledge of optics, simply by combining elements, created a short-focus, large aperture lens which enabled him to make high ly detailed photographs of large groups. The characteristics of this lens made possible photograph under poor light, while retaining good depth of field. As Boldyrjev did not patent his design, the precise configuration of the elements is not known, although images taken by the lens survive.

In 1878 the fifth department of Russian Emperor's Technical Society in Saint Petersburg (RETS), the photography department, was established by a group of photographers including Boldyrjev. The first public meeting of the society was devoted to the discussion of technical potentialities of the lens. Photographic test were carried out in the studio of the famous photographer, Andrey Denier, and in the presence of such Russian authorities in photography like Sergey Levitsky and others. Being aware of the typical problems of studio photography, they stood in the depth of the hall at about 8.5 meters from the photographer thus trying to create the maximum hard photographic conditions. As a result, they got a photograph of high acutance on the foreground as well as on the background with the linear perspective wonderfully rendered. Nevertheless, even the positive results of the experiment didn't gain approval of the specialists.

In 1875, Boldyrjev returned home and developed an interest in photographing the Don kazaks' way of life with his lens. Some Russian photographers had already created superb ethnographic photographic series, for instance, William Carrick made a series of photographs in the Simbirsk region in 1870s.

Boldyrjev's camera recorded scenes of folk life with its routine and holidays, and the same scenes Boldyrjev witnessed in his childhood. The lens he used made his photographs multidimensional, so the images seemed to be snatched from real life as there was practically no posing or staging by the photographer. His photographs combined reality with refined taste, and artistic rendering of life filled with energy is found in his works. He only used photographic methods and thought of the reality of his photography as an expressive means. Choosing different plots from the lives of common people, Boldyrjev tried to get away from posing and costumes and instead sought reality in his works. Additionally, one of Boldyrjev's techniques was to render linear and aerial perspective and consciously employ depth as an expressive device.

His photographs were highly regarded by a leading Russian art critic of the time, Vladimir Stasov. He even bought an album of prints for the collection of the Emperor's Public Library in St. Petersburg. Stasov mentioned, "The 75 pages comprise not only neighborhoods and people that are very interesting and are brilliantly done, but also picturesque and so naturally presented groups of the Don kazaks, men and women, at their field and house work, at service. Lots of the groups are real "true life pictures" created by an artist of talent."

Boldyrjev was one of the pioneers of Russian realistic photography and the aesthetic principles he lived up to were later developed by some other prominent photographers in the trend, such as Maksim Dmitrijev. Differences about the assessment must have led to the tense relationship of Boldyrjev with the members of RETS.

Boldyrjev kept inventing and making photographs. Because he traveled round Russia frequently he often felt uncomfortable using fragile glass negatives. It was out of this concern that he had the idea of inventing a flexible photographic. In 1881, following a period of diligent work and experiments, he invented flexible film for negatives, which he presented at the All-Russia Industrial Exhibition in Moscow in 1882. The film was an plastic transparent film that was resistant to high temperature and humidity. It is regretful that neither the description of the chemical elements of this kind of film survive, nor photographs take with this film, as Boldyrjev didn't patent this either. Only the basic review of its properties, mentioned in the newspaper *The All-Russian Exhibition* (No. 30 1882) exist: the film was a flexible resin-like plate, similar to glass by its density and transparency. This plate did not deform while being rolled up into a tube. The well-known chemist D. Mendeleev expressed his approval of the film. Vyachjeslav Sreznevsky, a famous Russian expert in photography labeled the film as "a rather useful invention," even though the invention was not commercially implemented.

However the fifth department of RETS paid due attention first to Eastman's paper-based film that entered the market in1885 and then to Hannibal Gudwin's (1822–1900) celluloid film, which he patented it in 1887, and then to the first mass produced sheet films in 1888. The photography press was full of reviews of Russian photographers who admired the films produced abroad and the advantages of using them for outdoor photography.

As Boldyrjev didn't find much support as far as his inventions were concerned, he kept taking photographs. The range of events he recorded in 1870–1890s was really wide. In the funds of Russian National library in St. Petersburg, the former Emperor's Public library, there are photographs of physiological experiments in the hospital named after S. Botkin, where Ivan Pavlov worked as a young man, of curing séances through electroshock therapy in the Military medical academy in St. Petersburg. One can also find photographs of the celebration of Rafael's 400th anniversary at the Russian

Academy of Fine Arts, as well as expositions of the peredvizshniks and some photographic portraits.

In 1880 V. Stasov ordered a series of photographs for the "Bakchisaraisky palace" album from Boldyrjev. Bodyrjev went to the Crimea and made brilliant photographs of the facade and the interior of the Bakchisaraisky palace as well as a couple of marvelous landscapes. Currently, these photographs are in the collection of the St. Petersburg Public library.

In 1889 at the World exhibition in Paris, Boldyrjev was awarded a certificate of merit for his works and in 1898, at the fifth exhibition of RETS he received a diploma for photographs made in lamp light and night photographs of illumination.

Boldyrjev was a drawing teacher by profession and therefore he reckoned himself among photographic amateurs. Still though, some photographers considered him to be a professional. In 1883 and 1886 he issued a booklet called "Inventions and improvements in photography made by Boldyrjev. In this booklet Boldyrjev describes his findings in a rather detailed way. Boldyrjev died in 1898 in St. Petersburg.

Boldyrjev's creative activity was not estimated at its true worth by his contemporaries. However, his works did much for the advancement of photography as an independent art form because he developed purely photographic expressive images.

ALEXEY LOGINOV

Biography

Ivan Vasiljevich Boldyrjev was born in Ternovskaya stanitsa into the family of a Don kazak. His birth is unknown, but sources indicate dates of birth from 1848 to 1850. When he was 18 years old he moved to Novocherkssk and became an apprentice photographer at a studio. In 1872 he moved to St. Petersburg, where he worked at the studio of Alfred Lorens and visited at leisure the drawing school of the Society for Fosterage of Artists. After leaving Lorens' studio Boldyrjev became a non-credit student of St. Petersburg Academy of Art. At the same time he became interested in photography as an amateur. By combining lenses Boldyrjev created a short-focus lens. In 1875 he employed the new lens in making photographs of the land where he was born. He made photographs of scenes of traditional folk life. On returning to St. Petersburg Boldyrjev decided to present the lens he invented at the meeting of the fifth department of Russian Emperor's Technical Society (RETS). In1881 he made first flexible film to use instead of glass plates and demonstrated it at All-Russia industrial exhibition in Moscow in 1882. Boldyrjev didn't enjoy the support of his contemporaries as far as his inventions were concerned, and kept making photographs of the wide range of events in the life of his country in 1870–890s. Boldyrjev died in St. Petersburg in 1898. He was one of those who developed the foundation for realistic photography in Russia and introduced the aesthetic principles further developed by other prominent photographers of the trend.

BONAPARTE, PRINCE ROLAND (1858–1924)

Prince Roland Bonaparte was great nephew of Napolean Bonaparte. Barred from a military career he took up science and was taught by the distinguished French

Bonaparte, Prince Roland Napoleon. Betty, Fillette Hotentotte (Hottentot Girl), 9 ans. from album "Boschimans et Hottentots"
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

physical anthropologist Paul Broca. His photography was a central part of his wide interest in anthropology, geography and natural history on which he published extensively. He is best remembered for his anthropological photographs. Many of them were undertaken at the various international exhibitions of the late nineteenth century. He photographed and measured indigenous people from Surinam at the Amsterdam Colonial Exhibition (1883), the Omaha Native Americans and and Kalmouks at the Jardin d' Acclimitation (1884), and Australian Aboriginal people toured by Cunningham as 'exotics' (1885) who were appearing at the Folie Bergère. He also undertook similar photography during his scientific travels. In 1884 he went to northern Scandinavia where he photographed the Saami people and in 1887 he travelled to North America and Mexico. His photographs were published privately as portfolios of mounted albumen prints, stamped with Bonaparte's coat of arms. Focussing on a specific cultural or racial group, each portfolio was accompanied a pamphlet of names ages and basic anthropometric information. These portfolios were presented to scientific societies around the world.

ELIZABETH EDWARDS

BONFILS, FÉLIX-ADRIEN (1831–1885), MARIE-LYDIE CABANIS (1837–1918), AND ADRIEN (1861–1929)

French photographers and photo publishers

Born on 8 March 1831 in Saint-Hippolyte-du-Fort (Gard, France), Félix Bonfils was a bookbinder-turned-photographer. Little is known about his beginnings. Although there is no contemporary confirmation, he is believed to have opened a studio in the nearby town of Allais in 1864, and in 1866–67, he apparently perfected his technique with Abel Niépce de Saint-Victor. This was just before embarking on what would become the adventure of his life, the creation in 1867 of a photographic studio in Beirut, soon to be known worldwide.

Félix married Lydie Cabanis in 1857. Both traveled to Lebanon before 1867, Félix as a soldier in 1860, and, a few years later, Lydie accompanied their son Adrien, who was recovering from illness. These sojourns prompted them to settle in Beirut. From 1864 to World War I, the city was the capital of "Mount-Lebanon," a Syrian autonomous province under Turkish domination, but administrated by a catholic governor approved both by Turkish and European governments. Mount-Lebanon was prosperous, peaceful, and at the very heart of a multicultural Middle East. Another European photographer, Tancrède Dumas, settled in Beirut in 1867, but while most of guidebooks for tourists mention both studios, they favor Bonfils works as better.

In December 1871, Félix Bonfils reported his achievements to the Société Française de Photographie: he had no fewer than 15,000 albumen prints in stock, obtained from 590 negatives made in Syria, Palestine, Egypt, and Greece. This core ensemble also comprised 9,000 stereographic cards. In 1876, the flourishing company published its first official catalogue, listing 395 views of various Mediterranean sites explored before, with the notable addition of Constantinople. In addition, the catalogue featured 33 "Diverse Costumes," actually types ranging from "Arab Musicians" (no. 240) to "Turkish Woman" (no. 261), and 537 stereographic views, 99 of them devoted to costumes. Other catalogues were published c1885 (F. Bonfils & Cie), 1901 (A. Bonfils), 1907 (Veuve Bonfils), and c1925 (Photographie Bonfils, A. Guiragossian Successeur).

Retailers were mentioned for the first time in the c1885 catalogue. Apart from Beirut, Bonfils' photographs were available in Paris and London, in Egypt (Cairo, Alexandria, and Port-Said), and in Damascus. One important distributor was not mentioned, because their collaboration had ceased by 1885. As early as 1872, Bonfils contracted with an American publisher, Charles Taber & Co., of New Bedford, Massachusetts. Nothing is known about the terms of their contract, but Taber actually published the first Bonfils catalogue. In 1872, four years before Bonfils' catalogue was published, Taber & Co., the "Sole agents for the United States," released their *Catalogue of Views in the East, Egypt, Palestine, Syria, Greece (Original), 9 × 11 inches, on 16 × 20 mounts, and Stereoscopic Views of Palestine from New Original Negatives by Bonfils, Photographer, Beirut, Syria*. The catalogue listed 367 views and 158 stereocards, available in the United States, for almost a decade. Taber's next catalogues mentioned Bonfils photographs until 1881. As a result, many of Bonfils' prints in various repositories in the United States, such as the University of Chicago Library, were mounted on a distinctive board with a printed caption in English and bore the imprint of Charles Taber.

At the same time, Félix re-opened a studio in Alès, and started the publication of his *opus-magnus*. *Souvenirs d'Orient*, a five-volume compilation of his 250 best photographs was released in 1878. This ambitious work earned him a medal at the 1878 *Exposition universelle* in Paris. Bonfils' commercial ambition manifested itself in the trilingual brief texts accompanying each plate—French, English, and German. *Souvenirs d'Orient*, which also existed in a small size, was conceived as the perfect record for an international clientele travelling on a Grand Tour. In 1880, Bonfils established in Alès a collotype printing factory, where his photographs were printed, some assembled in portfolios. Few examples of this production survived; it probably ceased upon Félix' death on April 9, 1885.

Bonfils, Felix. Colonnes de la salle hypostyle, vue de nord. Karnak, Thebes.

Bonfils' varied production raises many issues. The numbers attributed to one specific view changed from one catalogue to another. It is therefore often impossible to give a precise date for Bonfils photographs. Moreover, the same site was sometimes photographed several times, using the same reference number, rendering difficult any attempt at classification. As with many studios of the time, the issues of authorship are very difficult to solve, too. While it is generally admitted that Félix produced the majority of the first campaigns, it is also thought that Lydie herself took several photographs, especially for the costumes series featuring women—Oriental women being more inclined to pose if the operator were a woman herself. Other photographers worked there, according to the short presentation of the c1885 catalogue: "Our employees are constantly traveling in order to renew our negatives in accordance with every latest development in photographic art." Adrien was one of them. Together with his mother, he ran and developed the business after his father died. In 1909, they formed a partnership with Abraham Guiragossian, who eventually bought their archives after Lydie died in 1918. Adrien eventually became a hotel manager.

Bonfils' story epitomizes the venture of many international studios flourishing from the 1860s to the end of the century. Most of them were devoted to views, reproductions of works of art and architecture, and types. They developed in popular sites such as Italy (Sommer, Alinari, or Naya) and the Near East (Sebah, or Zangaki). Often considered as mere commercial photographers by many historians in the field, their production is worthy of interest not only for history of photography, but for art history—artists such as Lawrence Alma-Tadema or Mariano Fortuny collected such photographs, including Bonfils'—and cultural history. Moreover—and this is certainly the case for Bonfils—a significant part of their work appears as more original than the mass-produced clichés aimed at tourist crowds.

BONNARD, PIERRE (1867–1947)

French Painter

Best known for paintings pervaded by brilliant light and radiant color, Pierre Bonnard is less renown for his photographic experiments. It was not until the late 1970s that the artist's photographic oeuvre was recognized at all, and only in the 1980s, was his work in photography given analytical consideration and viewed in relationship to his paintings.

Bonnard's interest in photography seems to have been more the result of historical circumstance than genuine technical curiosity. By the 1880s, when cameras became smaller and lighter and negatives were industrially prepared, photographic equipment became accessible to amateurs. With the creation of the Kodak portable camera, its small negatives, pliable film, and instant photos in 1888, the camera became a necessary accouterment for many artists. It has been speculated that Bonnard's brief foray into photography was spurred not by his desire to employ it as a serious medium but rather by the fact that many of his peers had cameras. Writers Emile Zola, August Strindberg and painters Edgar Degas, Edvard Munch, Franz von Stuck, and Bonnard's close friend Edouard Vuillard all took up the camera and allowed the medium to influence their other artistic and literary experimentations.

Bonnard may have been introduced to the photographic process by Vuillard, who was himself an avid photographer of notable technical accomplishment, even involving his mother in the developing process, but Bonnard was also acquainted with the Lumière brothers, Auguste and Louis, through his musician brother-in-law Claude Terrasse and spent time with them at the family estate at Le Grand-Lemps. These interactions may have influenced Bonnard's own photographic vision as well as the vision he subsequently took from the viewfinder and applied to his canvases.

In contrast to Degas, who approached photography with a preconceived aesthetic end, utilizing the then obsolete glass plate negative, a tripod and dramatically lit interiors in order to study the movement and form of his dancer models, Bonnard was more casual in his photographic work. He neither went to the trouble of learning how to develop or enlarge his work, as did Degas and Vuillard, nor did he require elaborate poses of his subjects. He was also conspicuously silent about this segment of his oeuvre, providing no written insight into his intentions, theories, or techniques. Ultimately, he seemed to regard this work as secondary to his painting and not necessarily an end in itself.

While Bonnard's earliest known photo, an image of his cousin Berthe Schaedlin dates from the early 1890s, he did not begin photographic work in earnest until 1898. It is not clear why a gap exists in Bonnard's photographic productivity. Critics and historians have suggested that he may have been dissatisfied with his earlier attempts in a relatively new medium and kept only those photographs having sentimental value.

It was between 1898 and 1916, when Bonnard's photographic output was at its highest level and

developed thematically and technically in tandem with his experiments in painting and drawing. His subjects were the same as those of his paintings: scenes of domestic interchange, pictures of the his sister's children playing in the pools outside Le Grand-Lemps, and images of the nude and bathing Marthe, Bonnard's model, long-time companion and eventual wife. His most technically adept and visually arresting photographs seem to answer to the same laws he applied to painting. According to his late notebooks of 1939, written long after his abandonment of photography, he noted that nature and observation should be secondary to the harmony and overall tone of a pictorial work. Therefore, it might be said that Bonnard originally sought with his camera not to scientifically record minute details about people or events for replication on canvas, but rather apprehend the flavor of a mood, a personality, or a moment.

Bonnard never directly quoted his photographs when painting. Rather, he employed compositional variations on the frequently domestic subjects evident in his photos. Sometimes he appropriated a silhouette or form that appealed to him. It appears that he viewed his photographs as sketches; both were meant to inspire a mood or capture a fleeting movement for later reference. For Bonnard, who denied any preconceived compositional structure or arrangement in his paintings, the Kodak he carried to family gatherings and the candid shots he captured with it were well suited for his desire to seize and elevate the transitory and happy accidents of the moment. It was in his illustrations for the literary works of his peers that Bonnard seems to have looked directly to, lifted and modified figures from his photographs, particularly those involving Marthe bathing. A photograph dating from 1900-01 and titled *Marthe Standing in the Sunlight* is ostensibly the model for Bonnard's lithograph *Chloe Bathing*, which appeared in Vollard's *Daphnis and Chloe* of 1902. Other overt examples of Bonnard's appropriation of photographed figures for his literary illustrations can be found in Paul Verlaine's *Parallèlement*.

Bonnard's interest in photography began to dissipate in 1905, and he completely abandoned the medium by 1920. Again, his waning enthusiasm for the photographic medium seems to have followed the lead of the same writers and artists who had taken it up in the 1890s. In his last years, particularly those following Marthe's death in January 1942, Bonnard focused all his creative efforts on painting. Dubbed the 'celestial reporter' by artist André Lhote for his ability to imbue the mundane with the sublime, Pierre Bonnard revealed his unique symbolist-inspired vision in photographs by bringing his plastic and painterly approach to a largely mechanical, often unforgivingly literal medium.

Savannah Schroll

Biography

Bonnard was born at Fontenay-aux-Roses, near Paris on 3 October 1867 to the head of a department in the War Ministry and an Alsatian mother. He spent most of his time at the family estate, Le Grand-Lemps, near Côte Saint-André. Between 1886 and 1887, he studied law while also attending the Académie Julian, where he met Paul Sérusier, Maurice Denis, Henri-Gabriel Ibels, and Paul Ranson. A year later, he enrolled at the Ecole des Beaux-Arts, where he encountered Ker-Xavier Roussel and Edouard Vuillard. After a brief period of military service, he rented a studio in Rue Le Chapelais in the Batignolles district and, with Sérusier, organizes the Nabis. In 1889, while still reluctantly pursuing a civil service career, Bonnard submitted a painting that was rejected for the Prix de Rome. He did, however, succeed in selling a poster for "France-Champagne," which led him to embark in earnest on a painting career. He also became involved at this time with the Nabis, a group of artists thus dubbed by the poet Henri Cazalis, lead by Paul Sérusier, took its name from the Hebrew word for 'prophet.' In the early 1890s, Bonnard began experimenting with a portable Kodak camera, then popular with the middle class. He exhibited at the Salon des Indépendents in 1892 and 1893. In 1896, he collaborated with his brother-in-law, the musician Claude Terrasse, and Paul Sérusier to produce sets and music for Alfred Jarry's *Ubu-Roi*. Bonnard also had his first solo show of paintings, posters and lithographs at Durand-Ruel and illustrates Peter Nansen's novel *Marie*. In 1898, Bonnard takes up photography more seriously, carrying his Kodak camera with him to many family gatherings at Le Grand-Lemps. Between 1900 and 1908, he created lithographic illustrations for written works published by Vollard, namely Verlaine's *Parallèlement*, Vollard's *Daphnis and Chloe*, and Octave Mirbeau's *628 E8*. Bonnard participated in the Salon d'Automne in 1913. 1924 sees a large retrospective of his work at Druet's, and in 1925, he married his long time companion Maria Boursin, who called herself Marthe de Méligny and whom Bonnard met in the early 1890s. In 1926 he was appointed to the Carnegie International jury and briefly visited the United States. In 1927 Octave Mirbeau's *Dingo*, containing 55 etchings by Bonnard was published. The following year, he exhibited brightly hued painting at New York's De Hauck Gallery. Kunsthaus Zurich mounted a large exhibition of Bonnard's and Vuillard's works in 1932, and in 1933, forty of his portraits appeared at the Galerie Braun. In 1934, he has an exhibition in New York's Wildenstein Gallery. In 1936 he wins second prize at the Carnegie International. Bonnard died at his villa, Le Bosquet, in Le Cannet, France on 23 January 1947.

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1840s

The world's first photographic manual was, understandably, a modest affair. Published in April 1839 by Ackermann and Company, *Ackermann's Photogenic Drawing Apparatus* was an eight-page pamphlet offering detailed instructions for using Henry Fox Talbot's pioneering paper negative process. A single copy of the pamphlet —apparently written with Talbot's approval and cooperation—forms part of the Royal Photographic Society's Collection at the National Media Museum in Bradford, England. The introduction refers to the pioneering nature of this publication:

> In offering to the public the following directions for the practice of Photogenic Drawing, which may emphatically be called the *New Art,* we must claim the indulgence of our readers for the necessarily imperfect nature of some of the details; the art itself is but in its infancy, and until the mode in which the drawings were made was liberally disclosed by Mr. Talbot, a Fellow of the Royal Society of London, the whole subject was involved in mystery.

Problems with nomenclature were already evident in that first year of photographic publication, with the English *photogenic drawing* apparently seen as an alternative and interchangeable description of the French *daguerreotype*, despite the two being radically different processes. Thus, amongst the three texts published during 1839 by Louis Jacques Mandé Daguerre, a translation by J. S. Memes (published in London by Smith and Elder), was entitled *The History and Practice of Photogenic Drawing on the True Principles of the Daguerreotype, with the new method of Dioramic Painting*. London publishers W. Strange offered a 46 pp. English translation of *History and Practice of Photogenic Drawing by means of the Daguerreotype with notes and explanations of M. Arago.*

Talbot's own sixteen page treatise, *Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the aid of the artist's pencil* appeared in the same year, published by R. and J. Taylor. The most substantial of these early publications, was Daguerre's *An Historical and descriptive Account of the Various Processes of the Daguerreotype and the Diorama*, published in London by McLean and Nutt. By the end of the 1840s, despite a rapid growth in photography's popularity, only a further twenty-nine English language manuals and pamphlets were published, although several of these were translations from French and German.

Talbot appears to have been content to let others compile manuals for his photogenic drawing negative process, and two such pamphlets were published in 1840—Alfred Swain Taylor's *On the Art of Photogenic Drawing* (London: Jeffrey, 38 pp) and Nathaniel Whitlock's *Photogenic Drawing Made Easy: A manual of Photography* (London: J. Robins, 16 pp). He did, however, arrange for the publication of his own important paper to the Royal Society in 1841 in which the calotype process was introduced. *The Process of Calotype Photogenic Drawing, Communicated to the Royal Society, June 10th 1841*, a 4 p. pamphlet, was published by J. L. Cox of London.

The first of several seminal texts by Robert Hunt was published in 1841. *A Popular Treatise on the Art of Photography, including Daguerreotype, and All the New Methods of Producing Pictures by the Chemical Agency of Light* was published in Glasgow by Richard Griffin and Company, and at 96 page, was the most comprehensive account of photographic practice published to that date. It ran to several editions, the most important perhaps being the 234 page 1851 volume *Photography: A Popular Treatise on the Chemical Changes Produced by Solar Radiation, and the Production of Pictures from Nature by the Daguerreotype, Calotype, and Other Photographic Processes* published by J. J. Griffin of London. Hunt's 1844 treatise, *Researches on Light: An Examination of All the Phenomena Connected with the Chemical and Molecular Changes Produced by the Influence of the Solar Rays; Embracing All the Known Photographic Processes, and New Discoveries in Art*, published by Longmans, Green and Longmans was, at 303 page, the largest volume on photography published in that first decade.

In addition to Daguerre, Talbot and Hunt, other writers whose works would exert major influence over the practice of the new art also appeared in print during the 1840s. Significant amongst these was the American Henry Hunt Snelling. His volume, *The History and Practice of the Art of Photography; or the Production of Pictures Through the Agency of Light; Containing all the Instructions necessary for the Complete practice of*

the Daguerreian and photogenic Art, both on Metallic Plates and on Paper, was published by G. P. Putnam in New York in 1849, and subsequently ran to several editions throughout the 1850s. It was the first manual to detail the American approach to photography, and to explain the practical differences between European and American methodologies. In this book, Snelling consistently uses the term 'photogenic drawing' as a generic description of photography, differentiating between 'photogenic drawing on paper' and 'photogenic drawing upon metallic plates.' Significantly, for a book so early in the published literature of photography, there are numerous insightful and critical references to the restrictive effects of early patents contained within an historical overview of the art's first decade.

The practical descriptions within the book set a pattern which many later volumes followed—that of summarising the text of other books and journals. Thus chapter two is a resumé of Hunt's *Researches on Light*, and chapter thirteen explains Antoine Claudet**'s** Photographometer, the description being drawn in large measure from an article in the March 1849 issue of the *Art Journal*.

Self or private publishing, was an established feature of the nineteenth century book world, and several amateur photographers published their own descriptions of, and instructions for, the new processes. First amongst there was W. Vaughan Palmer's 1842 book *The Electrotypist's Manual: being a description of the art of working in metal by voltaic electricity, and on electro gilding and plating, 6th edition, improved and enlarged, to which is added a brief description of the Calotype, Daguerreotype, or Photographic Processes.*
Monsieur C. mansion, whose skill with the colourist's brush is evident in many of the fine tinted daguerreotypes by William Kilburn, published his own *Instructions for Colouring Daguerreotypes* in 1845, while Brighton amateur Joseph Ellis published what is believed to be the first reflective and retrospective look at the birth of photography. His booklet *Photography, A Popular Treatise designed to convey correct general information concerning the discoveries of Nièpce, Daguerre, Talbot and others, and a preliminary to acquiring a practical acquaintance with the art* was self-published with apparently limited circulation in 1847, two years before Snelling's *History and Practice of the Art of Photography*.

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1850s

It might have been expected during the 1850s, with the introduction of the wet collodion process and the establishment of several significant photographic periodicals, that as the number of people engaged in photography both as amateurs and professionals grew exponentially, the number of manuals on the subject would have increased at an equal rate. The relaxation of patent restrictions increased the number of people taking up photography as a profession, while the introduction of photographic societies and periodicals contributed considerably to the increased popularity of photography as a hobby.

Despite that growth in the potential market for literature on the subject, there was not a significant increase in the scale of photographic book publishing. 1850 saw the publication of only five English language books and manuals, with four in 1851 and only two in 1852. During 1853, however, a total of sixteen such books appeared, with twenty in 1855.

While the number of new books and manuals available to the photographer did not increase significantly in total over the previous decade, the books themselves were generally of a much more substantial nature, as befits a maturing subject.

Robert Hunt set the pattern with his 1851 *A Manual of Photography* published as part of J. J.Griffin's series *Encyclopaedia Metropolitana—or System of Universal Knowledge: on a Methodical Plan Projected by Samuel Taylor Coleridge*. A second edition was published in the following year and periodically expanded and updated. At 34 pages, the 1857 5th edition published by Richard Griffin and Company, was the most comprehensive, and most popular. The London *Art Journal*, in reviewing the title, noted that it "must prove of infinite service to those engaged in the pursuit of this entertaining science."

In the same year in which *A Manual of Photography* first appeared, a 2nd edition of Hunt's *Popular Treatise on Photography*, first published in 1841, appeared under the title of *Photography: A Popular Treatise on the Chemical Changes Produced by Solar Radiation, and the Production of Pictures from nature, by the Daguerreotype, Calotype, and Other Photographic Processes*. The

British edition, at 236 pages was substantially smaller that the more heavily illustrated American edition (294 pp.) published in the following year (New York: S. D. Humphrey). Humphrey, as editor of the American edition, was personally responsible for additional text specifically related to American practice.

If there was a restraining influence on the expansion of the library of photographic literature, it was the high cost of books in the mid nineteenth century. At six shillings, Hunt's *Manual of Photography* cost over half the average weekly income of a skilled artisan, placing it well beyond the reach of all but the affluent. Photography at the time was still the pursuit of those in society with sufficient funds and sufficient leisure time. To underline that exclusivity, membership of the Photographic Society of London cost one guinea— twenty-one shillings per year. Joseph Cundall's 32 page very basic booklet *The Photographic Primer for the use of Beginners in the Collodion Process* (London: Photographic Institution 1854) was available for one shilling, or one shilling and sixpence by post. In advertisements for this book, a selling point was that it contained "A fac-simile (*sic!)* of a Photographic Picture of Birds, showing the difference of Tone produced by various Colours." This was probably the first attempt to explore visually the impact of the collodion plate's blue sensitivity of tone reproduction.

It is a measure of the expanding photographic market that it could sustain so many practical manuals. In addition to Hunt, manuals were written by several other eminent photographers and writers.

Philip Delamotte's *The Practice of Photography: A Manual for Students and Amateurs* (London: Joseph Cundall, 1853) went to three editions—the second published in 1854 and the third in 1855 (London: Sampson Low and Son). An American edition appeared in 1854 (New York: Office of the Photographic and Fine Art Journal). Each edition was embellished with an albumen print from a collodion negative as frontispiece. For the 1855 edition, this was one of Delamotte's own photographs of the interior of the Crystal Palace at Sydenham.

Marcus (William) Sparling, Roger Fenton's assistant during the Crimean War contributed his only publication *Theory and Practice of the Photographic Art* (London: Houlston and Stoneman, 1856), while Robert J. Bingham—who periodically promoted himself as the "inventor of the collodion process"—produced a new edition of his *Photogenic Manipulation* (London: Knight and Sons) in 1854. The first edition had appeared in 1848 and went to eleven editions in total. Worthy of note here is the observation by Charles Heisch in *Photographic Manuals No.1* (London: T and R Willats, 1853) that the first publication of a workable wet collodion process was probably by Gustave le Gray in June 1850 in *A Practical Treatise on Photography Upon paper and Glass* translated by Thomas Cousens and published in English a few weeks later (London: T and R Willats). Heisch himself noted that he had first heard collodion suggested as a possible carrier for the light-sensitive chemistry as early as 1847. The widely acknowledged inventor of a detailed practical collodion process, Frederick Scott Archer—who dismissed both le Gray's and Bingham's claims as nothing more than 'ideas'—produced his own volume, *A Manual of the Collodion Process,* in 1852 (London: self published) and a second edition, retitled *The Collodion Process on Glass* (London: self published), in 1854.

Amongst more specialised books, Sir David Brewster's *The Stereoscope, Its History, Theory and Construction* (London: John Murray, 1856) is significant —the first major publication to deal exclusively with stereoscopy and stereo vision.

The earliest attempt to publish a photographic encyclopaedia was Henry Hunt Snelling's *A Dictionary of the Photographic Art* (New York: H. H. Snelling, 1854) published jointly with Edward Anthony's *Comprehensive and Systematic Catalogue of Photographic Apparatus and Material; Manufactured, Imported and Sold by E. Anthony, 308 Broadway New York* This volume was reprinted in 1979 as part of the Arno Press series *The Sources of Modern Photography*, which series also reprinted Anton Georg Martin's 1854 *Handbuch der gesammten Photographie*, Ernest Lacan's *Esquisses Photographiques* (Paris, 1856) and Claude Marie François Niépce de Saint Victor's 1855 *Recherches Photographiques* (Paris, 1855). Arno's earlier 1973 series *The Literature of Photography* reprinted many of the early manuals and handbooks of photography from the 1850s and 1860s, including A. Bisbee's *History and Practice of the Daguerreotype* (Dayton, Ohio, 1853). While more common that the originals, many of the Arno reprints have themselves acquired significant scarcity in the thirty years since their publication.

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1860s

During the 1860s, with photography having become an established feature of the Victorian world over the preceding two decades, the medium was mature enough to indulge in some reflection. Over seventy textbooks on the subject had already been published before the end of the 1850s, and many of them had perpetuated inaccuracies about the genesis of the medium.

In the 'Prologomena' of the 1934 translation of Victor Fouque's 1867 book *The Truth Concerning The Invention of Photography,* Fouque observed "It is evident, incontestable, that if an error is published, it is soon, without preliminary examination, accepted and adopted as the truth." The error to which he was specifically referring was the widespread contemporary acceptance that Daguerre was the inventor of photography. His purpose was to ensure proper recognition be given to the work of Joseph Nicéphore Niépce.

Three years earlier, in his book *The Silver Sunbeam*, Dr John Towler had also included a brief history of photography as the first chapter of his manual, and had acknowledged the contributions of, amongst others, Wedgwood, Davy and Niépce.

While the majority of the manuals of the 1850s had been concerned with the publication of as many individual variations on current processes as possible —paraphrasing many of the process descriptions which had already appeared in the emerging photographic press—by the end of the decade and the beginning of the 1860s, the structure of new books such as William Lake Price's 1858 *Manual of Photographic Manipulation* (second edition 1868) reflected the maturity of the medium and offered descriptions of a 'standard' set of processes and procedures which individual readers and users could adapt to their own needs.

Alongside such books, later editions of several established 1850s manuals continued the earlier more fragmented approach and, in some cases, simply added new processes, techniques and approaches to descriptions contained in earlier editions. Thus, manuals inevitably got larger. Nathan Burgess's 184 page *Ambrotype Manual*, for example, originally published in 1856, had expanded to 283 pages.—and considerably extended its title—by the time the twelfth edition was published in 1865 as *The Photograph Manual: A Practical Treatise, Containing the Cartes de Visite Process, and the Method of Taking Stereoscopic Pictures, Including the Albumen Process, the Dry Collodion Process, the Tannin Process, the Various Alkaline Toning Baths, etc.*

Thomas Sutton's first British *Dictionary of Photography*—originally published in 1858 four years after Snelling's *Dictionary of the Photographic Art*—was understandably expanded for its second edition in 1867, reflecting an increase in the material which demanded to be included.

Towler's *Silver Sunbeam*, originally published by Joseph H. Ladd in New York in early 1864, quickly became in international best seller. The earlier processes were confined to the historical chapter, giving the later sections of the book a clarity and simplicity which contributed to its success. The initial print run of one thousand copies sold out almost immediately in the United States, and by the end of the first year, was in its 'fourth edition'—although in modern parlance that would simply be described as 'fourth printing,' each of the 'editions' being identical. The first editions were marketed in Britain by John Atkinson of Liverpool and publicised through his extensive catalogue of American photographic products and ephemera, but later editions bore the shared imprint of Ladd and London publisher Tribner & Co.

Later editions—that continued through the 1870s —added new material to the original as appendices, causing the clarity of the first edition to be lost. The ninth edition filled almost twice as many pages as the first. A Spanish language edition *El Rayo Solar*, appeared in 1876, with a second and third in 1884 and 1890 respectively.

Other more specialised manuals also appeared during the 1860s—including Alfred H. Wall's 1861 *A Manual of Artistic Colouring as Applied to Photographs*, and Edward Livingstone Wilson's 1868 treatise *The American Carbon Manual*, the first American textbook devoted exclusively to the carbon process. The first British book on the process was probably George Wharton Simpson's *On the Production of Photographs in Pigments, containing Historical Notes on Carbon Printing and Practical Details of Swan's Patent Carbon Process* published by Piper & Carter in 1867.

Two important books from the Belgian photographer and scientist Desiré van Monckhoven appeared in the 1860s. *A Popular Treatise on Photography*, published in 1863 with an enlarged second edition in 1867, was translated into English by William Thornthwaite, and published by Virtue. His *Photographic Optics* appeared in 1868, under the London imprint of R. Hardwicke.

With the medium having evolved to a level where creative considerations were assuming greater importance, several books appeared dealing with the art of photography, and the relationship of photography with established art forms. Important amongst these, and translated from the original French by Thomas Sutton, was Louis Desiré Blanquart-Evrard's 1864 pamphlet *On the Intervention of Art in Photography.*

Henry Peach Robinson's 1869 book *Pictorial Effects in Photography, Being Hints on Composition and Chiaroscuro for Photographers,* published by Piper &

Carter in London, was probably the most influential of these books, running to four editions by the 1890s. The original edition, however, contained three original photographs, one albumen and two carbon prints.

In addition to broadly-based manuals on photography, a number of books and booklets each devoted to a single process appeared during the decade. Small print runs, and a widening audience for books on photography made such publications both popular and economically viable. C. Russell's 80 page 1861 book *The Tannin Process* proved sufficiently popular to require a second edition by 1863, and Sutton's 1863 book *The Collodion Process, wet and dry* required a second edition within a year. Thomas Piper in London published Joseph Sidebotham's 1866 volume on *The Collodio-Albumen Process* while Sampson Low published Sutton's *A Description of Certain Instantaneous Dry Collodion Processes* in 1864. Intriguingly, with dry processes apparently sweeping all before them as the decade drew to a close, Sutton also published two books in 1869 which included a new wet collodion process.

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1870s

In the chapter 'The Future of Photography,' in Gaston Tissandier's *History and Handbook of Photography*, published in 1875 with a second edition three years later, the author suggested, "The day may perhaps come when the negative will be taken at a distance by means of the electric wire; and if some reader exclaims *Impossible*, I shall refer him to certain telegraphic systems, lately discovered, which allow us to anticipate this new miracle." The book's translator and editor of the English-language edition, John Thomson, offered, as a footnote, the observation, "I believe that there is nothing Utopian in the notion that, ere long, means will be discovered of telegraphing a photograph from one end of the earth to the other."

While Thomson and Tissandier were both very perceptive in their view of the future, the book's historical section is somewhat of a curiosity, perpetuating several misunderstandings and over-simplified accounts of the early years. One surprise inclusion for the 1878 second edition, given the late date, was an essay by William Henry Fox Talbot on the introduction of photogenic drawing and the calotype, and an essay on the photoglyphic process by Talbot's son, the inventor having died the previous year. Two years earlier, Tissandier had published *Les merveilles de la photographie* in Paris.

The 1870s was the decade of transition from homemade wet and dry plate photography, to commercially produced materials. Paper photography had all but disappeared by the mid 1860s and, in Britain, Bolton & Sayce had pioneered emulsion-based plate technology, and companies such as the Liverpool Dry Plate Company, J.T. Chapman in Manchester and others had entered the market. Thus many of the publications produced during the decade in both Europe and America were small books or pamphlets produced by the emerging plate-making industry to promote the effective use of their own products.

Gernsheim in his *Incunabula of British Photographic Literature 1839–1875* lists three such publications in the first two years of the decade—George Dawson's *The Russell Dry Plates* (1871), The Liverpool Dry Plate Company's *Rapid Collodio-Bromide Plates* (1872), Mawson & Swan's *On the Collodio-Bromide Process* (1872)—and these serve as typical exemplars of the material being published in other parts of the world as well. That transition rendered most of the earlier manuals out of date, and signalled the need for both major revisions of earlier texts, and entirely new manuals reflecting the new era of photographic manipulation.

Two books from Dr Hermann Wilhelm Vogel, the discoverer of dye sensitisation and orthochromatic emulsions amongst other things, appeared during the 1870s—his *Handbook of the Practice and Art of Photography* first appeared in German in 1870, with an English-language edition specifically for the American market published in Philadelphia in the following year. The more important volume *The Chemistry of Light and Photography in Their Application to Art, Science and Industry* was published in London in 1875, with subsequent editions into the middle of the 1880s. Vogel was also a prolific contributor of letters and opinion to the photographic press for over a quarter of a century until his death in 1898.

One of the major figures in 19th century physics, chemistry and photographic theory, William de Wiveleslie Abney, privately published the first edition of his book *Instruction in Photography for Use at the School*

of Mining Engineers, Chatham, in 1871, while subsequent editions were commercially published by Piper & Carter in London. The book remained in print, through many editions, into the 20th century, being progressively expanded from 120 pages to 676. The School of Mines evolved into today's Imperial College.

Another volume destined to become a standard text for photographers was Matthew Carey Lea's 1868 *Manual of Photography*, published in Philadelphia by Benerman & Wilson. For the second edition in 1871, the 148 pages of the original had been expanded to 336.

Books and pamphlets on the expanding range of equipment available to the photographer sought to explain the choices available. Amongst them, John Henry Dallmeyer's 12-page *Photographic Lenses: On their choice and Use* was published in 1873, and an expanded 34 page American edition in the following year.

Alphonse Liebert's 1864 book *La Photographie en Amerique* was reissued as a second edition in 1874, two years before his *La photographie au charbon mise à portée de tous* in 1876. The latter title was published in an English language edition as *A Manual of the Carbon Process of Photography* in 1878. Liebert, is also remembered for his 1879 decision to open the first professional portrait studio in Paris equipped with electric lighting.

The ferrotype, or tintype, achieved much greater popularity in the USA than it did elsewhere, so it is not surprising that the first manual devoted exclusively to this humblest of portraiture mediums was published in America. *The Ferrotype and How to Make it* by Edward M Eastabrooke was published in 1872 by Gatchel & Hyatt in Cincinnati, Ohio, and Louisville, Kentucky, and was aimed at amateurs and professionals alike. Uniquely, it was illustrated with two genuine tintypes —both portraits taken by Eastabrooke—one made on the Phenix Plate Co's 'Chocolate Tinted Egg Shell Plate' and the other on 'John Dean & Co's Adamantean Chocolate Tinted Egg Shell Plate,' marketed by the Scovill Manufacturing Company, and E & H T Anthony respectively. Interestingly, in the introduction, the author makes a distinction between the 'ferrotype' and the 'photograph,' lamenting the instability of the latter and lauding the permanence of the former.

The prolific polymath Dr John William Draper published his *Scientific Memoirs* in 1878, his sole book to touch on photography—amongst the many books he wrote on arts, literature and science. Like the Tissandier volume and many others, *Scientific Memoirs* was considered of sufficient importance in the history of photographic books to be republished in 1973 by the Arno Press in New York, as part of their series 'The Literature of Photography.' Also reprinted in the Arno Press series was H. J. Rodgers' 1872 memoir *Twenty Three Years Under a Skylight; or, Life and Experiences of a Photographer*, the first manual specifically dealing with studio portraiture.

Amongst the other specialist books published in the 1870s, J Waterhouse's *Report on the Cartographic Applications of Photography*, believed to have been published in Calcutta in 1870 was, at 240 pages, a detailed description of a relatively limited use of the medium. Lieutenant, later Colonel, Waterhouse was for many years in charge of the photographic unit attached to the Indian Survey Office, later rising to the position of Assistant Surveyor-General in India.

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1880s

The 1880s saw the continued expansion of publishing in photography, fuelled by increased demand for smaller cameras and the introduction of mass produced gelatine dry plate, which increased the number of practitioners. Publications become more specialized as the field matured and the traditional spheres of endeavor—professional and amateur work, technological development, and scientific research—became more separate.

The work of trained photographic scientists encouraged rapid technological change in the 1880s. Numerous books and periodical articles appear, which established photography as a field of academic study, and furthered research into the scientific basis of the process. Chronicling all the new technical developments was the photochemist Josef Maria Eder, teacher and later Director of the Graphische Lehr- und Versuchsanstalt in Vienna, the first major educational institution devoted to photography. Eder himself was one of the first professional scientists to write about photography. Author of numerous books and treatises Eder wrote on a variety of subjects, including dry plates, oil and gum processes, lenses, instantaneous photography, as well as the theory of photographic process. Most notable is the *Ausführliches Handbuch der Photographie*, a multi-volume textbook, which first appeared in 1882, and continued to be revised and expanded until 1929, eventually

numbering 46 volumes. The volumes of this set offered practical and scientific information on photography and now documented every major advancement of the era. Eder also published *Jahrbuch für Photographie und Reproduktionstechnik* (Halle: Wilhelm Knapp) in 1887, which summarized photographic progress during the previous year.

Dr. Hermann Vogel, another established photo scientist, teacher, author, and editor of the German periodical *Photographische Mitteilungen* (Berlin: Verein der Förderung der Photographie im Berlin, 1864–1911), contributed a survey, *Die Fortschritte der Photographie seit dem Jahre 1879* (Berlin, R. Oppenheim, 1883), translated into English as *Progress of Photography Since 1879* (New York: Wilson, 1883). The book was heralded as very thorough, scientific, well-written, and included chapters on recent developments in emulsion photography and amateur photography. Vogel's research was as wide-ranging as Eder's and his work on dye sensitization led to his taking part in the development of the first orthochromatic dry plate, which allowed photographs to represent colors at the appropriate degree of intensity. His *Die Photographie Farbiger Gegenstände in den Richtigen Tonverhältnissen : Handbuch der Farbenempfindlichen (Isochromatischen oder Orthochromatischen) Verfahren*. (Berlin: R. Oppenheim, 1885), is currently considered the first handbook of orthochromatic photography.

A broader look at progress in the field was contributed by the Englishman William Jerome Harrison, whose *A History of Photography; Written as a Practical Guide and an Introduction to its Latest Developments* (New York, Scovill, 1887) chronicled in detail every development to date. Harrison, very interested in preserving the history of photography in libraries and museums, also compiled what may be the first bibliography of photographic literature, published as a series of articles in 1886 and 1887 in the periodical *Photographic News* (London: Cassell, 1858–1908).

Another prolific author, Léon Vidal, educator, photochemist, and editor of the French journal *Le Moniteur de la Photographie* (Paris: Leiber, 1861–1905), also contributed several key texts. His research in photomechanical processes and permanent printing methods resulted in several books on the subject in the 1880s: *Traité pratique de photoglyptie* (Paris: Gauthier-Villars, 1881), *La Photographie appliquée aux arts de reproduction* (Paris: Gauthier-Villars, 1880) and *Cours de reproductions industrielles* (Paris, Delgrave, 1880). He also revised and updated Alphonse Poitevin's important 1863 book on photomechanical processes: *Traité des impressions photographiques sans sel d'argent* (Paris: Gauthier-Villars, 1883) and wrote two books for the new amateurs: *Manuel du touriste photographe* (Paris: Gauthier-Villars, 1885) and *La photographie des débutants: procédé négatif et positif* (Paris: Gauthier-Villars, 1886).

By 1880 the process of making photographs had reached a point where a scientific background wasn't necessary. Manufactured dry-plates freed photographers from mixing chemicals and coating the plates themselves. Amateurs entered the field in greater numbers and publications came out which catered to their need for straightforward, not-too-technical information on the photographic process. Manuals for these new photographers were numerous, and only a few need be mentioned. Indicative of this new class of amateurs was the title of the book *The New Recreation. Amateur Photography: A Practical Instructor*, by D. J. Tapley. (New York, S. W. Green's son, 1884). The text provided information on taking, developing and printing photographs from dry-plate negatives. Books with the most basic instruction as well as cheaper books came available, such as the 10¢ *How to Make Photographs and Descriptive Price List* (New York: Scovill Manufacturing Company, 1883), which appeared in numerous editions during the 1880s and was basically a short, simple manual attached to a manufacturer's catalog. Appealing to more sophisticated practitioners were manuals like William de Wiveleslie Abney's exhaustive *Photography with Emulsions: A Treatise on the Theory and Practical Working of Gelatine and Emulsion Processes*. (New York, Scovill, 1882), and Paul E. Liesegang's *Die Bromsilber-Gelatine : ihre Bereitung und Anwendung zu photographischen Aufnahmen, zu Abdrücken und zu Vergrösserungen* (Düsseldorf: Ed. Liesegangs Verlag, 1882).

Several new journals marketed only to amateurs appeared for the first time in the 1880s, including the British *Amateur Photographer* (London: Hazell, Watson and Viney, 1884–present), the *American Amateur Photographer* (New York: American Photographic Publishing Company, 1889–1907), and the German *Der Amateur-Photograph* (Düsseldorf: E. Liesegang, 1886?–?). These periodicals were written for the person without a scientific background, who saw photography as a hobby and a pastime. Their tone was upbeat and they offered practical advice through articles and answers to reader's letters, discussed artistic and aesthetic issues, critiqued readers work, sponsored contests and featured articles on subjects appealing to the new amateur such as vacation and family photography.

The first Kodak came on to the market in 1888, starting another revolution in photography. With the camera came *The Kodak Manual* (Rochester, N.Y.: Eastman Dry Plate and Film Co., 1888) containing complete instructions on taking photographs and packing the camera to send back to the factory for development and film reloading. George Eastman wrote the text for the pamphlet *The Kodak Primer* himself, emphasizing the simplicity and ease of the system, writing that the Kodak system

would "furnish anybody and everybody, (man, woman and child,) who has sufficient intelligence to 'Point a small box straight and press a button,' the material that will make a hundred fine negatives."

Several publishers of photographic publications came into prominence, and maintained a virtual monopoly on the field. The majority had ties to the industry, either manufacturing or distributing (or both) photographic goods. The books and periodicals served to furnish information on using equipment to the new amateur, but also served to promote their products through advertisements and editorials. The Anthony company, which began distributing photographic materials in 1840, published *Anthony's Photographic Journal* (1870–1902) as well as books, many appearing in the *Anthony's Series of Photo Publications*, with titles by such luminaries as H.P. Robinson and Josef Maria Eder. Their 1882 booklet, *The Amateur Photographer, or Practical Instructions in the Art of Dry Plate Photography for Young and Old*, provided instruction on every aspect of photography as well as descriptions and prices of Anthony photographic outfits. A rival manufacturing firm, Scovill & Adams, published the important American journal *Photographic Times* (1871–1902) as well as technical books in the *Scovill Photographic Series*, the majority of which were pitched towards the new amateur. The series started in 1881 with the popular book *The Photographic Amateur*, by John Traill Taylor, and included titles other key titles such as Henry Clay Price's *How to Make Pictures or Easy Lessons for the Amateur* (1882 and later editions). The firm also published E.J. Wall's comprehensive *Dictionary of Photography for the Professional and Amateur Photographer* (New York: Scovill & Adams, 1889) which appeared for over fifty years in 17 editions.

Bennerman and Wilson was another venerable name. Edward Livingston Wilson was a prominent figure amongst photographers, a publisher of photographic books, editor of the important American journal for professional photographers, *Philadelphia Photographer* (later *Wilson's Photographic Magazine*), and distributor and manufacturer of equipment and supplies. Acting as journalist for the profession, Wilson's editorials chronicled important events and technical advances. He had some technical experience, and also authored several books, including two important textbooks. *Wilson's Photographics: A Series of Lessons, Accompanied by Notes, On all the Processes Which are Needful in the Art of Photography*. (New York: E.L. Wilson, 1881), comprised a series of lessons touching on art and technical matters, theory, and history. *Wilson's Quarter Century in Photography. A Collection of Hints on Practical Photography Which Form a Complete Text-book of the Art* (New York: E.L. Wilson, 1887), equally as comprehensive, included supplementary information gleaned from the pages of the *Philadelphia Photographer*.

In France the house of Gauthier-Villars, publisher of scientific books, catered to both professional, scientist and amateur. They offered photographers an enormous number of books, including translations of important German and English texts. They also published the 4 volume *Traité Encyclopédique de Photographie* by Charles Fabre (Paris: Gauthier-Villars, 1889) an important milestone in publishing as each aspect of photography discussed included historical information on preceding developments.

The 1880s saw an awakening of debates on art photography with amateur photographers at the center with two British photographers dominating the discussion. In 1889 P.H. Emerson's *Naturalistic Photography for Students of the Art*, a theory of art photography with technical instructions (London: S. Low, Marston, Searle & Rivington) was published, essentially a rebuttal to H.P. Robinson's 1869 *Pictorial Effect in Photography* which had been republished in an inexpensive edition in 1882 and was widely considered *the* book on artistic matters. Robinson, author of several other books and many articles in the 1880s (*Art and Practice of Silver Printing*, *Picture Making by Photography*, *The Studio and What to do in It*), had been a spokesperson for art photography since the late 1860s and P.H. Emerson's book ushered in a decade of lively debate over the merits of Emerson's versus Robinson's style of photography and the basic question of the place of aesthetic matters in photography.

A few projects of the decade warrant noting as they had associated publications which documented these activities. Edward Muybridge's initial attempts at photographing running horses, his experiments underwritten by Leland Stanford, were first reproduced as line drawings in Jacob Davis Babcock Stillman's *The Horse in Motion* (Boston: J. R. Osgood, 1881). In a milestone project of the era, photography was used to document an important celestial event. Photographers were stationed in the U.S. and around the world to photograph the transit of Venus. Data from the photographs would allow scientists to determine the distance of the sun from the earth. A booklet of exact instructions to be used by the photographers was printed for the event, *Instructions for Observing the Transit of Venus, December 6, 1882* (Washington, D.C.: Government Printing Office, 1882).

BOOKS AND MANUALS ABOUT PHOTOGRAPHY: 1890s

The most important development to affect photographic publications in the 1890s was an intensification of discussion and debate around photography as art. Amateur associations and groups had grown tremendously during the 1880s, as technological changes opened photography to more practitioners. In the 1890s, new groups focused on one issue—the aesthetic potential of photography—were established in major European cities. One of the first of these groups, the Photo Club de Paris had been established in 1888, specifically separating their goals and ambitions from those of amateur clubs already in existence. Another milestone, and symptomatic of the shift, was the *International Ausstellung Kunstlerische Photographie* organized by the Club der Amateur Photographen in Vienna in 1891, the first international exhibition limited to just artistic photography. Shortly afterwards the Brotherhood of the Linked Ring, an international group of photographers protesting the lax standards of the Photographic Society of Great Britain exhibitions, formed in England. Eventually major cities in England, France, Germany, Belgium, Austria and the United States had its own photography group that aspired to elevate the creative potential of photography. An international artistic photography movement with ties to avant-garde art and literary groups took off in the 1890s, and this activity generated numerous publications, including the record of exhibitions, manuals on new processes and aesthetic trends, and new periodical titles devoted to artistic photography.

Chief among these publications were salon catalogs, many illustrated with finely printed photogravures on special papers. The 1894 *Première Exposition d'Art Photographique* of the Photo-Club de Paris had an substantial accompanying catalogue that contained 56 photogravure plates and an introduction by Armand Dayot, Inspecteur des Beaux-Arts that extolled photography's potential as an art form and compared the spirit of the works to paintings. *Nach der Natur: Photogravüren nach Originalaufnahmen von amateurphotographen* (Berlin, 1896), the catalog of a competition sponsored by the Berlin Photographische Gesellschaft also featured fine reproductions. The Association Belge de Photographie began focusing on art photography in the 1890s, publishing albums of prints conjunction with their special exhibitions. A juried exhibition took place at the Pennsylvania Academy of the Fine Arts in 1898, and the *Catalogue of the Philadelphia Photographic Salon* commemorates the event which is considered the first exclusively fine art photography exhibition in the United States. Even Eastman Kodak Company found reason to associate with the movement and published *Kodak Portfolio: A Souvenir of the Eastman Photographic Exhibition 1897: A Collection of Kodak Film Pictures by Eminent Photographers* (London: Eastman Photographic Materials Co., 1897), which contains original photogravures from negatives on Kodak film by J. Craig Annan, H. P. Robinson, Francis Benjamin Johnston and other well known photographers. This explosion of publishing extended to clubs outside the large metropolitan centers as well, and their annual exhibitions usually have at the very least some sort of modest check-list of participants and their works.

Many associations and clubs published journals, which provided the usual mix of news of people and events, articles on technical matters, and print critiques. Many also included beautifully printed reproductions, often in photogravure, of the newest work. The finest of these illustrated publications included *Die Kunst in der Photograhie* (Berlin: Verlag von Julius Becker, 1897–1908) edited by Franz Goerke; *L'Art Photographique* (Paris: Georges Carré et Naud, 1899–1900); *Wiener Photographische Blatter* (1894–1898), organ of the Wiener Camera Club; and *Photographische Rundschau* (Halle: Wilhelm Knapp, 1887-–1903) representing both Austrian and German interests, which expanded coverage to include aesthetic issues. From Belgium came *Sentiment d'art en photographie* (Bruxelles: Xavier Havermans, 1893–?), featuring work chosen from a monthly contest. In the United States, the Camera Club of New York began publishing *Camera Notes* (New York: Camera Club, 1897–1903), edited by a committee headed by Alfred Stieglitz, the most influential figure in the art photography movement in the United States. Another American title, *Photo-Era* (Boston, 1898–1932), edited by Juan C. Abel, tried to educate Americans about artistic matters with exhibition reviews, print critiques and high-quality reproductions. Not quite as luxurious, but supplying important information and articles on relevant issues to art photographers were *Bulletin du Photo-Club de Paris* (Paris: The Club, 1892–1902), the British *Photogram* (London: Dawbarn and Ward, 1894–

1920) and *Photograms of the Year* (London: Dawbarn and Ward, 1895–1960) as well as *Amateur Photographer* (London: Hazell, Watson & Viney, 1884–1908). Journals which were long established also took up the cause, and the pages of the *Bulletin de L'Association Belge de Photographie* (Bruxelles, L'Association, 1874–1930) can be consulted as well as *Photographische Correspondenz*, organ of the Club der Amateur-Photographen in Vienna. *Wilson's Photographic Journal* (1864–1914), edited by Edward Wilson, an American editor and entrepreneur very interested in artistic photography, brought news of developments in Europe to professional and amateur photographers in the United States.

Signaling another new development, The *Photogram* (London: Dawbarn & Ward, 1894-1920), began publishing a supplement on "process work," reporting on new products and trends in photomechanical reproduction, which had become popular among photographers as well as a growing industry in this period. In 1896, it grew to several pages and had its own title, *Process Photogram* (1894–?). Two more titles on the subject appeared at the same time, *Process Work* (London: Percy, Lund, 1894–1920), and *Process Work Year Book*, (London: 1894–1982), which was published into the 1980s as *Penrose Annual.*

Manuals appeared which emphasized aesthetic over technical matters, dealing with such subjects as schemes for lighting portraits, marine or mountain photography, and choice of subject. They were generally written by leaders of the movement and include *Amateur Photographer* editor A. Horsley Hinton's *Art photographique dans le paysage: étude et pratique* (Paris: Gauthier-Villars, 1894) and *Practical Pictorial Photography*; H.P. Robinson's *Art Photography In Short Chapters* (London: Hazell, Watson, & Viney, 1890) and *The Elements of A Pictorial Photograph.* (Bradford, England: Lund, 1896); Photo Club de Paris founder Emile Puyo's *Notes sur la Photographie Artistique*, and W. I. Lincoln Adam's *Sunlight and Shadow: A Book for Photographers, Amateur and Professional* (New York: Baker and Taylor, 1898).

The decade saw creative experimentation with various print-making processes, both silver and non-silver, and technical advances led to new interest in and appreciation of photo-mechanical processes (in particular photogravure) as photographers tried to stretch the accepted boundaries of the conventional photographic print. Gum-bichromate was extensively used, as photographers could incorporate color or manipulate the process to painterly ends, and manuals and technical treatises appear to support this new interest, including Alfred Maskell and Robert Demachy's *Photo-aquatint, or, The Gum-Bichromate Process: A Practical Treatise on a New Process of Printing in Pigment Especially Suitable for Pictorial Workers* (London : Hazell, Watson, & Viney, 1897). A platinum based printing process called platinotype became very popular for its velvety blacks and long tonal range, leading to several new books including A. Horsley Hinton's *Platinotype Printing: A Simple Book On The Process.* (London : Hazell, Watson, & Viney, 1897) and William de Wivesleslie Abney and Lyonel Clark's *Platinotype, Its Preparation and Manipulation* (London : Sampson Low, Marston, 1895).

The Emerson-Robinson debate over photographic aesthetics, which reached its heighth in 1889 with P.H. Emerson's *Naturalistic Photography for Students of the Art*, continued, but the personal hostilities came to a startling finish in 1891. In that year Emerson published an article/pamphlet titled *Death of Naturalistic Photography*, where he rebuts his own theory and proclaims that photography cannot be an art. This was by no means the end of the debate, it was continued in the journals, and was an important focus of the period. Emerson continued to publish as well, issuing a third edition of *Naturalistic Photography* that included *Death of Naturalistic Photography* in 1899.

The publication of books and periodicals on specific applications for photography continues unabated as scientists, artists, archaeologists, and others employ photography in their work. Of special note is Alphonse Bertillon's *Photographie judicaire avec un appendice sur la classification et l'identification anthropométriques,* (Paris, Gauthier-Villars et fils, 1890), essentially a police manual on photographing criminals. Applications were varied: the discovery of x-rays by Roentgen in 1895 led to several new books on the subject; Etienne-Jules Marey used photography to analyze human and animal motion, resulting in several important publications; and the new popularity of bicycles and photography for leisure activities can be seen in their pairing in the journal *Cycle and Camera* ([London] : Jefferson and Welford, 1897–) and several manuals on these subject. And finally, on the lightest of notes, Walter Woodbury published *Photographic Amusements* (New York: Scovill & Adams, 1896) containing directions for manipulating and making new kinds of photographs using ordinary household materials. The popularity of this book continued through 11 editions in 41 years.

Photography was a part of modern culture and civilization by the 1890s and generally accepted as a pastime, a profession and a tool. Photographic technology fueled modernization as photography was applied to every kind of scientific endeavor, aided medical research, revolutionized publishing, and continued to contribute a visual component to research in less technical enterprises, from archeology to art. Books on photography for all these areas of endeavor continues at a prodigious rate, really a harbinger the explosion of publishing in the twentieth century.

BOOKS ILLUSTRATED WITH PHOTOGRAPHS: 1840s

In October 1844, William Henry Fox Talbot and Nikolas Henneman, travelled to Scotland to undertake a project which would have an enduring effect on the future direction of photography. With support from Lady Elizabeth Fielding, Talbot had determined to publish a photographically illustrated book, *Sun Pictures in Scotland*, which would draw its inspiration from the life and works of Sir Walter Scott who had died twelve years earlier.

In publishing this volume, he not only gave the world its first themed photographically illustrated book, but also provided the inspiration for a publishing direction which endures and grows to this day—the travel book. It can be argued, however, that is not a book, but a portfolio, as it has no text, simply picture captions.

Sun Pictures in Scotland was published in an edition of one thousand copies, all subscribed for in advance, and required the production of twenty three thousand hand made salted paper prints from calotype negatives. Each print was pasted in by hand.

While the book can undoubtedly be recognised as the first photographically illustrated book published in a significant edition, it was not the first photographically illustrated publication.

There remains some debate over what constitutes a publication, and what distinguishes a book from an album. Claims have been made for L.L. Boscawen Ibbotson's *Le Premier Livre Imprimé par le Soleil* from 1839 to be accepted as the first photographically illustrated publication, but this was no more than an album of contact prints of grasses, flowers and ferns, circulated in a small edition. It was exhibited at the 1851 Great Exhibition at the Crystal Palace in London as being 'the first book published by the sun'.

Hill and Adamson's *A Series of calotype Views of St Andrews, Published by D.O. Hill and R. Adamson at their Calotype Studio, Calton Stairs, Edinburgh* in 1844 also falls into this category.

Similarly, Anna Aktins' meticulous volumes of contact prints of flowers, algae and ferns, illustrations and texts printed by the cyanotype process, cannot be seen as 'books' in the modern sense of commercial publications.

The case for identifying the privately published *Record of the Death-Bed of C. M. W.* privately (printed in January 1844 with a text by John Walker Jnr, and illustrated by a calotype by Nikolas Henneman of a bust of the deceased) as the first photographically illustrated publication, is problematic. It conforms to the modern conventions of publication—printed text accompanied by a photograph—but was not published in any real sense.

Photography's first illustrated publication was Talbot's *The Pencil of Nature*, published in six parts between 29th June 1844 and 23rd April 1846. It was also the world's first partwork.

Also in 1846, the German publisher Hermann Johann Kessler produced *Gedenblätter an Goethe*, the first photographically illustrated book outside the United Kingdom.

Perhaps more significantly in terms of scale and impact, the journal *The Art Union* illustrated its June 1846 issue with a salt print from one of Talbot's calotype negative. Seven thousand copies were produced, making it the largest photographically illustrated edition of the decade.

Talbot went on to produce sixty six calotype illustrations for a fourth volume to augment William Stirling's three-volume *Annals of the Artists of Spain* in 1848.

BOOKS ILLUSTRATED WITH PHOTOGRAPHS: 1850s

As with the 1840s, many of the photographically illustrated publications of the 1850s were little more than portfolios of captioned photographs. In that era, publishers do not seem to have made the clear distinction that would be made today. As most were made available in significant and sometimes substantial editions, and were advertised and sold to the public, they were accepted as publications, and publishers did not differentiate between those with texts and those with captions. Thus the majority of publications by Joseph Cundall's London publishing house are seen today as albums. Titles included *The Photographic Album* edited by David Bogue and published each year from 1852 to 1854, containing albumen prints by Roger Fenton, Philip Delamotte, Hugh Owen, Alfred Rosling and others. He also published James Robertson's *Photographic Views of Constantinople* (1853) and *Photographic Views of the Antiquities of Athens, Corinth, Aegina etc* (1854). London publisher Charles Whittingham published a similar volume from the members of the Photographic Club in 1857, featuring the same photographers together with Francis Bedford, Hugh Diamond, Robert Howlett, John Dillwyn Llewellyn, William Lake Price and others.

A considerable number of books containing a single tipped-in photograph were also published—perhaps more to promote sales rather than using photography to expand and develop the ideas within the text. Amongst these, and also published by Cundall, was Philip Delamotte's textbook *The Practice of Photography: A Manual for Students and Amateurs*. Each of the three editions, published in 1853, 1854 and 1855, had a different albumen print tipped in as a frontispiece. David Frederick Markham's *A History of the Markham Family* (London: J. B. Nichols, 1854) had a single photographic copy of a painting as a frontispiece, while John Collis Warren's *Remarks on Some Fossil Impressions in the Sandstone Rocks of the Connecticut River* (Boston: Ticknor and Fields, 1854) included a salt print. Hugh Miller's *The Testimony of the Rocks, or Geology and its bearings on the Two Theologies, Natural and Revealed* (Edinburgh: Shepherd and Elliot, 1857) included a portrait of Miller himself by J. G. Tunny, the Edinburgh portrait photographer.

Amongst those books to make significant use of photography, were Hugh Owen's and Claude-Marie's. Ferrier's illustrations (printed in France) for the *Great Exhibition of the Works of Industry of All Nations. Reports of the Juries on the Subjects in the 20 Classes into which the Exhibition was Divided* (London: Spicer Brothers, 1853) ranks as one of the earliest. Within the four volumes, of which an edition of one hundred and fifteen copies was prepared, one hundred and fifty five photographic illustrations were used. Owen used post-waxed calotype negatives, while Ferrier took his photographs on albumenised glass plates. Of the edition, fifteen copies were reportedly given to William Henry Fox Talbot in return for his permission to proceed with the project, as he had patented the idea of publishing photographically illustrated books.

Photographic dealers Harvey and Reynolds of Leeds published their *Catalogue of Photographic Apparatus illustrated by Photographs of Such* in 1855, the earliest recorded use of photography in a sales catalogue, but few details of it survive.

Roger Fenton's photographs of the Codex Alexandrinus in the British Museum were used in *Photographic Facsimiles of the Epistles of St. Clement of Rome, made from the unique copy preserved in the Codex Alexandrinus* with a foreword by Sir F. Madden (London: British Museum, 1856), the earliest recorded photographically illustrated museum publication. Sir John Charles Robinson's *Catalogue of the Soulage Collection, Being a descriptive Inventory of a Collection of Works of Art, formerly in the possession of M. Jules Soulages of Toulouse, now exhibited to the public at the Museum of Ornamental Art, Marlborough House, December 1856* (London: Chapman and Hall/Marlborough House, 1856) is the earliest known photographically illustrated exhibition catalogue in the English language. Ten tipped in albumen prints were included. Three years later P. & D. Colnaghi in London, and Thomas Agnew in Manchester published the five-volume *Photographs of the Gems of the Art Treasures Exhibition, 1857, Ancient and Modern Series* with fifty illustrations in each volume by Caldesi and Montecchi, and Robert Howlett, later combined into two volumes with a total of two hundred photographic illustrations. No text was included, but each photograph was captioned.

During the decade, however, the emergence of the true photographically illustrated book can be chronicled alongside a growing number of published albums and portfolios of photographs.

Rivers, Mountains and Sea-coast of Yorkshire with essays on the climate, scenery, and ancient inhabitants of the county by John Philips (Oxford: probably self-published, 1854) may well be the first book in which tipped in photographic prints were offered as an alternative to the more conventional engraved illustrations. The ordinary edition was illustrated by thirty-six engrav-

ings, while in a deluxe edition these were replaced by the same number of albumen prints, from photographs taken by the author. He was, at the time, Keeper of the Ashmolean Museum in Oxford, and author of several books on geology.

Francis Frith's partwork *Egypt and Palestine photographed and described by Francis Frith* was originally published in portfolio form (London: James Virtue, 1858) but in 1859 was republished as two books, with a third volume published in the following year. The extensive text in both the partwork and the books offers a definitive and first-hand account of Frith's travels to Egypt and the Holy Land in 1857.

1858 also saw the publication of *Stereoscopic Views in North Wales photographed by Roger Fenton* (London: Lovell Reeve)—containing twenty-one stereoscopic views and an accompanying descriptive text—one of several collaborations between Fenton and Reeve which continued into the 1860s. 1858 also saw the publication by Reeve of Charles Piazzi Smyth's *Teneriffe, an Astronomer's Experiment* at 452 pp. with twenty stereographs, and *Narrative of a Walking Tour in Brittany* with text by Reeve and John Jephson, containing a stereo frontispiece and accompanied by a boxed set of ninety stereocards. Reeve's periodical *The Stereoscopic Magazine* was already well established, offering three stereo views and accompanying text per issue.

Seven illustrated books containing photographs of India by Captain Linnaeus Tripe appeared in the same year, published by the Madras Presidency.

Little more than a hundred English language publications appeared between 1850 and 1859. As the 1850s drew to a close, and the price of albumen prints reduced, the number of photographically illustrated books as we would recognise them today started to increase. That number was increased considerably during the following decade.

BOOKS ILLUSTRATED WITH PHOTOGRAPHS: 1860s

The 1860s is considered as a 'Golden Age' in printmaking—particularly in Great Britain—and a plethora of reprographic processes were available. In 1859 William John Stannard listed no less than 156 in his privately published *Art Exemplar*. Photographically illustrated publications formed part of this great expansion in illustration during this decade.

Technological and economic aspects were influential in the rise during the 1860s of books and other publications illustrated by photographic processes. The 1860s saw an economic boom period and commercial photography benefited accordingly. Books became cheaper to manufacture through both new printing technologies and the economies of scale enabled by the increasing disposable income of the burgeoning middle class. A transition took place whereby photographically illustrated books moved from being the domain of the very rich to a wider and more diverse audience.

As a result of these conditions, it is likely that ten times the number of photographically illustrated titles were published during the 1860s than had during the 1850s. However, the scale, scope and significance of the 19th century application of photography to the illustration of books and other publications containing printed text largely awaits discovery and interpretation. Nevertheless, it is clear that the publishers of Great Britain, Germany and France were the leaders in producing books illustrated by photography.

The physical form of photographic illustration developed in the 1850s was continued in the following decade. Photographic prints were pasted onto one side of separate sheets of paper of heavier stock than the text pages, and these were inserted amongst the signatures. Frequently these folios were unpaginated though they might include letterpress captions and credits. There are few examples of photographically illustrated books in which photographs had been pasted into specifically created blank spaces on text pages, thus pointing to full integration of photographic image and text. One such title was William and Mary Howitt's *Ruined Abbeys and*

Castles of Great Britain published in 1862. However, this format remained uncommon.

Photographic publishers adopted a number of standard publishing marketing strategies. One was the use of pre-publication subscription, particularly for deluxe titles. The part work or serial was another hallmark of photographically illustrated publications. Frequently, once a full year of a serial had been published the parts were given a special title page, bound as individual volumes—often available in a variety of different bindings and sold to the Christmas market. These approaches were a mixture of the practical issues and challenges inherent in the nascent mass production techniques, marketing strategies to attract a wide range of buyers and attempts to limit financial liabilities. Thus prices of photographically illustrated books could range from a couple of shillings to several guineas. Nevertheless, from the 1860s advertisements in periodicals chronicle the path of unsold stock, via price reductions, remaindering and specialist auction houses offering the entire remaining stock of photographically illustrated books that had failed to sell.

Photographic publishers exploited the 19th century fascination for celebrity and biography. A total of some 125 portraits by A.A.E. Disdéri were published in Paris between 1860 and 1863 under the title *Galerie des Contemporains*. Some 144 portrait photographs by Ernest Edwards were co-published in London by Lovell Reeve and A.W. Bennett between 1863 and 1867 under the title *Portraits of Men of Eminence in Literature, Science and Art*. Other portraits by Edwards were published between 1865 and 1868 by Churchill in London as *Photographs of Eminent Medical Men of all countries*. The work of another leading portrait photographer—John Jabez Edwin Mayall—was published between 1867 and 1868 as *Mayall's celebrities of the London Stage, a series of photographic portraits in character*.

The photographically illustrated publications on works of fine and decorative art and architecture proliferated during the 1860s. The reproduction of engravings after paintings was common, though by the end of the 1860s photographic art publishers such as Adolphe Braun of Dornach began to photograph directly from paintings. Braun's Carbon prints of the frescoes of the Sistine Chapel published in 1869 form one of the landmarks in the influence of photography to change art historical scholarship.

In Great Britain photographic publishers included Samson Low, Bell & Daldy, A.W. Bennett, Day & Son, Seeley, Jackson & Halliday and Bickers & Son. Specialist art societies, such as the Arundel Society, also played a key role and in the late 1860s and early 1870s this society collaborated with the South Kensington Museum and the Department of Science and Art in a series of photographic publications titled *Art Workmanship of Various Ages and Countries*.

The 1860s also saw the limited introduction of a number of permanent photographic and photomechanical processes that were applied to book illustration. The Carbon print and the Woodburytype are particular examples. An advantage of the Carbon process was that the pigments that formed the photographic image could be tinted as a single colour. The Autotype Company, founded in Brixton in south London in 1868, became a key promoter of the Carbon process both as a printer and publisher of photographically illustrated books.

Photozincography was exploited by the Ordnance Survey Office in Southampton to reproduce the Domesday Book and other historic manuscripts. Photolithography began to be used to reproduce graphic art and line drawings in a variety of publications, including books, serials and periodicals.

Early examples of photogravure began to appear in the late 1860s such as Eduard Baldus' *Palais du Louvre et des Tuileries* that commenced publication in 1869.

By the later part of the 1860s photographic illustration had already encompassed a very wide range of human activity from medical treatises to local history. It ranged from cheap consumer titles, through de luxe volumes for the rich collector to the periodicals of scholarly societies, though this latter area was not large-scale.

BOOKS ILLUSTRATED WITH PHOTOGRAPHS: 1870s

The 'golden age' of photographically illustrated publications of the 1860s was consolidated during the 1870s. The number of photographically illustrated publications continued to rise, and compared to the 1860s probably by a factor of more than three times. However, the commercial success of photographically illustrated publications during the 1870s, and how this market was affected by the serious economic recession in the middle of the decade, has yet to be fully evaluated.

The 1860s had seen a very rapid rise in photographically illustrated publications and the scope of application was largely defined. In physical terms the vast majority of photographic illustrated publications of the 1870s continued to be in the form of pasted in Albumen prints. However, during this decade a wider range of photographic print processes was exploited for a variety of objectives. These included the Carbon transfer process, and a variety of photomechanical processes ranging from the Woodburytype through the Collotype to photolithography.

Sales and marketing strategies of photographic publishers varied during the 1870s. Some publishers aimed at the luxury end of the market and exploited the characteristics of the Woodburytype. Other publishers built on the industrialised production of the Albumen print, while others aimed to exploit photomechanical processes to improve productivity, cut costs and thus target a wider audience. The part work continued to be a staple.

The photographically illustrated art serial reproducing well-know paintings were popular during the 1870s. In 1875 the contemporary press reported that the 'artisan classes' of the principal manufacturing towns in the north of England flocked to obtain an issue of *The Picture Gallery* (published by Sampson Low, Marston, Low, and Searle of London) dedicated to the artist Sir Joshua Reynolds (1723–1792). Curiously, the photographic illustrations were in fact almost exclusively taken from engravings after the paintings.

The Carbon transfer process produced a permanent photographic print, which coupled to a broader tonal range differentiated it from the ubiquitous Albumen print. Since different coloured carbon 'tissue' could be used, the Carbon process was particularly well suited to reproducing artists' drawings created in a single colour. B.B. Woodward's *Specimens of the Drawings of Ten Masters, from the Royal Collection at Windsor Castle* published in London in 1870 contained a variety of different coloured and achromatic Carbon prints printed by Edwards & Kidd. However, a wide range of subject areas were covered by the Carbon print including medical treatises such as *On Tracheotomy, Especially in Relation to Diseases of the Larynx and Trachea* published in Philadelphia in 1876.

The Woodburytype, characterised by its rich, dark shadow detail, was patented in 1864 and rose to prominence during the 1870s. Though the prints were photomechanical, they were time consuming to print and then needed to be trimmed and individually mounted. This degree of labour intensity was to eventually lead to the processes demise. One of the most notable Woodburytype publications was *Galerie contemporaine* published in Paris between 1876 and 1884. The large sized portraits of eminent French men—almost exclusively from life—were printed by Goupil et cie, one of the pre-eminent photographic publishers.

The Collotype, patented in 1869, came of age during the 1870s, though the principles behind the process dated back to the mid 1850s. It differed from the Woodburytype since the image could be printed directly onto the paper support. However, as with the Woodburytype, the Collotype could not print both image and text together. The rotary Collotype was announced by the photographer and printer Joseph Albert (1825–1886) of Munich in 1873 and in the following year he made the first colour Collotype. The art critic John Ruskin (1819–1900) was an earlier adopter of the Collotype using the process to illustrate his *Aratra Pentelici. Six Lectures on the Elements of Sculpture* published in 1872. John Thomson's *Illustrations of China and its people* was published in London between 1873–1874 and its 218 illustrations were Collotypes.

In the UK two companies were prominent in their exploitation of Collotype for book illustration; The Autotype Company was the first firm to produce and market Collotypes through the brand 'Autotype' covered a variety of photographic print processes. The Heliotype Company, whose printing works was run by Ernest Edward (1837–1903), was also prominent. In 1872 Edwards moved to Boston to become manager of the Heliotype Corp., part of the James R. Osgood Co. that published a range of photographically illustrated books using the Collotype process.

Photolithography had based its commercial market on the reproduction of line drawing. During the 1870s the process was increasingly used to reproduce drawings that appeared as illustrations in architectural periodicals such as *Building News*. The London trade directories of the 1870s indicate that the number of photolithographers had more than quadrupled in this decade. James Akerman was one of the leading exponents. William Griggs (1832–1911) continued his pioneering photolithographic work. Perhaps the most important work photolithographed at his works in Peckham, south London was the reproduction of Pantanjali's *Mahabhashya*—one of the great Sanskrit grammars written in the 2nd century BC—from originals borrowed from Bombay. These were published in 1874 at a cost £6000 less than an estimate put forward by a firm who proposed to copy the manuscript by hand. Griggs, a pioneer of colour photolithography, also created many photolithographic illustrations for the influential periodical *Indian Antiquary* that commenced publication in 1872.

There were sporadic uses of photogravure during the 1870s. It was the introduction of the practical and commercially viable process of Karl Klič (1841–1926) in 1879 that spawned a new chapter in the history of books illustrated by photography.

BOOKS ILLUSTRATED WITH PHOTOGRAPHS: 1890s

By the 1890s, book illustration had evolved from the old methods of using original photographs in books to include photo-mechanically reproduced illustrations. Many photographers continued to make valued and rarified objects containing tipped-in photographs while others looking for a wider audience relied on a variety of photomechanical reproduction processes.

The book topics benefiting most from the addition of photo illustration included scientific and ethnographic studies, promotional pieces for tourism or relocation, and children's stories and nursery rhymes. At turn of the century photographically illustrated books coincided with the first period of consistent development of art photography. Not withstanding photographers responded in a number of directions to imaginative and factual writing when coupling their images to the text.

Preserving memories and a nostalgic look at gentler times in the face of industrialization is what appears to have motivated many authors. When Naturalist photographer Peter Henry Emerson published *Wild Life on a Tidal Water* (1890) his images of Britain's East Anglia captured the disappearing rural lifestyle yet were reproduced in the new halftone printing process.

Perhaps inspired by an equivocal need for flight of the imagination, other photographers illustrated books about travel and people of the world. William Shepard Walsh produced *Around the World in Eighty* Minutes (1894) showing some of the most interesting monuments and beautiful scenes on the earth's surface. Books expressing to preserve family memories and mirror society's desire for more leisure time are enunciated in E. A. Allen's *A Jolly Trip: Or, where we went and what we saw last summer* (circa 1895), Frank G. Carpenter, *Travels Through North America with the Children* (1898), and Mary Abigail Fowler's *Snap Shots with Tales of Travel Truthfully Told* (1898) Lida Brooks Miller features a number of halftone reproductions of scenes taken in Africa, Europe American and Asia in *Round the World with Notebook and Camera* (1897).

Savoring the historic past and vastly changing present through the photographic image appeared to inspire some photographers. In New England, during the 1890s, a number of quite gifted regional photographers took pictures of people at work, interesting local events, and beautiful views. One such photographer, Henry S. Wyer, ca. 1890–95, published a number of books illustrating the sights and characters of his native Nantucket. Wyer's book, *Nantucket: Old and New* featured local townsfolk at their occupation.

Contrasting somewhat in purpose, photographically illustrated books about the American West aspired to attract new residents and tourism to the developing frontier. Illustrated government publications about the American West using the halftone printing process were widespread by the early 1890s. Most books of the West followed one of four main categories: private memorial projects to commemorate an individual or their adventure, commercial business enterprises geared to attract new pioneer settlement, historical documentation of local interest, and books or manuals aimed at promoting tourism.

Government published books on the peoples and places of the western frontier bring together historical and statistical data coupled with photographic illustrations. Two such books were published in conjunction with the demographic report of the 1890 census, *Moqui Pueblo Indians of Arizona and Pueblo Indians of New Mexico* (1893) and *Report on Indians Taxed and Indians Not Taxed* (1894).

During the final decade of the century, photographically illustrated children's books continued to be a popular form of expression among amateur photographers.

Photographic images advanced the narrative of nursery rhymes, poetic verse and prose. When illustrating a text, some photographers considered their subject by recording the story setting, while others enacted staged realities or *tableaux vivant*. Photographically illustrated children's books were popular as keepsake mementos and not necessarily intended for children even though children were the subject. Amateur photographers gravitated toward the genre of photographically illustrated books for children. Mary A. Bartlett produced three such books in the decade, *Old Friends with New Faces* (1892), *Mother Goose of '93* (1893), and *A Girl I Know* (1894). The first two featured allegorical narratives depicting young children within a domestic setting acting out nursery rhymes. Bartlett integrates calligraphic text with charming photographs printed in the gravure process on tipped-in Japanese rice paper. *Mother Goose of '93* was

promoted as a souvenir, available at three locations at the World's Columbian Exposition. *A Girl I Know* is an homage to Bartlett's teenage-daughter Madelon shown in cap and gown on the occasion of her graduation. Each of Bartlett's books was published in an edition of 500 by Joseph Knight Company of Boston who appears to have been a major producer of the children's book genre.

Photographically illustrated children's books appear to have been authored equally by men and women. Alexander Black produced at least a half-dozen in the 1890s; his *Captain Kodak: A Camera Story* published in 1899 references the craze for amateur snapshot photography. In addition to Black, two of the more highly recognized photographers producing books related to children's themes were Lewis Carroll, *The Story of Lewis Carroll* (1899), and Rudolf Eickemeyer, *In and Out of the Nursery* (1899).

The idea of combining photography with poetic verse was taken up by Helen E. Stevenson when she published a book, *Pictures from Nature and Life* (1894) of her photographs coupled with poetry written by her twin sister, Kate Raworth Holmes. In part a personal diary the book appears intended for a very private audience yet some of the themes are universal. The images recall the sisters' personal experiences traveling to romantic castles in England, a pair of happy lovers, a young bride dressed for her wedding day, and a mother cradling her child. Dedicated to their mother, the sister's drawing-room book offers a sentimental view of family life.

The late nineteenth-century interest in all things *japonisme* reached its apogee in the Mikado edition of J.B. Millet Company's *Japan: Described and Illustrated by the Japanese* published in Boston between 1897 and 1898. Possibly the last great book to be illustrated entirely by original photographs, the ten folio volumes, sumptuously bound in Japanese silk brocade and lace are illustrated with a plethora of tipped-in photographs. Published in 250 copies, each set featured ten brilliant full-page color collotypes of Japanese flowers by Ogawa Isshin (1860–1929), sixty full-page hand-colored albumen prints individually mounted and matted with tinted, and some two-hundred smaller hand colored albumen prints mounted within the text. This enormously complex publishing project was at once a summation of the cultural and political interchange between Japan and American in the late nineteenth century.

BOOL, ALFRED (1844–1926) AND JOHN (1850–1933)

Studio owners

The Bool brothers, Alfred Henry & John James opened two studios in London's Pimlico in the 1860s. In 1875 they were commissioned by Alfred Marks (1833 –1912) to take the initial series of negatives for the newly established Society for Photographing Relics of Old London. Each series consisted of 6 carbon prints, specially printed by the firm of Henry Dixon. Series 1, 1875, contained views of the Oxford Arms coaching inn; Series 21876, views of Lincoln's Inn; Series 31877 views in the Smithfield area; Series 4 views of Temple Bar & Gray's Inn Lane.

From Series 5 1879, however, both negatives and prints were made by Dixon alone. Each series was increased to 12 prints, and from 1881 brief texts were included with subscribers' copies.

Alfred Bool died in Wimbledon on December 91926; he was an early advocate of women's employment in photography. John Bool continued the brothers' Pimlico studio on his own until 1918; he died on the premises on December 14 1933.

DAVID WEBB

BOTANICAL PHOTOGRAPHY

A true history of botanical photography begins well before the 19th century, and even before the invention of photography as we know it. The desire for nature to be able to reproduce itself is ancient. Often credited with the one of the first observations of this phenomenon, Aristotle, during an eclipse, described seeing an image of the sun projected through tree leaves onto the ground. Acting as a primitive camera obscura, nature seemed to act out the title and philosophy of one of the earliest photographic books, "The Pencil of Nature."

As photography literally means "sun writing," it is no surprise then that some of its earliest subjects were of a botanical nature. A British scientist and one of photography's earliest practitioners, William Henry Fox Talbot (1800–77), used flowers during his first experiments. As he wrote to a botanist friend about his discovery, "I believe that this new art will be a great

von Gerlach & Schenk. Plum Blossoms.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

help to botanists…especially useful for naturalists since one can copy the most difficult things with a great deal of ease…I have practiced this art since the year 1834." Vegetation made for a perfect subject for typically long photographic exposures: they were inexpensive and they did not move. Prior to photography, woodcuts were the primary method for plant illustrations, yet most were not drawn from life and thus inaccurate.

At first one would think black and white photography less than ideal for reproducing such a vibrant entity as flowers. Although the autochrome process was not perfected until 1907, early experiments often used botanical specimens for their rich variety of hues. André Louis Ducos Du Hauron utilized leaves, stems, and flowers in an early attempt at a three color carbon assembly print. Later developments in light sensitivity allowed film, normally overly sensitive to blue, to more accurately reproduce more natural tones.

Botanical photographers drew from many sources—both scientific and aesthetic. Dutch painters had long turned to the exact copying of still-lifes. In French, still-life was literally "dead nature." Other prototypes for the botanical photographer included tromp-l'oeil paintings in the manner of William Michael Harnett and the Peale family. Meant to be hung in dining rooms, these pieces, like the Dutch "breakfast piece," were intended to speak of the bounty of nature as well as their host. The Victorians saw in flowers a symbolic vocabulary. Dubbed the "language of flowers," many ladies used small bouquets called "tussie mussies" to express their emotions. Like these varied precedents, 19th century botanical photograph also had a touch of "*vanitas*," or the brevity of life and, "*memento mori*," or a reminder of death. The photograph preserved forever short-lived blossoms. For this reason, documenting extravagant floral casket sprays was also common.

Relatively little is known about the small cadre of botanical photographers even at the height of their activity (1860–1880s). Pietro Guidi's stark albumen prints evoke subsequent examinations in their stark insistence on form. Richard Tepe's images share affinities with shadowy pictorialist studies. Other lesser names such as Eugène Colliau, Eugène Chauvigné, and Tony Boussenit, commingle with other anonymous artists working in the same vein. Some travel photography outfits based in exotic locations, such as Scowen and Co., specialized in recording rare specimens for museums. Numerous others, including British was photographer Roger Fenton, did at one time produce still-lifes as brief ventures into the realm, but few devoted their entire careers to the botanical. Four photographers, however, Anna Atkins (1799–1871), Adolphe Braun (1812–1877), Charles Aubry (1811–1877), and Karl Blossfeldt (1865–1932) seem to have come to define the genre.

Starting in 1843 and for the next ten years, Atkins collected and documented all the known species of algae in the British Isles with the help of her father, John Children, and her friend, Anne Dixon. Using the camera-less contact printing method of the cyanotype (also known as the blueprint), she made thousands of plates that were later bound into albums. The blueprint process not only recorded an exact replica to scale, but the intense color suited the subject well. The French textile designer Braun, also worked on a large project, yet for different reasons. Intending them as aids for the decorative arts, Braun completed a six-volume work of 300 photographic studies of flowers. His efforts met

with so much success at the 1855 Exposition Universelle that he left to pursue photography full-time, eventually opening a tourist photography firm. Like Braun, Aubry was trained as an industrial designer. As he explained in his *Studies of Leaves* (1864), his photographs were meant to "facilitate the study of nature, I caught it in the act, and I hereby offer to workers some models that may increase our productivity in the industrial arts."

Although most of his pioneering efforts occurred during the 20th century, mention must be made of German botanist, teacher, and sculptor Blossfeldt. Blossfledt began as an ironworker during the height of the German equivalent of the Art Nouveau movement. In 1890, he accompanied his professor to collect plant specimens for the purpose of lecturing on design. Self-taught in photography, Blossfeldt photographed primarily foliage for over thirty-five years. After taking his first photographs in 1896, he later reproduced his lantern slides in two books: *Urformen der Kunst* (Archetypes of Art, 1928) and *Wundergarten der Natur* (The Wonder Garden of Nature, 1932). Appearing against a background of either light or dark gray, Blossfeldt's studies emphasize sculptural form and graphic qualities.

During the waning years of the 19th century, flowers were used allegorically, in the manner of symbolist painting, or for purely formal modernist arrangements. Dreamy-eyed youths stared languidly into poppies in the works of F. Holland Day and lilies floated in bowls—all under the characteristic haze of the pictorial aesthetic. The linear quality of Asian prints also influenced photography in their inclusion of botanical motifs. It would not be until the 20th century, with photographers such as Imogen Cunningham, that the solo flower, namely the calla lilly, and its simple abstract quality would come to the fore.

BÖTTGER, GEORG (1821–1901)

German photographer

Georg Böttger was born in Hildburghausen, Thuringia on 9 July 1821. He was first a lithographer and engraver, before beginning as a portrait photographer in Nuremberg and Erlangen in 1850. In 1852 he moved to Munich, specialising in architectural images of monuments erected by Ludwig I and Ludwig II in Munich and Bavaria, and later teaching photography and selling collodion dry plates and photographic equipment. In 1854 he participated in the *Deutsche Industrieausstellung* [German Industrial Exhibition] in Munich. Named photographer to the Bavarian royal family in 1872, Böttger was well known for his landscape and city views as well as his art reproductions. One of his most famous works is a monumental 360-degree, 460-cm long panorama of Munich taken in 1858 from the tower of St Peter's church. Lesser known, but important was his documentation of railroad engineering and bridge building activity in Bavaria at the end of the 1860s. Much of his photographic work resides in the *Stadtmuseum* Munich and the *Deutsche Bahn* [German Railroad] *Museum* Nuremberg.

STEFANIE KLAMM

BOURDIN, JULES ANDRÉ GABRIEL (1832–1893)

French photographer and inventor

Jules Bourdin earned his place in photographic history with what has subsequently been recognised as the world's first 'instant picture camera'. Bourdin was a Parisian photographer who made little mark with his images, but a significant name for himself with his innovative camera designs.

The Dubroni No.1—the name is an anagram of Bourdin's own surname—which he invented and patented in 1864, was a novel camera designed for wet collodion photography which permitted the processing of the collodion plate to take place within the camera body, thus freeing the travelling photographer from the need to carry on location all the paraphernalia usually associated with wet plate operation in the field. In Britain, the smallest size Dubroni outfit, complete with an instruction book, could be purchased for £2. It was one of a significant number of camera designs which he marketed from the early 1860s until into the late 1880s, and by far the most important historically.

Contrary to many written accounts, however, it was not the first such design. William Henry Fox Talbot proposed a design for a daguerreotype camera with an integral processing facility as early as 1839, and Antoine Claudet suggested a similar design two years later. For collodion photography, the first camera with integrated processing was suggested by William Newton in 1851, and the inventor of the wet plate process, Frederick Scott Archer became the first to put such an idea into practice with his original camera design of 1853.

What made the Dubroni camera successful, when introduced a quarter of a century after such an instrument had first been suggested, was the compactness of its design, and the simplicity of its operation. While earlier suggestions involved designs in which large processing tanks were suspended beneath the back of the camera, Bourdin's design used the camera body itself as the sensitizing and processing chamber. So successful was the idea, that Bourdin eventually manufactured and marketed the camera in at least five different sizes, from the smallest which took a plate 45mm square, through quarter plate, to the largest which equated with a 'postcard' format of approximately 88 × 127mm.

The camera was of a simple wooden box design inside which was a ceramic or glass lining, with a bowl shaped recess at the bottom to contain the sensitising and later the processing chemicals. The glass negative plate, already coated with collodion, was placed against the open back of the ceramic lining, and held in place by the hinged back plate of the camera. The silver nitrate sensitizer was introduced via a pipette at the top of the camera, and allowed to flow over the collodion plate by tilting the camera on its back. The excess sensitizing solution was sucked out using the same pipette, and the camera was ready for exposure.

The camera was fitted with an f/4 lens, permitting exposures on the small plate of about three to five seconds outdoors, after which, the lens cap firmly back in place, the camera became the processing chamber.

Pyrogallic acid was used to develop the plate–again introduced through the top via a pipette–and the camera tilted on its back to facilitate development. As the camera back was fitted with a red or yellow glass inspection hatch, the progress of the development could be checked visually. After the developer had been sucked out, a conventional 'hypo' fixer was introduced, and the camera tilted on its back again.

The camera's major drawback was the rigorous cleaning which was required before a new plate could be fixed to the back, and a second exposure made as any trace of hypo left in the camera body would ruin the next exposure.

BOURNE, JOHN COOKE (1814–1896)

English engraver and photographer

John Cooke Bourne was born in London on September 1st 1814, the son of a hat-maker in Covent Garden. He became a pupil of the J M W Turner's favourite engraver John Pye in the 1830s, and was quickly recognised as an accomplished artist in his own right.

Bourne was commissioned to illustrate the construction of the London and Birmingham Railway, and later the Great Western Railway, and his plates, drawn with the aid of the camera lucida, have a quality which today would be described as photo-realistic.

In 1848 he was commissioned by the engineer Charles Blacker Vignoles, initially as an artist and later as both artist and photographer, to chronicle the construction of the first permanent bridge over the River Dneiper in Kiev. The project involved weekly photography of the project from late 1848 until the bridge's completion in October 1853. The images represent the first such use of photography to record progress. In 1852, Roger Fenton worked alongside him in Kiev. A small number of Bourne's images survive. They were exhibited in London in 1854 and 1855.

In 1855 Bourne was granted a patent for a novel camera design with integral processing which was lightweight and could be collapsed into a small case for travelling photographers. No images produced with such a camera have yet been located.

JOHN HANNAVY

BOYER, ALDEN SCOTT (1887–1953)

Born in Iowa on January 29, 1887, Alden Scott Boyer was an important and enthusiastic collector. His professional life began as a pharmacist, which led him to open a business in Chicago specializing in chemical products, perfumes, and cosmetics. Collecting dominated the pri-

vate sphere of his life. His collecting interests ranged from coins to curiosities, including photography and related publications. Boyer's collection, the "Alden Scott Boyer Museum for the Preservation of American Curiosities (Free)," was housed in a bank building in Chicago. His intense interest in photography began after reading *Photography and the American Scene* by Robert Taft in 1938. Boyer acquired many items from dealers and scouts in several countries. Additionally, he contacted the descendants of many photographers, such as Southworth and Hawes, to procure images, documents, and ephemera from their careers. Boyer also sought out relationships with photographic scholars and collectors. One such association with Beaumont Newhall led Boyer to donate his photographic collection to The George Eastman House in 1951. The 4½ tons of what Boyer called "photo junk" became a foundation for the history of photography. Boyer died on June 16, 1953 in the bank building that housed his remaining collection.

SARAH TEMPLETON

BRADY, MATHEW B. (1823–896)

American photographer

Few reliable facts are known about Mathew Brady's early life other than he was born to Andrew and Julia Brady circa 1823 in Warren County, New York. His father had immigrated to the United States from Ireland and made his living as a farmer in the southern Adirondacks. By 1840 Mathew had moved to New York City, and may have studied with the artist and inventor Samuel F.B. Morse. In 1843 he manufactured cases for jewelry, miniatures, and daguerreotypes. A year later, he opened his first daguerreotype studio on the corner of New York's Broadway and Fulton Streets, near P.T. Barnum's museum.

Among the dozens of daguerreotype studios operating in New York City in the 1840s, Brady's Daguerrean Miniature Gallery was one of the most prominent. Immediately after opening his studio, Brady received widespread recognition for his daguerreotypes. Beginning in 1844 and continuing throughout the decade he regularly received awards at the annual American Institute fairs. The New York City fairs, which promoted advancements in agriculture, commerce, manufacturing, and the arts, included exhibitors from across the United States. Indeed, in the 1840s and 1850s Brady's work was praised for its artistic qualities both nationally and abroad. Countless New York celebrities frequented Brady's studio. The portraits displayed on his gallery walls represented a "Who's Who" of American notables, including politicians, actors and actresses, writers and artists, and religious leaders. Through his association with these famous sitters, Brady became the first celebrity photographer. He lured famous sitters to his studio with the promise of a complementary daguerreotype, if they allowed him to keep one for display in his gallery. The general public flocked to his studio, excited to view portraits of famous personalities, and to be seen by the other visitors. His gallery provided an educational, experience for the emerging middle class who not only became more familiar with important Americans, but also joined them by having their own portrait made at Brady's studio.

Due to his poor eyesight, Brady usually did not operate the camera himself. Instead, he thoughtfully posed his sitters and made them feel comfortable during the procedure. In the January 1851 issue of *The Photographic Art Journal,* art critic C. Edwards Lester wrote: "While he offered inducements to the best operators and chemists to enter his studio, he superintended every process himself, and made himself master of every department of the art ..." Some of his camera operators and gallery managers became well-known photographers, including George S. Cook, who ran Brady's New York City gallery in 1851 when Brady traveled to Europe and Alexander Gardner who, in 1856, was hired to work in Brady's New York studio.

As his reputation grew, Brady moved his original New York studio to larger and more prestigious locations on Broadway. His later studios were celebrated for their richly appointed reception rooms and extensive portrait galleries. Photographs were displayed floor to ceiling, along with large portraits in oil of prominent Americans, their likenesses based on Brady daguerreotypes. The darkroom and finishing rooms were located away from public view. Brady pioneered in the use of skylights to increase the natural light entering the studio, reduce exposure time, and produce evenly lit portraits. Most of his daguerreotype portraits are bust-length, with the sitter's face angled slightly away from the camera. Brady's early images usually do not include props, but his later studio portraits regularly use a variety of props, including chairs, a table, an ornate gold clock, books, a column, and drapery.

In 1848 Brady opened a studio in Washington, DC, hoping to attract members of the U.S. House and Senate and to add to his growing collection of portraits. Among the personalities he photographed were President Zachary Taylor and his cabinet. Brady's original Washington studio was not financially successful and he was forced to close it within the year due to high operating expenses and competition from other experienced studios, such as the one run by John Plumbe, Jr. Ten years later, Brady was more fortunate when he opened a studio on Washington's Pennsylvania Avenue. Alexander Gardner successfully managed this studio, combining business skills with his talent as a photographer.

Brady met his future wife, Juliette Handy while in Washington, where they were married at the E Street Baptist Church. The exact date of their union is unknown. However, in 1851 he and his wife traveled to England, attending the Crystal Palace exhibition in London, where a group of his portraits of famous Americans was on display. He received a bronze medal for overall excellence.

During the daguerreian era, Brady's most significant undertaking was the publication of *The Gallery of Illustrious Americans*. This series of twelve lithographs by French artist Francis D'Avignon from daguerreotypes by Brady was among the most handsome publications of its time. Subjects included Daniel Webster, John C. Fremont, and Henry Clay. Brady's project differed from other series of printed portraits of the time, which were based on portraits in oil, and thus believed not to convey as truthful a likeness as those made from daguerreotypes. The publication received many positive reviews. The 2 March 1850 *Living Age* reprinted a review from the *Evening Mirror* of the first lithograph in the series, a portrait of General Zachary Taylor. It stated: "There are so many pompous announcements made of enterprises which are never carried out, and so many pledges given of this kind, which are never redeemed, that we can hardly express our satisfaction, on finding that the first number has more than made good on all the promises which were given." It continues: "... the whole work, surpasses anything that we have ever seen as a specimen of the art of typography." Subsequent prints were praised for their beauty as well as the lively and concise accompanying text. In spite of the quality of the publication and the extensive praise it received, sales were weak. The publication, which had planned to include twenty-four printed portraits, was discontinued after twelve.

In the mid-1850s photographic technology changed and Brady began to use glass plate negatives to produce multiple salted paper and albumen prints. He specialized in large "Imperial" portraits which were much easier to view than the mirrored surface of the small daguerreotype plate. (Imperial prints measured up to 22 × 17 inches compared with 6½ × 4¼ inches for a half-plate daguerreotype.) Later, when the *carte de visite* format became fashionable, Brady marketed his portraits of famous people to the general public who delighted in collecting these cards and placing them in albums.

Throughout his career, Brady's photographs were widely reproduced in the leading journals of the day. Both *Harper's Weekly* and *Frank Leslie's Illustrated Newspaper* used woodcuts based on Brady images to illustrate articles on politics and the arts. Both of these periodicals used Brady's first portrait of presidential candidate Abraham Lincoln, made on 27 February 1860, the day of the latter's pivotal lecture at New York's Cooper Union hall. Brady published this image as a *carte de visite*, and after his victory, Lincoln claimed: "Brady and the Cooper Institute made me President." The Brady studio frequently photographed Lincoln's family and his political associates during his presidency.

Brady, Matthew. Commodore Matthew Calbraith Perry. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Joseph M. Cohen Gift, 2005 (2005.100.84) Image © The Metropolitan Museum of Art.*

Brady's most important contribution to American history was his documentation of the Civil War. In 1861 he began sending photographers into the field. Many of the best Civil War photographers got their start working with him. Alexander Gardner and James F. Gibson transferred their studio skills to working outdoors, making conventional portraits, scenes in camp, and views of the aftermath of battlefields. Photographers were outfitted with portable darkrooms to process their wet-plate negatives in the field. Actual battle scenes were technically impossible to photograph, but the devastating impact of the war was nonetheless documented. Photographs of dead soldiers after the battle at Antietam were displayed at Brady's Broadway gallery where visitors were shocked to see such graphic depictions of war. After the war, Brady's views were displayed at the New-York Historical Society. A 30 March 1866 review of the exhibit in the *New York Times* reported "The faithful camera ... has written the true history of the war .... It is not merely what these representations are to us, but what they will be to those that come after us." General Ulysses S. Grant

stated: "... the collection will be valuable to the student and artist of the present generation; but how much more valuable it will be to future generations." Brady hoped to market these images to the public, but after the war there was little interest in purchasing views of a conflict that most were ready to forget.

Brady's business began to suffer during the war. In an effort to obtain a more complete set of Civil War negatives for his use, Brady purchased or copied negatives from other photographers, and assumed credit for the images. This was a common practice at the time, but it alienated Brady from some of his peers. While Brady became famous, his talented operators remained anonymous. In 1862 lack of credit prompted Alexander Gardner to leave Brady's studio and start his own business. After the war, he published *Gardner's Photographic Sketchbook of the War*, dutifully crediting each photographer and printer on the photographic mounts.

In order to keep his photographers supplied during the war, Brady entered a relationship with Edward and Henry T. Anthony, a photographic supply and publishing firm. Brady acquired photographic supplies from the Anthonys, using his negatives as collateral. The Anthonys published *Brady's Album Gallery,* a series of *carte-de-visite* from Brady's negatives, making copies of Brady's portraits widely available to the public. Although Brady received royalties based on the sale of the *carte-de-visite*, the Anthonys retained the negatives. As Brady's financial situation deteriorated, the Anthonys acquired thousands of his negatives which they continued to print for nearly twenty-five years. Brady was never able to regain ownership of these negatives. Over the years, these negatives changed hands many times, until 1940, when they were purchased by the Library of Congress.

After the war, Brady's studio was unable to maintain its high standards, and it lost favor with the public. His former employee, Alexander Gardner, was now one of his main competitors. In debt and unable to pay his creditors, in 1867, after operating for nearly ten years in Washington, Brady was forced to sell a portion of the studio to James F. Gibson, his studio manager. Brady declared bankruptcy the following year, but was able to repurchase his Washington studio with the proceeds from the sale of his home in New York. By 1873, however, he had lost both his New York and Washington studios, and the following year his stored property was sold at auction. More than 2,000 of his glass plate negatives were purchased by the War Department and in 1875 Brady sold an additional group of material to the War Department for $25,000. Even the poet Walt Whitman supported Brady's effort to sell his collection to Congress. He wrote: "... these typical men gathered together from opposing parties and convictions, representing in their varieties and oppositions after all a Common Country-seems to me peculiarly appropriate to the Library of the Capital." In 1940 this material was transferred to the National Archives.

With the proceeds from his sales to the government, Brady remodeled his Washington studio. A few prominent political figures familiar with Brady's reputation visited the studio, but it never regained its earlier popularity. His nephew, Levin Handy, carried on the day-to-day business, but it was not long before Brady was in financial trouble again. In November 1881, Brady's National Photographic Art Gallery on Pennsylvania Avenue closed its doors permanently.

In 1895 while crossing one of Washington's busy downtown streets, Brady was seriously injured in an accident with a horse-drawn carriage. After he recovered, he moved back to New York City. Brady was scheduled to present a magic lantern show on Civil War photography at Carnegie Hall, but he became ill with a kidney ailment. He died on 15 January 1896 and was buried at Congressional Cemetery in Washington, D.C.

Brady's career spanned the early history of photography. He utilized most of the nineteenth century processes in vogue during this time period, including daguerreotypes, ambrotypes, salt prints, and albumen prints. Major holdings of Brady's work are housed at the Library of Congress, National Portrait Gallery, Harvard University, Chicago Historical Society, and the National Archives. Brady's work is also held in numerous private collections.

Carol Johnson

Biography

Mathew Brady was born circa 1823 in Warren County, New York. In 1844 he opened a daguerreotype studio in New York City. From the start of his career, Brady realized the historical importance of photography and concentrated his business on photographing society's elite. Beginning in 1844 and continuing throughout the decade, his work was exhibited at the annual American Institute fairs. Brady's daguerreotypes of criminals were used to illustrate *Rationale of Crime* by Marmaduke Sampson. In 1850 *The Gallery of Illustrious Americans,* a joint project between Brady, C. Edwards Lester, and Francis D'Avignon, was published. The following year, Brady's work was exhibited at London's Crystal Palace exhibition. In 1853 Brady's work was exhibited at the New York Industrial Exhibition. In 1857 Brady's Imperial photographs were exhibited at the American Institute. Brady's staff photographed extensively during the Civil War. In 1866 these photographs were exhibited at the New York Historical Society. Brady published a catalogue of his well-known personalities and Civil War views in 1869 entitled, *National Photographic Collection of War Views and Portraits of Representative*

Men. It listed 700 Civil War views and more than 2,500 portraits. His work was exhibited at the 1876 Centennial Exhibition held in Philadelphia. After three decades of financial difficulties, Brady died on 16 January 1896. He is buried at the Congressional Cemetery in Washington, DC.

Brady's career spanned the early history of photography. He utilized most of the nineteenth century processes in vogue during this time period, including daguerreotypes, ambrotypes, salt prints, and albumen prints. Major holdings of Brady's work are housed at the Library of Congress, National Portrait Gallery, Harvard University, Chicago Historical Society, National Archives, and the New York Historical Society. Brady's work is also held in numerous private collections.

BRAGGE, JAMES (1833–1908)
English photographer

James Bragge (1833–1908) was born in South Shields, England and moved to New Zealand with his family, arriving in Wellington shortly after it had been made the seat of Government in 1865. Having established a successful portrait business, he soon became known for his excellent landscape studies which were very popular with residents and visitors to the Capital whose business brought them to Wellington. Bragge not only made a feature of having on hand a constantly changing selection of Wellington views in whole plate and *carte-de-visite*, but he mastered large format photography. His largest camera took a plate measuring 16 × 14 inches. It was not long before civic dignitaries called upon his talents and commissioned him to make a series of views which were officially entered in the Sydney and Melbourne International Exhibitions of 1879 and 1880/1881. These submissions earned him several awards. He also made a spectacular series of views of a district close to Wellington called the Wairarapa. Using a horse-drawn van which he had fitted out in a fully equipped darkroom, he made over a hundred 10 × 8 inch to 12 × 10 inch views which were later bound into leather albums. These photographs did much to direct the attention of land investors to the district's potential, the negatives of which are currently housed in the Museum of New Zealand—Te Pap Tongarewa.

William Main

BRANDSEPH, GEORG FRIEDRICH (1826–1915)

Georg Friedrich Brandseph was born May 5, 1826, in Stuttgart as illegal son of Friederike Brandseph. He received training in lithography, and in 1851 he could be found in the city's address book as "lithographer, silhouetteur, and painter." Around this time he gained knowledge in the daguerreotype process through Karl Reutlinger who lived in Stuttgart as well. The idea of a professional career in photography occured to him while living in Hamburg between 1852 and 1853. Before opening his own studio in Stuttgart in late 1853, Brandseph went to Paris and visited a number of important studios including the one of Adrien Tournachon's. Brandseph's studio in Stuttgart grew to an extraordinary size in the 1870s and was handed over to his son Hermann Brandseph (1857–1907) in 1884. G.F. Brandseph retired to Kennenburg near Esslingen and died on Nov. 24, 1915.

During his involvement with photography, Georg Friedrich Brandseph was a true contemporary. He started his Stuttgart business in 1853, and starting with the Daguerrean process, switched to Collodion processes the next year, and then later introduced the carte-de-visite to Germany as soon as it was available in Paris. The extraordinary size of his company—around 1870 is reported to have had more than 40 employees and reflects the variety of his engagements. Of course, he had a portrait studio but there were printing departments, as well and a publishing house, which took care of the many photographs Brandseph produced of Stuttgart's edifices, streets, and places. In addition to this, Brandseph was an expert draftman and a painter, too. Typical for his time, Brandseph encouraged the Wurttemberg ducal family to collect photographs and to begin with their own experiences as amateurs. When Georg Friedrich Brandseph resigned in favor of his son Hermann in 1884, he handed over one of the biggest studios in the German speaking countries of his time. Unfortunately, Hermann was not as prosperous. When he died at the

age of 50 in 1907, the business had already shrunk to small size.

ROLF SACHSSE

BRANDT, CHRISTIAN FRIEDRICH (1823–1891)

Christian Friedrich Brandt was born on July 1, 1823, in Schleswig as the second child of the bookbinder Christian Wilhelm Brandt. From 1837 to 1840, he learned the craft from his father and went journeying subsequently throughout the German countries. It is likely that he learned more of the craft of the graphic arts when he was traveling. When he returned to take over the father's workshop in 1848, he already had some basic knowledge in the Daguerreotype method. From 1852, Brandt worked as a photographer and dealer in photographic equipment in the town of Flensburg. During the first decade he ran his own workshop, between 1852 and 1863, there was nothing remarkable about Brandt's work except that he produced good quality portraits. In 1863, he reproduced the altarpiece of Hans Brueggemann at the Schleswig cathedral. It was with this commissioned photograph that he immediately became one of the leading figures in the interpretation of late medieval sculpture. His idea was to take the altarpiece apart and have the scenes taken under daylight conditions in front of a dark cloth and sometimes even under sunlight giving the figures more expression through shadows. The images were not sold before 1865. Before Brandt expanded his business by photographing other altarpieces and private collections of medieval art, he received a commission to take photographs of the German troops at the final battle of the Danish-German war. These photographs were reprinted over and over in the years of 1865 to 1866 and were very successful economically. In 1865, he was commissioned to photograph the collection of medieval sculpture of Gustav Thaulow in Kiel being published relatively successful in 1867. He returned to large reproduction campaigns of altarpieces in the Rhinelands by 1868 but these compaigns suffered from being published more than a decade later when he was bankrupt. From 1869 to 1883, he worked as a portrait photographer in Flensburg. Closing his workshop in 1883 and unable to work, Brandt's last years remained in total poverty and he and his wife lived in a number of the city's poorhouses; he died on June 3, 1891.

ROLF SACHSSE

BRAQUEHAIS, AUGUSTE BRUNO (1823–1875)

French photographer

Braquehais was born in Dieppe on January 1823. After having studied at the Royale Institute of deafs and mutes of Paris, he worked as a lithographer in Caen. Back in Paris in 1850, he met Alexis Gouin, photographer with whom he joined to make portraits, reconstitutions, colored daguerreotypes and stereoscopic images on plates. His official photographer's beginnings dated from 1851, when he appeared on the *Bottin,* the Parisian commercial directories. 1852 marked his first collaboration with Gouin's daughter, Laure, who was as well a photographer and colourist trained by her parents. She did the colouring on his pictures printed on oil cloth. The same year, he moved to his own studio rue de Richelieu, 110.

In 1854, he proposed and registered—for copyright purposes—seven numbered copies of artistic female nudes, printed out by E. Péruche and entitled *Daguerrian Museum*. His deafness is shown through these pictures in which the models seemed to be "alone" and isolated notably because of their theatrical stances and the numerous accessories (statues, veils, armours, paintings…) around them. In *La Lumière*, E. Lacan, even if he regretted the recurrent appearance of a Venus plaster, mainly noted about these images that it was

> … impossible to handle collodion more skillfully. His prints are altogether limpid. The lines are finely marked without being hard, the tones are both highly translucent and remarkably forceful; the modelling is at once well-defined and mellowed; the lighting is deftly handled, thus conferring striking relief to the forms, which we are made to see down to the last detail….

He supposedly married Laure upon her father's death in 1855 (the sources don't come to an agreement about the exact date of their wedding) and took over Gouins' studio with her and his mother-in-law at rue, Louis-le-Grand, 37. Mrs Gouin continued her miniaturist work and decided to sell Gouin's colours. The couple worked in creating nude figure studies and producing stereoscopic portraits. They specialized in daguerreotypes, a process they would be the last to use in Paris. At this level, their works looked the closest to Alexis Gouin's.

From 1863, following the death of Gouin's widow, the Braquehais set up to Boulevard des Italiens, 11, at the sign of *La photographie parisienne*. Bruno Braquehais then lived an intense period of activity. In 1864, he presented with Despaquis some carbon prints warmly received at the Société française de photographie. He also participated to several exhibitions: he exhibited his images in Berlin in 1865 and at the Paris Exhibition in 1867 where he received a honorable mention. Two years later, he teamed up again with Despaquis, author of "Carbon photography for amateurs" (Lieber, 1866), who had been granted Poitevin's carbon process patents and proposed him to produce the paper for L'arbon prints.

However it is above all because of *La Commune de*

Paris (1870–1871), very first event to be photographed in France—photographs on the War of Crimée and the Secession War had already been produced respectively by Fenton, Brady and Gardner—that Braquehais' name is known today. Publicly rediscovered at the time of the Centenaire (1971), his singular pictures were put into light again by Musée d'Orsay and Musée de Saint-Denis exhibitions in winter 2000.

In spite of the many technical restraints (equipment difficult to move, slowness of the exposure time…) and of the censoring against "all images propicious to disturb the law and order," Braquehais "escaped" from his studio and made about 150 negatives (whose only 109 were registered) of the event. In a context in which the great photographers of the period were almost absent and the commercial images by the studios Hyppolite Collard, Alphonse Liébert, Pierre Ambroise de Richebourg or Jules Andrieu Disdéri focused on ruins and fires, Braquehais also chose to photograph people. Indeed, even if these pictures are marginal (about 30) compared to his whole work on the subject (quite similar to the common production), his bystanders portraits and negatives of Fédérés with their families posing in front of the barricades, gave *La Commune* a human face and some "public celebrations" ways where all the generations and social classes were represented. Therefore, Braquehais is considered as one of the first reporter, *the* precursor of photojournalism in France. Naturally, the affinities he felt for the communards cause as well as the authorizations he could obtain to photograph some scenes thanks to his connivances can't be ignored and give rise to interrogation. Although no document or evidence can prove that he was put in charge of some mission by *La Commune*, Braquehais' work could be related to an arranged and methodical account of the event in favour of the communards… Anyhow, the Versailles troops at the Tuileries and in the Minister of Justice interior yard, the Fédérés at Porte Maillot, the cannons in Montmartre, the Maison Thiers destruction and the Colonne Vendôme demolition on the same-named place offer another point of view and remain among the most significant pictures of the event.

Before disappearing from the *Bottin* in 1874, Braquehais signed an advertising order for a clocks-maker in 1873— because of a lack of work ?—which were doing very few photographers in the 19th century. He went bankrupt this same year and was condemned for abuse of confidence. Locked away in Mazas prison during 13 months, he died at La Celle-Saint-Cloud without known heir(ess) on February 1875, a few days after his release.

Like the erotic photographs of this period, his artistic nudes are sold as postcards and his pictures of *La Commune* illustrate the textbooks relating this historical event often anonymously… His works can be seen at the Bibliothèque Nationale (Paris, Département des estampes et de la photographie), Musée Carnavalet (Paris), Musée de Saint-Denis, Bibliothèque Historique de la Ville de Paris, Budapest Museum, Agfa-Photo Historama (Cologne), Printenkabinett (Leiden), and in several collections such as Mack's (New York) or Nazarieff's (Geveva).

FRÉDÉRIQUE TAUBENHAUS

Biography

Bruno Braquehais was Born in Dieppe in 1823. Previously lithographer in Caen, he joined Alexis Gouin's parisian firm towards 1851 and made portraits, reconstitutions, colored daguerreotypes and stereoscopic images on plates. In 1854, settled in his own studio, he proposed artistic female nudes collected on the title : *Daguerrian Museum*. He married Gouin's daughter, Laure, who coloured his images and with whom he worked since 1852. His photographs draw attention in several exhibitions among which the Paris Exhibition where he get an award in 1867. During *La Commune de Paris* in 1870–71, whereas his colleagues focused on ruins after the fights, Braquehais participated to the birth of photojournalism making a real report of the event with the demolition of the Colonne Vendôme and the portraits of Fédérés and bystanders. Condemned in 1873 for abuse of confidence, Braquehais was locked away during 13 months and died in 1875 at La Celle-Saint-Cloud, few days after his release.

BRASSEY, LADY (1839–1887)

English author, photographer, and patron

Lady Brassey, born Anna Allnutt on October 7, 1839, near London, England, was a world traveler, writer, collector, and photographer. She was raised by her grandfather and educated at home by a governess. In 1860, she married Thomas Brassey, the son of a wealthy railroad baron and an avid sailor. Lady Brassey wrote five books based on her travels with her husband: *A Cruise in the Eothen* (1872), based on their voyage to North America, *A Voyage in the "Sunbeam"* (1878), recording their trip around the world, *Sunshine and Storm in the East, or Cruises to Cyprus and Constantinople* (1880), *In the Trades, the Tropics and the Roaring Forties* (1884) that recorded a trip to the Bahamas and West Indies, and *The Last Voyage to India and Australia in the "Sunbeam"* (1889), which was published posthumously. Her trips enabled her to pursue her interests in photography and botany. Seventy albums, filled with 6,000 photographs that were either purchased or made by Lady Brassey, document sites of interest on her travels. She also collected specimens and artifacts, which comprised the Brassey Museum in London, opened by her husband after her death at sea on September 14, 1887.

Andrea Korda

BRAUN, ADOLPHE (1812–1877)

The career of Adolphe Braun illustrates the close relationship that existed between art and commerce in the early years of photographic practice. It offers insight into the manner in which photography became both a commodity and a force for cultural change. Braun and his company were involved not only in making photographs, but also in developing alternative reproductive processes that would make the camera image available well beyond the individual silver print. Braun's activities represent in microcosm photography's early shift from craft to manufacture.

Like many of his generation, Braun began his career as an artist-draughtsman. A designer of floral decoration for the textile industry in his native region of Alsace, he soon recognized the camera's potential for improving decoration on fabrics produced there. In 1853, he began to use the newly discovered collodion-albumen process, which entailed a glass negative coated with a mixture of soluble gun-cotton and silver salts and a paper positive coated with egg white and silver salts to make studies of botanical specimens. Issued as *Fleurs Photographiés*, consisting of 300 large format photographs of flowers, it was followed by some two hundred smaller scale images of similar material. Besides their practical use, the photographs were recognized by the art establishment as having artistic value on their own.

The artistic and commercial success of this venture necessitated the creation of a workshop to make exposures, develop the glass plates, and print the images. Employing his sons Henri and Gaston, and several additional workmen, the factory established at Dornach (a suburb of Mulhouse) eventually produced all the materials other than paper needed to produce photographic prints. Additionally, it used steam driven machinery to mechanize processes that formerly had been done by hand.

In establishing this facility, Braun recognized the necessity of producing other photographic commodities than floral prints. Among them were *carte-de-visite* and cabinet size portraits, stereographic views, and panoramas. It is estimated the company produced some seven thousand stereographs (double images taken by a camera with two laterally placed lenses), which required a special viewing device (stereoscope) to create the illusion of three dimensionality; they were mainly landscape views. The popularity of painted panoramas in the mid-nineteenth century undoubtedly influenced Braun's decision to make photographic panoramas. Using a camera called a pantascope, modeled on a device patented by the English inventors John R. Johnson and John H. Harrison and improved by David Hunter Brandon, in the mid-1860s the company began to produce expansive views of Alpine scenery. These appealed not only to tourists, but to patriots celebrating France's acquisition of the mountainous region of the Savoy.

Besides experimenting with a variety of formats, the Braun Company undertook to produce a diversity of subjects. The floral prints were followed by other saleable subjects. These included scenic landscape views of Alsace, Germany, and Switzerland, posed costume pieces of the distinctive dress of peasants in the Swiss cantons, and views of Parisian streets. By far the most successful and enduring project undertaken by Braun and Company was the photographic reproduction of works of art housed in major European museums. Starting in 1866 with a selection of the master drawings in the Basel Museum, the project eventually embraced collections of paintings and sculpture in Florence, Paris, Rome, and Vienna as well as works by contemporary artists. The Braun *équipe* negotiated rights, arranged for scaffolding, paid gratuities, and coddled art critics in order to photograph in the Louvre, the Vatican, and the Albertina, among other venues. The art reproductions were meant to improve the taste of the French middle-class, only recently elevated from peasantry, by introducing it to the masterworks of western European art. Commercially marketed in France, Germany and the United States, Braun art reproductions also enabled art students to become acquainted with works of art that otherwise would have been inaccessible. By making available throughout the world identical reproductions

of a unique work, this aspect of photography made possible the discipline of art history.

The reproductions of drawings were especially accurate because they were printed by special processes that replicated the color of the original and also did not fade. Recognizing the impermanence of albumen prints, which tended to discolor depending on how carefully they were processed and kept, the Braun Company experimented with non silver methods of printing. They turned first to Woodburytypes and then to carbon printing. Both methods were based on early discoveries by the amateur Scottish scientist Mungo Ponton that potassium bichromate (now called dichromate) hardened when exposed to light. The Woodburytype, named for its English inventor Walter B. Woodbury, used dichromated gelatin to form a relief matrix, from which a print could be produced under pressure. Made without screens or any particulate matter, it was exceptionally accurate, but required trimming, which increased production costs. Following improvements to the sensitivity of dichromated potassium by Edmond Becquerel and the addition of carbon black coloring matter by Alphonse Poitevin, the carbon process took shape. It was made practicable finally by the manufacture of carbon tissues in various colors by a company set up in London by Joseph Wilson Swan. In 1866, Braun purchased a franchise for carbon printing in Belgium and France, and the art reproduction business entered a period of growth. Despite three wars fought in the region of Alsace, the Company, which eventually substituted gravure printing for the carbon process, produced art reproductions up through the mid-twentieth century. In an effort to demonstrate the artistic potential of photography, Braun also produced a number of large-scale original compositions based on popular "after-the-hunt" scenes. The Braun enterprise symbolized the idealism felt by many nineteenth-century artists, inventors, and scientists that photography would bring untold cultural and economic benefits to ordinary people.

NAOMI ROSENBLUM

Biography

Jean Adolphe Braun was born on June 13, 1812 in Besançon, France to Antoinette Regard and Samuel Braun, a mounted police officer. He was the first of three siblings (Charles Nicholas Braun, born 1815 and Marie Barbe Madeleine, borne 1823). On the father's discharge from the police force in 1822, the family moved to the ancestral homeland in Mulhouse in Alsace. As an industrial center that specialized in the printing of textiles—especially cotton fabric—and wallpapers, Mulhouse offered young men training in design, chemistry and mechanics. The young Braun demonstrated talent as a draftsman and in 1828 was sent to Paris to complete his education in decorative design. In 1834, he married Louis Marie Danet, with whom he had three children, Marie, Henri and Louise. Also in 1834, with his brother Charles, he opened the first of several unsuccessful design partnerships, finally succeeding in 1840. Two years later he published *Recueil de dessins servant de matériaux, destinés à l'usage des fabriques des fabriques d'étoffes, porcelaines, papiers peints &. &. Dédiés à Mr. Daniel Dollfus par son ami A.Braun* [Collection of Designs Offering Materials Intended for Use by Manufacturers of Textiles, Porcelains, Wallpapers, etc. Dedicated to Mr. Daniel Dollfus by his Friend, A. Braun]. The dedication of the album, which consisted of thirty plates of drawings in black and white and some with color mainly of floral motifs reproduced by lithography, attests to his ongoing connections with the business community of Mulhouse, of which Dollfus was a member. On the premature death of his wife in 1843, Braun sold his Paris design studio and returned to Mulhouse. There, in the same year, he became chief designer in the studio of Dollfus-Ausset and married Pauline Baumann, the daughter of a famous horticulturist, with whom he fathered two children, Gaston and Marguerite. In 1847, Braun opened his own studio in Dornach, a suburb of Mulhouse, which became the headquarters for the expanding textile design business that counted English as well as French clients. In the early 1850s, Braun became interested in the newly announced collodion process of photography, which made possible the multiple reproduction of positive prints from the glass plate negative. To improve the floral decoration on textiles by presenting the actual appearance of botanical material, in 1854 Braun issued an album of three hundred photographic prints on albumen paper of cut flowers, shrubs, wreaths, fruit, leaves, and grasses entitled *Fleurs Photographiées* [Flowers, Photographed]. At the Universal Exposition held in Paris the following year, he exhibited a second series of prints. These were highly commended in 1856 in an article in *Le Moniteur universel* by Ernest Lacan, a leading critic of photography. In 1857, Ad. Braun et Cie, as the company was known, embarked on a project to photograph well-known sites and monuments in Alsace, completing *L'Album del'Alsace* [Album of Alsace] in 1859. From that date, also, the company began making stereoscopic views and landscapes taken in France, Germany, Italy, and Switzerland in various sizes and formats, including panoramas. These were taken by hired cameramen, among them his brother Charles and son Gaston. In 1867, Braun issued a series of large format images (32 × 24 inches) entitled *Panoplies de gibier* [After the Hunt Scenes], which were printed by the carbon method. Two years later, the company embarked on a project to produce small scale images in a variety of sizes and formats, entitled *Costumes de Suisse*

Braun, Adolphe. Deer and Wildfowl.

[Costumes of Switzerland], a theme to which he returned in 1871 after the Franco-Prussian war when he portrayed two women costumed as Alsace and Lorraine. With sons Henri and Gaston supervising, a project to photograph artworks in museums occupied Braun from about 1866 on. The reproduction of works of art soon became the mainstay of the company, remaining so until well into the twentieth century. After Adolphe Braun died on December 31, 1877 (preceded by son Henri), Gaston Braun continued the work of the firm which underwent several name changes becoming Braun, Clément et Cie in 1889 and Braun et Cie in 1910.

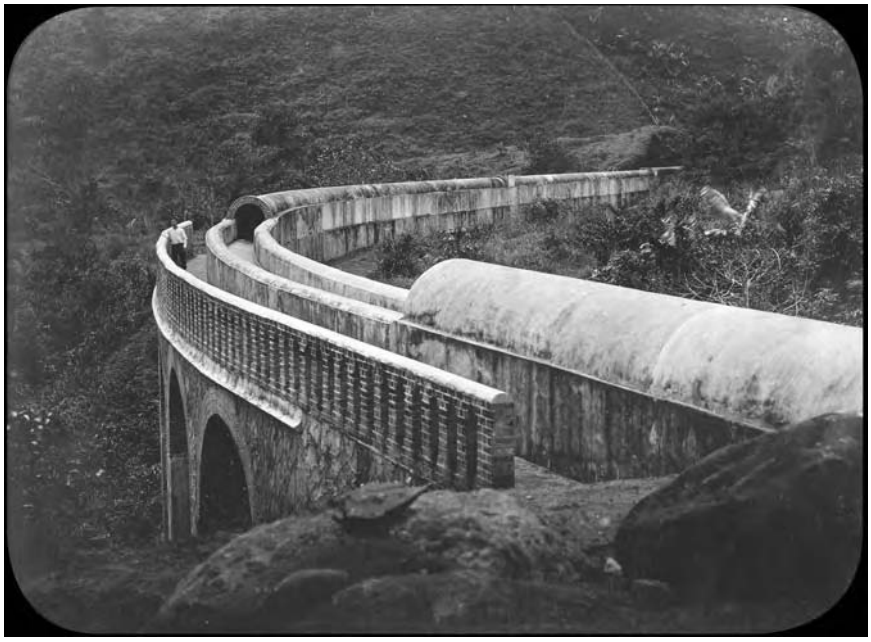
BRAZIL

The first reference in the Brazilian press to the invention of photography occurred on May 1st 1839, when the newspaper *Jornal do Commercio*, based in Rio de Janeiro, published an extensive article on the daguerreotype, which was officially unveiled in Paris later that year, on August 19th 1839. The new process of image-making was then introduced in Brazilian soil soon after its European announcement. In January 1840, the French abbot Louis Compte arrived in Rio de Janeiro on board the school-ship *L'Orientale* with a daguerreotype camera. He demonstrated the new medium by taking three pictures of the central area of Rio: one view of the Imperial Palace, another one from the Candelaria Market and a picture of the beautiful fountain nearby, designed by the Portuguese architect, Mestre Valentim. In March of the same year, the future Emperor of Brazil, D. Pedro II, who was then a 14-year-old boy, purchased himself a daguerreotype equipment, becoming the very first Brazilian photographer. Today we know very little about these early pictures taken by D. Pedro II. More significant is the fact that his great interest and enthusiasm for photography were fundamental to its development in Brazil. The Emperor not only supported various photographers around the country, granting the title of "Photographer of the Imperial House" to 23 professionals between 1851 and 1889, he was also the first Brazilian collector of photographs, accumulating during the course of his life more than 20,000 examples of Brazilian and international photos, representing a wide range of subjects. After being exiled from Brazil in 1889, D. Pedro II donated his precious collection to the National Library, based in Rio, where it is now kept, under the title of "Coleção D. Thereza Christina Maria," in homage to his wife.

The hallmark of the introduction of photography in Brazil is the fact that it was carried out mainly by foreigners—Americans and Europeans—who often changed their first names into the Portuguese version. Driven by the ambition of making money in a relatively new country, with very little competition, and lured by



Ferrez, Marc. The Curved Bridge of the St. Anthony River Aqueduct. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

the adventure of traveling to a tropical land, the first generation of foreign photographers found Brazil a virgin market. This situation determined much of the genres practiced in early Brazilian photography, mainly portraiture and landscape. And despite the technical difficulties of the times, they left some valuable bodies of work, still to be appreciated by a wider public. It is believed that the total production of photography in Brazil, in the 19th century was much bigger than what we know now. It is possible that many works were taken by the photographers back to their home countries or simply deteriorated due to neglect in public or private archives.

Many of these pioneer photographers spent just a few months or years in Brazil, establishing studios in urban centers and/or traveling through the provinces, in the search of casual clients. In the 1840s and 1850s, when the daguerreotype reigned as the dominant photographic technique, some of the most outstanding photographers were the American Augustus Morand, the German Francisco Napoleão Bautz, the Swiss Louis-Abraham Buvelot, the Portuguese Joaquim Insley Pacheco and the Hungarians Birayi and Kornis. Other exponents in the dawn of Brazilian photography were the German Revert Henrique Klumb, an early practitioner pioneer of stereoscopic photography in Brazil, and Frenchman Victor Frond, who in 1861 published the album 'Brazil *pittoresco*,' the first book with photographs made in Latin America.

In the 19th century, Rio de Janeiro, the capital of the Empire and a vibrant economical and artistic center, became invariably the main spot for making, selling and learning photography in Brazil. Also in Rio, photography made a very early appearance in the traditional arts frame, taking part in the 3rd General Exhibition of the Imperial Academy of Fine Arts, in 1842. On that occasion, owing to the lack of a specific category, like painting and sculpture, daguerreotypes were simply shown in the office of the Academy's director, the French artist Felix Emile Taunay.

In addition, the business of photography also flourished beyond the capital. Thanks to the brave initiative of a few individuals, it also spread out in more provincial cities and villages like São Paulo, Salvador, Porto Alegre, Recife and Belém. Some of the finest photographers who worked outside Rio are Albert Frisch, Militão Augusto Azevedo, Alberto Henschel, Guilherme Gaensly, Charles DeForest Fredricks, and Benjamin R. Mulock with his work on the building of the Bahia Railway.

From Rio de Janeiro emerged probably the most prolific and talented Brazilian Photographer of the 19th century, Marc Ferrez. Son of the artist Zepherine Ferrez, who came to Brazil in 1816 as member of the French Artistic Mission, Marc Ferrez learned his profession with German Franz Keller, from the prestigious studio Casa Leuzinger) and was appointed in 1860 as the official photographer to the Court. In 1865, he opened his own studio in Rio downtown, at the age of 21 years old. Ferrez produced an extraordinary amount of photographs, mainly portraiture and topographical work, the result of 50 years of intense activity. He is best remembered for his stunning views of Rio de Janeiro, but Ferrez was also an indefatigable traveler and recorded with his camera images of the large and diverse country.

It is a descendant of Ferrez, the historian Gilberto Ferrez, who can be regarded as the first great researcher of 19th century photography in Brazil. Gilberto Ferrez

started studying this subject in the 1940s, in a time when still very little was written about Brazilian photography. In 1953, G. Ferrez published an essay entitled "Photography in Brazil and its most dedicated user Marc Ferrez (1843–1923)," a seminal text that inspired Brazilian historians to investigate further and shape Brazil's own history of photography. Since then, and especially in the last two decades, studies of 19th century photography in Brazil have progressed and expanded, with new achievements in the form of publications and exhibitions, making the public more aware of the country's photographic heritage.

BRESOLIN, DOMENICO (1813–1899)

Italian painter and photographer

Domenico Bresolin was born in Padua in 1813. His father, also named Domenico, was a bricklayer. Domenico the son worked as a decorator and in 1841 enrolled at the Academy of Fine Arts in Venice. Here he studied with the architect Francesco Wucovich Lazzari, the painters Francesco Bagnara and Tranquillo Orsi, the sculptor Luigi Zandomeneghi. Around 1845 he studied in Florence with the Hungarian landscape painter Kardis Markò (1791–1860). During the same period he worked in Rome, where he showed his paintings in various exhibitions. Subsequently he continued working in Milan and in Venice as a landscape painter. After 1850 he began to take photographs using the calotype process and became famous for the clarity of his positive prints of Venetian palaces and monuments. His works became known mainly through Carlo Ponti, the photographer and publisher of famous Venetian photographers such as Carlo Naya and Antonio Perini. In 1864 he gave up photography and began teaching landscape painting at the Academy of Fine Arts in Venice. In the same year he transferred his photographic archive to Carlo Ponti. He had many pupils who later became famous painters, such as Guglielmo Ciardi, Giacomo Favretto, Alessandro Milesi and Luigi Nono. Domenico Bresolin died in Venice in 1899.

SILVIA PAOLI

BREUNING, WILHELM (1816–1872)

Friedrich Wilhelm Philipp Breuning was born on Dec. 20, 1816, as the son of a bookseller in Erlangen. After unfinished studies he pursued his first career as an actor, mostly in neighboring cities, like Nuremberg, Bamberg, and Wuerzburg. He seems to have taken up photography in 1843. In 1846, Breuning asked for permanent residency in the town of Hamburg where he already had opened a ball room in 1844. According to personal records, he may have spent a few weeks as an assistant to Carl Ferdinand Stelzner in 1844. Well known for his perfect production of daguerreotypes, Breuning was the first to announce the introduction of the calotype process in Hamburg. In 1847, W.B. moved to a large studio in St. Georg, Hamburg, where he stayed until his death on August 1, 1872. His studio was well kept by his widow Sophia Auguste until 1895.

Wilhelm Breuning is best remembered for a large number of daguerreotype images of people of prominence in Hamburg, e.g. the singer Jenny Lind, a numbered of famous actors, as well as scientists and visual artists. Compared to work of his contemporaries, the photography look astonishling friendly and well-tempered.

ROLF SACHSSE

BREWSTER, HENRY CRAIGIE (1816–1905)

Scottish soldier and photographer

Henry Craigie Brewster was the youngest son of Sir David Brewster. A career soldier, he joined the 76th "Hindoostan" Regiment of Foot in 1833. Brewster appears to have shared his father's scientific interests, for he was elected an honorary member of the St Andrews Literary and Philosophical Society in November 1840. He is first mentioned in the context of photography in July 1842 in a letter from Sir David to William Henry Fox Talbot. In this letter, sent from Leamington Spa, Sir David mentions that he is about to return to St Andrews, because his son, "a Captain in the 76th," has been granted leave from his regiment.

During this leave, Captain Brewster took part in the photographic experiments being carried out by the group of enthusiasts that had gathered around Sir David at St Andrews—Dr John Adamson, Robert Adamson,

William Holland Furlong and Hugh Lyon Playfair. In *The Home Life of Sir David Brewster,* a memoir of her father, Margaret Gordon records that Henry practised photography under his father's "superintendence." "It was one of [Sir David's] means of relaxation from heavier work," she recalls, "to take positives from the negatives of his son and others."

A letter of 22 October 1842 from Sir David to Talbot suggests that Captain Brewster played an important role in the early development of photography at St Andrews. In additon, this letter establishes that Brewster continued to practise photography after rejoining his regiment in Ireland. Sir David informs Talbot that his son, "who has got a fine camera from [Thomas] Davidson is now practising the Calotype with great success at Cork with his Regiment and I hope to send you soon some of his works." He mentions also that he himself had been very busy in the "secondary department" of taking positives from his son's negatives and that he had made "some essential improvements" in the process. Sir David goes on to mention Henry's "many successful experiments in applying *oil* to the *negatives*." "We have all tried this here," he continues, " but not successfully." "He, however, got into the way of doing it; and independent of the quickness with which it gives a positive in the darkest day, he finds that the *grain* of the tint is much finer, resembling the finest aquatints. There is great risk, however, of spoiling the negative, and he lost several before he succeeeded." Sir David concludes: "I regret that I cannot send you two of himself which my son and I took, he being the manipulator; because one of these has been thought by Dr Adamson and Major Playfair the best portrait done here, but I will desire him to send you them."

In a subsequent letter to Talbot, written on 2 November, Sir David writes: "Dr Adamson was here today with his little book of Calotype Gems for you, but he still requires to get a good positive of one of me before he can send it. What is the strength of your saline solution …? Do you *dip* the paper in the solution or *wash* it? And do you dry it in blotting paper, and is this blotting paper always new? Be so good as to answer these questions."

"My son writes me," he reports, "that he *never* fails in taking positives, by dipping in the solution." Six months later, on 1 May 1843, Sir David exhibited two series of calotype portraits at a meeting of the St Andrews Literary and Philosophical Society, "the one executed by Mr Henry Collen, London, and the other by Capt. Brewster 76th Regiment." Eight days after this meeting, he mentions his son once more in yet another letter to Talbot, writing: "My son Captain Brewster of the 76th has gone with his regiment to Plymouth; and he has been told that it is not lawful for him to practise the art in England.… I therefore promised to write to you to ask permission for him to Calotype for his amuseument." This is the last reference in Sir David's correspondence with Talbot to the photographic activities of Captain Brewster.

A self-portrait by Captain Brewster is preserved in the Graphic Arts Collection at Princeton University. This is presumably one of the portraits mentioned by Sir David in the aforementioned letter of 22 October 1842. Contemporaneous with this photograph is a portrait of Dr John Adamson, dated September 1842. This exists in several versions, including one in the Royal Museum of Scotland in Edinburgh. The principal collection of photographs by Captain Brewster is contained in the Brewster Album in the J. Paul Getty Museum. This group contains ten portraits of Brewster's fellow officers in the 76th Regiment of Foot and several architectural views depicting their barracks at Cork and at Buttevant. The portraits exemplify military bravado and discipline in equal measure, while the architectural views show a complex and sophisticated approach to light, space, and surface. In one of the views of Buttevant Barracks there appears to be snow on the ground and on the roofs of the buildings. The majority of these photographs must have been taken between October 1842, when Captain Brewster rejoined his regiment, and 1 May 1843, when Sir David exhibited them at the St Andrews Literary and Philosophical Society. The uniform worn by William Hugh Barton in one of these photographs suggests, however, that it must date after 6 October 1843, when Barton was promoted to Lieutenant. Also in the Brewster Album is an unattributed group portrait, in which Sir David appears with his daughter and with his son Henry, the photographer. This photograph was probably taken in St Andrews in 1845, when the 76th Regiment of Foot was stationed at Edinburgh.

GRAHAM SMITH

Biography

Henry Craigie Brewster was born in Edinburgh in 1816. An obituary published in *The Times* on 21 September 1905 records that he died at the Marine Hotel, North Berwick. "He was an enthusiastic golfer," remarked his obituarist, "and had a wide circle of friends, both in England and Scotland." The obituary records that Brewster formerly commanded the 76th "Hindoostan" Regiment of Foot and retired in 1872 without having seen war service. Brewster joined the 76th on 18 October 1833, his seventeenth birthday. His record shows that he was promoted to Lieutenant in 1836, to Captain in 1839, and to Major in 1858. He was appointed Lieutenant Colonel in 1863 and retired with the honorary rank of Major General. During the period he was active in photography, Brewster was stationed at Newry, Cork, Portsmouth, and Edinburgh. He served abroad in the West Indies, Bermuda, the Ionian Isles, Malta, and the East Indies.

BREWSTER, SIR DAVID (1781–1868)

Recognised as a pre-eminent natural philosopher far beyond the borders of his native Scotland, Sir David Brewster's reputation suffered in the course of his lifetime, until eventually he became a relatively forgotten figure in the history of science and photography.

David was the third of six children and the second of four brothers. His father, James Brewster (c.1735–1815) was a tutor at Dundee Grammar School and later became Rector of Jedburgh Grammar School. His mother, Margaret Brewster (1753–1790), died soon after the birth and death of her sixth child. David was only nine years old at the time. David and his three remaining brothers were then brought up by their sister, Grisel. All of David's brothers, James, George, and Patrick, were educated for, and eventually took, careers in the Church of Scotland.

The Brewster family considered education to be important, and from an early age David's appetite for learning was encouraged by adult scholars close to the Brewster family. As a boy, David read his father's old university lecture notes on physical science, and at the age of ten he built his first telescope with the help of astronomer, James Veitch (1771–1838), who lived nearby. As a youth David also became an aide to Dr Thomas Somerville, a local minister, scholar and author. All of this helped David acquire skills that would be of use in his future career as a writer and editor.

At the remarkably tender age of twelve, David began to attend the University of Edinburgh. Up until then it would have been fair to assume that David, like his brothers, was destined for a career in the Church. However, David was no public speaker. It is said that on one occasion he fainted, having being asked to say grace at a dinner party. This impediment may have helped lead towards a career in academia. In 1799 he began contributing to the *Edinburgh Magazine*, and in 1800 he graduated from university. In 1802 Brewster progressed to become editor of the *Edinburgh Magazine*, and remained so until around 1807. About this time he began experimenting in optics, and made unsuccessful applications for posts in mathematics at the universities of both Edinburgh in 1805, and at St Andrews in 1807. In 1808, poised on the brink of a successful scientific career, Brewster became the editor of the newly published *Edinburgh Encyclopaedia*. This was a useful post for Brewster. Not only did it put him in touch with other scientists who contributed to the encyclopaedia, it also helped him keep him up to date with new developments in the field.

Brewster contributed to the fourth, fifth, sixth, seventh and eighth editions of the *Encyclopaedia Britannica*, which was published in Edinburgh at that time.

Brewster's writing was not always intended for a specialist audience. His 'Treatise on Optics,' published in *Dr Lardner's Cabinet Cyclopaedia* (1831) was written for a general audience. As was his *Life of Sir Isaac Newton* (1831). This was followed by the larger, more scholarly *Memoirs of the Life, Writings and Discoveries of Sir Isaac Newton* (1855), which remained the best biography of Newton until recent years (1980).

On the 31 July 1810, Brewster married Juliet Macpherson (c.1776–1850), the youngest daughter of the alleged translator of Ossian's ancient poetry, James Macpherson (1736–1796). The couple had four sons and a daughter together. It was their daughter, Margaret Brewster (later Margaret Gordon, 1823–1907), who published a candid biography that is the main source of information on what Brewster was like as a person. Capable of charm, but also difficult at times, she describes Brewster as having a strong personality. Incidentally, he was knighted in 1832.

The beauty of the daguerreotype did not beguile the pragmatic Brewster. He considered Talbot's calotype to be superior because copies could be generated easily using cheap and simple materials.

Brewster was involved in photography from its very beginnings: he was in correspondence with W.H.F. Talbot from a number of years prior to when Talbot published his findings in 1839, and Talbot sent Brewster examples of his early photographic work from an early stage in its development. This association meant that the first place outside England to practise the calotype was St Andrews in Scotland. Also, Talbot did not patent his invention outside England on Brewster's advice. Although Brewster collected photographic prints and wrote fairly extensively on the subject he does not appear to have practised photography himself.

Throughout his life, Brewster was involved in setting up numerous societies, including the Society of Arts in Edinburgh, which later became the Royal Scottish

Society of the Arts, and the Edinburgh School of Arts which was the first of many mechanics' institutes which were to later be set up all over Britain. He also played an important role in the founding of the British Association for the Advancement of Science, which was founded in 1831 with the aim of lobbying the government to promote science in Britain. Brewster became its president in 1850, despite his old fashioned views on the wave theory of light. Brewster believed that science in Britain was in decline, while it was on the ascendancy in Europe, and wanted the government to help remedy the situation by financially supporting science and scientists. In 1838 he set up the St. Andrews Literary and Philosophical Society, where Talbot first displayed his calotypes. Talbot sent examples to Brewster through the post, thereby stimulating Brewster's interest in photography. Arguably, one of Brewster's greatest contributions to the history and development of photography in Scotland was the fact that Brewster helped teach Robert Adamson how to take photographs using Talbot's new calotype process, and then introduced Adamson to the painter, David Octavius Hill, thereby initiating a partnership that bore one of the most remarkable bodies of photographic images ever to be produced.

Brewster succeeded in increasing the resolving power of microscopes by using jewels for lenses instead of glass, but the development proved to be impracticable because of the increased costs involved (successful, but expensive).

Today Brewster is remembered for his work on stereoscopy, [and for the invention of the kaleidoscope]. He was not the first to invent a stereoscopic viewer, but Brewster did study the physiology of binocular vision, and did develop a device which made the viewing of stereoscopic photographs viable. Brewster's stereoscope was pre-dated by Charles Wheatstone, who was also interested in binocular vision. Wheatstone had succeeded in inventing a stereoscopic viewer prior to Brewster, and even before the invention of photography itself, in 1832. But Wheatstone's apparatus was large and relatively cumbersome compared to Brewster's stereoscopic device. Prior to the invention of photography, stereoscopic images had to be drawn, or created in a manner other than photography. But there was enough of a similarity between the two creations to cause conflict, and Brewster let his feelings towards Wheatstone be known when he published papers on his lenticular stereoscope, and his binocular camera, in 1849. In 1850 he took prototypes with him to Parisian opticians, Françoise Soleil and Jules Duboscq. They built a rudimentary stereoscopic camera, which produced daguerreotype photographs, and constructed a stereoscope viewer to accommodate them. They displayed these in London at the Great Exhibition in 1851, where they attracted the attention of Queen Victoria. So, an example was made and presented to Victoria by Brewster, in Soleil's behalf. This 'Royal Patronage' led to public demand and commercial success for Brewster's stereoscopic viewer. But Wheatstone and Brewster entered into a public quarrel conducted through the letter pages of *The Times*, over priority. Sir John Herschel summarized the situation when he said, 'Wheatstone invented the stereoscope; Brewster invented a way of looking at stereoscopic pictures' (N. J. Wade ed., *Brewster and Wheatstone on vision*, 1983, 36).

Brewster influenced the development of scientific instrumentation by improving existing devices, inventing new ones like the kaleidoscope and lenticular stereoscope. As a major figure in optical research he was able to influence patent law reform, and was invited to be part of the jury for the Great Exhibition of 1851 and for the Paris Exhibition of 1855. In his lifetime he published around 300 scientific papers, and over 1,200 books, articles and reviews. He was instrumental in enabling Talbot's new photographic process to be used free of patent restrictions in Scotland. In 1808 he was elected a Fellow of the Royal Society of Edinburgh and was its General Secretary from 1819 to 1828, and its President from 1864 until his death. In 1815 he was elected Fellow of Royal Society and was awarded its Copley medal (1815), Rumford medal (1818) and Royal medal (1830) for his work on optics and the nature of light. In 1820 he became a member of the Institution of Civil Engineers. In 1816 the French Institute awarded him a cash prize. In 1849 he was made one of only eight foreign associates of the Académie des Sciences. He was made a corresponding member of the French Institute, and of the Royal Societies of St. Petersburg, Berlin, Brussels, Copenhagen, Stockholm and Vienna. In 1847 he was awarded an Order of Merit by the King of Prussia. In 1855 he was awarded the Cross of the Légion d'Honneur by Emperor Napoleon III. This list of honours is not exhaustive.

Brewster's reputation as a scientist was considerable, until he began to outlive his contemporaries, and found himself unable to accept the new ideas coming from a younger generation of scientists, until eventually his refusal to relinquish an outmoded position based on a Newtonian theory of light became untenable. From then on his reputation began to suffer, until eventually, towards the end of his life, he was marginalized, and much of the important work he did was subsequently not attributed to him.

At the age of seventy-four, Brewster re-married. Jane Kirk Purnell (b. 1827) was the second daughter of Thomas Purnell of Scarborough. David and Jane had a daughter together. On the 10 February 1868, at the age of 87, Brewster died of pneumonia and bronchitis at *Allerly*, the house he had built outside Melrose, in the Scottish borders.

The principles of reflection that Brewster's kaleido-

scope make the most of had been known since antiquity, but Brewster attempted to patent the construction of a device manufactured in the from of a brass tube and sold as a toy (1819?). He foolishly entrusted his prototype to a London instrument maker, and the idea was leaked before Brewster had a sound patent in place. The result was other people made a lot of money on the back of Brewster's invention.

The kaleidoscope is a toy which uses simple principles of reflection noticed by Brewster when experimenting in 1816 … but." Brewster defended his "brainchild" in print, in a series of articles that appeared over the next few years in encyclopaedias and journals [to bolster his claim], culminating in the "grand" *Treatise on the Kaleidoscope* (1858). A patent was "expensively" obtained "which was negated when the enthusiasm of the London instrument maker to whom he had entrusted the prototype led to the principles of the device becoming known." His expensively produced brass tube was copied—he wrote to his wife, 'had I managed my patent rightly, I would have made one hundred thousand pounds by it!' (M. M. Gordon, *The Home Life of Sir David Brewster*, 1869, 97) … "first example of a national / fashionable craze … creation of markets in newly industrialized society.

BRIDGES, REVEREND GEORGE WILSON (1788–1863)

English photographer

George Wilson Bridges was born to an old established Essex family and like many eldest sons of the landed-gentry trained to become a member of the clergy. However, Bridges confounded his family by eloping to Scotland with Elizabeth Raby Brooks, marrying on 24th October 1815 at Gretna Green. The elopement and the fact that their first child, Henry, was conceived out of wedlock appears to be the major cause of his banishment to the colonies, becoming ostracized by his own family and eventual marital breakdown.

In 1816 Bridges accepted an appointment from the Governor General of Jamaica, William Montagu, to become the rector of St Ann's parish. Bridges was highly paid during his incumbency, according to William Henry Fox Talbot's mother, Lady Elizabeth Fielding (who knew Bridges); he was paid the then huge sum of £3,000 per annum (almost certainly an exaggeration). When in Jamaica Bridges wrote *The Annals of Jamaica* (1828) which was a history of the island and slavery and the British attitudes to it. Evidently Bridges was a staunch supporter of the slave trade and the book caused some controversy.

In 1834 Bridges' wife suddenly left Jamaica taking their son Henry and leaving Bridges to look after three daughters (another daughter was at school in England) and an infant son. Eight month's later Bridges returned to England to collect his eldest daughter and to try and find his wife. He stayed in Ireland with former Governor of Jamaica, Lord Belmore, for nearly a year and then returned to Jamaica. More tragedy was to follow when all four young daughters were drowned during a boating trip on New Year's Day 1837. Deeply distressed after this tragic event Bridges took his young son, William, who survived the boating accident, to Upper Canada (which was still a British Colony) where in 1837 he built Wolf Tower, an octagonal wooden tower house on the south shore of Rice Lake near Peterborough. In 1842 he left Canada with William, who was ill, for England. They took first ship they could find from Quebec, which took the pair to Palermo, Sicily; eventually returning to England via Naples and Malta in 1843.

On his return Bridges became rector of Maisemore near Gloucester and his son attended Maisemore School. Talbot's half-sister Caroline and her husband Lord Valletort, the Third Earl of Mount Edgcumbe (1797–1861) had a son, William Henry (1832–1917), who attended Maisemore School and became a great friend of Bridges' son, William. It was at Maisemore that Bridges first saw a copy of *The Pencil of Nature.* It was through the Mount-Edgcumbe family Bridges became known to Talbot.

Keen to take up the new art of photography and to travel to the East, Bridges sought advice in the new art of photography from Talbot, who arranged for his assistant Henneman to give him basic instruction as well as providing him with the prepared paper on which he would make his first calotypes. Talbot hoped for a return on his investment and Bridges agreed to send back his studies to be printed at his Reading printing works.

In January 1846 Bridges left Britain on his seven-year photographic odyssey, stopping in Paris where he had a camera made for him by the optician Charles Chevalier (1804-1859). Chevalier had already made an instrument for Calvert Richard Jones, who Bridges was to shortly to meet and take instruction from in Malta. While in Paris Bridges met the American merchant, poet and traveler Richard K Haight who was also having a camera made before traveling to England. Bridges, attracted by the American's plans for using the calotype in the United

States, wrote to Talbot to introduce his new friend and suggest the two should meet in England.

Bridges arrived in Malta on the 2nd March 1846 armed with his new camera. He met up with Calvert Jones, who had been asked by Talbot to help Bridges, and Talbot's wealthy Welsh cousin Christopher Rice Mansel Talbot (1803–1890) who were on a yachting tour of the Mediterranean.

Bridges wrote to Talbot from Malta on March 30th 1846 telling of the death of Kit Talbot's wife, Lady Charlotte Butler, and also sends condolences to Talbot on the loss of his mother, Lady Elizabeth Feilding. A further letter, in April 1846, tells of Bridges' first success, producing negatives of the local landscape, often including figures in his compositions. In his letters Bridges asks for any further technical advice Talbot can offer as well as constantly requesting further prepared paper. He often laments on the quality of the paper he receives, complaining that many iodized sheets are "specky."

Bridges left Malta for Sicily in mid 1846 where he made many studies, including the Benedictine Convent at Catania (where he stayed) and Etna. Generally he made two exposures of each subject, one example of which was returned to Talbot's "Reading Establishment" where Talbot's business agent and land agent, Benjamin Cowderoy (1812–1904), arranged for them to be printed. Bridges generally signed and titled his negatives in ink and copies were returned to the photographer at Malta for display and possible sale there, although it appears that Bridges' work met with little commercial interest both at home and abroad.

In October 1846 Bridges sent at least 73 negatives of Sicily to Talbot and in a covering letter mentions photographing an erupting Mount Etna, exposing the negative for three and a half minutes. Other exposure times mentioned were as long as seven minutes. As well as negatives Bridges often sent seeds taken from native plants to Talbot, who was a keen botanist.

During his photographic travels Bridges also visited Greece, where he made many studies of the Acropolis, Constantinople, The Holy Land and Egypt. By November 1850 Bridges had arrived in Jerusalem and by January 1851 he was in Egypt on the final leg of his seven year journey.

He returned to Gloucestershire in 1852 where he was appointed private secretary to the Bishop of Gloucester and Bristol, James Henry Monk (1784–1856), who was a former tutor of Talbot at Cambridge University. Bridges later became Vicar of Beachley near Chepstow, where he received a stipend of £40 per annum.

Bridges attempted to publish selections of some of the 1,700 photographic studies that he had struggled to make over the previous seven years. A Cheltenham print-seller named Alder had a selection of his views for sale, however Bridges complained that the studies of Syria and Egypt were ignored, although the "more picturesque Athens, Pompeii, Sicily and Naples sell." Bridge's pictures never really appealed to the public; people were wary of buying photographs and his views of parched landscapes weren't to all tastes.

Bridges had a selection of his work published locally: *Selections from seventeen hundred genuine photographs: Views-Portraits-Statuary-Antiquities taken around the shores of the Mediterranean between the years 1846–1852, with or without notes, historical and descriptive by a Wayworn Wanderer.* Mary Hadley, Cheltenham (containing 12 calotypes). This, along with a two-part supplement showing a total of 65 studies of The Acropolis, is listed by Gernsheim (Incunabula nos. 11–13).

There was a proposed series depicting views of Palestine, due to be published in 20 monthly parts, with four prints in each, by the Hogarth Press, beginning in December 1858, but was probably uncompleted.

On the death of his estranged wife in 1862 Bridges had a booklet privately printed in which he tried to explain the breakdown of his marriage: *Outlines and Notes of Twenty-Nine Years* is a sorry tale of life without his wife from 1834. Bridges himself died in 1863 and his remains were placed with those of his wife beneath a rock inscribed with an epitaph remembering their daughters, in the churchyard at Beachley.

IAN SUMNER

Biography

George Wilson Bridges was an English clergyman, author, traveller and early photographer. Married Elizabeth Raby Brooks, they had six daughters (two died in infancy, four drowned Jan 1st 1837) and two sons. Lived in Jamaica and Canada and produced 1,700 calotype negatives during seven years' travels (1846–52) in the Mediterranean and Middle East.

BRIGMAN, ANNE (1869–1950)

American author, photographer, and studio owner

Anne Brigman was born Anne Wardrope Nott on December 3, 1869 in Honolulu, Hawaii to Samuel and Mary Ellen Nott. She moved with her family to Northern California as a teenager, and was married in 1894 to Martin Brigman, a sea captain. She took up photography in 1901 and began working in the Pictorialist style. She became an associate member of the Photo-Secession in 1903 and was elected a fellow of the group in 1906. After separating from her husband in 1910, she spent eight months in New York City where she participated in Clarence H. White's first summer photography class. She took many of her photographs during yearly camping trips to the Sierra Nevada mountains of Northern California between 1904 and 1927, and would later rework and print the negatives in her studio.

She is best known for her photographs of nude women in the landscape, such as "The Soul of the Blasted Pine" (1908) and "The Bubble" (1910). In 1929, she moved to Southern California and began producing abstract studies of landscape. In 1949, she published a book of her poems and photographs entitled *Songs of a Pagan*. She died on February 18, 1950 in Southern California.

Andrea Korda

THE BRITANNIA WORKS COMPANY

British materials manufacturer, established 1879

The Britannia Works Company, which later became Ilford Limited, grew out of the decision by Alfred Hugh Harman (1841–1913) to turn his back on a successful photographic service business—he was one of the first to offer printing and enlarging services to professional studio photographers—and devote his energies instead to the manufacture of dry plates.

In 1879, he moved from Peckham, London, to Ilford, Essex—because of the clean and dust-free atmosphere there—and established his new business in a converted house. With a five employees, Britannia Works—as the operation became known—produced all its plates by hand, eschewing early coating machines and instead opting for hand-poured emulsion from large teapots!

The first successful formulation for the gelatin dry plate had been published in 1871 by Richard Leach Maddox, and subsequently improved and refined by others, significantly Frederick Wratten, John Mawson, Joseph Swan and Hermann Vogel.

By 1879 several companies in Britain were making dry plates, most significantly Wratten & Wainwright, Mawson & Swan and the Liverpool Dry Plate Company. Undaunted by established competition, Harman quickly built up a successful business, mixing the emulsion himself to ensure the secrecy of his formula. Initially supplying his products direct to professional photographers, within little more than a year, Harman had appointed Marion & Company as his exclusive agents for the distribution of his "Britannia Dry Plates." Marion subsequently registered "Britannia" as a brand name, the ownership of which later became a source of contention when Harman fell out with them in 1885.

Harman was determined that only the highest quality plates left his works, and consistent quality control with early coating machines was not guaranteed. Coating plates individually by hand may have been labour-intensive but, followed by individual inspection, the required quality was assured. Using the large teapot for delivering the liquid emulsion because a teapot spout pours from the bottom, he ensured that a bubble-free emulsion reached the plate. Any froth floated on the surface of the liquid in the pot and stayed there. As was normal practice at the time, whole plate or oversize whole plate sheets of glass were coated, and once dried were cut down to half or quarter plate. Until 1894, cutting was also done by hand. Harman's original team of six—two men, three boys and himself—could produce several thousand plates per day with these primitive techniques.

The success of the "Britannia" dry plate was rapid and considerable, and in little over a year he had outgrown his original property and bought a nearby cottage where coating could take place. Further premises were added until, in 1883 a factory was built on the site of one of his houses, and the entire production process moved under one roof.

Two years later, after the rift with Marion & Company and an acrimonious court case in which he eventually lost the right to the "Britannia" title, the company was renamed the "Britannia Works Company," and the plate renamed the "Ilford Dry Plate." The introduction of a new logo on all plate boxes—a paddle-steamer with an "Ilford" flag streaming from its forward mast—provided a new identity for the company and its products. Competitive price-cutting—reducing the cost of a box of one dozen quarter plates from two shillings to one shilling—gave photographers a powerful incentive to try the newly branded plates.

Marions continued to market "Britannia" plates, but from 1887 their formulation was changed, and they were manufactured at Marion's new factory in Southgate.

From 1879 the Britannia Works Company produced only one type of plate until a second "Rapid" plate, only slightly more sensitive than the "Ordinary," was added in 1886.

1888 saw the introduction of two new emulsions, "Ilford Red Label" at twice the sensitivity of the ordinary

plate, and the similarly speeded "Ilford Isochromatic Instantaneous" plates. The isochromatic plate, dye sensitised with erythrosin extended sensitivity into the green and yellow bands of the spectrum, giving Harman his first orthchromatic emulsion.

Since 1884, before the split with Marion, he had also been developing a range of printing materials, and by 1889 had a range of bromide emulsions available on paper, opalescent glass and lantern slides.

With the company well established, and with a growing business, Harman set about expanding his workforce. In 1889 he appointed Andrew Agnew to supervise quality control, and John Howson as his first business manager. Howson was responsible for raising the company's profile through advertising and through publications such as *Photographic Scraps*, a magazine offering tips to photographers and promoting Ilford plates, which appeared within a year of his appointment. His most enduring contribution was *The Ilford Manual of Photography* which first appeared in 1891 under the editorship of Charles Herbert Bothamley, ran to many editions, and became the standard primer for generations of photographers and photographic students. Over 300,000 copies had been sold by 1920, and its successor, *The Manual of Photography* remains in print to this day.

By 1891, the Britannia Works Company claimed to be the largest manufacturer of photographic plates in the world, and in that year it became a limited company, with an innovative structure which extended the possibility of share ownership to Harman's employees. The share capital in the new company was £120,000, and of the 24,000 ordinary shares however, employees acquired only 46, while Harman held 23,540!

The acquisition of a smaller manufacturer in 1895 expanded the company's product range to include sheet film, and over the next two years, Harman's chemists experimented with cellulose rollfilms. In 1897, he rejected a proposal from George Eastman that their two companies should merge their interests, and Eastman went on to establish a manufacturing facility in London. In the following year, with profits rising rapidly, Harman converted his company from a private to a public limited company under the name of "The Britannia Works Company (1898) Limited."

Shortly thereafter, Frank Forster Renwick (1877–1943)—who as Scientific Director of Ilford Limited would later pioneer multigrade printing papers—joined the company.

One further company name change, in 1901, established "Ilford Limited."

BRITISH JOURNAL OF PHOTOGRAPHY, THE

First published in Liverpool, *The British Journal of Photography* began as the *Liverpool Photographic Journal* on 14 January 1854 and continued through to December 1856 (vols 1–3). It continued as the *Liverpool & Manchester Photographic Journal* from January 1857 to December 1858 (vols 4–5). Following this it continued as the *Photographic Journal* from January to December 1859 (vol 6) and then as *The British Journal of Photography* from January 1860 (vol 7) to the present. Initially a monthly journal belonging to the Liverpool Photographic Society, it was sold during 1856 to Henry Greenwood, the printer and publisher since inception. The firm moved from Liverpool to London in 1864 remaining as the journal's publishers. From 1 January 1857 the *Journal* became a fortnightly and from 1 January 1865 a weekly publication. At the same time, the earlier size of large 8vo also changed to 4to.

The Liverpool Photographic Society and later the Liverpool Amateur Photographic Society included amongst its membership; Francis Frith, then a printer; George Berry, a professional photographer; Henry Greenwood, a printer; as well as B.J.Sayce, W.B.Bolton, Peter Mawdsley and later Vero C. Driffield. It was a suggestion made by George Berry that led to the publication of the Journal. The first editors were members of the Liverpool Photographic Society; Charles Corey, Frank Howard and George Berry. For a short period it was edited by William Crookes, and from June 1857 to February 1858 by T. A. Malone, one-time assistant to William Henry Fox Talbot. With the March issue of 1858 it came under the editorship of George Shadbolt, and from January 1865 William Crookes and George Dawson edited it for a few months until J. Trail Taylor took over in the same year. Taylor remained editor until 1879 when he left for New York to take over the *Photographic Times*. W. B. Bolton held the reins until 1886 when Taylor returned to his previous post, remaining editor until shortly before his death in 1895.

The British Journal of Photography was far more informative than its contemporary, *The Photographic Journal* published monthly by the Photographic Society of London. The scope of contributions and contributors were both national and international and was admired wherever English was spoken. This was due in part to the magazine's separate Colonial and Overseas edition;

a quarterly containing all the best articles featured in the *Journal*. With the increased popularity of lantern slide lectures, from October 1892 onwards the *Journal* publishe d a monthly supplement *The Lantern Record*, which added considerably to the already substantial bulk of information.

During the able editorships of Taylor and Bolton the *Journal* grew in importance and pages. A volume in the 1880s and 1890s typically contained over 800 quarto pages and these pages were frequently used to announce the progress of photography. The important developments in the gelatine dry plate as well as other processes were first published in its pages. Since 1860 *The British Journal of Photography* has retained the enviable position of being one of the most influential photographic journals in the world.

MICHAEL HALLETT

BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, THE

The British Journal Photographic Almanac is the oldest photographic yearbook in the world and was first published as a wall calendar for the year 1860, and given away as a supplement to the 15 December 1859 issue of *The British Journal of Photography*. It was issued free of charge to subscribers of the *Journal* and could be bought by non-subscibers for 3d. The *Almanac* for 1861 was a small pocket-book, 16mo (4 × 2 ½ inch) size, containing in addition to the calendar a miscellany of photographic information including meetings of societies, formulae and tables. With a subtitle *Photographer's Daily Companion*, it was edited by Samuel Highley. The 1886 issue was produced in Crown 8vo format, 4½ × 7 in., and sold as a separate publication with 118 pages of text and 44 of advertising, priced 6d.

The editorial chair most frequently mirrored that held by the *Journal*. Highley was editor for 1861 and 1862. He was succeeded by James Martin in 1863 and by Emerson J. Reynolds in 1864. J. Trail Taylor was editor between 1865 and 1879 and again between 1887 and 1896, while W. B. Bolton was editor in the in-between period of 1880 and 1886. Thomas Bedding was in the chair from 1897 to 1905.

Introductory remarks made by Taylor in the 1871 edition of the Almanac typifies the attitudes of the period. "… the first feeling is that something has been done, although not very much; but this is almost immediately followed by the rather ludicrous thought that almost ever since photography was practically introduced the same has been said year after year. And, looking back from this point of view, at the close of 1870 we were rather gratified to discover that in no previous year had any startling discovery been made, no great advances been effected." Articles in the *Almanac* reflect the progress of the period and demonstrate the high regard with which the publication was held and still is held as a point of reference. They includes M. Carey Lea on the development of the chlorobromide process, modifications of the collodio-bromide process by Bolton and Sayce and Walter Woodbury's perfected system of photo-engraving.

By 1891 Taylor had returned to England and was again in the editorial chair. The *Almanac* had 1,144 pages of which 327 were editorial and boasted a frontispiece of "Conway Castle," "an example of an average print on bromide paper." Alfred Watkins considers the "Standards for factors affecting exposures" while F.T. Bennett offers a specialist formula for "Portraiture and hydroquinone." There is "Hints for Retouchers," a discussion about "Artistic Landscape Photography" and a tale of "A trip of 25,000 miles with the Camera." Additionally there is an eclectic collection of short articles that make up the 'epitome of progress' with 'notes of passing events, original and selected. In this particular year it includes 'copying glass positives,' 'pin-hole photography' and more reference to the 'composition of pictures.' A continuing list of patents, formulary, tables and equations complete this increasingly essential compendium of reference in the nineteenth century.

BRITISH LIBRARY

The British Library was formed in 1973, bringing together the collections of the British Museum Library, the National Central Library, and the National Lending Library for Science and Technology. The British Museum Library, established in 1753 as the Museum's Department of Printed Books, itself amalgamated several significant collections. Formed from the library and natural history collection of Sir Hans Sloane, the manuscript collection of Robert and Edward Harley, the first and second Earls of Oxford, and Sir Robert Cotton's collection of manuscripts and antiquities, the British Museum Library specialized in printed books, manuscripts, and papers of historic and scientific importance.

The public announcement of Louis Jacques Mandé Daguerre's and William Henry Fox Talbot's photographic

processes in 1839 did not have an immediate impact at the British Museum. Although individual Museum Trustees and staff became interested in photography over the course of the 1840s, photography was not embraced at an institutional level as quickly as it was, for example, at the South Kensington Museum. The first demonstration of photography at the Museum was undertaken by Talbot, inventor of the calotype process. In the summer of 1843, when Charles Fellows considered using the calotype process on an archaeological expedition, Talbot was invited to the museum to conduct experiments. However, because of the difficulty in producing good results, the process was deemed unsuitable for the harsh conditions of the journey.

It was the 1850s when the British Museum became significantly involved in photography. By the early part of the decade, the Museum had received donations of photography, including books illustrated with calotypes, and Museum officials had received requests from photographers seeking to take pictures of objects in the collection. Museum Trustees gave serious consideration to the reproductive possibilities of photography in 1852, and they agreed that photographs would be useful for scholars interested in deciphering the cuneiform inscriptions on tablets in the Museum's collection. In 1853, Edward Hawkins, Keeper of Antiquities, pressed Museum Trustees and Principal Librarian, Henry Ellis, to support the in-house production of photographs. Plans to build a photographic studio on the roof of the Museum were discussed, and equipment and cost estimates were solicited from two photographers, Roger Fenton and Philip Henry Delamotte. On the recommendation of Sir Charles Wheatstone, inventor of the stereoscopic camera, Fenton was given a temporary appointment as museum photographer in the fall of 1853. The Trustees gave Fenton permission to purchase equipment, and they asked him to produce a trial series of photographs. The first results of Fenton's work, produced in early 1854 using the wet collodion process, were photographs of recent acquisitions of antiquities and Assyrian tablets from the collection.

Fenton's relationship with the Museum was productive and, from his point of view, profitable, but it was not without interruptions and disputes. The Trustees approved further expenditures on photography after the initial trial, however Fenton's excursion to the Crimea in the summer of 1855, and his subsequent illness, meant that he was absent from the Museum until 1856. Upon his return, Fenton earnestly resumed producing photographs of items in the collection. One significant undertaking was the reproduction of the Clementine Epistles in an early Christian manuscript, the *Codex Alexandrinus*, for divinity professors at Oxford and Cambridge. The professors proposed that reproductions of the epistles should be published because they had been omitted from recent editions of the codex. With Fenton's expertise, fifty copies were produced for sale by a London dealer. Despite the scholarly value of photographic reproductions, mounting costs from photography and failed attempts to recoup expenses through the sale of prints signaled the commercial failure of photographic operations at the Museum. Ultimately, the Trustees decided that photography was too costly, and they suspended Fenton's work in 1858.

Another figure who had a significant impact on photography at the Museum was Anthony Panizzi. As Keeper of Printed Books, he suggested new applications for photography. He proposed that photographs could replace missing plates and pages in incomplete copies of books and that photographs of pages from selected rare books could be consulted by researchers. Upon his appointment to Principal Librarian in 1856, Panizzi became increasingly involved in photographic work. Enthusiastic about photography's potential as a reproductive tool, Panizzi was nonetheless challenged by the administrative task that the photographic operations presented. In response to the Trustees' concerns about high costs, Panizzi began to monitor all photography requests. When Trustees decided to terminate the arrangement with Fenton in 1859, Panizzi organized the transfer of photographic reproductions to the Department of Science and Art at the South Kensington Museum. The agreement only lasted from 1860 to 1863, but it caused Fenton's association with the Museum to end bitterly.

In subsequent years, the Principal Librarian continued to administer arrangements with the many photographers requesting to photograph objects in the collection. While photography continued to serve primarily as a means of reproducing objects in the Museum's collection, photographic reproductions of carefully selected documents were purchased in an effort to build comprehensive collections in various British Museum departments. One instance of this was the purchase of a photographic copy of a sixteenth-century French *mappemonde*. Throughout the 1890s, a high demand for photographic work meant that library staff spent a great deal of time supervising photographers. Richard Garnett, Keeper of Printed Books at the time, recommended establishing a photography department to handle the work; however, it was not until 1927 that a new museum photographer was hired.

Today, the British Library has an impressive collection of photographs and photography-related materials. Among the Library's holdings of nineteenth-century texts are significant works in the history of photography. Notable examples include Daguerre's *Historique et description des procédés du daguerreotype* (1839), Talbot's *The Pencil of Nature* (1844), Eadweard Muybridge's eleven-volume *Animal Locomotion* (1887), and

a presentation copy of the official catalogue of the Great Exhibition of 1851, illustrated with over one hundred and fifty calotypes. The Library's collection of nineteenth-century photographs is particularly rich in work from the Indian sub-continent and Egypt. Highlights include hand-colored photographs from the early 1850s, taken in Calcutta, Madras, and Ceylon by Frederick Fiebig; photographs of monuments, architecture, and sculpture, produced for the Archaeological Survey of India between the 1850s and 1920; and photographs of the monuments of Egypt by Maxime du Camp, Felix Teynard, and Francis Frith. Public access to the British Library's collection of nineteenth-century photographic material improved with the conservation and electronic cataloguing projects of the 1990s.

BROGI, GIACOMO (1822–1881), CARLO (1850–1925) AND ALFREDO (d. 1925)

Italian photographers

A novice in Achille Paris's studio, a calligrapher in Florence, and then a retoucher of chalcography in Luigi Bardi's, Giacomo Brogi became a photographer in 1856. He established his studio in 1860 under the name "Giacomo Brogi Fotografo" (1 via Tornabuoni) and took part in the international exhibition in Florence the following year.

In 1862, he organised a photographic campaign in the Holy Land (where he will return in 1868) and publish a sixty views in his *Album of Palestine.* He began to photograph works of art and edited his first catalogue *Dei Soggetti artistici* in 1863. In 1865, he transferred his portrait and reproduction studio to 15 Lungarno alle Grazie and opened a shop at 79 Corso dei Tintori. He showed his work in several exhibitions (Forli 1871, Vienna Universal Exhibition 1873) and offered his Palestine Album to Victor Emmanuel and to Umberto I, who nominated him "Photographer of the Emperor." Brogi developed a chain of shops in the tourist cities of Italy, first in Rome at 419 via del Corso, then Naples in 1879, at 61–62 piazza dei Martiri and later in Sienna in 1909 at 6 via Cavour.

In all likelihood, Giacomo published his first catalogue entitled *Firenze e Toscana catalogo* in 1878. He sold his print collections in France and Europe in 1880 thanks to Adolphe Giraudon, who was established at Bonaparte Street in Paris, in front of the Art School.

In 1879 and 1880, he created the first photographic campaign of Pompeii. The next year, he exhibited these photographs with his son Carlo in Milan. He won a silver medal and received the first prize of landscape and architecture Photography in Melbourne. Soon after achieving those accomplishments, Giacomo died.

Giacomo's son Carlo (1850–1925), helped by his brother Alfredo (?–1925) managed the firm. Together they specialised in painting reproductions, and published in 1893–1894 a new three volume catalogue filled with photographs of frescoes, mosaics and drawings of the great masters from the royal galleries of the Offices of Pitti Palace and the Ambrosian Library. They also developed new photographic campaigns in Naples and Pompeii, but kept the same catalogue numbers, which makes dating the prints difficult. Two other catalogues were published on this subject in 1895 and in 1902, entitled *Supplément au catalogue spécial des photographies de Naples et environs publiées par la maison Brogi: peintures, vues, sculptures, etc…*

Concerned by copyright and reproduction rights, Carlo took an active part in the Photographic Italian Society, of which he became vice-president. In 1885 he published two brochures entitled *Sulla proprieta delle Fotografie* in Florence and *In proposito della protezione legale delle fotografie* in Rome, discussed with colleagues an international approach. He was one of the first to establish the interdiction of reproduction without authorisation by inscribing on negatives the two letters "R.I." ("Riproduzione Interdita"). Carlo displayed his images in 1886 in Florence, and organised the first photographic exhibition there in 1887.

In 1889, Carlo Brogi published a catalogue of 308 pages in several languages entitled *Catalogo delle Fotografie artistiche dallo stabilimento Giacomo Brogi,* listing the prints he had available. This catalogue was

be republished and completed by supplements in 1899, 1903, 1907 and 1912.

Brogi travelled to and participated in, with his colleagues Alinari and Anderson, the Berlin International Exhibition of Amateur Photographs in September 1896. There he showed panoramas of Florence, paintings and sculptures of the Uffici Museum. With the intention of satisfying the new tourist bourgeois and following the market tendency, Carlo published in 1898 a special catalogue of stereoscopic views of paintings, sceneries and sculptures. Less expensive and smaller in dimension, those images of popular entertainment were more attractive for the larger public, and in 1900 at the Universal Exhibition in Paris, Carlo received a gold medal for this work.

During this time, Carlo kept publishing photographs separately and in albums on specific subjects and in exhibitions. In 1904, the drawings of civil and military Italian architects from the 15th to 18th centuries from the Offices museum were displayed in a fourteen page catalogue with one hundred and twenty six illustrations. That year at the exhibition in Florence, he documented the antics and works of art from Sienna. In 1909, he reproduced the museum of Sienna and in 1911 an exhibition of portraits. From 1911 to 1919, Carlo edited a monthly bulletin that covered the publications of his firm's "Giacomo Brogi, Fotografo-editore," as the Braun company did in the 1930's. This self-advertisement provided an effective method to communicate to the public and his clients.

Carlo died on April 25, 1925, a few weeks after his bother Alfredo. Their sister Eugenia took over as the manager with her husband Laurati who died in 1926. In the 1940, their son Giorgio and his operator Gino Malenotti, very appreciated for his sculpture reproductions, gave a new impetus to the firm. Subjected to the competition with Alinari, to the 1944 bombardment and to the Arno flood 1966, which destroyed a part of the archives, the prosperity of the firm collapsed.

Almost 50,000 negatives were given up to Earl Vittorio Cini, who also bought both Alinari and Anderson in 1963, which placed the three most prestigious collections into one. A hundred of prints of various techniques from the Brogi production of the end of the 19th century and from the Giorgio Laurati settlement were added to this collection in 1988. Brogi's archives are kept in the Alinari Museum in Florence. One can also find a large number of his photographs all over Europe and the United States in 19th century tourists albums, libraries photographic collections, artists' private collections, Gustave Moreau and Rodin for instance, and in University collections. These images remain an important source of documentation of Italian art and architecture from antiquity to the modern age.

BROMIDE PRINT

Silver-based photographic materials depend on a compound of silver nitrate and a halogen such as chlorine, iodine, and/ or bromine. This produces a chemical reaction, apparent as a darkening of the sensitised area in the presence of actinic light. Silver bromide paper uses the most sensitive of these halogens, and was derived from Richard Leach Maddox's formula for dry plate negatives; silver nitrate and cadmium bromide in a gelatin binder, exposed for a latent image and amplified through chemical development. In 1874, gelatin silver bromide paper was advertised by Peter Mawdsley's Liverpool Dry Plate Company, but the paper was not successful. In 1879, Joseph Wilson Swan patented and initiated the manufacture of 'bromide printing paper,' as did E. Lamy in France. Improvements in coating technology were introduced by Eastman and Company in Rochester in 1884, and gelatin bromide paper was perfected over the following twenty years. By the 1920s, it had become the standard paper for black-and-white photographs, modified in the 1970s as a mixed emulsion variable contrast paper, combined with silver chloride.

Pure silver bromide paper had commercial and industrial applications, but was initially too finicky for amateurs: its sensitivity required a safelight for the darkroom, and it printed so rapidly that the correct exposure was difficult to judge. Photographers were accustomed to daylight contact printing-out paper; developed-out paper produced only a latent image and so could not be printed by inspection. Although the timing was crucial, mechanical timers were rudimentary. Furthermore, each manufacturer made paper of a different sensitivity, so that exposure times varied and had to be determined through trial and error. For these reasons, the first commercial bromide paper was effectively contact-speed. It was used for enlarging from the early 1890s, once photosensitivity could be gauged and timers improved.

While many art photographers wished for prints with a plain or laid surface like that of drawing or watercolour paper, this was hard to achieve with contact papers, which needed a relatively smooth finish to provide a good contact with the glass plate negative and a reasonable resolution in the positive print. A bumpy surface would scatter the light, soften outlines and break up detail. Projection-speed papers addressed the problem, as they did not need a smooth surface for contact printing, and this encouraged the production of rough or textured papers. Although a number of companies introduced rough papers in the 1890s, they were not widely available, as the demand was limited. Rough papers were hardly suitable for small format portraits, and these made up the bulk of the photographic market.

Until the early 1890s, matt silver papers had only a thin gelatin silver emulsion and often omitted the baryta (barium sulphate in a gelatin binder) subbing layer. Baryta, once adopted for bromide papers, could be embossed for a textured surface. 'Platino' bromide papers used added starch flour for a matt finish. Bromide papers did not adopt the pastel pink, blue, and purple bases of silver chloride printing-out papers, as these clashed with the neutral image colour; instead, the baryta subbing layer was tinted cream or ivory.

Bromide developing-out paper tends to a grey-black image colour, because developed-out silver is deposited as a tangle of filamentary silver whose light absorbing properties gives the appearance of a neutral image. From 1892, Eastman produced an 'Extra-Rapid Bromide Paper' advertised as producing a range of hues from black to sepia. Sepia toning with sodium sulphide was not common practice until the early 1900s, but by 1890, uranium nitrate was used as a toner for brown hues on matt silver bromide paper. In the nineteenth century, the most common toner for bromide papers was platinum.

Although John Herschel's early work with platinum chloride had focused on its suitability for toning, this application was not perfected until the late 1880s, when Lyonel Clark adapted William Willis's cold-bath platinotype process for toning commercial gelatin silver and home-made salted papers. Valentine Blanchard introduced other formulas for a warm brown or black image colour, and represented 'Blanchard's Platino-Black Paper' with eleven prints at the 1890 exhibition of the Photographic Society of Great Britain. Others, including Alfred Stieglitz, announced similar methods, and Lyonel Clark published a book on the subject. Platinum toning of silver bromide was most common from about 1895 until the early 1920s. Platinum was sometimes combined with palladium, particularly for toning homemade silver chloride papers. Pure palladium was also used for toning, but the results were unreliable and not believed to be any better than the combined platinum-palladium or uranium toning.

In the 1890s, the escalating price of platinum encouraged cheaper substitutes, and 'platino' bromide papers were manufactured with a matt finish and cold-neutral image colour to mimic the visual characteristics of platinotypes. In 1891, the Fry Manufacturing Company introduced a 'Naturalistic' Bromide Paper on a rough-surfaced Whatman base, which the *Amateur Photographer* reported as readily producing "soft tones, almost equalling those of a platinum print."

Increasingly, manufacturers made this comparison explicit: in 1894, Eastman brought out 'Platino-Bromide' paper, and Wellington and Ward followed with 'Platino-Matt Bromide.' This advanced the acceptance of silver bromide paper for art photography and exhibition prints. But bromide prints were vulnerable to the residual sulphur compounds from the thiosulphate fixing bath, which led to yellowing and fading of the metallic silver image. Indeed, many 'platino-bromide' papers were intended to be toned with platinum, which substantially enhanced their stability and more nearly approximated the hue and tonal characteristics of platinotypes.

Silver bromide papers are susceptible to oxidative-reductive 'tarnishing' from acids (from handling or airborne contaminants) and staining and sulphiding from residual fixing chemicals. The gelatin binder may show damage from moisture, evident in spots of mould and in delamination from the paper base. These issues persist in modern gelatin bromide paper.

BROTHERHOOD OF THE LINKED RING

The Brotherhood of the Linked Ring was an elite international society founded in London in 1892 to promote photography as a fine art. The style of art photography then in vogue was known as pictorialism. The Brotherhood was the first group in England with a vision of art photography broadly shared with others in Europe and the USA. The Vienna Camera Club exhibitions started in 1891 and the salon of the Photo-Club de Paris was formed in 1894, both groups becoming affiliated to the Linked Ring by 1895. In the United States, art photographers in Boston, New York and Philadelphia invited foreign photographers to their sixth exhibition in 1893. Crucially, Alfred Stieglitz founded the Photo-Secessionists in New York in 1902. By then, many of his group were already in the Brotherhood.

Art photography in Britain, as elsewhere, tended towards domestic and conventional genre and landscape subjects, and scarcely recognised contemporary radical fine art movements such as Aestheticism and Symbolism. The determination to stay with gentler subjects eventually destroyed the Brotherhood in 1908-10, as it tried and failed to eradicate the influence of those Photo-Secessionsits who did engage with Aestheticism and Symbolism.

But those battles lay in the future. In the 1890s, before the Brotherhood existed, the growing interest in modern art photography in England had little support from the medium's oldest institution, the Photographic Society of London (founded in 1853 and named the Royal Photographic Society of Great Britain from 1894). Instead of actively supporting art photography, the Photographic Society had, for most of its existence, favoured science and technology, and resisted changes in its art photography salon.

The Brotherhood was formed as a result of a squabble among members of the Photographic Society over what pictures to include in the salon. The row took place in 1891 when The Hanging Committee rejected George Davison's "The Onion Field" (1889) on the grounds of late submission. But this was a nit-picking attempt to sidestep the real issue. The Hanging Committee rejected "The Onion Field" because it was a soft-focus, impressionistic pin-hole photograph made without a conventional camera and lens. The impressionism and the lack of technology clashed with the Committee's established ideas on art photography, which required beautifully composed scenes of known subjects and of recognisable artistic merit in the manner of eternal standards. In their view, Davison's work stood for transient and unskilled whimsy. Davison was a new type of artist—but the die-hards on the Hanging Committee were either uninterested in modern art photography or were determined to stop its progress in the Photographic Society.

The vice-president of the Society, Henry Peach Robinson, though not a member of the Hanging Committee, ensured that Davison's work was after all given pride of place. Someone then complained and officials removed the work, insisting that Robinson leave the gallery. Robinson and Davison resigned from the Society and, along with Ralph Robinson, William Willis, Alfred Horsley Hinton, Henry Herschel Hay Cameron and nine others, founded the Brotherhood of the Linked Ring.

The name was derived from the gimmal ring, a jointed finger-ring which could be worn by two people at the same time, linking hands. The Brotherhood was deliberately exclusive, and the circle could only increase when existing Links (as members were known) proposed and unanimously approved new names. The total number of different Links was 114, though the estimate for the greatest number in one year is 74 (in 1902). There were about 50 Links when the group disbanded in 1910.

Apart from membership by invitation, there were few rules in the Constitution. The Links were held together by their enthusiasm for pictorialism, which encouraged individual expression while expecting practitioners to be familiar with optics, chemistry and the mechanics of photography. Of course, there was never one single style of pictorialism and, increasingly, different approaches divided the fraternity. Though Robinson and Davison were founding members, their differences summarise the arguments that eventually wrecked the Brotherhood. Robinson was the greatest exponent of combination photography of a moralising or narrative kind, whereas Davison (despite his pin-hole experiment) preferred to compose naturalistic scenes in the viewfinder and print in photogravure. His opposition to storytelling and darkroom "faking" made him a natural ally of Alfred Stieglitz, who became a Link in 1894. The Links agreed that a photograph was not artistic if (in the words of Stieglitz) it was technically perfect but pictorially rotten. So although the Links became expert in techniques, the artistry lay in the evocation of mood rather than the statement of fact.

Despite the importance of the final effect, the Links engaged in often bitter disputes over processes. Some advocated print manipulation in the darkroom while others believed the photograph should be printed 'straight,' insisting on the purity and integrity of the chemical process. The opposing factions never resolved the matter in arguments stretching over twenty years and, from this distance, the differences between them are less striking than their similar aim: to make rare and unique prints. This they achieved either through various oil pigment processes which enabled them to make pictures look like lithographs or mezzotints, or through the use of platinum salts and gravure printing, produc-

ing images that were equally remote from everyday snapshots or printed illustrations.

In the 1890s, it was still possible to ignore artistic differences and enjoy the benefits of an exclusive club. The Brotherhood enjoyed the vague mysticism of rituals. The Links used quaint language and (in many cases) took pseudonyms. For example, after the debacle at the Photographic Society, Robinson became "High Executioner," denoting his responsibility for arranging the Brotherhood's annual Photographic Salon in London. This exhibition was the showcase for the best recent art photography from Britain, Europe and the United States of America, and took place in September from 1893–1909.

Whereas the row that led to the foundation of the Brotherhood was short and sharp, the row that ended it dragged on for almost two years from 1908. By then there was even less agreement about pictorialism than in the 1890s. Robinson died in 1901, but his preference for combination prints with a strong narrative continued, notably in the work of Francis James Mortimer. Although a newcomer to the Ring in May 1908, Mortimer was to be as influential in its demise as Robinson had been in its foundation. Mortimer became Centre Link in October that year. The structure of the Brotherhood was designed to keep power in the hands of the Centre Link (elected monthly) and his allies, who tended to be British. This was a strength as long as the Brotherhood was united but was inadequate in the crisis of 1908–10, when the various Centre Links represented divided camps within the Brotherhood, and decisions about the future of the Brotherhood swayed first one way and then the other.

The fundamental disagreement occurred when members or supporters of Stieglitz's Photo-Secession appeared to have taken over the Photographic Salon of 1908, leaving no room for British pictorialists. Many American pictorialists, such as Rudolf Eickemeyer and Fred Holland Day, exhibited at the Salon. However, from 1899 to 1906 the main American representatives were those who (in 1902) became members of the Photo-Secession, including founding members such as Frank Eugene, Gertrude Käsebier, Joseph Keiley, Edward Steichen and Clarence White. After a lull in 1907, when the Salon included only one minor Photo-Secessionist, in 1908 the so-called "American Committee" controversially swamped the Salon with work by innovative Photo-Secessionists and their supporters. When some British Links attempted to regain control of the Salon, they forced others to declare their allegiance either to the Brotherhood or the Photo-Secession. The unexpected result, eventually, was the unlinking of the Ring in 1910.

In the controversial Salon of 1908, fewer than half the 203 exhibits were by Photo-Secessionists. Annie Brigman, S. R. Carter, Alvin Langdon Coburn , Fanny Coburn, Eugene, Keiley, Steichen, White, Stieglitz and White (who collaborated on six images) and Eva Watson-Schütze showed a total of 95 pictures between them. Further, only Coburn, Steichen and Keiley were actually in London during the selection process, though White, Eugene and Stieglitz were supposed to have taken part in the selection earlier on. However, other members of the Committee, including James Craig Annan, Robert Demachy, and the Baron Adolph de Meyer were supporters of Stieglitz, and between them had 58 works on show. Two other selectors, Davison and Heinrich Kühn, supported Stieglitz but did not exhibit their own work. In all, the selection committee awarded themselves three-quarters of the exhibition space. Another 15 Links showed only 29 pictures between them, which left 21 places for outsiders.

But the supposed American take-over of the Salon provoked a crisis in the Ring. Francis Mortimer quickly organized a Salon des Refusés of rejected photographs in the offices of *The Amateur Photographer* which he edited from 1908. More importantly, he printed the work of the rejected Links in the magazine. Most of the photographers included in the Salon des Refusés played a part in Edwardian photography but few of them are now included in histories. They successfully reflect the certainties of Edwardian Britain, especially the comfortable life of the English upper middle-classes. Appreciative critics described the work as "decorative" or "tasteful." In the preface to the list of exhibits Mortimer claimed that the "progress of art" would be advanced by the "expression of nature and beauty" rather than by seeking "ephemeral notoriety" in "temporary art crazes."

Despite Mortimer's leadership against Photo-Secessionist influence, many Links favoured it, and others supported them. The editor of *Photography and Focus*, R. Child Bayley, thought that the 1908 Salon might be "eccentric" and "puzzling," but at last the Photographic Salon had lost its "heavy respectability." Now it would "shock and startle many" and was "all the better for it" (*Photography and Focus,* 15 September 1908).

The American work was Symbolist whereas the English was just anecdotal (compare Steichen's "Globe" series with Alexander Keighley's "A Word in Passing"). The work was urban where the English was rural (compare Coburn's "Flip-Flap" with John Dudley Johnston's "Snow on the Hillside"). It was erotic where the English was cosy (compare Eugene's sexually-charged portraits with Will Cadby's "Baby Study"). It dealt with the hurly-burly of life whereas the English was full of peace and quiet (compare Stieglitz's "At the Steeplechase" with Mrs G.A. Barton's "Morning").

Some writers, such as the critic A.J. Anderson, did not approve of current British pictorial photography but they thought that the American invasion was dangerous. The British and European Links must act quickly to prevent the Salon from collapsing or becoming "annexed" by the Photo-Secession.

The Links acted and, led by Mortimer, they managed to defeat Davison over arrangements for the Salon of 1909. Davison had wanted rigorous selection, excluding all but the best pictorialists, which would have meant the return of the Photo-Secessionists. But led by Mortimer, the Links voted to invite individuals only. The Photo-Secessionists could no longer exhibit as a group, and so they all resigned in May. Their mass resignation took place months before the Photographic Salon of September 1909, but it led to further in-fighting among the Links and the Brotherhood collapsed in 1910.

Some former Links decided to continue their version of pictorialism and founded the London Salon in 1910. Pictorialism flourished there though it remained more or less where it had been in 1909. The Links who believed that everything British was correct were in the ascendance. Ignoring evidence to the contrary and changes abroad, they reasserted the Victorian belief in moral and improving art in gentle, picturesque photographs. Their victory marked the path of art photography in Britain for years to come. Significantly, the Brotherhood of the Linked Ring, in all its vicissitudes, represents the exclusive and conservative attitudes that help to define the artistic cultural life of Britain in the late Victorian and Edwardian epoch.

BROTHERS, ALFRED (1826–1912)

English studio owner and photographer

Alfred Brothers operated a studio at No14 St Ann's Square in Manchester from 1858 until at least 1894. He took over premises which had formerly been operated by Beard & Foard since 1854.

He was born in Sheerness, Kent, England on January 2nd 1826, and later apprenticed to a bookseller. After a period of employment as an insurance agent, during which time he took up photography, he opened his Manchester studio. In 1858 he suggested a method of silvery recovery from spent chemicals.

He had a lifelong interest in astronomy, and wrote and lectured on the subject from the mid 1860s.

Brothers became one of the leading figures in both the Manchester Literary & Philosophical Society—where he met Roscoe and others—and the Manchester Photographic Society. He therefore knew of Roscoe's experiments with magnesium wire as an illuminant. In 1864, using magnesium ribbon made by flattening Roscoe's wire, Brothers took the first portrait lit solely by magnesium light—of Roscoe—and in the same year took the first photographs underground, at the Blue John Mines in Derbyshire also using the ribbon.

His 1892 book *Photography, its History, Processes, Apparatus and Materials*, went to several editions, he published several albums of photographs, and was a frequent contributor to the photographic press.

JOHN HANNAVY

BROWN JR., ELIPHALET (1816–1886)

An early-American expeditionary photographer

Although Eliphalet Brown, Jr. is best remembered as the daguerreotypist with Commodore Matthew Perry's 1852 mission to open Japan to the West, he had an extensive career prior to that famous role.

He was born in Newburyport, Massachusetts in 1816, and by his early twenties was working as an artist in New York, among a growing number of young men producing the numerous drawings and lithographs required by a burgeoning publications industry seeking to satisfy the curiosities of a public eager for a more visual depiction of the world.

He spent the next thirteen years working for various establishments, including Currier and Ives, producing portraits and historical and marine lithographs, sometimes on his own, and occasionally in partnership with others. In 1841 he exhibited his work at the National Academy of Design in New York.

A younger brother, James Sydney Brown, had also come to New York to pursue a career as an artist. With Eliphalet's help, he began as a silversmith's apprentice, then opened his own portrait studio, but soon gave that up to become the first operator for the newly opened daguerreotype gallery of Matthew Brady. By 1846, James had left Brady to join Eliphalet Brown as a partner in their own business, but it is unclear if he was making daguerreotypes during this period. By 1848 James was working alone as a daguerreotypist at his American Gallery, and from 1851 to 1854 had moved back to his original portrait studio at 181 Broadway, but by then as a daguerreotypist.

It seems likely that Eliphalet had learned daguerreotype from James during their partnership together, but the puzzle is why Matthew Perry selected Eliphalet over James to be his official photographer for the expedition to Japan. Perhaps Perry was looking for a more broadly talented person with a little more maturity and experience. In 1853, after the expedition to Japan was underway, James had an exhibit at the New York Crystal Palace of a series of daguerreotype portraits of Perry and his officers, so he was known to Perry. He was also on friendly terms with Samuel Morse and Napoleon III, so he apparently travelled in influential circles, but while James specialty seems to have been daguerreotype, Eliphalet's expertise was in drawing and lithography, and since that was the primary means of reproduction at the time, those skills probably assumed a greater importance for Perry.

Eliphalet left his brother's partnership in 1848 and in 1851 joined with Charles Severyn, a lithographer, but by the time he was selected by Perry, he was again working for Currier and Ives. Apparently his drawing ability was as important as his photographic expertise, yet there is no official mention in the final government report of his dual role beyond an occasional reference to "the artists." The lithographs made for the government report listed twenty-five drawings in which Brown was listed as co-artist, almost always credited for drawing the figures, while the landscape or surroundings were credited to William Heine, a twenty-five year old German who was the official artist on the expedition.

The expedition got underway from Annapolis, Maryland on November 24, 1852, and sailed the southern route around Africa, making stops at Madeira, Capetown, Mauritius, Ceylon, Singapore and Shanghai before stopping in Naha, Okinawa, in the Ryuku Islands on May 26, 1853. Perry rented a house there and ordered Brown to commence making daguerreotypes.

On 2 July1853 Perry set sail for Japan with the black painted, four ship fleet.

Arriving 8 July, after 9 days of tense negotiations, the Japanese Government accepted Perry's letter from President Millard Fillmore, requesting a treaty of trade and supply with Japan. Promising to return in the spring of 1854 for the Japanese response, they returned to Hong Kong and Macao, where they set up headquarters till the return trip. Many of Eliphalet Brown, Jr.'s daguerreotypes produced during this extended stay show him working in a less formal way, with casually posed people portraying cultural details, as opposed to the later, more formal portraiture from Japan.

Returning to Japan on 14 January 1854, the Emperor's positive response was received, and treaty negotiations commenced on 9 March 1854. By 31 March 1854, a treaty had been signed giving the United States the right to use the ports of Shimoda to the south and Hakodate to the north. Perry then sailed to each port for evalution and diplomacy with the local officials, allowing Brown numerous opportunities to make many of the approximately four hundred daguerreotypes he reportedly made during the expedition. On 17 August 1854, they finally set sail again for Hong Kong and Shanghai.

After the return of the expedition to the U.S. in early 1855, a report of the expedition was published by the Congress of the United States on 1 January 1856, utilizing ninety lithographic illustrations, of which nineteen were derived from Brown's daguerreotypes.

It has been widely publicized that all of Eliphalet Brown, Jr.'s daguerreotypes were destroyed in an 11 April 1856 fire at the Peter S. Duval Lithographic Company of Philadelphia, Pennsylvania, but an examination of the official report reveals that they only made six of the nineteen daguerreotype-derived illustrations in the report, with the balance distributed among three other lithographic firms, one other in Philadelphia and the other two in New York. Although those six at the Duval firm may have been lost, by no means were all of them destroyed and, although the rest have not been accounted for, they may yet turn up in some obscure archive in Washington, D.C.

After his return from Japan, Brown seems to have given up both art and photography, instead spending the next twenty years in the U.S. Navy, as a Master and Ensign during the Civil War, and later in the Mediterranean as an Admiral's secretary. He retired from the Navy about 1875, married and seems to have lived quietly until his death on 24 January 1886.

Today, Eliphalet Brown, Jr.'s artwork can still be found in the Library of Congress, the New York Public Library and the Museum of the City of New York, all signed E. Brown, Jr. The only identified daguerreotypes

by him consist of four portraits in Japan, and one portrait of Gohachiro Namura, a translator to the expedition, in the B. P. Bishop Museum in Honolulu, Hawaii.

Although, as with so many other early expeditionary photographers, the actual artifacts of his career have largely disappeared, we are fortunate in having enough access to their facsimiles to appreciate the vision and skill Eliphalet Brown, Jr. brought to a difficult role.

Bruce T. Erickson

Biography

Eliphalet Brown, Jr. was born in 1816 in Newburyport, Massachusetts. An accomplished artist, he excelled at lithography and worked for many of New York's principal lithographic publishers in the mid 1800s, including Currier and Ives. He learned daguerreotype from his younger brother James Sydney Brown, who had also come to New York to earn his living as an artist, but who became instead Matthew Brady's first daguerreotype operator, leaving after several years to practice daguerreotype.on his own. When Commodore Matthew Perry of the U.S. Navy embarked on the famous expedition to open up Japan to the West, he selected Eliphalet Brown, Jr. to be his official photographer. From 1852 to 1855, Brown made approximately four hundred daguerreotyes in Japan and other locations in the orient. Nineteen of these were rendered as lithographs and published in a three volume U.S. Government report, usually designated or credited as "dag by E. Brown." At the conclusion of the expedition, Brown continued in Navy service, never again being active in any area of art or photography. He retired around 1875, married and lived quietly until his death on 24 January, 1886.

BROWNELL, FRANK A. (1859–1939)

Frank Brownell was born in Canada in 1859 and moved to Rochester, New York, where he was apprenticed to Yawman & Erbe. He opened his own cabinet-making and camera shop in Rochester and began working for George Eastman in 1885. In 1892 Eastman established the Camera Works with Brownell working exclusively for the Kodak company. He designed over sixty cameras for Kodak between 1885 and 1902 including the Brownie camera. After finally leaving Eastman Kodak in 1906 he moved into making motors for marine and automobile use. He died on 2 February 1939.

Frank Brownell was born on 4 February 1859 in Vienna, Canada. He moved to Rochester, New York, after graduation in 1875 aged 16 and was apprenticed to the machinists Yawman & Erbe. In his own time designed a plate camera that was accepted by the Union View Camera company for manufacture. In 1883 he opened his own cabinet-making and camera shop at 282 State Street, Rochester, and produced a large range of studio and professional cameras.

In 1885 George Eastman, founder of the Eastman Dry Plate and Film Company asked Brownell to produce the Eastman-Walker roll film holder, a largely wooden device which carried a paper roll for producing a negative and could be fitted on to any camera with a standard back. After legal threats derailed Eastman's first attempt to introduce a detective camera in 1887 Eastman turned to Brownell around the 10 October 1887 with his idea for a new camera. Brownell began making the wooden parts on 12 October 1887 and Yawman & Erbe were asked to produce the metal parts and shutter mechanism and to undertake the assembly. The camera was sold as the Kodak and introduced in 1888.

Although Brownell's involvement in the original Kodak was confined to making the wooden body and transporting them to Yawman & Erbe by 1889 he was designing much of the first Folding Kodak camera which he patented and in 1891 he developed a daylight loading cartridge and a series of three Daylight Kodak cameras which could be loaded and unloaded in subdued light.

In April 1892 Brownell's factory suffered a fire for which he was largely uninsured and Eastman constructed a new building at 333 State Street close to his own factory to manufacture cameras for a cost not exceeding $60,000. The building had 55,000 square feet of floor area and a 126 horsepower engine to drive machinery. The provision of plenty of daylight was a particular feature. Eastman called the factory the Camera Works and rented it to Brownell who signed an exclusive contract with Eastman to design and make Kodak cameras. It was occupied from 1893 and, in reality, was Eastman's first step in establishing his own camera manufactory.

In 1896 the factory employed 700 people which had grown to over 1,000 by 1902.

The Pocket Kodak camera was designed by Brownell in 1895 and was produced at a cost price of 80¢ and sold to Kodak for 87¢ who retailed it with film for $5.00. The Cartridge Kodak followed in 1897. By the end of the 1890s the Brownell Manufacturing Company was the largest volume producer of cameras in the world. Eastman described Brownell as 'the greatest camera designer the world has known.'

Brownell was by all accounts a benevolent employer and offered an employee reward scheme, a hospital, meals, a lending library and social events. The Brownell Manufacturing Company (and also the Eastman Kodak Co) received a silver medal in 1900 at the Universelle Exposition in Paris from the Department of Social Economy.

On 5 June 1897 the Eastman Kodak Company purchased the machinery, tools and fixtures owned by Brownell for $23,195.79 in Kodak stock and under a new agreement Brownell paid rent to Kodak for their investment and produced cameras at agreed prices with an aggregate profit not to exceed 10 percent. The following June this was reduced to 5 percent so that Eastman could keep his camera's competitively priced.

In 1899 Eastman asked Brownell to design a camera that was cheaper and easier to use than any previous Kodak camera. The Brownie was the result, and the camera was the subject of several United States patents one of which from 11 April 1899 was of direct relevance. It was shipped to dealers on 1 February 1900, and by the time the original Brownie model was superseded by the No. 1 Brownie in October 1901 around 245,000 had been sold.

Brownell was increasingly being seen as a bottleneck to further mass camera production. Plans for a new camera building at Kodak's main site, Kodak Park, were produced as a way of easing Brownell out but the expense of the building meant that the existing camera works were extended and Brownell was retained. Brownell, although similar in age to Eastman and originally with the same innovative approach to design which had first attracted Eastman to him, had not kept up with new production methods and he was failing to come up with enough new camera models. He was also seen as a poor manager and his handling of a labour dispute in 1901 had not impressed Eastman.

On 1 October 1902 Eastman, recognising Brownell's past importance to his business, proposed buying him out from the camera making business for $130,090.64 and to retain him as a camera design expert at the substantial sum of $12,000 a year. Brownell accepted the offer and continued to work at Eastman's new Camera Works Division of the Eastman Kodak Company.

He finally left the Eastman Kodak Company on 1 May 1906 to go into business on his own account. Between 1885 and 1902 when Brownell left the day-to-day running of the camera business over sixty new models and designs had come from him. He had been responsible for the design and mass-production of all Kodak's cameras and was cited as co-patentee for many cameras including models such as the Panoram and was behind the camera industry's most successful camera ranges: the original Kodak, the Cartridge Kodaks, the Folding Kodaks, the Pocket Kodaks and the Brownie camera.

After leaving Eastman Kodak Brownell bought into a previously existing business and established the Brownell-Trebert Company between 1906–1907 producing marine and automobile motors, and then the F A Brownell Motor Company from 1908–1913 and finally the Rochester Motors Company Inc. from 1913–1919. He built a range of 15–160 HP engines and supplied the first gasoline powered motor yacht for the United States Navy.

Brownell remained friendly with Eastman until Eastman's suicide in 1932 and was involved with several organisations in Rochester. The economic depression of the early 1930s had affected his own financial position, and at the time of his death on 2 February 1939 in Rochester he had lost most of his fortune.

BRUCKMANN VERLAG, FRIEDRICH (1814–1898)

German fine art publisher

Friedrich Bruckmann, born to wealthy parents in Deutz (Cologne) on 4 June 1814, was already 44 years old when he set up a publishing house for art and science —the *Verlag für Kunst und Wissenschaft*—in Frankfurt am Main in 1858. It was born more from his interest in art than in publishing. Friedrich's father, Johann Wilhelm Bruckmann, was a successful merchant, land

owner and mayor. In his younger years he undertook several educational journeys, including both France and Italy, spending two years in Paris. He even served as an apprentice at the Sèvres porcellain factory, founding his own short-lived factory in Deutz on his return.

After first moving the company, which he called Friedrich Bruckmann Publishers, to Stuttgart in 1861, Bruckmann finally settled it in Munich in 1863. In 1864 a photographic institute and printing workshop were added. This setup was unique to the *Bruckmann Verlag* at the time, permitting Bruckmann to realise his products completely and autonomously within his own facilities.

His first success as a publisher came in the first half of the 1860s with a photographic portfolio of Goethe's *Frauengestalten,* the photographs reproducing drawings by the director of the Munich Academy of Arts Wilhelm Kaulbach. Kaulbach's so called *Goethe-Galerie*, drawings of female characters found in Goethe's fiction, was reproduced in large-size photographs by Josef Albert. Bruckmann also issued this work in different techniques, formats and prices (a sales strategy that would become typical for him) and tried to launch a *Schiller-* and *Shakespeare-Galerie* as well.

To use the enhancement of orthochromatic material by the photographer Eugen Albert, the son of Josef Albert, the *Photographische Union* [Photographic Union] was created in 1884 as a photographic institute, separate from the *Bruckmann Verlag* although it remained under its ownership. The institute issued photographic reproductions of contemporary 19th century art, mainly paintings, in different formats.

Around 1900 the firm consisted of a printing workshop, engraving manufactory, another printing room for collotype and photogravure, photographic laboratories and studios. From its base in Munich, the publishing house became renowned, with branches opening in Vienna, Berlin, Paris, London and New York by 1868. Bruckmann was also innovative in his utilization of new means of advertising. He maintained good relationships with bookstores in order to have his products presented in the best and most effective way. The company sent out leaflets, colored posters and multilingual catalogues to promote its books.

The *Bruckmann Verlag* soon became famous for its high-quality reproductions produced to the newest technical standards. Friedrich Bruckmann adopted a variety of new developments in photomechanical printing and developed them further. He took up the Woodburytype in 1869, in 1875 the more reliable and efficient collotype and in 1882 the printing office acquired the new process of photogravure as well as the Autotype process. The firm was the first German one to apply a rapid collotype in 1885, a rotogravure press in 1900, and in 1890 they began to produce some of the first multi-color prints by multiple plate photogravure. By advancing the use of photomechanical reproduction, Bruckmann was able to supply a larger quantity of images faster, and to satisfy the wider public demand for reasonably priced art prints.

By this contribution, Bruckmann pioneered modern German fine art publishing. Munich, where he evolved his company, was at the turn of the century a center for art publishers and booksellers as well as reproduction and printing. The *Bruckmann Verlag* published mostly within the archaeological and art sector, focussing on antique art, the Renaissance and the 19th century, thereby particularly enhancing artists with a high reputation. It published costly and elaborate deluxe editions for the well-equipped bourgeoisie as well as in smaller, cheaper formats intended for broader consumption. The company also produced standard works in art history, monographs of famous artists, as well as large and expensive picture-atlases and documentation for scholarly use. These latter were made possible by the technical developments encouraged within the company. It specialised in reproducing complete museum and private collections as well as publishing portrait series and portfolios of famous paintings and sculptures, which were usually image collections with minimal text.

One of Bruckmann's most important contributions was the first illustrated German art journal, begun in 1885, the *Kunst für Alle* [Art for All] which concentrated on contemporary art. It was one of the most influential and long-running publication at the time since it addressed a wide non-specialist public both in its arrangement and its low price. The journal incorporated all genres but focused on paintings, and, since illustrations played a conspicuous role in it, many new methods of photomechanicalprinting were used. Thematically, it was to a large extent restricted to national realistic art—being an organ of the middle class—and was much in favor of the Impressionists. As a consequence, it excluded other avantgarde art forms almost completely. From 1891 to 1899 the journal had a division called *Der Amateurphotograph* [The Amateur Photographer] edited by Adolf Miethe which dealt with technical questions and the use of photographs for reproductions. In 1899 *Kunst für Alle* was combined with the *Dekorative Kunst* [Decorative Art] (founded in 1897 for international applied arts) under the name *Die Kunst* [The Art] under which name it was issued until 1944, at which time it was renamed *Die Kunst und das schöne Heim* [Art and Beautiful Home] and continued until 1984.

In 1883 *Bruckmann Verlag* was transformed into a private limited company, run by Bruckmann's two sons, Alphons (1855–1945) and Hugo (1863–1941), who had joined the firm in 1870 and 1881 respectively. In 1883 it was renamed *Verlagsanstalt für Kunst und Wis-*

senschaft, vormals Friedrich Bruckmann and changed name again in 1896 to *Verlagsanstalt F. Bruckmann A.G.* After Friedrich Bruckmann's death in Arco, South Tyrol, 17 March 1898, both sons directed the company, Alphons as technical director and Hugo as publisher.

Friedrich's son Hugo was an early supporter of Adolf Hitler and an active member of the National-Socialist Party (NSDAP) which he joined in 1925. Although the company did not publish a considerable amount of ideological literature, it remained an extremely conservative voice in art criticism, producing the catalogues and posters for the *Great German Art Exhibitions* in the *House of German Art* in Munich. In 1941 the grandson Alfred Bruckmann, who had joined the firm in 1922, became executive secretary. The *Bruckmann Verlag* was still considered essential during the war until 1943 and thus received sufficient paper supplies. After World War II the company was officially dismantled as a result of its relationship with the Nazi regime, but was refounded in 1948 and again developed into a leading publisher of art prints. To the hitherto existing areas art history and art books were added geography, travel, leisure and alpine literature from the 1930s onwards. In 1966 the company was taken over by the Stiebner family. From 1999 onwards the art sector was abandoned, leaving only publications on travel, leisure and alpine subjects.

Friedrich Bruckmann had both a paedagogical and commercial interest in popularizing art as one can see from his art journals. He was in favour of artistic education for wider sections of the public and discovered a profitable source of income in the distribution of large quantities of art reproductions to a broader public.

BUCHAR, MICHAEL
(active 1860s–1870s)
Professional photographer

Michael Buchar worked as a photographer in Orenburg in 1860–1870s. He was the master of landscape and ethnographic photography. He prepared an album of photographs showing national types of the Orienburg Province to present to the future Emperor Alexander III. To make the ethnographic images look more naturalistic he hand-coloured the monochrome prints. These photographs were created in the studio and Buchar later painted landscapes into the prints' background.

The 1860s and the beginning of the 1870s in Russia was the time in which Buchar was one of many photographers who created ethnographic albums which, apart from being valuable for scientific purposes, depicted the various regions and societies of the Empire as well. Such albums were usually presented to the Emperor or other members of the Romanov family. At the same time as Buchar, photographer A. Karelin together with the famous Russian landscape artist I. Shishkin, created the album "Nizhniy Novgorod" which included the landscapes of the city and its suburbs and included photographs illustrating the nations living in Nizhniy Novgorod province. Like Buchar, both Shishkin and Karelin painted the prints using watercolor. The sole copy of the album was presented to the Emperor Alexander II. The Photographer Nekhoroshev created "The Turkistan Album" published in 1871–72. One of the copies was also presented to the Emperor Alexander II.

ALEXEI LOGINOV

BUCKLE, SAMUEL (1808–1860)

Active in photography in Peterborough from at least 1851 and in Leamington from 1853, Buckle is undoubtedly a pioneer though his reputation never really became evident due to his ill-health in the later 1850s. He built at the rear of his house in Leamington a 'laboratory' presumably a combination of camera workshop and studio. From an early stereo photograph by Buckle this is clearly a purpose-built three-storey brick structure quite unlike other modest or temporary glasshouse studios in Britain: if this is the case it is one of the earliest example of a substantial structure purely erected for photographic purposes in Britain.

There is some evidence directly linking Buckle with H.P. Robinson: they lived only ten minutes apart and they were both in contact with Joseph Glover, a local publisher and bookseller, so this connection warrants further investigation. Robinson must have been well aware of Buckle as a photographic pioneer and could even have received instruction from him. Robinson does not appear in Buckle's account book but there are references to J.D. Llewellyn, Henry White, G.S. Nottage, Marion & Co., and P.H. Delamotte as well as a series of photographic equipment suppliers including Ross. Buckle exhibited extensively, and amongst over fifty of his topographical images contained within two unpublished albums in the National Media Museum, Bradford, are several of his widely-exhibited images. One album contains a beach view showing Buckle with Sir David Brewster and 'Mr Roslyn.' The other album also contains two prints of glassware on shelves taken by Fox Talbot.

At least fourteen original prints exist at Peterborough Library, others are in Rugby Library and others will exist in Warwickshire archives. The Wheatstone Papers at King's College London contain stereo views by Buckle.

Despite a few advertisements, there is no evidence for any commercial portrait work so he is an example of how 'new money' could attain 'gentleman' and 'amateur' status within one generation. This shift is signified by his fashionable Leamington address after having spent much of his life in Peterborough or Cambridgeshire. Buckle's usual medium was the calotype but it is clear from Fox Talbot correspondence that this had changed by 1858. Buckle tells him "I work now—when I do take a picture at all—by the Collodion Albumen Process... Portraits I never take nor can I tolerate any but those which are corrected by subsequent painting. Views have not relief enough for my artistic eye and pure untouched Photographic Portraits are great distortions, as you are fully aware" (Fox Talbot correspondence 6 May 1858).

No evidence exists of a photographic career prior to the calotype prints exhibited at the Great Exhibition of 1851 which received a Council Medal—but since he used Whatman paper with a 1849 watermark earlier work is possible. The Council medal may have brought him to the notice of Prince Albert who acquired nine calotype prints in 1854. Thereafter he exhibited over 140 prints in London, Dundee, Glasgow, and Birmingham between 1852 and 1857. From advertisements and his account book it is apparent that Buckle made and sold his own lightweight cameras for paper or glass negatives and that he gave instructions in calotype photography.

All known views by Buckle were produced before 1857 and almost all are topographical using the picturesque conventions of the period. These views are among the earliest to survive for the areas he covered in Northamptonshire, Cambridgeshire and Warwickshire but he also is known to have travelled in the Gloucestershire, the Isle of Wight, Sussex and Wales. Thirty of his views were privately published in *Calotype Pictures by Samuel Buckle* with a printed list of subjects. Prince Albert's copy of this was sold at Sotheby's 1 July 1977 (Lot 171) with a paper label 'Prince Albert's Library.' What is certain is that purchases of prints by Buckle were certainly made by Prince Albert by 1854 since they are included in a list of prints acquired from Eduard Baldus and Antoine Claudet among others.

His only other photographic reputation relates to the 1855 "Buckle Brush" for coating calotype paper. Apart from a few advertisements and just one obituary there appear to be no other references to Buckle in any of the post-1854 photographic journals—it appears that his "long and painful illness" meant that his photographic activities ceased at the very point where he may have become better known.

Ian Leith

Biography

Samuel Buckle was born in Orton Longueville, Huntingdonshire [now near Peterborough, Cambridgeshire] 14 September 1808 [christened 2 October]. His father was the famous jockey Francis Buckle, and the family inherited a substantial brewery in Peterborough which was managed by Samuel Buckle from about 1841 until its sale in 1853. He married Anne Ball at St John the Baptist church in Peterborough 1845 and had moved to Royal Leamington Spa, Warwickshire by December 1853 where he lived at No.5 Beauchamp Square. Buckle died in Leamington 30 May 1860 leaving an estate including property valued under £5000. His tomb is in Brunswick Street Cemetery, Leamington.

BULL, LUCIEN GEORGES (1876–1972)

Irish chronophotographer

Born January 5, 1876, in Dublin, Ireland, to a British father and French mother, he lived mostly in France. His brother was cartoonist and photographer René Bull. Lucien Bull was a prolific innovator, responsible for pioneering high speed cinematography in order to view movement in slow motion. Engaged in 1895 by the French physiologist Etienne-Jules Marey, Bull assisted with chronophotographic experiments; his duties included developing and printing the sequence-picture negative strips for analysis. He was also sent out onto the streets of Paris to shoot scenes with Marey's Chronophotographe camera, which used non-perforated film. Bull later remembered trying to project one of Marey's filmstrips, at a time when many inventors were making efforts to present their celluloid-based photographic sequences as moving images on a screen. Lucien Bull's major contributions to the Marey Institute started after Marey died in 1904, and included high-speed cinematography of insect flight (some stereoscopic), and balistics. Bull also patented an improved version of the electrocardiogram (ECG) in 1938. He remained at the Institute as sub-director for decades, receiving honors from the French and British. He was active until his death on August 25, 1972.

STEPHEN HERBERT

BUNSEN, ROBERT WILHELM (1811–1899)

Chemist

Robert Wilhelm Bunsen was born March 31, 1811, in Goettingen as the son of a professor of modern languages. At the age of 19, he earned his PhD in chemistry in Goettingen and went to teach in Marburg and Breslau. In 1852 he began his own laboratory at the Heidelberg University and stayed there until his death on August 26,1899. In more than forty years of work Bunsen made German chemistry one of the leading sciences in the world. The only thing he seems to have less contributed to bears his name: the Bunsen burner.

This extremely versatile man contributed to many sciences through the use of chemical analysis, and some of his efforts helped photography. When experimenting with the carbon-zinc electric cell he invented the first grease-spot photometer in 1844. In the 1850s, he was the first to obtain magnesium in metallic state and measure its qualities. By following the suggestion to use burning magnesium as a fast burning but bright light source, he eventually named the base of flash light for photography in 1859. Similar to Edmond Becquerel and in cooperation with Gustav Kirchhoff, Bunsen found that each element emits a light of characteristic wavelength thus contributing tremendously to the basic researche on color photography. In 1862, Bunsen and Roscoe published the first law of blackening as reciprocity of light: Each photo-chemical effect is the product of the light intensity and the time involved, each product producing the same effect of blackening by light emission. This law was later corrected by Karl Schwarzschild. Bunsen's later enquiries lead him away from photography to more ecologic and industrial questions.

ROLF SACHSSE

BURGER, WILHELM JOSEPH (1844–1920)

Austrian photographer

Born into a comfortable middle-class Viennese family, Burger received a classic education but displayed a great talent for art. Accordingly, in 1855 his parents enrolled him in the *Akademie der bildenden Kunste* where he studied until 1860. Moving to Munich to continue his studies he was increasingly attracted to photography, thanks to the influence of his uncle. Burger returned to Vienna in 1863 and studied photography at the University where he demonstrated remarkable ability. By 1868 he was regularly lecturing and publishing articles. He had come to the notice of the Court which, that year, appointed him photographer to the Austria-Hungary mission to the Far

East which set off to initiate diplomatic and commercial relations with Siam, China, and Japan. Burger took many outstanding photographs in the Far East—portraits, landscapes and of works of art. He returned to Austria in March 1870 and was rewarded by being appointed Court photographer. In 1872 he was the photographer to the Austria-Hungary Arctic Expedition, and later for expeditions to Asia Minor. Constantly experimenting with new technology and refining his technique, Burger became the most celebrated photographer in Austria. He died in 1920. (A portfolio of his 1869 Far Eastern photographs is in the *British Library*: (Burger, Wilhelm), *Bilder Aus Japan*, Wien: Druck V. M. Munk, 1871.)

TERRY BENNETT

BURKE, JOHN (1843–1900)

English, photographer

As a teenager, Burke served in India as an apothecary assistant in the Royal Artillery. He left the army in 1861 to join William Baker, a retired sergeant who had started a photographic studio in Peshawar. Together they formed Baker and Burke Studio (1867–72), the first commercial studio in that region. In 1873 Baker left the firm and it became J. Burke & Co. with studios in Peshawar, Rawalpindi, and Lahore; it continued to operate until 1900. Perhaps because of his military background, Burke was able to accompany, in an quasi-official capacity, most of the British military campaigns along the North West Frontier and Afghanistan from the late 1860s to 1897. He was the first to photograph Kabul after it was taken by the British in October 1879. Burke offered his photographs from the region—present day Pakistan, Kashmir, and Afghanistan—in a series of commercially produced albums collectively known as the *Afghan War Album*. There are a number of variants of *Afghan War Album*, corresponding to the Second and Third Afghan Wars and related campaigns. The albums and individual prints were available through Burke's studios and through a number of booksellers in India and London. In addition to military subjects, Baker and Burke, then Burke, provided views of landscapes and archaeological sites, as well as a range of subjects in Lahore—imperial offices and pageants, bazaars, mosques, and palaces.

KATHLEEN HOWE

BURNETT, CHARLES JOHN (1820–1907)

Born 1820 at Kenmay, Aberdeenshire, educated privately and at Edinburgh University, he became an innovative photochemical experimenter, and founder-member of the Photographic Society of Scotland. Burnett made the first photographic prints employing light-sensitive uranium salts, which he described to the 1855 meeting of the British Association for the Advancement of Science in Glasgow, illustrated by prints and photograms in the accompanying exhibition. The images were of uranyl ferrocyanide or silver, depending on development. Burnett was a prolific contributor to photographic journals, and he showed an early application of platinum toning silver prints at the Edinburgh Photographic Society exhibition in 1856–7. His uranium sensitizers furnished gold images (a form of chrysotype) in 1857, when he also made the first prints in palladium, antedat-

Burke, John. Camp Scene Jellalabad.
The J. Paul Getty Museum, Los Angeles

ing William Willis's palladiotype by 60 years; Burnett's "cuprotype" of the same year anticipated Obernetter's process of 1864.

Burnett admitted his lack of perseverance: "I cannot well find time for the prosecution of discovery, and for pretty specimen making, and as soon as I see unmistakable indications of what are the real capabilities of any process, I am generally off to something else." His priority was challenged in 1858 by Abel Niépce de Saint-Victor publishing identical uranium processes. Burnett showed his "Experiments in Printing" at the London International Exhibitions in 1859 and 1862, and was commmended with an Honourable Mention, but none of his prints is known to have survived. He died a bachelor in Aberdeenshire in 1907.

BURTON, ALFRED (1834–1914) AND WALTER (1836–1880)

English photographers and studio owners

Alfred Henry Burton born 1834 and Walter John Burton born 1836 were the eldest children of John Burton and Martha Heal. John Burton who started as a printer, bookbinder and bookseller opened a photography studio in Leicester in 1858 and his four sons trained in the business. Alfred went to New Zealand in 1856 and worked as a printer in Auckland then Melbourne, Australia before returning home in 1862 to manage the Nottingham branch of John Burton & Sons. Walter immigrated to Dunedin, New Zealand in 1866, where he set up a studio in Princes St. In 1868 he was joined by Alfred. The Burton Brothers plied a trade in portrait photography which was mostly done by Walter while Alfred travelled, taking landscape views including panoramas. Walter left the partnership in 1876 and travelled to Europe, returning to Dunedin in 1878 with new equipment and he traded as the Royal Gallery of Photography in George St. His life was cut short when he committed suicide by cyanide poisoning on 10 May 1880. Alfred was joined by his brother John William in 1877 who opened an Australian branch of Burton Brothers in Dean St, Albury in 1880. Alfred formed a partnership with Thomas Mintaro Muir in 1882, and they produced some of the best landscape work in New Zealand, some on 18" x 20" plates, as well as studies of the Maoris. Losing an arm due to gunshot wound in 1890 Alfred passed work over to employee George Moodie who joined Thomas Muir in the firm Muir and Moodie when Alfred Burton retired in 1898. The Albury studio had closed in 1895. Alfred Burton died 2 February 1914 in Dunedin.

MARCEL SAFIER

BURTON, WILLIAM KINNINMOND (1856–1899)

English engineer and amateur photographer

Burton was born in Edinburgh and educated at the Collegiate School. Despite coming from a family of lawyers, Burton decided to pursue a career in engineering and, in 1873, apprenticed for five years to a local firm of engineers—there being no engineering degree course in those days. He progressed to the post of resident engineer of the London Sanitary Protection Association and was offered, in 1887, the post of Professor of Sanitary Engineering at Tokyo Imperial University. Amongst many engineering achievements, Burton is credited with having designed the water supply systems for most of Japan and Taiwan's major cities.

Prior to going to Japan, Burton had become a keen amateur photographer and a noted expert and writer in the field. In Japan he formed relationships with Japanese photographers such as Ogawa Kazumasa and Kajima Seibei, and was instrumental in introducing the country to many new photography techniques. In 1889 he founded the *Nihon Shashin Kyokai* [Photographic Society of Japan], and in 1893 organized Japan's first international photographic exhibition. He immersed himself in Japanese society and became one of the first Westerners to marry a Japanese. If Burton had not gone to Japan, arguably photography in that country would have developed at a slower pace. He died in Japan in 1899.

TERRY BENNETT

BUSCH, EMIL (1820–1888)

German photographer, merchant, and mechanic

Emil Busch was born August 6, 1820, in Berlin as the grandson of Johann Heinrich August Duncker who had

founded the Optische Industrie Anstalt at Rathenow in 1801 for the production of reading glasses. Trained as a merchant and mechanic, he began working for the company in 1845. The production of photographic apparatus and lenses from 1852 on bore the name Emil Busch Rathenow, and in 1872 the company became a stock company. Emil Busch died in Rathenow on April 1, 1888.

When Emil Busch took over the Optische Industrie Anstalt at Rathenow, not far from Berlin, from his uncle, in 1845, he gained a prospering business manufacturing glasses for reading and military purposes, and at that time, was without a competitor for miles. From 1850 on, this industrial paradise several competitors came into Rathenow and its surroundings. In 1852 Busch established the Busch-Rathenow Company for photographic apparatus and soon specialized in lenses, and later the wide-angle lenses invented in 1865 by members of his staff. Busch installed modern production facilities in his company by which he converted common manufacturing into a large scale photographic production process. When the Prussian-Danish War started in German countries between 1864 and 1871, Busch became the main military supplier of telescopic glasses, field cameras, and photographic lenses. In 1872, Busch converted his business into a stock company allowing many benefits for his employees. Up until the outbreak of World War I, Busch Rathenow was one of the leading German companies engaged in optical manufacture, producing, amongst other things, large glass mirrors and early mirror lenses, and their products remained unrivalled in quality until the end of the nineteenth century.

ROLF SACHSSE

BYERLY, JACOB (1807–1883)

American daguerreotypist

Jacob Byerly became the first operator of a permanent daguerreian gallery in Maryland, outside Baltimore, when he opened an establishment in Frederick in 1842. He changed the original spelling of his surname from Bierly.

Among his known daguerreotypes are a street scene of Frederick and a portrait of Barbara Frietchie, who is said to defiantly hung an American flag from her window as the Confederate army entered Frederick in 1862, inspiring John Greenleaf Whittier's famous poem with the line, "Shoot if you must this old gray head…." One source says Byerly's second wife, Catherine E. Hauer, was a niece to Frietchie.

The first issue of the Frederick business directory, published in 1859, lists Byerly with an ambrotype and photograph gallery at 55 Patrick Street. The 1860 census reports that he produced 1,500 images annually with the help of two male employees. Byerly continued operation the Frederick studio until 1868, when his son, John Davis Byerly, took over. The Byerly studio was eventually taken over by a grandson, Charles, and continued as a leading Frederick photographic business until 1915, when the building that housed the studio collapsed.

C

CABINET CARDS

The cabinet format was designed to recreate the success of carte de visite photographs, which were produced in the millions worldwide beginning around 1859. In the United States, business at photography galleries slowed after the Civil War, and the trade began looking for a new product. The answer came from Britain, where a similar business slowdown led F. R. Window of the London studio Window & Bridge to suggest the cabinet format in 1866. In England, *The Photographic News* championed the new format; in the United States, *The Philadelphia Photographer* campaigned for its adoption. Manufacturers also benefited from the new format, selling lenses, printing frames, mounts and albums designed for cabinet cards. Like the *carte de visite* before it, the cabinet card format became an international standard; cards produced in Bombay or Yokohama would fit albums in the parlors of Edinburgh or Chicago. The format remained popular into the early years of the 20th century.

Cabinet cards are generally albumen print photographs from wet-plate collodion negatives**,** mounted on cards measuring 4.25 × 6.5 inches. The size of the print is 4 × 5.5 inches, allowing for a border all around and an extra deep border in the lower portion of the card. This extra-deep portion is intended to allow the card to be grasped and inserted into an album without handling the photographic print. Later cabinet cards—those made in the late 1890s and early in the 20th century—are often silver prints made from dry-plate negatives, but it is their size and type of mounting that makes them cabinet cards. A brisk trade was done in albums for this format, ranging from simple velvet-covered styles to elaborate leather-bound versions with miniature music boxes that played when the cover was opened. Some albums featured chromolithographs decorating their pages; rarer examples, often produced in Japan, have pages hand-decorated in ink and watercolor.

Because each cabinet card offered nearly four times the image area of a *carte de visite,* photographers suddenly had many more compositional options. *Cartes* were usually limited to a few simple poses—full-length standing figure by a column, vignetted bust portrait, or seated figure beside a table. Cabinet cards offered more opportunities to show groups or to introduce elaborate backdrops and props. As with the earlier format, photographers sold cabinet cards of celebrities and royalty, which people would collect in albums along with their family portraits. Some of the most creative work in the cabinet format can be seen in the theatrical images produced by leading studios in New York, London, and Paris.

Significant photographers utilizing the cabinet format included Nadar**,** Charles Reutlinger, Napoleon Sarony, W. & D. Downey, Elliott & Fry, Charles D. Fredricks and Mathew Brady. Julia Margaret Cameron's magnificent large compositions were rephotographed and issued in the much-smaller cabinet format. Sarony specialized in photographing theatrical people and produced many striking images. Often these were simple and direct, such as his portraits of Ellen Terry and Oscar Wilde. But Sarony was justly famed for his use of props and backdrops, capable of turning his New York studio into the Egyptian desert or the icy North Pole. The studio featured a mummy, ancient armor, stuffed birds and a Russian sleigh. Sarony's eye for potentially picturesque props made his sitting-room a "dumping ground for the dealers in unsalable idols, tattered tapestry, and indigent crocodiles."

The cabinet format was also used for purposes other than portraiture. In France, Eugene Appert issued a series of photomontages intended for political purposes during the Franco-Prussian War and the Siege of Paris (1871). City views and pictures of prosperous merchants in front of their stores were popular. The works of lead-

ing landscape photographers, such as W. H. Jackson, Carleton E. Watkins, and Adolphe Braun appeared in the cabinet format, especially after the financial panic of 1873 caused havoc with the American economy and made large format landscapes too expensive for most patrons. Occasionally cabinet cards were used for advertising, harnessing the versatility and ubiquity of the format to hawk locomotives, face powder, fruit trees, machinery and patent medicines. The vast majority of cabinet cards served loftier purposes, recording for posterity the tangible evidence of family milestones—from the birth of a new baby to college graduations and the burial of a beloved relative. Millions of these personal mementos were made in studios around the world, and they account for the longevity and popularity of the cabinet card format.

CADETT AND NEALL DRY PLATE LTD.

The business of Cadett & Neall was established in August 1892 as a collaboration between James William Thomas Cadett, a chemical engineer, and Walter Neall, a photographic dry plate and paper manufacturer and a medical doctor. The company's trademark 'swift as light' was registered on 16 September 1892. Cadett appears to have been the technical force behind the business.

James Cadett had patented a pneumatic shutter (British patent number 4367 of 21 November 1877) and patented two further shutters in 1878 and 1884. He was elected a member of the Photographic Society in 1878. Two further patents in 1894 in collaboration with the Reverend James Randolph Courtenay Gale MA described improvements to packing and storing photographic chemicals as semi-liquids in tins and for photographic dark slides. His career between 1877 and 1892 is unknown.

Cadett's principal contribution to photography was to the mechanisation of plate and film coating. His first and most significant patent was number 9886 of 31 July 1886 which described a coating machine with two improvements for regulating the thickness of the emulsion being laid down on to the plate or film and for regulating the delivery of the emulsion from the storage trough to the glass plate. His two subsequent patents of 10 October 1887 and 2 April 1889 further refined these.

From it's founding in 1892 Cadett and Neall grew very rapidly and by October the firm reported that it's plate sales were doubling every month. In Spring 1896 it reported an increase in sales of 62 percent for the ten months ending October 1895 compared to the previous year and an increase of 52 percent for January and February 1896 compared to the equivalent period in 1895. By February 1898 the firm claimed sales of 'millions' of plates and the largest sale in the United Kingdom of any make.

To cope with this growth, the firm enlarged its Greville Works in late 1892 and the following year built it's Crampshaw Works which would double production capacity and these were enlarged in 1896 and in 1898 its Victoria Works were built for paper and film production. All were located in Ashtead, Surrey. New machinery was installed in mid-1894 for meeting the demand for its Velox developer.

From the outset the firm adopted the marking of its sensitised materials with Hurter and Driffield numbers indicating sensitivity to a carefully calibrated standard. Marion & Co had been the first to adopt the H & D scale and Alexander Cowan from Marions assisted Cadett & Neall in applying the standard to their own plates and manufacturing. This was partly responsible for the high quality of the firm's goods. Film was added to the firm's output from late 1892–1893 and specialised plates for photomechanical work in 1893. The orthochromatic plate was discussed by Cadett in a paper read to the Photographic Society and published in the *Journal of the Photographic Society* on 28 February 1896 and the firm began making an orthochromatic plate commercially that same year under the name Spectrum, with a fine grain high speed version being introduced in February 1899. The firm claimed it was 'the only plate of its kind in the world.' Its Lightning plate was claimed the 'quickest in the world.' The firm's plates were rated the second most popular in a vote by readers of *Photographic Life*.

Away from plates the firm produced a range of chemical developers with Velox being the most popular and in 1898 a range of Printing Out Papers, Bromide and other specialised papers were launched in various sizes and surface finishes. The following year two types of gelatino-chloride papers were added with different tonal characteristics and speeds and in late 1899 a platinum black bromide paper in a variety of surfaces was announced.

To support it's sensitised goods the firm promoted a range of exposure tables and calculators. 10,000 of its own calculator had been sold by November 1897 and sales of nearly 20,000 for Dibdins calculator, were claimed by July 1899. Cadett also designed exposure tables with Lambert which sold under their joint name.

Between 1892 and 1899 the firm published a free periodical called *Dry Plates* which went from an initial circulation of 5000 copies to 10,000 by the third number and 30,000 copies by 1898. Cadett authored a number of photographic publications including some with his earlier co-patentee James Gale who also later edited *Dry Plates*.

Cadett & Neall's plate coating machines, based on Cadett's patents, were widely acknowledged as superior. They were manufactured by R W Munro of London at a cost of £175 and they were used by several large plate manufacturers in Britain, including the Britannia Works Company, later Ilford, Limited, who all rented them for £100 a year.

In 1897 the firm's growth and size led to it becoming a limited company with a share capital of £75,000. Cadett explained in *Dry Plates* that this change of status was required to extend the business and to add printing papers to the firms output for which capital was required. The new company was formally incorporated on 20 May 1897.

A standard agreement between the two partners and the company dated 20 June 1897 confirmed that the company would purchase all the goodwill, trade names and trade marks, freehold premises and plant and machinery, stock, and all property in connection with the business. Cadett and Neall would continue to manufacture plates by a 'secret process known as Cadett's process' for which the consideration would be 60,000 shares in the company.

All shares were initially owned by the two families but Cadett and Neall resigned as permanent directors in 1903. The reason for this became apparent by 27 April 1904 when George Davison, the managing director of Kodak Ltd, become a director and a special resolution which was passed on 17 May was presented for filing by Kodak Ltd. By 1907 all shares in the company were held by Kodak through George Davison, George Eastman, Henry Strong and the Eastman Kodak Company. The following year the registered office of the company moved to Kodak's manufacturing plant in Headstone Drive, Wealdstone. The company was formally wound up on 28 November 1946.

Kodak's interest in Cadett and Neall Ltd lay not so much with the retail competition that the firm provided, although the popularity of it's plates and sales success would have been attractive, but in it's technical expertise in the mass-production of plates and film using Cadett's own machinery at a time when Kodak was looking to stifle competition in photographic manufacturing and to take-over competitors. Its approach in 1902 to take over Ilford Ltd had attracted bad publicity and had ultimately failed and Cadett and Neall Ltd offered a less high profile but significant business which could bolster Kodak's own manufacturing output and allow it an insight into its competitors in the sensitised goods business.

Following their departure from the business both Cadett and Neall appear to have had no further significant involvement in photography. Walter Neall had a new home designed by the architect Douglas G Round with a garden by Gertrude Jekyll between 1909–1911 in Guildford, Surrey. Cadett remained in Ashford.

CAFFIN, CHARLES H. (1854–1918)

American art critic

Caffin was born in Sittingbourne, Kent, England on 4 June 1854 to Reverend Charles Smart Caffin, a Church of England minister and his wife Harriet. Both parents were skilful amateur artists and fostered a lifelong appreciation of art in their son. Caffin graduated from Pembroke College at Oxford University in 1877 and, following a stint as a teacher, turned to the stage. Caffin worked as an actor and manager with Ben Greet and His Shakespearean Players, an itinerant troupe offering outdoor plays. He married a fellow player, Caroline Scurfield, and immigrated to the United States in 1892. In America, Caffin found employment in the decorations department of the Columbian Exposition at Chicago where he painted mural decorations from the artists' designs. The fair celebrated the promise of a modern world and probably affirmed Caffin's belief that a new age requires a new art. After the fair, he made cartoons from artists' sketches for use by mural painters at the new Library of Congress in Washington, D.C. and used the experience to receive his first writing assignment. For the handbook published at the completion of the library, Caffin contributed a critical appreciation of art. He settled in New York in 1897, spending several years in Mamaroneck on Long Island, before moving to New York City by 1908. In 1897, Caffin also began his journalistic career and soon immersed himself in every aspect of the New York art world.

Although he frequently lectured, it is as a writer that Caffin made his mark. In an era when photographers battled for recognition as members of the art world, Caffin devoted his life to the belief that photography could be viewed as more than just the application of a mechanical recording device. Although credited as one of the most influential proponents of photography as art, Caffin began his writing career on the other side of the fence. As the new art critic for the *New York Post*, he entered the melee over the merits of photography with a scathing review of the 1898 Philadelphia Salon in *Harper's Weekly.* The subject of the attack, Alfred Stieglitz, met with Caffin and persuaded the critic to take a second look at his images. Convinced of the merits of photography, Caffin's subsequent writings reflected a changed attitude. He wrote time and again that photography could be practiced as a fine art since it requires the methods of other arts: sound technique, knowledge of formal principles and the ability of the artist to control the processes for the aim of personal expression. Caffin soon earned a reputation as a proponent of modern art and, especially, pictorial photography. He never explained his advocacy of photography, but he may have been influenced by the Arts and Crafts Movement theory that all products may be formed artistically. He clearly felt that the possibility of art exists in all human endeavors. Attacked by other critics for his tolerance, Caffin received praise from Stieglitz, a fellow member of the Photo-Secession society (later 291 group), who described him as the only art critic who was utterly honest and who took the trouble to look at every picture before making up his mind.

A highly moral and devoutly religious man, Caffin turned to art to find a rationale for these sentiments and later wrote that religion, morality, and art were inseparable aspects of a full life. It remained his conviction that an artist's character is revealed in his work and his criticism often involved comment on the artist as well as the art. He persistently denounced the efforts of some photographers to imitate other media, calling for a practice that would respect photographic properties and not seek to imitate painting. Caffin advocated "straight" photography, which values immediate effects with little or no manipulation of the print. He noted often that he was not a photographer and, since he lacked extensive knowledge of technical matters, he rarely commented on them. Caffin stayed with the *Post* until 1901, when he became the art critic for the rival *New York Sun.* He cemented his reputation as one of the most influential turn-of-the-century critics by serving as the art editor for two very influential magazines, *Harper's Weekly* and *International Studio*. He also found time to contribute pieces to two journals edited by Stieglitz, *Camera Notes* and *Camera Work*.

Although Caffin published many works on art, he produced only one book on photography and it is the work for which he is best remembered. *Photography as a Fine Art* (1901) first appeared in the form of a series of articles in *Everybody's Magazine* and *Camera Notes*. While Caffin's aim was to assert photography as an art independent of painting, his monograph includes important assessments of both photography and painting. He implied that both painting and photography have the same goals of harmony and beauty. Dismissing the objection that the camera is a mechanical device that prohibits artists from being inventive, he stated that every art has its limitations. The photographer overcomes this difficulty, Caffin wrote, by selection of the view and the moment of light and further control may be asserted in the developing and printing process. *Photography as a Fine Art* opens with a history of the photographic process and includes as illustrations photographs that made false claims to the rank of fine art. Caffin then reviews the work of progressives: Alfred Stieglitz, Gertrude Käsebier, Clarence H. White, Edward Steichen and others.

To boost the cause of photographers, Caffin frequently compared photography with painting. In the summer of 1905, he contributed "The Development of Photography in the United States" to *International Studio* for a special "Art in Photography" edition. In the article, Caffin suggested that the growth of American photography had been influenced by the success of American painting since the latter offered art as a means of personal expression while exploring the possibilities of the medium. In his 1913 book, *Art for Life's Sake*, Caffin asserted that photography confirms that mechanization may serve art and that an important consequence of photography has been the improvement of painting —more imaginative pictures have been produced. Caffin died in New York City on 15 January 1918.

Caryn E. Neumann

Biography

Charles Henry Caffin was born in Sittingbourne, Kent, England, on 4 June 1854 to Reverend Charles Smart Caffin, a Church of England minister, and Harriet C. Caffin. He attended Pembroke College, Oxford University, where he received his B.A. in 1877. Following graduation, Caffin taught for several years before joining an itinerant theater troupe, Ben Greet and His Shakespearean Players. Married in 1888 to actress Caroline Scurfield, the couple had two daughters, Donna and Freda. The Caffins immigrating to the United States in 1892 and Charles found work in Chicago with the Columbian Exposition. He then worked as a mural painter for the Library of Congress in Washington, D.C. in 1897. He published his first essay on art in Herbert Small's *Handbook of the New*

Library of Congress before moving to Mamaroneck, New York and entering the journalistic ranks. A prolific writer, he served three New York newspapers, *New York Evening Post* (1897–1900), *New York Sun* (1901–1904) and *New York American* (1913–1918). He also held the position of art critic for two influential publications, *Harper's Weekly* (1897–1901) and the American supplement to *International Studio* (1901–1905). His landmark article, "The New Photography," appeared in *Munsey's Magazine* (1902). Caffin wrote pieces on photography for *Century Magazine* and *Everybody's Magazine* while finding time to publish dozens of articles on other forms of art and to also lecture for clubs and school groups. A member of Photo-Secession (later 291 group) between 1908–1917, he wrote often for Alfred Stieglitz's *Camera Notes* and *Camera Work*. His 1901 book *Photography as a Fine Art* cemented him as the photographer's friend by portraying Photo-Secession as part of the modern art world. In 1905, he penned "The Development of Photography in the United States" for the art journal, *International Studio*. His art books include *American Masters of Painting* (1902) and *American Masters of Sculpture* (1903). *The Story of American Painting* appeared in 1907, followed by books on Dutch, Spanish and French painting. Caffin summarized his art theories in *Art for Life's Sake* (1913). *How to Study Pictures* (1905) may be Caffin's most influential work since it had wide distribution in schools throughout the country. He held membership in the National Arts Club. Active until the end, Caffin died on 15 January 1918 in New York City.

CAIRE, NICHOLAS JOHN (1837–1918)

Australian photographer

Caire was born in Guernsey and probably arrived with his family in Adelaide, South Australia in 1858 aboard the *Bee*. Initially working as a hairdresser, he then trained in photography in Townsend Duryea's studio. In 1865 he travelled to the Gippsland district of Victoria photographing the aborigines and the landscape. In 1866 he opened a studio at 97 Hindley St, Adelaide producing carte-de-visite portraiture. In 1869 he moved to the Victorian goldfields, first working in Talbot then he opened a studio in View Place, Bendigo around 1872. In 1876 Caire took over Thomas Chuck's studio in the Royal Arcade, Melbourne, in 1878 he managed the (Anglo) Australasian Photo Co. at 57 Bourke St., East, Melbourne then he took over A. J. Davis' Bristol Portrait Rooms at 139 Bourke St. By 1880 he returned to his former location and opened the Royal Arcade Portrait Rooms producing carte-de-visite and cabinet photo portraiture. From 1884 he worked from his home in South Yarra. He made frequent tours of the countryside taking landscape photographs that were sold mounted on card or in albums. These had been his stock in trade since his arrival in Victoria and he was a great champion of the bush, even publishing a book with photographer J. W. Lindt "*Companion Guide to Healesville etc.*" in 1904.

Marcel Safier

CALDESI, LEONIDA (1823–1891) & MONTECCHI

London-domiciled Italian photographers

Leonida Caldesi was born in Florence, Italy in 1823 and arrived in England as a political refugee around 1850, though whether he was a photographer at this time is not clear. His brother Vincenzo (1817–1870) served as a major on the staff of the Italian patriot and revolutionary Giuseppe Garibaldi (1807–1882).

Comparatively little is known about Caldesi's career though he was one of the leading London photographers during the 1850s and was acknowledged by contemporaries as one of the foremost photographers of fine art from the 1850s to the 1870s. He had a number of short-term professional partners including Mattia Montecchi (1858–59), Blandford (1861–62) and Lombardi, though throughout his career he maintained a business relationship with the print publisher and art dealer Paul and Dominic Colnaghi. Caldesi had important dealings with the Royal Family as well as three major public art collections in London; The National Gallery, the British Museum and the South Kensington Museum. He also carried out society portraiture and worked for learned societies and private collectors.

In August 1854, probably as part of a project lead by Paul and Dominic Colnaghi, Caldesi had requested permission to photograph the Raphael Cartoons at Hampton Court though he did not carry out his campaign until 1858 when he photographed in tandem with the South Kensington Museum's photographer Charles Thurston Thompson [qv].

1857 was probably the most important year in Caldesi's photographic career. In May Caldesi and his

professional partner Mattia Montecchi, a compatriot who travelled to England with him, were summoned to Osborne on the Isle of Wight to take a series of photographs of the Royal children. His growing reputation was sufficient for him to be established in April on the premises of P&D Colnaghi by John Scott, one of the firms' partners, and by June 1857 this establishment was noted in the columns of the *Art-Journal*. Colnaghi was to remain the primary publisher of Caldesi's reproductions of works of art.

Although Caldesi specialised in the photographic reproduction of works of art, his core business was centred on society portraiture and he exhibited several of these at that year's Art Treasures exhibition in Manchester. Caldesi and Montecchi also were engaged to photograph many of the paintings exhibited at this seminal exhibition. Alongside Robert Howlett [qv], they produced the majority of the 200 photographs for the two-volume 'Ancient' and 'Modern' series of *Photographs of the Gems of the Art Treasures Exhibition, Manchester*. Caldesi found difficulty in photographing some of the paintings in Manchester and successfully negotiated with the Royal Collection for some of its works to be subsequently moved outdoors to be photographed.

In the summer of 1857 Caldesi and Montecchi photographed a smaller exhibition of portraits of Mary, Queen of Scots held at the Archaeological Institute, London. Theseat were published in 1858.

In 1859 *The Gallery of the Most Noble The Marquess of Hertford, K.G.,* a selection of Caldesi's photographs from the Manchester exhibition, was published. At that year's exhibition of the Société française de Photographie Caldesi and Montecchi exhibited twenty-one photographs of paintings displayed at the 1857 Manchester Art Treasures.

Caldesi advertised a studio at Porchester Terrace in London's Bayswater and he began carrying out photographic work for Prince Albert's Raphael Collection project. Perhaps as a result of this commission, Caldesi recorded the paintings in Buckingham Palace and was given permission to remove them to his studio. These photographs were published by P&D Colnaghi as the *Royal Collection of Pictures at Buckingham Palace*, and comprised forty small Albumen prints mounted on cards with printed captions that credit Caldesi, Blandford & Co. as the photographers, Montecchi having disappeared from the scene. This publication may bear the hand of the Prince Consort. Caldesi received further royal patronage that year when he was commissioned by Grand Duchess Marie of Russia to photograph the Elgin Marbles in the British Museum and he exhibited some of these views the following year at the Photographic Society's exhibition in London.

Caldesi advertised in the influential *Athenæum* in the early 1860s stating that he personally took carte de visite portraits at 13 Pall Mall East, the Colnaghi premises, while 'portraits, Carriages, Horses, &c.' were taken at the branch studio at 6 Victoria Grove, Kensington. He photographed a number of prominent people including Sir Charles Eastlake, director of the National Gallery. In 1864 Caldesi published carte de viste portraits Giuseppe Garibaldi and his fellow patriot Giuseppe Mazzini (1805–1872) during their visits to London.

During the 1860s Caldesi also produced cartes de visites of paintings though it appears that he did not use the stereoscopic or Cabinet formats to any significant degree.

In 1860 Caldesi carried out a photographic campaign in the National Gallery in London, exhibiting some these photographs of paintings at the 1861 exhibition of the Société française de Photographie. Between 1868 and 1873 *The Pictures by the Old Masters in The National Gallery*, a series of photographs of 360 paintings, was published by Virtue & Company. At this time Caldesi photographed a number of paintings in the Gallery on behalf of the director Sir William Boxall (1800–1879).

During the 1860s Caldesi was to carry out photographic campaigns to record important private art collections such as the Farnley Hall collection of drawings by J.M.W. Turner These photographs, published by Colnaghi in 1864, seem to have had little impact and were not reviewed by the contemporary press. Another Colnaghi publication of 1864 was the *Photographic Historical Portrait Gallery,* which required Caldesi to photograph just under 200 Albumen prints of Tudor portrait miniatures.

An account of the latter years of Caldesi's life has yet to be assembled. *Photographs by Cave. Leonida Caldesi, of Ancient Marbles, Bronzes, Terracottas, & C, & C. in the British Museum* was jointly published with Colnaghi's between 1873–1874 but the photographs may have been taken some years before. Caldesi appears to have returned to Bologna in around 1870 and died there in 1891.

CALOTYPE AND TALBOTYPE

On February 8, 1841, William Henry Fox Talbot (1800–1877) patented a paper negative process he christened the calotype. The process revolutionized photography by introducing two substantive improvements: it greatly reduced exposure length, in some cases by a factor of more then one hundred, and secondly, it yielded a chemically robust negative capable of enduring repeated contact printing for positive copies.

The evolution of photography until this moment had been significant but rudimentary. Thomas Wedgwood (1771–1805) in 1802 was the first to conceptualize and create images with photosensitive silver salts. But no one, including Wedgwood, had cracked the code for fixation: captured images inevitably faded from the presence of chemically reactive compounds in the paper. By 1839, two novel photographic systems on paper demonstrated significant gains in photochemical stability. The first was Talbot's photogenic drawing, the second by Hippolyte Bayard (1801–1887), was the lesser-known direct paper positive. But both required lengthy exposures, yielded delicately delineated images and were subject to fading despite their improved durability. The daguerreotype was a third process known at this time; it produced a clear and bright silver amalgam image on a silver plate and its mirror-like detail captured the imagination of everyone who saw one. Like the direct paper positive, it produced a unique object.

The fledgling photogenic drawing process was hailed by many but was also heavily criticized, especially when compared to the extraordinary images rendered by the daguerreotype. Talbot had also not been fully satisfied with the photogenic drawing and he continued his research. On September 20, 1840, while searching for ways to increase its sensitively, he made a pivotal discovery.

> I had been trying pieces of sensitive paper, prepared in different ways, in the camera obscura, allowing them to remain there only for a very short time, with a view of finding out which was the most sensitive. One of these papers was taken out and examined by candlelight. There was little or nothing to be seen upon it, and I left it lying on a table in a dark room. Returning some time after I took up the paper, and was very much surprised to see upon it a distinct picture. I was certain that there was nothing of the kind when I had looked at it before, and, therefore (magic apart), the only conclusion that could be drawn was that the picture had unexpectedly developed itself by a spontaneous action. (*Literary Gazette*)

Talbot immediately retraced his steps and realized that papers given only a brief exposure to light could be further developed with gallic acid. Sir John Herschel and the Reverend John B. Reade were also aware of the ability of gallic acid to act as developing agent (see Schaaf 1992 and Wood, 1980 for a thorough description of these historic events). Until this time, the presence of the latent image was not known and the sun acted as the developing agent. Images were created by placing a flat, thin object (such as a piece of lace or botanical specimen) in close contact with a sensitized sheet of paper and exposing directly to sunlight. A photochemical reaction occurs in the sensitized sheet and the portions unprotected by the specimen turn rich, purple and red toned hues. The longer the exposure, the darker the image, but achieving this richness could take an hour or more. This is called the printing-out process, and is the basis of photogenic drawings, salted paper prints, and many other photographic processes. These processes, were, however, used primarily to create positive images, and at the time were called "transfers" or "copies."

The word "calotype" originates from the Greek *kalos* and *typus* meaning "beautiful image." In the 20th century, it came to be used as a general term for positive prints from paper negatives, but it is recommended that the meaning remain faithful to Talbot's original definition, that of a paper negative. The calotype was never used to directly make positive prints, largely because the image tonality did not yield the beautiful colors offered by the printing-out process. Shortly after its creation, another term for calotype, "Talbotype," was promoted by many of the inventor's supporters. It appears in the literature, patents and Talbot's commercial printing and publishing establishments in Reading and London. Because many photographers modified Talbot's formula to suit their individual needs, the term calotype specifically refers only to Talbot's patent process. The many other paper processes, whether developments from Talbot's process, or from (sometimes serendipitous) discoveries made while trying to improve it, are not calotypes. The distinctions between 'calotype,' 'plain paper,' 'waxed paper,' et cetera were clearly understood in Victorian time.

The photographic image is created through the light sensitivity of silver halides, the chemical amplification of the latent image and the removal of unexposed silver halides from the paper with a fixing agent. The final image silver is attached to the paper fibers, literally imbedded within their matrix. The five essential components of the paper negative process are the paper substrate, sensitizing chemistry, developer, fixer and post processing alterations. Each of these components is applied and combined by hand and thus subject to any number of subtle variations that alter its physical character. The final result is a sheet of high quality paper with a neutral gray image in reversed values: highlights in the original subject appear as dark image areas, while the shadows of the subject appear in increasingly lighter tones on the paper, the deepest shadows translate as pure paper. For example, if the image captured was a bright outdoor scene, the negative will appear very dark over-

all. Because the paper support is partially opaque, the negatives do not need to be viewed through transmitted light to see an image.

The nineteenth century photographer considered the paper substrate to be the most important component of the calotype. It's physical properties and characteristics translated directly into the negative's final appearance, and thus into any prints made from it. Dimensions varied from 2 × 2" to greater than 15 ×18", the size being directly proportional to the capacity of the camera. From exquisitely thin to stout and thick, the photographers explored a wide range of papers. Wove papers were preferred to laid and chain papers, and even water marks were trimmed away, since they would be visible in the image and print. Thin, uniform papers yielded a crisper image, while a thick, fibrous paper a softer effect. Greater or lesser absorption properties in a paper created denser or more ethereal tones. Sizing affected the outcome as well, from fine gelatin sized English papers which yielded warmer tones, to the cooler tones of the starch sized French and German papers. Finally, the purity of these papers was paramount. Uneven distribution of the size in the pulp could result in a mottled image. Any fillers or impurities such as bits of metal or other inorganic contaminants could create uneven results, even spots or stains.

Locating a reliable source for paper of suitable quality proved difficult and troublesome before mid century. Industrialization of mechanical printing and paper making in the 1820s claimed the lion's share of available cotton and linen rags, making handmade papers less available and more expensive. The new photographers required the greater quantities that mass production provided, but of a consistently superior quality not readily available from the average paper mill. Between 1843 and 1853 the three most frequently recommended papers for the calotype were Whatman, Turner and Canson. After 1852, qualified paper makers were persuaded to create a "niche market" for photographic papers. An important milestone came from the Chafford Mills in Kent that produced the paper watermarked "RTurner Patent Talbotytpe." The paper was highly regarded for it's even texture, consistent production quality and longevity and used by many practitioners such as Benjamin Bracknell Turner (1815-1894). From 1853 and continuing well into the 1860s, increasing paper selections were available by Turner, Whatman, Canson, Sanford, Papier Saxe, Hollingsworth, Papier Rive and Towgoods. There was also variety in preparation, from plain to gelatinized to iodized, in an effort to simplify the steps and encourage purchases. Given the demand for such high quality stock, surviving negatives are often in excellent condition. Apart from mechanical wear, such as tears, creases and skinning, the paper remains supple and if properly processed, will retain clear, bright highlights. Usually the paper is a natural cream color, although negatives exist on papers tinted with bluing agents.

Sensitization takes place in two steps. First the paper is "iodized" by applying a halide salt solution usually potassium iodide and a smaller proportion of silver nitrate. In the second step, just before use, the iodized paper is coated with gallic acid and silver nitrate. If the solutions are lightly brushed onto the paper, the resulting silver image layer may be thin to moderate. Alternatively, if the paper is immersed, floated or repeatedly coated, it will absorb a maximum amount of solution potentially resulting in a dense image, printing through to the verso from this saturation.

In-camera exposures could range from 30 seconds to six minutes or longer, depending on conditions. During exposure, the latent image is created: atom-size irregularities or flaws inherent to silver halide crystals will condense after irradiation from light. Even a brief exposure is enough for the condensed irregularities to become sensitivity specks, which in turn become the points of attack for chemical development. Alternatively, if the sensitized paper is continually exposed to light, the latent image will visibly print out and can eventually completely blacken the paper.

The calotype developer was gallic acid and silver nitrate. A component found in nutgall, mangoes and other vegetable matter, gallic acid has a strong chemical affinity to the halides. The image development in paper negatives is different from the image forming in salted paper prints and albumen prints which are printing-out processes. It is called physical development, and in it, the developing agent (gallic acid) donates electrons to the silver ions in solution (from the silver nitrate) so that metallic silver is deposited at the site of the latent image. This coating or plating of the latent image amplifies until the image reaches visible size. Its spherical morphology and size dictates the particle's reflective properties and chemical robustness, and a well-processed image will appear neutral gray. The temperature and purity of the developing solution and washing baths were identified as important variables because the rate of chemical reaction increases when temperature rises and impurities could react with the chemistry. Technical difficulties such as over- and underexposure were compensated for with under-and over development, much as they are now.

The image was stabilized by removing unexposed halides by washing with either potassium bromide or sodium thiosulphate, then known as "hyposulfite of soda." Talbot initially preferred potassium bromide. John Herschel discovered the ability of the thiosulphates to dissolve the insoluble salts of silver chloride in 1819 and was the first to use the compound in photography. Eventually sodium thiosulphate became the standard chemical fixer, although improper use resulted in acute staining and fading and the loss of many early photo-

graphs. As sited by Ware (1994), there should be distinct yellow high values indicative of the presence of silver iodide after potassium bromide fixation. This striking characteristic is present in the negatives held in the *National Portrait Gallery of Scotland* by the Scottish team, Robert Adamson (1821–1848) and David Octavius Hill (1802–1870) who produced an outstanding body of work.

With impressive raw talent and skill in the arts and sciences, the first photographers brought a wealth of materials, technical expertise and finesse to the new art form. Nowhere is this more evident than in the post-processing treatment and preparation for printing. Negatives could be altered for printing in a number of ways: retouching, masking, trimming, inscribing, use of tabs for handling and wafers for affixing sheets for printing, coating, re-fixing or chemical intensification.

One of the most dramatic modifications to the paper negative was saturating the paper with wax, resin or oil, rendering the substrate more translucent. When viewed under normal illumination, the paper can appear waxy, shiny with yellow or orange tones overall. Creases appear as opaque lines and the paper itself may feel heavier. When the same negative is viewed through transmitted light, however, the highlights blossom, causing details to appear crisp and clear. Beeswax was a familiar and well-known material to 19th-century artists and was the primary material for waxing paper negatives. Numerous methods existed for preparing waxed tracing papers such as sprinkling grated wax onto paper and warming with an iron or immersing the paper in a shallow tub of molten wax. Excess wax could be removed by placing the paper between blotters and warming with an iron. Experiments using oils, gums and resins were also reported in the photographic literature, although the rare examples in extant collections of negatives suggest their use was not widespread.

The narrow range of latitude and strong contrasts of paper negatives could be reduced or enhanced by waxing which enhanced the translucency and shortened printing time by applying media such as graphite powder or pigmented washes, by ironing the paper or by selective coating portions of the image with additional transparentizing agents. Similarly, flaws were retouched and image details could be outlined with these same materials. Many photographers inscribed their negatives with information, ranging from dates or numbers, to extensive descriptive text. Perhaps the ultimate modification was post processing chemical treatment by refixing or image intensification and is an example of how close dark room procedures of the 19th century are to those of silver halide photography in the 21st century.

Each formulation described above was subject to adaptation by devotees, and often the variant was identified by name as a separate method, such as "plain paper process" or "wet paper process." In 1856, Sparling lists six calotype formulas by photographer's name. Typically, changes were made by adjusting or adding chemical constituents, organic components (including gelatin, albumin, collodion, and sugar), by altering the temperatures of processing baths, even by exposing the paper negative while damp. After the introduction of the waxed paper negative process in 1851 by Gustave LeGray (1820–1882), a French encyclopedia (Blanchère, 1865) lists no less then 44 paper negatives processes, most of which are close variants of either the calotype or the waxed paper negative process.

Travelling photographers from the West were quick to exploit the advantages of the paper negative and many hundreds survive documenting places as far away as the Holy Land and the Orient. Subjects in all formats included regional architecture, local people and costumes, scenes, views, and documentation of scientific specimens. Shorter exposures and assembly of familiar materials appealed to the early travelling photographers. The daguerreotype could not compare to the paper negative's lightweight ease and flexibility, especially in extreme climates. Photographers of the 1850s modified their processes when travelling in hot, arid zones where unexposed, sensitized negative papers would easily spoil. A notable example is the aforementioned "wet paper process" whereby the sheets are iodized the night before, fully sensitized the next morning and placed into the negative frame while damp. Exposure and processing must occur within 24 hours. Each of the halides (chloride, bromide and iodide) have different reactivity rates, and the sensitizing solution was adjusted by changing their ratio. After Irishman John Shaw Smith (1811–1873) traveled in the Middle East between 1850 and 1852, he read his formulations to the Dublin Photographic Society,

> When the temperatures rose above 85, these papers would not keep during the day, they became spotted. This difficulty I overcame as follows: -an iodizing bath was prepared similar to the last mentioned, only leaving out the solid iodine and substituting as follows:- four drops of 'bromure d'iode'' were added to the bath, … the effect of this addition of the 'bromure,' while it nearly doubled the required time of exposure in the camera, was, to cause the papers prepared to keep well during the whole day, under the highest temperatures, the papers being excited in the morning and developed the same evening." (*Journal of the Photographic Society*, April 21, 1857)

The calotype united photography and the printed word. Daguerreotypes could never be realistically included in multiple book editions, nor could the fragile photogenic drawing process withstand the rigors of printing. But many dozens of positive prints could be produced from a single calotype. The first photographically illustrated book was the Pencil of Nature, with a

total of twenty-four tipped-in salted paper prints from calotypes. The work was published by Talbot and released as a limited edition in six installments between 1844 and 1846.

The paper negative process was passionately practiced by a devoted group of practitioners from 1841–1860s, some of who brought the art to it's highest achievement. In addition, there were at least three hundred amateurs who embraced the calotype as their process of choice in the 1850s. In addition to those mentioned above, interesting and important early work exists by Talbot's relative, Welshman Rev. Calvert Richard Jones (1804–1877). The French excelled in the process, among the leaders Hippolyte Bayard, Maxime DuCamp (1822–1894), Eduard-Denis Baldus (1815–1882), and Louis-Désiré Blanquart Evrard (1802–1872). The Philadelphia daguerreotype studio of Fredrick (1809–1897) and William Langenheim (1807–1874) are virtually the only known examples of Americans practicing the art.

The calotype reached its apex in the late 1850s, side by side with its sister process, Le Gray's waxed paper negative. At that time there were three equal pillars of photography: the daguerreotype, paper negative photography, and glass plate photography (collodion and albumen). But however fine and delicate, the details of paper negatives were never as sharp as the glass plate negative, to which it was constantly compared. Increasingly, the fibrous softening of the optical edge was seen as a drawback. In 1863 papers for the calotype were still readily available by photographic suppliers, but the direction of photography was moving towards the glass plate negative and its complement, the albumen silver print. Despite brief revivals in the 1900s and 1920s, by 1870 the golden era of the calotype had come to an end.

CAMERA ACCESSORIES

The original daguerreotype apparatus was manufactured for Louis Daguerre by Alphonse Giroux of Paris in 1839 was offered as a complete outfit—everything the aspiring photographer needed except plates and chemicals was included. The outfit weighed over 45 kilos, and the camera could be used successfully without any additional accessories.

As the art and science of photography matured, however, a range of additions and accessories were introduced to improve the reliability and repeatability of the procedures.

Tripods and Camera Supports

The earliest cameras were operated on tables or any other usable support, but camera stands or tripods were included in many complete outfits. Initially, they were of fixed height, chosen to give the operator a comfortable working position.

Adjustable camera stands were introduced before 1850, and by 1853 advertisements offered both fixed and adjustable height tripods, and camera stands embodying either rack or screw height adjustments. The adjustable tripod was inspired by the quest for lighter, collapsible, and easily transportable equipment as photography was taken out into the landscape. Folding tripods and collapsible darktents were included in many designs for a photographer's backpack.

Even the earliest tripod designs featured a hinged camera platform, allowing the elevation of the camera to be adjusted upwards or downwards as required.

Plate, Paper and Film Holders

The earliest removable camera accessory was the plate holder or dark-slide, frequently referred to in early literature as the "plate shield." In Daguerre's original specification, the metal plate was affixed to a wooden board—the plate holder or frame—with four small metal bands, an operation which required a hammer and small nails, before being inserted into the plate shield for transfer to the camera. In later modifications of this design, the plate was held firmly in the holder by four small corner plates, considerably reducing both the risk of damage to the plate surface, and the loading and unloading time.

William Henry Fox Talbot's specification in his 1841 calotype patent—No. 8842 Obtaining Photographic Pictures—required the sensitized paper to be "defended from the light" while being placed in the camera, and early calotype cameras were supplied with paper holders either with a removable "screen" or a system of light-tight doors. As the calotype could be used while still damp, the holder had a flat surface, often glass, against which the (moist) sensitized paper could be held easily.

In some designs of double-sided holders two sheets of paper, separated only by a sheet of blotting paper, were held flat between two sheets of glass, and exposed through the glass. In later examples the glass was dispensed with, and the paper was held flat on a board by a series of calico strips which also determined the boundaries of the image area.

Designs for holders for wet collodion glass plates often included a ceramic trough to catch any residual chemicals which might drain off the still moist plate surface.

By the early 1850s, plate shields with multiple inserts facilitated the use of a variety of plate sizes in a large camera.

As the wet collodion plate had to be coated and exposed immediately before use, holders for that process needed only be single-sided. Double plate holders did not enter into common usage until the advent of the commercially produced dry plate in the 1870s.

The popularity of the waxed paper process in the early 1850s, permitting negative papers to be sensitized days or even weeks before exposure, resulted in the first example of a roll-holder, enabling the photographer to make several exposures without reloading the camera. Designed in England by Arthur Melhuish and Joseph Spencer (Provisional Patent No. 1139 1854), the holder was loaded with several sheets of waxed paper which had been taped together to make a continuous roll. In 1855, Humbert de Molard designed a roll-holder which was loaded by taping several sheets of plain or waxed paper to a roll of silk. Camille Silvy's 1867 roll-holder introduced an early version of a light-tight cassette, and in 1870 also included a leader of yellow silk to protect the unexposed sensitised negative paper from accidental exposure to light.

The first roll-holder to accommodate film was introduced by Leon Warnerke in 1875, for collodion stripping film. The introduction in 1884 of the Eastman Roll Holder, as an accessory for dry plate cameras, marked the first such device to enjoy commercial success, its popularity being enhanced by the fact that it could be customized to fit many cameras.

Holders capable of exposing several separate sheets of paper without reloading were introduced in 1853, an example being the design of G. Montefiore Levi, which could carry up to fifteen waxed paper negatives.

In the dry plate era, multiple plate holders were introduced enabling several exposures to be made without reloading.

The changing box performed a similar function, but away from the camera. Thomas Ottewill's 1870 design which held eighteen plates was one of the first, although George Hare's 1875 design for twelve plates, available in a range of formats, was the more popular.

Shutters

With the long exposures required with early materials, shutters were initially unnecessary. Daguerre's original camera was fitted with a swivel plate to uncover and cover the lens, whereas a later design by Lerebours utilised a black cloth for the same purpose. Calotype and early wet plate cameras used a simple lens cap. As the sensitivity of materials increased, the accessory shutter, which could be fitted to an existing camera or lens was introduced.

The first roller-blind shutter capable of giving repeatable instantaneous exposures was demonstrated by W. H. Cooke in 1853. It fitted over the front of the lens and replaced the lens cap. Later designs were fitted between the lens and the lens panel, but retained the basic principles of Cooke's design. The Kershaw Instantaneous shutter of 1885 and the Thornton-Pickard Time & Instant shutter of 1888 were both popular patented designs. Pneumatic shutters extended the range of shutter speeds available from the early 1890s, but by the end of the century, the majority of lens designs incorporated an internal shutter.

Interchangeable Lenses

Few sliding box cameras were designed to accommodate more than one focal length of lens, but an early example to offer such a facility was the full-plate daguerreotype camera introduced by Pierre-Ambroise Richebourg about 1842. With the extended focussing range of later bellows cameras, the interchangeable lens panel became a much more available option. An early example of a bellows camera offering this feature was introduced by

Andrew Ross in 1850. John Henry Dallmeyer's 1862 camera could be operated with a single portrait lens and panel, or with binocular lenses for stereoscopic photography. From the 1860s, the interchangeable lens panel was a universal feature of bellows camera design.

CAMERA DESIGN: 1 (1830–1840)

The camera obscura was used by the earlier experimenters as the first photographic camera to produce images using light-sensitive chemicals on a paper or metal support. Thomas Wedgwood and Humphrey Davy circa 1801 used one to expose sensitised paper with limited success. Davy reported in the *Journals of the Royal Institution* in 22 June 1802 that 'the images formed by means of a camera obscura have been found too faint to produce, in any moderate time, an effect.' Joseph Nicéphore Niépce in 1816 also using a camera obscura was able to produce images but had no means to fix them. Daguerre, continuing Niépce's work, carried on using the camera obscura in the development of his own process.

William Henry Fox Talbot in late 1834 or early 1835 also made use of a camera obscura to expose his sensitised paper but found that the exposure was too long to make a strong impression. In the summer of 1835 Talbot had more success using new chemistry and a camera obscura made from a small box and produced the well-known Lattice Window image of August 1835. Talbot also made use of a solar microscope to make images.

Niépce and Talbot also made use of the first purpose built photographic cameras. Niépce, for his experiments using bitumen-coated pewter plates, constructed cameras in the form of a plain box and with two boxes sliding within each other—a design that was resurrected and became popular in the 1850s. These designs offered rigidity, a means of securing the plate, a fixing for the lens and a size that was more appropriate to the optics then available. These two forms of camera were based on typical camera obscura designs.

Talbot also made himself or had constructed small boxes for the purposes of making photogenic drawings. Reputedly these were made by the village carpenter in Lacock but Arnold argues that their crude construction would suggest that they were made by Talbot himself. These crude wood boxes were briefly described by Constance Talbot as 'mousetraps,' a name that has endured. The cameras were no more than 2 or 3 inch cubes with a simple brass bound lens at one end and a back to which sensitised paper was pinned. Later versions of the cameras were better constructed with refinements such as a viewing hole to examine the progress of exposure and detachable plate holders.

The announcement of Daguerre's process on 7 January 1839 and Talbot's photogenic drawing process on 25 January 1839 provided the catalyst for commercial manufacture of photographic cameras. Daguerre's relative by marriage Alphonse Giroux of Paris launched a sliding box daguerreotype camera designed by Daguerre. The camera was to make daguerreotype plates up to 16.5 × 21.5cm., which became known a whole-plate, and had a lens from Chevalier at a cost of 400 francs. It was available from 21 August 1839 the day of the public disclosure of Daguerre's process. Giroux had signed a contract with Daguerre for the sole right to make daguerreotype apparatus under Daguerre's direction. The camera bore a seal on one side featuring Daguerre's signature and was the first commercially manufactured camera.

Other manufacturers soon produced their own designs of camera. Charles Chevalier of Paris produced a collapsible box form camera that offered a degree of portability limited only by the accompanying processing apparatus that was required to be carried. Alexis Gaudin designed a box form camera manufactured by N. P. Lerebours in 1841 for 7 × 8 cm. daguerreotype plates. The camera was contained with all its associated chemicals and processing equipment in a box. In America by 1842 John Plumbe had produced a sliding box camera copied from Daguerre's original design for 2¼ × 3¼ inch plates. The camera may have been constructed for Plumbe by a Boston scientific instrument maker. In the later 1840s what became known as the American-pattern of boxform camera with chamfered front edges became popular although there is some evidence that this design had been copied from an 1840 design by Chevalier.

In Britain from February 1839 Talbot began purchasing cameras, mainly from the London lens and instrument maker Andrew Ross. In 1839 this included three camera obscuras, a solar microscope and one experimental camera with four lenses. Ross supplied seven cameras in 1840–41 and another instrument maker Watkins and Hill of London supplied a camera and ancilliary equipment. Talbot also purchased cameras from France.

In Germany the firm of Voigtländer made an all-brass camera incorporating a four-element lens designed by Max Petzval in 1841. The camera was shaped like a cannon and was set on a brass stand. Plates were held in a separate metal holder and gave images of 3.7 inches diameter. Carl von Steinheil also designed a tubular camera for paper or daguerreotype plates.

The first patent for a photographic camera was Alexander S. Wolcott's camera for the daguerreotype process which was patented in America on 8 May 1840 and in Britain by Richard Beard under British patent number 8546 of 13 June 1840. The boxform camera body made use of a concave mirror set at the back of the camera to reflect the image on to the plate. Antoine Claudet on 18 December 1841 patented the first camera with interchangeable lenses for plates of different sizes and processing taking place within the camera body.

The basic design of camera up to 1850 was the rigid or collapsible box form camera or the sliding box camera with two or three sections sliding within each other. Within this basic design there were continual improvements. Willat's *Manual* of 1845 shows a camera with a handle and threaded rod running through the baseboard to move the rear box for focusing. The camera also had different positions for the darkslide and focusing screen within the body of the camera, to allow for lenses for different focal length.

Most cameras of this period seemed to have been designed for daguerreotype use, although by the later 1840s manufacturers were usually describing them as being suitable for paper, glass or daguerreotype processes. In 1845 George Knight and Sons advertised Cundall's Calotype camera that had first been described in May 1844 in the *Philosophical Magazine*. The camera was of the sliding box type but without a baseboard but was important as it had a focusing scale, internal baffles to reduce light reflections inside the camera and a lens with lens hood.

Cameras were made in a variety of plate sizes with five standard French sizes and four English sizes which had reduced to seven sizes by the end of the 1840s. Most cameras were made by established optical or philosophical instrument makers with the British maker's favouring mahogany or rosewood and lacquered-brass and continental Europe maker's favouring walnut and unlacquered brass construction.

CAMERA DESIGN: 2 (1850)

Although Smith has argued that the patents of Daguerre in Britain and Talbot held back the development of new and innovative designs of cameras during the 1840s there were equally few developments elsewhere in Europe or America. The 1850s saw the development of specialist photographic manufacturers, the development of more sensitive and easier processes and a rise in amateur and professional photography which probably did more to stimulate new designs of camera. The predominant boxform designs of the 1840s lasted through the 1850s and beyond, but they were joined by new designs, smaller and more specialist cameras.

Folding cameras were not new but new designs appeared. Bland and Long of London produced a design for paper processes and a similar design was registered by Ottewill on 25 May 1853. Hinges in the centre of the box allowed the camera to collapse in on itself once the lens panel and focusing screen were removed. Other makers copied or adapted the design. At the 1851 Great Exhibition Richard Willats showed a prototype of a collapsible camera that had a black cloth body. In America W. and W. H. Lewis of New York introduced cameras using square-cornered bellows to a design patented on 11 November 1851. Although their design was intended to give extra extension and made the camera suitable for copying purposes the idea of using bellows to make a compact camera gained favour.

Major Halkett showed a camera to the Photographic Society in April 1853 that used unpleated rubber to connect the lens standard to the back standard. Other designs of cameras using cloth, or bag bellows, continued to be shown. British provisional patent number 1295 of 31 May 1856 granted to Francis Fowke described a folding bellows camera with bellows between the front and back and this design in a modified form was made by P. Meagher and quickly established itself as a standard design for later improvement. The most influential collapsible bellows camera was designed by C. G. H. Kinnear of Edinburgh in 1857. The camera made use of tapered bellows which gave greater compactness. The designed was taken up by many camera makers. These two bellows designs were refined and remained in production into the twentieth century.

During the decade the rising and lateral moving front panel holding the lens was also added to boxform cameras. In most cases the movement was allowed by a simply cut-out in the lens panel which allowed a screw to be secured to the camera body. The effect of the small movement permitted was limited. Other cameras permitted in the entire lens panel to move in one direction only with only the protruding back of the lens limited movement. More mechanical and precise controls using a rack and pinion or adjustable supports did not enter camera design until later in the century.

The retention of sensitised materials in the camera were wholly held in removable holders which slotted into the back of the camera. Wet collodion glass plates were usually retained with small wire clips at their corners and one plate fitted each holder. As dry plates became more common holders containing two plates separated by a metal sheath allowed for more compact outfits to be made.

Cameras which allowed the photographer to process his plates inside the body of the camera also saw some popularity throughout the 1850s. Their designers saw internal processing as a way of reducing the size and weight of the apparatus the travelling photographer needed to carry. Henry Talbot patented the first design in 1851 and Archer's portable camera of 1853 was widely discussed and over twenty British patents were granted for such cameras over the next thirty years.

The 1850s saw the rise of interest in stereo-photography and camera were made to reflect this. There were two methods of producing stereo pairs of photographs. The first was to make two separate images with one camera with a variety of methods employed to ensure the correct spacing between the two pictures. The second was to construct a camera with two lenses that took the pictures at the same time.

The first significant design was shown by Latimer Clark to the Photographic Society on 5 May 1853. A single camera was mounted on a jointed parallelogram that moved the camera a set distance between exposures. A pulley system moved the plate holder so that the second exposure could be made quickly. Other designs moved the camera across a bar which was fixed to a tripod and John Harrison Powell's design registered on 27 December 1858 and made by Horne and Thornthwaite moved the camera across a box and it's lid which also contained the camera and plate holders. A third method shown by John Spencer in 1854 moved the lens across the front of the camera and had an internal septum to divide the camera so the two photographs did not overlap. Two cameras placed side by side would also achieve the same effect and was described in British provisional patent number 1629 of 8 July 1853.

The first twin lens stereoscopic camera was demonstrated in October 1853 to the Liverpool Photographic

Society and the first binocular boxform camera was offered for sale by J B Dancer of Manchester. His design was patented in September 1856 and was a more advanced design of one made in 1853. The camera incorporated a number of innovations. The first folding bellows stereoscopic camera was George Hare's Portable Binocular camera of 1860. Other designs followed until interest in stereoscopy waned before a resurgence of interest in the 1890s.

Throughout the 1850s cameras continued to be made from wood. The first metal-body folding camera was described by A J Melhuish in two patents in 1859. A single and stereoscopic version were described and one example of the single lens version is now in the National Museum of Photography, Film and Television, UK. Melhuish was also responsible for a roll-holder for paper negatives which had been designed in 1854.

Various patents were published describing cameras that allowed processing to be undertaken internally and specialised cameras for, for example, panoramic photography were also made and different styles of photography became possible through the development of new processes. Cameras designed for enlarging or copying were announced by the late 1850s. Despite the many significant camera designs during the decade relatively few were patented with the more successful innovations being copied and refined by different manufacturers.

CAMERA DESIGN: 3 (1860s–1870)

The main theme for camera design during the 1860s and 1870s continued to be portability and the general improvement of existing designs of camera. During the later part of the period there was an increasing separation between professional studio and amateur cameras with latter generally being more innovative.

In 1861 F. R. Window described a new arrangement of the long-established sliding box camera. The smaller inner box was moved to the front of the camera and carried the lens and was focused by a double rack and pinion mechanism for moving the front box on a base-

Ponti, Carlo. Megalethoscope.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

board. The design was more compact, more rigid and easier to focus. Window's design remained popular and in revised forms were popular into the twentieth century. Most later hand and field cameras retained the double rack and pinion focusing at the front of the camera. The design was incorporated into professional studio cameras and smaller amateur cameras. By the mid-1860s front-focus bellows cameras were introduced to take advantage of the improved rigidity and advantages of moving the lens rather than the back standard.

The 1860s also saw the widespread introduction of tailboard cameras. Atkinson's Portable camera was described to the Photographic Society in 1857 but it was not until commercial manufacture by P. Meagher, George Hare, W. Watson and others for stereoscopic and single-lens use that the design gained widespread acceptance and by the 1870s it was very popular. The design had a moveable back focusing screen connected by bellows to the lensboard. For storage the back was moved by rack and pinion to the front and the hinged baseboard lifted up to protect the focusing screen and, if present, a side gate was swung across to secure everything.

George Hare manufactured W. J. Stillman's design as the New Universal camera. The design was provisionally patented on 14 November 1871 and gave greater flexibility to move the back and front standards around a fixed central point.

During the period a number of features became standardised and remained an integral part of camera design until the 1900s. With acceptance of the dry plate process from the early 1870s the book-form plate holder holder became standard holding two plates either side of a metal divider. By 1860 most cameras incorporated some form of rising front and, later, a laterally moving front especially on professional studio or more advanced cameras. At the same time a swing-back was incorpo-

rated on most studio cameras. On these the bottom of the back standard was bevelled to allow for the movement and pivoted around a centre screw. Some cameras were refined with a rack and pinion swing adjustment. Meagher produced a swing back that could be fixed in position by a slotted strut and screw.

The 1860s also saw the introduction of the repeating back on studio cameras to produce two or more images on a single plate. This was especially popular for the production of cartes-de-visite. Interchangable lens panels and cameras with removable septums allowed them to be used for stereo and normal photography. In-camera processing reached it's height with the introduction of the Dubroni camera in 1864 which had a ceramic interior to hold chemicals to process the plate internally. A range of models were made in different plate sizes and styles. Designs of stereo cameras continued although most adopted Window's design to hold two lenses with some of the best known being sold by J. H. Dallmeyer in the 1860s.

Travelling camera outfits also became popular with the camera, darkslides and chemicals usually being contained in one box or even within the camera.

Many of the designs that were introduced in the 1870s were still in production and use, especially by professional photographers and studios at the end of the century. It was developments with roll film and smaller hand cameras for amateur use that showed the greatest innovation and change over the next three decades.

CAMERA DESIGN 4 (1850–1900)

Studio cameras

The basic design of studio cameras did not change significantly after the early 1860s and the move from sliding box pattern cameras to front-focusing bellows cameras had taken place. Refinements to designs tended to reflect specific needs and the preferences of individual camera manufacturers to produce distinctive and marketable designs.

There is no precise definition of a studio camera. Field and tailboard cameras that were ostensibly designed for travelling with could quite easily be used in a studio. By end of the century companies such as Marion and Co. and George Houghton and Sons of London were listing cameras under the heading studio cameras that 'have been so designed, constructed, and finished, as to meet the demands of the most critical user.' The cameras were generally large with a minimum plate size of 6 inches square. They were constructed of mahogany with brass fittings, rackwork adjustment at the back and front and usually a double extension base. This allowed the camera to produce a variety of negatives by means of reducing and repeating backs, it could accept a variety of lenses and could be used for copy work as well as portraiture and it usually came on a wheeled studio stand. The stands would be adjustable vertically through a geared crank and would have adjustments for tilting. Cameras were generally advertised in standard plate sizes from 6½ to 24 inches square although larger models were occasionally advertised in the earlier period before enlarging became widespread.

The first commercially made cameras for the daguerreotype process such a Giroux and Wolcott cameras were rigid box form cameras and designed to be used in a studio close to processing facilities. The sliding box pattern of camera became more widespread and although models were made for travelling the design was also firmly used within the studio during the 1840s and 1850s. The cameras were generally whole-plate (8½ × 6½ inches) or larger and with sufficient extension to cope with full-length to head and shoulder portraits. They were generally mounted on a wheeled studio stand. The widespread introduction of bellows to studio cameras set their design for the remainder of the century.

Both the box form and bellows cameras performed the same task of keep light from between the lens and plate holder. Most of the innovations in studio camera design were concentrated around the lens and plate holding parts of the camera. Repeating backs were first introduced in the early 1850s for stereo photography and were designed to allow two images to be taken by a single lens camera. They were suggested by Claudet in 1851 although had probably been in use before this. With most an extended plate holder holding two separate daguerreotype plates or a single glass plate was pushed into position and was held in either position by a spring catch. The focusing screen was removed completely or pushed out of the way during the two exposures.

The craze for cartes-de-visite and cabinet cards from the early 1860s and non-standard format photographs through to the 1890s led to the development of backs and cameras to accommodate them. Repeating backs were designed to allow multiple exposures to be made on one plate which was contact printed to make the cartes or cabinets. Special cameras were designed with multiple lenses to allow identical images to be made with one exposure on a single plate. This technology also

Falk, Benjamin J. Wilfred Draycoff. Actor posing with a large format camera.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

allowed, through the use of special darkslides, which was essentially the selective uncovering or manipulation of some of the camera's multiple lenses via different poses, a different effect on the plate. F. R. Window's Diamond Cameo camera of 1864 allowed cameo sized photographs to be made on one plate by vertically and laterally moving the darkslide. The 1890s craze for stamp photographs lead to cameras with up to 15 lenses and repeating backs that could allow many images to be exposed on to one plate.

Multiple lens studio cameras were first introduced in 1855 in America when Albert R. Southworth was granted a patent for a four-lens camera, French and British manufacturers quickly produced their own designs with the most popular style producing four 2 × 3¼ inch negatives on a whole plate. Lancaster's Gem camera produced 12 1-inch square negatives on a quarter-plate. Fallowfield and other manufacturers produced cameras with four, nine or twelve lenses for meeting the demand for popular sizes of photograph. These cameras would either make one identical image through each lens on the sensitised plate, especially where six or more lenses were being used, or various methods were employed, notably the repeating back, so that different images could be exposed one or more lenses. The resultant plate was usually contact printed and the paper print with the multiple portraits cut up and mounted.

The distinction between amateur and professional or between studio or portable cameras was not clear and manufacturers such as W. Rouch would frequently advertise cameras as: 'New Folding Studio and Field camera. The most useful and portable instrument for both Amateur or Professional use, use aiming to maximise the market for their product.

The other important addition that the studio camera had was the reducing back which allowed the camera to make negatives smaller than the maximum plate size through smaller plate holders that fitted the camera and either a smaller focusing screen or, more usually, the full-size focusing screen marked with the smaller plate sizes. The use of full-size plate holders with reducing inserts for smaller plate sizes also allowed smaller negatives to be made where necessary. George Hare's Universal camera was advertised in 1874 as being 'adapted for the Single or Double Cartes-de-Visite, for Half or Whole-plate Portraits, for the new Cabinet Pictures, and can be used for Copying.'

The studio camera also encouraged the production of accessories for it. The studio stand was an essential part of the camera and ranged from basic fixed tripods with extra strengthening and a top for support the camera to elaborate tables with shelves and adjustments. All were mounted on wheels. The darkcloth was essential to aid focusing. The fashion for vignetting in the 1870s lead to special attachments to be added to the front of the camera and by the late nineteenth century shutters would be mounted inside the camera and operated by an air or mechanical release set into the camera.

CAMERA DESIGN: 5 PORTABLE HAND CAMERAS (1880–1900)

Whilst a small number of cameras designed to be hand-held had appeared as early as the 1850s, such cameras

were extremely unusual in the wet-collodion period when exposures of several seconds were the general rule. However, the introduction of more sensitive, commercially manufactured gelatine dry plates in the late 1870s made 'instantaneous' exposures fully practical for the first time. During the 1880s, cameras designed to be used whilst hand-held became popular. Hand cameras developed along three distinct lines—box-form or 'detective' cameras; folding or strut cameras; and hand and stand cameras.

In 1881, Thomas Bolas took out a British patent for a box-form plate camera. Because it could be used in the hand, inconspicuously, he coined the name 'detective camera' for his invention. The term came to be applied to almost all hand cameras that appeared up to the end of the century. The first detective camera to be widely sold was William Schmid's Patent Detective camera of 1883. A plain, oblong wooden box, this incorporated a shutter, focusing system and viewfinder, which were to become features of the hand camera. Most detective cameras were simple wooden boxes, sometimes covered in leather or even brown paper so as to resemble bags or parcels. Some, however, took concealment a stage further. During the 1880s large numbers of disguised cameras appeared, designed to resemble, for example, books or watches or to be hidden in ties, hats or walking sticks or under worn beneath a waistcoat.

During the 1880s a number of designs appeared for cameras that held a number of plates that could be exposed successively, thus doing away with the need to change plate holders after each exposure. Incorporating ingenious plate changing arrangements, these were known as magazine plate cameras and enjoyed their greatest popularity in the 1890s. Examples include, Rouch's 'Eureka' camera, Marion's 'Radial' camera and Fallowfield's 'Facile' camera—the favourite camera of Paul Martin. Magazine plate cameras tended to be bulky and the weight of the glass set a limit to the number of plates that could be conveniently carried. An alternative approach was to use sheets of celluloid film. One of the most popular cameras to use film packs was R & J Beck's 'Frena' camera, introduced in 1892. However, by the time the Frena appeared, hand cameras which used roll film were rapidly gaining popularity.

Roll-holders, which used bands of sensitised paper as an alternative to glass plates first appeared in the 1850s. The first roll-holder to enjoy any commercial success was designed by George Eastman and William Walker and went on sale in 1885. Eastman subsequently worked on incorporating his roll-holder into a simple detective camera. However, Eastman was pre-empted by two other Americans, Robert Gray and Henry Stammers, who patented their 'America' detective camera in May 1887. Whilst it was not a commercial success, this camera is significant as being the first hand camera to use roll film. The following year, Eastman introduced his detective camera which incorporated a roll holder and gave one hundred exposures on sensitised paper film. Eastman decided to create a new trade name for his camera—a name that would be novel, distinctive and easily pronounced in most languages. The name he came up with was 'Kodak.'

The Kodak camera was successful from the start and it was followed during the 1890s by a range of folding and box-form Kodak cameras of various formats. In 1900 the first Brownie camera was introduced—the camera that was to become synonymous with snapshot photography and was to transform the medium into a truly popular pastime. In 1889 Eastman introduced the first commercial transparent celluloid roll film in place of his earlier paper-based film and from 1895 onwards, film was supplied in 'cartridges' for daylight loading.

Whilst the Eastman Company soon came to dominate the market, the success of the Kodak prompted a number of other inventors and manufacturers to design hand roll film cameras. Examples include L'Escopette of 1888, the Luzo camera of 1889, and the Prizma Detective camera of 1890. However, none of these were to enjoy a fraction of the Kodak's success and popularity.

Following their initial novelty, box-form plate cameras—except for magazine plate cameras—became less popular during the 1890s. In their place appeared a variety of compact collapsing hand cameras in which the lens panel pulled out, attached to a bag or bellows, and was locked in position by struts. Strut cameras had the advantage of being lighter, more compact and easier to carry than box cameras. A number of popular designs appeared during the 1890s, including Shew's 'Xit' camera, Newman & Guardia's 'Nydia' camera and the Goerz-Anschutz folding camera of 1896 which was to be the basis of most press cameras right up to the 1930s. Folding roll film cameras also first appeared during the 1890s. Eastman's Folding Pocket Kodak camera, introduced in 1897, was the first of a range of popular folding cameras. The No 3 Folding Pocket Kodak camera of 1900, in which the camera front folded down to form a baseboard along which the lens panel was drawn out, set the standard pattern for the design of folding roll film cameras for the next fifty years.

Following the introduction of dry plates, the first folding hand cameras were simply traditional field cameras to which a shutter and viewfinder had been added. Smaller format field cameras could easily be hand-held. These evolved into cameras that were made specifically for hand use but also incorporated several features that were normally associated with stand cameras, such as rising-front and swing back movements. Since they could be used either in the hand or on a tripod, they were known as 'Hand and Stand' cameras. One of the most popular forms of hand and stand camera was introduced

by George Houghton & Son in 1899. A hand-held version of their innovatively designed Sanderson camera it remained on sale until 1939.

CAMERA DESIGN: 6 KODAK (1888–1900)

In 1888 George Eastman patented and introduced a small box-form camera which he named 'The Kodak.' This camera initiated a revolution in photography that was to quickly transform it into a truly democratic pastime within the range of everyone, regardless of income or technical knowledge. A hand-held 'detective' camera, the Kodak was fitted with an integral roll holder and took pictures on long rolls of sensitised paper. Extremely simple to use, it reduced taking a photograph to three simple actions: 1. Pull the string. 2. Turn the key. 3. Press the button. The camera itself did not embody any great technical advances; it was not even the first camera designed solely to take roll-film. The most revolutionary aspect wasn't in fact the camera, but Eastman's concept of separating the act of picture-*taking* from that of picture-*making*. The Kodak was sold already loaded with film for 100 exposures. After this had been exposed, the entire camera was returned to the factory for the film to be unloaded, developed and printed. The reloaded camera was then returned to its owner, together with a set of prints. The Kodak system was summed up by Eastman's famous advertising slogan—'You Press the Button, We do the Rest.' For the first time, anyone (as long as they could afford the 5 guineas which the Kodak cost) could become a photographer.

In 1889 Eastman introduced the first commercial transparent celluloid roll-film to replace the less satisfactory paper film. That same year, a larger version of the Kodak, the No. 2 Kodak camera, appeared, taking a 3 ½ inch circular negative. The next year, this was followed by the Nos. 3, 4 and 5 Kodak cameras, taking even larger negatives, up to 4 by 5 inches.

The first Kodak cameras had to be loaded with film in a darkroom. In 1891 Eastman introduced a new range of cameras which were designed to overcome this inconvenience. Externally, the aptly-named A B and C Daylight Kodak cameras looked very similar to the original Kodak cameras. However, the roll-film was contained in light-proof cardboard containers that protected the film when loading or unloading, the film being wound from one container to another through velvet-lined slots. Daylight Kodaks were not a commercial success. The following year, S. N. Turner of the Boston Camera Manufacturing Company came up with a much neater solution to the problem of daylight loading. His Bull's-Eye camera of 1892 used paper-backed 'cartridge' film wound on to a spool with flanged ends, which protected it from light. Numbers printed on the backing paper could be read through a little red window in the back of the camera. Realising the superiority of Turner's system, Eastman initially purchased a licence from Turner and in 1894 began production of a range of Bullet cameras which used cartridge film. In 1895 Eastman bought out the Boston Camera Company and began the manufacture of the very popular Pocket Kodak cameras which also used daylight loading cartridge film. The Pocket Kodak camera really was pocket-sized, being a small box measuring just 2 by 3 by 4 inches. It was the first Kodak camera to be manufactured using mass production techniques and 600 cameras a day were turned out by the Eastman factory in Rochester.

The Pocket Kodak camera was convenient to use but the negatives it produced were very small—just 1½ by 2 inches. In order to create a camera which was still compact enough to be easily carried but which took larger pictures, Frank Brownell, Eastman's camera designer, came up with an ingenious folding design. When closed, the Folding Pocket Kodak camera of 1897 was almost as small as the Pocket Kodak camera, but it opened up on spring-loaded struts for use and took negatives 2¼ by 3¼ inches. The Folding Pocket Kodak was the first of a range of folding cameras that were to be produced for many years and which were to prove enormously successful. Also in 1897, the first of a range of folding roll-film cameras aimed at the enthusiast appeared—the No. 4 Cartridge Kodak, taking 5 by 4 inch negatives. This was followed by the No. 5 Cartridge Kodak in 1898 (7 × 5 in) and, finally, the No. 3 Cartridge Kodak in 1900 (3¼ × 4¼ in). Comparatively expensive, these were available in a range of lens and shutter combinations and featured such refinements as rack and pinion focusing and rising and cross-front movements.

Whilst Kodak from the beginning concentrated on film cameras, during the 1890s they also produced a number of models designed to take glass plates. Their range of Kodet and Folding Kodet cameras, for example, could be used with either plate holders or a roll holder. Kodak also entered the specialised panoramic and stereoscopic arena with the No. 4 Panoram Kodak and the No. 2 Stereo Kodak, introduced in 1899 and 1901 respectively.

In 1900, Eastman addressed the financial constraints which still meant that snapshot photography was beyond the means of many people. Mass production had brought the cost of cameras down—the Pocket Kodak,

for example cost one guinea. However, this was still too expensive for many aspiring photographers. Eastman asked Brownell to design a camera which could be mass produced for very low cost. The result was the Brownie camera. A box camera fitted with a simple lens and shutter, the Brownie sold for just 5 shillings. Named after the Brownie characters popularised by the Canadian writer, Palmer Cox, the camera was initially aimed at children. Soon, however, it enjoyed much broader appeal as people realised that although very basic, the Brownie could produce very good results under the right conditions. Within a year, over 100,000 Brownie cameras had been sold. For the next eighty years, the Brownie name was to be synonymous with snapshot photography.

CAMERA DESIGN: 7 SPECIALIST AND NOVELTY CAMERAS

A large and increasing number of specialist and novelty cameras were introduced through the nineteenth century. Specialist cameras were designed to accomplish tasks that were beyond the standard studio or amateur camera such as panoramic photography and novelty cameras in design or appearance were manufactured to take advantage of new photographic processes or methods such as roll film or materials from which to manufacture cameras. Others were made to look unlike a typical camera and pass unrecognised. The definition of novelty changed over time.

Specialist cameras were introduced early on. Cameras designed for stereoscopic work in either single or double lens versions were introduced as early as 1852. The first stereoscopic camera is credited to J. B. Dancer who made a binocular camera in 1852, shown in 1853, and was refined in to the 1856 patented Binocular camera. Dancer's fellow Mancunian Petschler introduced his own design shortly after 1852. Latimer Clark introduced his single lens version on a special parallelogram in 1853. Most other manufacturers introduced their own versions of rigid box, sliding box, and front-focusing stereo cameras during the 1850s and 1860s until demand declined. From the later 1880s into the 1900s there was a renewed interest in stereoscopy and many manufactuers introduced stereoscopic versions of their regular models. These were all with two lenses as the single-lens camera was impractical for hand use. The stereo Photosphere of 1888, stereo-jumelle hand cameras of the 1890s, stereo versions of mahogany field cameras, the Stereo Sigriste of 1898, and detective hand cameras such as the Tit-Bit are all examples of stereo versions of regular cameras. There were also cameras such as the Richard Verascope of 1894 and the Stéréocycle of 1898 that only appeared in stereo models.

Panoramic photography was also in demand from photography's earliest days. In 1845 Frédéric Martens mounted a specially adapted daguerreotype camera on the roof of the Louvre and took 150 degree views of Paris on curved plates 12 × 38cm. Martens used a stationary camera with a lens rotated by clockwork. The camera was also adapted to make paper negatives. In Britain Thomas Sutton designed a water-filled lens in 1859 and a special camera designed to take curved glass plates was sold by Ross. The camera and lens appeared in a variety of sizes and produced 120 degree views. Johnson and Harrison's patent of 5 September 1862 described a camera that moved by clockwork on a turntable and could cover 110 degrees. Other designs such as Moëssoral's Cylindrographe of 1889, the Kodak Panoram of 1899 and the Al Vista of 1899 all moved the camera lens. The Cirkut , Wonder Panoramic camera of 1889 and Damoizeau Cyclographe all moved the camera on special turntables.

In-camera processing was also attempted early on and was suggested by Talbot who was the first person to patent such a camera in 1851. In his design the plate was dropped into a glass cell within the camera and silver nitrate added for sensitising purposes, after exposure the developing chemicals were added and drained as necessary. No record exists of the design having been produced.

Over twenty different British patents were granted for in-camera processing during the next thirty years up to the 1880s. The first such patent for a camera that was made commercially was designed by Frederick Scott Archer. Archer's portable folding camera was registered in February 1854 but first appeared the previous year and was discussed in the Photographic Society's *Journal* of 21 April 1853. Mr Shelley having seen the demonstration by Archer stated 'Mr Archer's camera possesses the advantage that the whole is carried in one box.' The same issue included Newton's patented design for a similar camera. Archer's camera was also described and illustrated in Robert Hunt's *Manual of Photography* of 1854. The camera was made commercially and improved upon by Mr Griffin and sold by him with a 2½ inch achromatic lens for views and chemicals for £16 6s. A tripod was £1 extra. The Dubroni camera of

1864 was a commercial successful and available in the 1870s in a variety of designs and plate sizes. The camera was patented by G. J. Bourdin in 1864 and contained a ceramic interior lining and an opening in the top which allowed a pipette to insert and remove processing chemicals. The camera back on some models held a red window for visual inspection. Allied to this were ferrotype or tintype cameras, producing photographs on metal plates within a few minutes, which gained popularity from the 1880s and variety of designs were produced by Fallowfield and other makers.

The end of the nineteenth century saw the introduction of three-colour cameras Frederick Ives's Krömsköp camera, viewer and projector were introduced from 1890. Louis Ducos du Hauron'a Chromographoscope of 1879 and Melanochromoscope of 1897 were all one-shot three-colour cameras. The next century would see these developed further.

Multiple lens cameras for producing cartes-de-visite, cabinet and Gem and stamp cameras were introduced from 1860 and remained popular in different forms throughout the century as studio cameras.

Specialised cameras were also designed for photomicrography. Many of the large scientific instrument makers such as Smith, Beck and Beck, Negretti and Zambra, John Browning and others produced cameras designed to be attached to microscopes from the 1860s onwards and these were developed and refined throughout the century. Collodion negatives with their sharp definition made possible micophotograptihic cameras for producing very small negatives of large objects for use in Stanhopes and on microscope slides. J. B. Dancer produced the first of these in 1856 but the best known was René Dagron's camera of 1860 which, via a repeating back, made 450 exposures 2 × 2mm on 4.5 × 8.5cm plates. The camera had twenty-five lenses.

The first novelty cameras in the sense of being very different to standard cameras date back to December 1858 when Thomas Skaife introduced his Pistograph camera. The metal camera produced circular negatives 1 inch diameter on wet-collodion plates. Thomas Ottewill produced a camera clearly based on the Pistolograph in 1860. A similar camera was produced by Marion and Co in 1884 as their All Metal Miniature camera for 1¼ inch square dry plates. The Kombi of 1893 was square metal boxform camera taking 1 inch negatives on roll film. The camera was also used to view the negatives. Other cameras such as the Escopette of 1889 and metal Demon of 1893 were of novel shape.

Cameras disguised as other objects start with the Thompson revolver camera of 1862 which was made by A. Briois in Paris. The camera made four exposures on a 7.5 cm diameter glass plate. Nicour's Photo-Binocular camera of 1867 appeared in the form of a pair of binoculars with a circular magazine holding 50 1½ inch square glass plates mounted on top. The 1880s and 1890s saw the greatest craze for disguised cameras when dry plates and roll film, faster lenses and a wider range of metals and construction techniques to make cameras allowed designer's ideas to be fulfilled. E. Enjalbert's Photo-Revolver de Poche of 1883 was designed using real revolver parts and made ten exposures on 2 × 2 cm plates. Stirn's Vest camera of 1886 was based on R. D. Gray's American patent and was designed to be hidden behind a waistcoat with the lens poking through a button hole. Krügener's book camera of 1889 was sold in different countries under different name and the Lancaster patent watch camera of 1886 was the first of a number of cameras disguised as pocket watches.

Cameras were also disguised as satchels, a group of books, binoculars, walking sticks, hats and cravatte. Some produced photographs that were acceptable within the limits of the negative size and lens, others, especially later on were novelties in the worst sense of the word and little more than toys.

CAMERA DESIGN: GENERAL

It may seem like an anachronism but the discovery and use of the camera actually precedes the discovery of photography by hundreds of years. The phenomenon of the *camera obscura* (Latin for 'dark room') had been known since ancient times. If a small hole is made in the window blind of a darkened room, an inverted image of the scene outside the window is produced on the opposite wall of the room. A clear description of the camera obscura is contained in the manuscripts of Leonardo da Vinci in the fifteenth century and by the middle of the sixteenth century, lenses had begun to be used to increase the brightness and sharpness of the image. By the seventeenth century, portable box-form versions had appeared and these were used widely by artists as aids

for sketching. Portable camera obscuras like these were used by the inventors of photography and are the direct precursors of the photographic camera.

The first photographic camera to go on public sale was manufactured by Alphonse Giroux in 1839. This was an adaptation of a camera obscura design and consisted of two wooden boxes, one sliding within the other, one fitted with the lens and the other holding the focusing screen and plate holder. Throughout the 1840s and 1850s, the sliding box design was the standard for general photography. Sliding box cameras had a number of advantages—they were robust and simple to make and use. However, they were heavy and bulky to carry around. To try and solve this problem, several manufacturers produced folding, collapsible versions of sliding box cameras. With the lens panel and focussing screen removed, hinged side panels could be collapsed to make a compact package. Most cameras were simple, wooden boxes, but there were some novel and ingenious uses of other materials and designs for specific applications. For example, Voigtlander's conical all-metal camera for daguerreotype portraits.

The camera design most popularly associated with the Victorian period is the folding stand camera, fitted with bellows. Several designs for folding cameras fitted with flexible bodies in place of solid wooden boxes appeared in the early 1850s. These used cloth bags and struts. In 1857, a camera design which used pleated bellows was patented by the Scottish photographer, Kinnear. Kinnear's design became the standard and was copied by most manufacturers. By the 1860s, folding bellows cameras had become established as the tool for general photography. There were many different manufacturers and variants but most differed from each other only in detail, the basic design remaining unchanged until well into the twentieth century. Folding bellows cameras were produced in a range of formats and for a variety of applications—for example, twin lens cameras for stereoscopic photography and large format cameras on heavy stands for studio-based portraiture.

The introduction of commercially manufactured gelatine dry plates in the late 1870s made 'instantaneous' exposures fully practical for the first time and the first cameras designed to be used whilst held in the hand camera appeared. Hand cameras developed along three distinct lines—box-form or 'detective' cameras; folding or strut cameras; and hand and stand cameras.

In 1881, Thomas Bolas took out a British patent for a box-form plate camera. Because it could be used in the hand, inconspicuously, he coined the name 'detective camera' for his invention. The term came to be applied to almost all hand cameras that appeared up to the end of the century. Following their initial novelty, box-form plate cameras became less popular during the 1890s. In their place appeared a variety of compact collapsing hand cameras in which the lens panel pulled out, attached to a bag or bellows, and was locked in position by struts.

Most detective cameras were simple wooden boxes, sometimes covered in leather or even brown paper so as to resemble bags or parcels. Some, however, took concealment a stage further. During the 1880s large numbers of disguised cameras appeared, designed to resemble, for example, books or watches or to be hidden in ties, hats or walking sticks or under worn beneath a waistcoat.

During the 1880s a number of designs appeared for hand cameras that held a number of plates that could be exposed successively, thus doing away with the need to change plate holders after each exposure. Incorporating ingenious plate changing arrangements, these were known as magazine plate cameras and enjoyed their greatest popularity in the 1890s. However, by this time, hand cameras which used roll film instead of glass plates were becoming increasingly popular.

Roll-holders, which used bands of sensitised paper as an alternative to glass plates first appeared in the 1850s but the first to enjoy any commercial success was designed by George Eastman and William Walker in 1885. Eastman subsequently worked on incorporating his roll-holder into a simple camera and in 1888 he introduced his detective camera which gave one hundred exposures on sensitised paper film. Eastman decided to create a new trade name for his camera—a name that would be novel, distinctive and easily pronounced in most languages. The name he came up with was 'Kodak.'

The Kodak camera was successful from the start and it was followed during the 1890s by a range of folding and box-form Kodak roll film cameras of various formats. In 1900 the first Brownie camera was introduced—the camera that was to become synonymous with snapshot photography and was to transform the medium into a truly popular pastime.

The early years of photography were characterised by a limited range of camera designs, which served for a very wide range of applications. However, the end of the nineteenth century witnessed an absolute profusion of camera designs, reflected in over a thousand pages of advertisements in the *British Journal Photographic Almanac*. Long established family businesses using craft techniques competed with international corporations exploiting the economics of mass production. The use of traditional materials such as mahogany continued but metal became increasingly used in camera manufacture. Folding bellows stand cameras rubbed shoulders with reflex and magazine hand cameras. Plate cameras competed with roll film models and there were cameras aimed specifically at the amateur or professional market—from Brownies for family snapshots to strut cameras for press photography. In addition, there were

specialised cameras for specific formats and applications such as stereo, panoramic and studio photography. In a period of sixty years, camera design had undergone a radical transformation, from hand-made wooden boxes to mass-produced precision engineering products.

CAMERA DESIGN: PANORAMIC CAMERAS

The history of panoramic photography can be traced back to the earliest days of the medium. William Henry Fox Talbot, for example, produced panoramic views in the early 1840s by rotating his camera after each exposure so as to produce a series of photographs, each overlapping the previous view slightly. Sequential panoramas such as these do not require a special camera. Soon, however, cameras designed specifically for making panoramic photographs in a single operation appeared. Panoramic cameras can be classified into three broad categories: cameras with rotating lenses and fixed plates or films; rotating cameras with moving plates or films; and, finally, cameras fitted with wide-angle lenses. Examples of all three types of panoramic camera were produced concurrently during the nineteenth century.

The first patent for a fixed-plate, rotating-lens panoramic camera was granted to an Austrian chemist, Joseph Puchberger, in 1843. His camera combined a curved daguerreotype plate with a lens that rotated by turning a hand crank, giving an image with an angle of view of about 150 degrees. Much better known is a camera designed on a very similar principle the following year by Friedrich von Martens, a German living in Paris. Called the Megaskop, this also produced panoramic daguerreotypes on curved plates. In 1856, Ludwig Schuller, Martens' nephew, used a version of this camera for wet-plate photography on curved glass plates. In 1884, P. Moessard was granted a patent for his Cylindrographe camera. This used paper negative film in a curved flexible holder and covered up to 170 degrees with its swivelling lens that was rotated manually by turning the viewfinder. The first panoramic camera to be sold in any quantity appeared in 1897. Made by the Multiscope & Film Co. in Wisconsin, this rotating-lens, roll-film camera was called the Al Vista. The rotating lens was driven by clockwork and covered an angle of nearly 180 degrees. Following the success of the Al Vista, Kodak soon entered the panoramic market with a hand-held snapshot panoramic camera. The first panoramic Kodak camera, the No. 4 Panoram Kodak, was introduced in 1899. This covered an angle of 142 degrees and produced 3 inch by 12 inch negatives on roll-film running in a curve inside the back of the camera. Two traversing speeds could be set for the lens by adjusting the tension of a spring. In 1900, Kodak introduced another, similar model, the No. 1 Panoram Kodak, which recorded a slightly smaller angle of view. Panoram Kodak cameras remained on the market until the 1920s and reflected the popularity of panoramic photography during the early years of the twentieth century. Panoram Kodaks were used by several prominent photographers of the time, including George Davison. They could be used both horizontally and, less commonly, vertically, to record subjects such as trees, tall buildings or waterfalls.

The second group of panoramic cameras are those that combine a rotating camera with a moving plate or film. In 1862, John R. Johnson and John A. Harrison took out a patent for their Pantascopic camera that produced panoramic photographs by rotating the camera and, at the same time, moving a glass plate. The camera body was rotated by a clockwork motor. As the camera rotated, a wet collodion plate was moved in synchronism, past an exposing slot in the camera back, to record an angle of view of 110 degrees. For cameras of this type, roll-film was much more convenient than glass plates. Following the introduction of flexible paper, then celluloid, film in the 1880s, a number of new designs appeared based on a similar principle. These included Stirn's Wonder Panoramic camera of 1889, Damoizeau's Cyclographe camera of 1890 and Stewart's Panoramic camera of 1895. The best-known and most widely used rotating and moving-film panoramic camera appeared at the beginning of the twentieth century. Patented in 1904, the Cirkut camera was produced in a variety of models and sizes which all worked in essentially the same way. The camera was rotated by a clockwork motor which also moved the roll of film past an exposing slot in synchrony with the turning of the camera. Cirkut cameras were still being produced in the 1940s and were extremely popular for panoramic large group photographs. Because the camera traversed relatively slowly, it was possible for a person standing at the end of the group where the camera started to run to the other end of the group before the camera reached there—and to magically appear twice on the same photograph.

The last, and least numerous, type of panoramic

cameras are those which are fitted with a wide-angle lens. The first panoramic camera to use such a lens was devised by an Englishman, Thomas Sutton, in 1859. Sutton was granted a British patent for a spherical, water-filled lens that gave a field of view of 120 degrees. He is said to have been inspired by looking at a glass 'snowstorm' souvenir, popular with Victorian tourists, that a friend had brought home from Paris. Cameras incorporating Sutton's innovative lens were made by London camera makers Frederick Cox and, later, Thomas Ross. To compensate for the lens's curvature of field, these cameras used curved glass plates. This meant, however, that they had to be supplied with a special, curved sensitising tank and a curved printing frame. It is estimated that only around thirty Sutton panoramic cameras were made.

CAMERA DESIGN: STEREO CAMERAS

The stereoscope was devised in 1838 by Charles Wheatstone to demonstrate the principle of binocular vision and its role in depth perception. Using pairs of drawings to represent the slightly different images seen by each eye, the stereoscope used mirrors to superimpose them into a single image with a three-dimensional appearance. With the invention of photography a decade later, the images used in the stereoscope could be infinitely more varied and detailed, and the effect of solidity more startling. Initially, a single camera was used to produce two daguerreotypes or calotypes in succession; the operator would move the camera a couple of inches to one side between exposures in the attempt to produce pictures that corresponded as closely as possible to what was seen by the two eyes. This was a process of trial and error—once superimposed in the stereoscope, the effect of three-dimensionality might be compromised by inadequate (or exaggerated) distance between the two exposures, or by alteration of the camera angle, the subject's position, or lighting conditions.

In 1849 Sir David Brewster invented a refracting, lens-based stereoscope that was more portable and easier to use than Wheatstone's reflecting model, and in 1851 the wet-plate collodion process was introduced. These two innovations cemented the alliance between stereoscopy and photography and gave rise to the stereoscopic industry. Photographers and camera manufacturers immediately turned their attention to the specific requirements of the Brewster stereoscope. Stereographs were—two 8.2 cm square pictures, separated by about 0.6 cm, mounted side by side on a 11.4 × 17.8-cm card. They were standardized, and mass-produced photographic images, dominating the commercial market from 1852 to 1880.

There were very early cameras which took two separate exposures on two separate plates. The camera body slid on a baseboard taking two separate and sequential square plates (Powell 1858 for example). Another device mounted pairs of cameras (Jacob Brett, 1853), where another camera had a sliding lens panel which took two sequential images on the same plate (Spencer, 1854).

Two basic types of cameras were designed to produce stereoscopic pairs: single-lensed and double-lensed. British engineer and photographic enthusiast Latimer Clark presented the first single-lensed stereoscopic camera at the fourth meeting of the Photographic Society, in 1853. Clark mounted an ordinary box camera on a grooved baseboard that allowed its position to be changed quickly and consistently between exposures. The direction or angle of the camera could be adjusted by pivoting the rulers mounted on the board. This accommodated an early theory of stereoscopic picture-making, known as toeing-in, according to which the camera's position should be adjusted and angled for the second exposure so that near objects in the center of the first exposure were also in the center of the second.

Clark further improved the single-lensed camera with a repeating back which allowed a stereoscopic pair to be produced on a single plate. With the camera pushed to the right side of the baseboard, the first exposure (representing what the right eye would see) was made on the left side of the plate. The camera was then slid to the left, the dark slide pushed home, and the second exposure (the left eye's view) made next to the first on the right side of the plate. Transposed in printing, the resulting pair could be viewed in the Brewster stereoscope.

Lens distance emerged as the most controversial aspect of stereophotography. A separation greater than the normal 6.4 cm between the eyes produces a slight reduction in scale but an increased illusion of solidity, enhancing landscape views in particular. Single-lensed camera with long baseboards, such as that designed by Andrew Ross, allowed experimentation with these hyperstereoscopic effects, which some criticized as deceptive, a perversion of the principle of binocular vision.

Double-lensed camaras fixed the distance between the two exposures, typically at about 8.9 cm, slightly

greater than average interocular distance. Developed in the early 1850s by Achille Quinet, the first double-lensed model to become widely available was patented in 1856 by John Benjamin Dancer. The Manchester instrument maker had experienced difficulties taking two separate pictures, and decided to construct a camera "in form somewhat like" the Brewster stereoscope. Dancer's advocacy of strict interocular distance went against the grain in the early 1850s; he later recalled that his camera was at first "much ridiculed by those who were supposed to be authorities on the subject." Yet they came into common use.

The simplest version of the binocular camera has two lenses with focal lengths of 10.8-14 cm mounted in a front panel; a central partition divides the rear box. With this design the lenses had to be uncapped one after the other. Various modifications provided portability, affordability, or rapidity—advantages that compensated for the fact that the side-by-side pictures, once printed, had to be transposed before being mounted to a cardboard support. For example, in some models, the partition was hinged at the top and spring loaded so it could be pushed out of the way to accommodate the lens panel, which folded inside the camera for protection of the lenses in carrying. Dancer reintroduced Noël Marie Paymal Lerebours's idea of placing wheel diaphragms in front of lenses with different apertures (12-4 mm). With lenses of 11.4 cm focal length, these provided effective apertures of f/9 to f/28. A flat strip of brass attached to the center of the lens panel served as a shutter; it could be pivoted to cover or uncover both lenses simultaneously.

Stereo cameras incorporated improvements that proved important to other branches of photographic practice. Since the image size is small, stereo cameras had short focal lengths and short exposure times—the first so-called instantaneous photographs (1/5 second exposure) were produced by George Washington Wilson in 1857 with a binocular camera. Stereo cameras were also adapted to produce the other leading commercial photographic format, the carte-de-visite. André-Adolphe-Eugène Disdéri designed a 4-lensed camera with a sliding plateholder in 1864, which efficiently produced eight poses exposures on a single plate. Cameras with even more lenses followed.

The introduction of dry plate photography in 1871 prompted manufacturers to design a wide variety of compete stereoscopic outfits, with lids forming trays where camera could be placed when in operation. A single-lens stereoscopic outfit, including darkslides and the grooved board, could be fitted into a wooden box about 33 × 18 × 15 cm. For binocular cameras, Dancer introduced an attached plate box with a rack-and-pinion system that allowed the photographer to expose a sequence of plates in full daylight.

The late 1850s and early 1860s represent the height of stereo camera production, with the most models were available for a range of prices. Amateurs (such as Viscountess Clementina Elphinstone Hawarden), professionals (such as Francis Frith, William England, Adolphe Braun, and Timothy O'Sullivan), and publishers (such as the London Stereoscopic Company and T. & E. Anthony) took up stereophotography for experimental or commerical purposes, and camera design generally adopted innovations introduced to ordinary cameras, as in George Hare's bellows design of 1882, for example. Later in the century, the portable hand camera eclipsed the stereo camera, which would reappear in different guises in the twentieth century.

CAMERON, HENRY HERSCHEL HAY (c. 1852–1911)

English photographer and studio owner

The youngest son of the great Julia Margaret Cameron, it is perhaps not surprising that one of the best known photographs by Henry Herschel Hay Cameron is a portrait of his mother, taken c. 1870. Like his mother, he also photographed Alfred Lord Tennyson (c. 1886) and the artist George Frederick Watts (c. 1885).

Despite reportedly having very poor eyesight, he established a well-deserved reputation as a fine photographer, combining commercial portraiture with active membership of the Linked Ring. Indeed he was one of

the founder members of the brotherhood in May 1892 and he was known to the brotherhood by the pseudonym 'Vintner.'

Cameron is listed in London trade directories as the operating a studio at 70 Mortimer Street in London from 1886, subsequently occupying premises at 20 Mortimer Street and in Hanover Square into the 20th century.

His technique—in a reportedly small and cramped studio—was to use only daylight from a small skylight, controlled by a simple calico blind.

Simplicity was his trademark, and in a letter preserved in the Royal Photographic Society (RPS) Collection at the NMPFT Bradford, Frank Meadow Sutcliffe remembered Cameron's advice on dress to a female sitter—'As little and simple as possible, madam, just a wisp of thin muslin over the shoulders will be quite enough, and will not date the portrait'.

JOHN HANNAVY

CAMERON, JULIA MARGARET (1815–1878)

British photographer of portraits and genre scenes

Julia Margaret Cameron was born in 1815 in Calcutta, a week before the Battle of Waterloo and a quarter of a century before the announcement of the invention of photography. Her father, James Pattle, was an Englishman working in India; her mother, Thérèse l'Etang, was French. Of the Pattles' ten children, three died in infancy, leaving Julia and six sisters, all with dark complexions and eyes—inherited from their mother's Indian great grandmother. As children, all seven girls were sent to Europe for the sake of their health and their education, spending much of their childhood with their maternal grandmother in Paris and Versailles.

At the age of 21, Julia and her parents were in South Africa, where they had gone—like many other Europeans living and working in India—to convalesce after illnesses. There she met Charles Hay Cameron, twenty years her senior and an important figure in the British administration of India. Two years later, back in Calcutta, they were married. In Cape Town, too, Julia met another man who was to become very important to her—the astronomer and scientist Sir John Herschel (whom she was later to call her 'Teacher and High Priest').

The newly wed Camerons were soon at the pinnacle of Anglo-Indian society. Charles had succeeded Lord Macaulay in 1843 as the only member of the Supreme Council of India not employed by the East India Company; a year later, when Sir Henry Hardinge arrived in Calcutta as Governor, he left his wife in England and Julia became—at the age of only thirty—his official hostess. Five years later, the Camerons returned to England. Charles was not a healthy man, and he seems to have assumed he could live off the income from his coffee plantations in Ceylon (Sri Lanka), a country he had got to first know when writing his 1832 report on its 'judicial establishment and procedure.'

Charles and Julia were soon as well placed in fashionable London life as they had been in India. The seven Pattle daughters all made 'good marriages' and one, Sara, had returned to London with her husband, Henry Thoby Prinsep, five years before the Camerons. The Prinseps set up house first in fashionable Mayfair, then in Little Holland House, where they surrounded themselves with a coterie of painters (notably George Frederick Watts, who soon moved in), musicians, scientists, and politicians. By then, the Camerons lived three miles away and, though the sickly Charles was often confined to his bed, Julia was frequently at Little Holland House, cultivating the company of the celebrities who would later become subjects of her portraits. She had already met two famous poets—Alfred Tennyson and Henry Taylor (who had been one of Tennyson's rivals for the post of Poet laureate in 1850).

In 1853, Tennyson moved to the village of Freshwater, at the quiet, west end of the Isle of Wight, off the south coast of England. Six years later, while Charles Cameron was visiting his estates in Ceylon with two of their sons, Julia took the two younger boys to stay with the Tennysons and, apparently on impulse, purchased two seaside cottages. Tennyson drove a road down across his estate to the sea to avoid the tourists who came to stare at one of England's most famous men (according to one witness, he was almost obsessed by the thought that everyone was staring at him), and opened a private gate from the grounds of his home, 'Farringford,' into those of 'Dimbola,' as the Camerons' house was called, after one of their estates in Ceylon. Soon, the two families were attracting as many celebrities of the day as at Little Holland House.

Organising musical evenings, poetry readings, plays (she soon built her own theatre) and parties apparently failed to satisfy Cameron's restless energy and intellect. Late in 1863, when Charles was again away in Ceylon, their daughter Julia and her husband, gave Cameron a camera 'It may amuse you, Mother, to try to photograph during your solitude at Freshwater.' There is evidence that Cameron had taken a few photographs before this, or at least collaborated with other photographers; she seems to have experimented with printing other people's negatives. She told Herschel that the painter David Wilkie Wynfield, who made a series of photographs of his fellow painters in fancy dress in the early 1860s, had given her a lesson. It certainly seems unlikely that her children would give her a cumbersome 11" × 9" camera, with its attendant chemical and other accessories, unless she had already shown some interest in the subject.

Cameron herself dated the beginning of her photo-

Cameron, Julia Margaret. Zoe, Maid of Athens.

graphic career from this acquisition of a camera of her own and wrote on most surviving prints of a portrait of Annie Philpot taken soon after, 'My first success.' She was immensely proud of the picture and immediately sent it to Annie's father (a minor Victorian poet) with a covering note: 'My first perfect success in the complete Photograph owing greatly to the docility & sweetness of my best & fairest sitter. This Photograph was taken by me at 1 p.m. Friday Jan. 29th. Printed—Toned—fixed and framed all by me I given as it is now by 8 p.m. this same day.'

Cameron had at last found an outlet for her restless energy and enthusiasm: 'I turned my coal-house into my dark room, and a glazed fowl house I had given my children became my glass house. The hens were liberated, I hope and believe not eaten. The profit of my boys upon new laid eggs was stopped, and all hands and hearts sympathised in my new labour, since the society of hens and chickens was soon changed for that of poets, prophets, painters and lovely maidens, who all in turn have immortalized the humble little farm erection.' These words, like all her others quoted in this article, come from the twenty manuscript pages of her autobiographical fragment *Annals of my Glasshouse*, written in 1864 but not published until 1889.

Among the many 'poets, prophets and painters' who came to be photographed at Dimbola were Charles Darwin, Benjamin Jowett, Henry Longfellow, James Spedding, Henry Taylor, Tennyson, Anthony Trollope and G. F. Watts. Others, such as the writers Robert Browning and Thomas Carlyle, had their portraits taken at Little Holland House, to which Cameron sometimes took her equipment. For a select few important subjects, such as Herschel, she went to their homes. By determined application over roughly a decade, she assembled a large portfolio of fine 'close-up' portraits of male heads, virtually life size by virtue of the large negatives she used (at first 11" × 9" and later 15" × 12"), photographic equivalents of the series which G. F. Watts painted as a 'Hall of Fame and donated to London's National Portrait Gallery.

These extraordinarily powerful portraits were arguably the first 'close-up' photographs in history (had the Frenchman Nadar made larger prints, he might have had a prior claim). All taken against a totally dark background, they show only the sitters' head and shoulders, while their bodies are draped in dark cloth. Some are in profile—a rather unnatural way of looking at people. Perhaps this was prompted by the intense interest at the time in human physiognomy as an indicator of character, and the widely practised 'science' of phrenology—deducing the power and range of a person's mental abilities from the shape of the head. Cameron's remarkably virtuoso control of lighting in these close-ups—usually from the top, from one side only—certainly highlights every detail, valley and bump.

Cameron's photographs of 'maidens' are blander and less dramatic. Though she did photograph such female celebrities as Marianne North and Marie Spartali (painters), Anne Thackeray (Thackeray's daughter, a successful author in her own right) and Christina Rossetti (no print of this portrait is known to survive), it was extremely difficult for women in Victorian Britain to achieve public status in their own right. Most of Cameron's female subjects were family and friends, and her main criterion for selecting them was their beauty—especially the sort of long-necked, long-haired, immature beauty familiar in Pre-Raphaelite paintings. Two of her favourite models were maids in the Cameron household—Mary Ann Hillier (frequently seen as some Madonna or other) and Mary Ryan, an Irish beggar girl whom Cameron had taken on at least partly, it seems, because of her good looks. The majority of her female models were teenagers, though their dress often makes them look older. With such subjects, she draws her camera back from its extreme close-up position, uncovers all the windows in her glasshouse studio and makes everything softer and prettier.

The children who appeared in her photographs were often local, too. Young Freddy Gould, who was posed as several Biblical characters, including Christ, was

the son of a fisherman. With him are often seen one or more of the four children of Thomas Keown, Master Gunner at Freshwater Redoubt, the Royal Artillery fort within sight of 'Dimbola.' One of the few local men portrayed as himself rather than as a fictional character was a young artilleryman, and officers from the fort were often entertained at Dimbola, sometimes taking part in productions at 'Mrs Cameron's Thatched Theatre,' in its grounds.

Though Cameron obviously had a taste for fancy dress—perhaps partly as a result of David Wilkie Wynfield's teaching—she never seems to have photographed scenes from the plays staged in her theatre. She did take the young Lionel Tennyson in costume as the Marquis of St. Cast, a character in Tom Taylor's potboiler *Payment on Demand*, typical of the Victorian melodramas and farces she put on, despite her otherwise rather sophisticated literary tastes. The home-made settings and heightened gestures used in her literary illustrations and genre scenes have a clear affinity with nineteenth century photographs of such performances and even the first efforts of silent filmmakers two decades later.

Though Cameron had made illustrations of literary, classical and Biblical stories throughout her short photographic career, this element of her work came to an obsessive peak toward the end of that decade, when she made—at Tennyson's suggestion—a series of illustrations for his *Idylls of the* King and other poems. These were published, probably largely at her own expenses, in two large format volumes, in 1874 and 1875. Her visualisations of poetry are different in style and achievement from those of any other photographer of the time. Her contemporaries decorated books of poetry by Burns, Gray, Milton, Scott, Shakespeare and others with picturesque landscapes, occasionally peopling these with attractively disposed figures in the scenery, but rarely illustrating actual characters or incidents from the story. Cameron certainly shares some of their taste for romantic imagery, but her illustrations are tougher, often conveying strong emotions—tragic as well as romantic.

It has been persuasively argued that many of them—not just the considerable number with Biblical or religious titles—were informed by her enthusiasm for Christianity but today, when public knowledge of such stories and symbols, and of classical literature, is minimal, her pictures still have a powerful directness and emotional impact.

In October 1875, at the height of Cameron's fame, she and Charles suddenly left Freshwater to return to Ceylon. As far as we know, she photographed only one celebrity there—Marianne North, the botanical painter. Cameron did take some pictures of 'natives' as she described them (just as she had called the residents of the Isle of Wight 'peasants'). But she took relatively few, even of these, and her photographic career was almost over. In 1879 she died and—as has often been quoted—the last word to pass her lips was 'Beauty.' Whether the story is true or not, no word could have been more appropriate.

COLIN FORD

Biography

Julia Margaret Cameron was born on 1815 in Calcutta, India. An extremely energetic and talented writer and artist, in an age when it was difficult for women to achieve success in such fields, she became interested in photography in the late 1850s, and took it up seriously at the beginning of 1864, having been given a large camera by her daughter and son-in-law.

She instantly began to take a series of compelling portraits (many of them, especially those of intellectual and artistic men of the day, in extreme close-up), illustrations of Biblical scenes, and of literature. Her enthusiasm for staging scenes from literature reached its peak in two volumes of illustrations for her friend Alfred Tennyson's *Idylls of the King* and other poems, published—largely at her own expense, it seems—in 1874 and 1875. Soon after, she and her husband left England to live in Ceylon, where he owned coffee plantations. She took a few photographs there, but spent most of her time helping her husband and his family run their estates. She died in 1879.

CAMMAS, HENRI (1813–1888)
French photographer

Henri Cammas was a typical figure of the amateur photograph. Born in 1813, he was interested in each new technique able to promote scientific progress.

This friend of Koenig Bey, the famous orientalist, decided to travel in Egypt, Syria, Palestine and Persia and asked for a mission at the French ministry for fine art in March 1859.

Accompanied by his wife and André Lefèvre, they left for Egypt in April 1859 and traveled three years long. They brought back about 200 photographs: eighty huge pictures (about 2 feet and 4 inches × 1 foot and 8 inches) and approximately one hundred other pictures, particularly using calotype technique (almost all conserved at the French national library) and wet collodion.

They also published in 1862 a report about Egypt called "La vallée du Nil, Impressions et photographies" ("The Nile valley, beliefs and photographs") where they described very precisely daily life during the travel as well as monuments, and gave advices for potential travelers.

He did not continue his photographic practice after his trip but he became member of the French photographic Society in 1863 and exploited his work for few years. Henri Cammas died near Paris, 26 December, 1888.

CANADA

The camera recorded a wide variety of subject matter in nineteenth century Canada, from the arrival of new immigrants to the country, to the construction of a transcontinental railway. As occurred in the rest of the world, the most common type of photography in this period was portraiture. Most major towns and cities had at least one permanent commercial photographic establishment or were visited on a regular basis by itinerant photographers. However, photography was also employed by the government to gather information about the largely unknown interior of the country often to the end of assessing areas for their resource value or suitability for cultivation. In this respect, the camera became a very powerful tool in the project of white settler colonization and nation building. Photographs frequently depicted Canada as vast and empty, and in need cultivation and settlement. Images of the land as limitless in both resources and opportunities, in addition to select representations of natural phenomena, operated to lure investors, settlers and travelers to the country. The depiction of indigenous peoples also entered this process with photographs reflecting the period's diverse ideas of the aboriginal as exotic, curious, savage or noble.

The first known practice of photography in Canada occurred in the year following François Arago's announcement of the daguerreotype process on August 19th, 1839. In early 1840, Hugh Lee Pattinson, an amateur photographer, is believed to have taken the first daguerreotype in the country while on a visit from England. His view of Niagara Falls was reproduced in an 1841 edition of Noël Marie Paymal Lerebours' *Excursions daguerriennes*. The first volume of this publication also included two works by Pierre-Gaspard-Gustave Joly de Lotbinière**,** a Swiss born French Canadian seigneur with property outside Quebec City. In October 1839, Joly de Lotbinière made several daguerreotypes while traveling in Greece. He continued to journey and photograph, producing in total thirty-five views of the Middle East, five of which were reproduced as engravings by Lerebours in his publications. Joly de Lotbinière's views were also published in Hector Horeau's 1849 publication *Panorama d'Egypte et du Nubie*.

The first recorded commercial daguerreotypists in Canada were two enterprising Americans, A.H. Halsey and Henry S. Sadd, who arrived in Lower Canada in September, 1840. They offered their services first to residents of Montreal, then to those of Quebec City only to leave two months later complaining they lacked the necessary amount of sunlight for proper exposures. A year later, an anonymous Frenchman, perhaps the lithographer Charles Severin (or Seweryn or Severyn, the spelling of the last name varies), also visited Quebec City, offering his services in the art of la daguerreotypie. In the same year, Montreal and Quebec City saw the arrival of Mrs. Fletcher, "Professor and Teacher of the Photogenic Art," who, with her phrenologist husband, settled in the area from August 10 to October 5, 1841. In Toronto, the artist and portrait painter Richard A. Pauling took daguerreotypes of the local citizenry. Further east, two itinerant photographers, Hodgkinson and Butters, advertised their skills as daguerreotypists in Saint John, New Brunswick in 1841. They also taught the daguerreotype process to others such as John Clow and Thomas Hanford Wentworth both of whom later opened portrait studios in the same city. In 1843, Hodgkinson and Butters recorded the "likeness" of Sam Martin, a

former slave and prominent leader of the black community in Charlottetown, Prince Edward Island.

The first known permanent daguerreotypist in Canada was the portrait painter William Valentine who operated a studio in Halifax from 1842 until his death in 1849. Valentine had also advertised his services in Saint John in 1841. His offer to teach the process resulted in the establishment of a partnership with his student Thomas C. Doane. In the spring of 1843, Valentine & Doane set up business at the Golden Lion Inn in St. John's, Newfoundland. When their partnership dissolved, Valentine remained in Halifax, and Doane moved to Montreal (by way of the West Indies) where he ran a successful business from 1847 to 1866. In Toronto, Eli J. Palmer opened a photography studio in 1849 that would continue to operate for thirty years. By the early 1850s, daguerreotype studios were established in every major city. Photographic materials, such as plates and cases, were imported, mainly from the United States. Individuals from all walks of life had their likeness recorded, from labourers to famous political figures. Other subject matter included views of cities, business establishments and natural scenery, the most popular of which was Niagara Falls.

The daguerreotype process was in general use in Canada until the early 1860s when it was replaced by the wet collodion method. This latter process was also used for the production of collodion positives, or ambrotypes, which were popular from the late 1850s to mid 1860s. By the late 1850s, commercial photography studios using the wet collodion method had become established in most major cities. The process also allowed for the production of stereoscopic views that Canadian photographic establishments began to market in the late 1850s. The production of photographic imagery using the calotype process, however, was practically nonexistent, with one known exception, which will be discussed below.

Certain works produced in the 1850s using the collodion process are crucial to the history of image making in Canada. In 1858, Humphrey Lloyd Hime (1833–1903), of the Toronto firm Armstrong, Beere and Hime, accompanied the Assiniboine and Saskatchewan Exploring Expedition to take pictures of an area now at the southern border of Manitoba and Saskatchewan. The expedition represents the first government use of the medium. Subject matter included landscape views, the inhabitants and buildings of the Selkirk settlement (near the present day city of Winnipeg), and the area's aboriginal populace. The expedition's leader, Henry Youle Hind (1823–1908), also used the photographs as the basis for illustrations in a book published on the expedition. In addition, a portfolio of thirty prints was made available for sale to the general public. Back east, from 1858 to 1860, Samuel McLaughlin (1826–1914) published small portfolios of photographic prints entitled *The Photographic Portfolio: a monthly review of Canadian scenes and scenery*. However, it appears that production of imagery was much less frequent than promised as only a dozen photographs have survived from this business venture. McLaughlin's most famous commission, begun in the early 1860s, was the documentation of the construction of Canada's Parliament Buildings, a project that earned him the title of "government photographist."

The 1850s were noteworthy for other photographic projects. In 1859, the London Stereoscopic Company sent British photographer William England to North America to create stereo views of Canada and the United States. In November of the previous year, William Notman, who will be further discussed below, began documentation of the construction of the Victoria Bridge in Montreal. The project lasted two years and resulted in forty stereo views of what was considered the greatest engineering feat in North America at the time. In the late 1850s, Henry J. Cundall produced views of Charlottetown and surrounding area using the relatively rare collodio-albumen, or dry plate process. From 1857–59, Paul-Émile Miot an officer in the French navy took photographs of the ports and fisheries of Newfoundland, Cape Breton Island and the French islands of St-Pierre and Miquelon, as well as the area's Micmac Indians.

The immense popularity of the carte-de-visite in the early 1860s fully established photography as a viable commercial activity. William Notman of Montreal capitalized on this interest, building large studios in Montreal, Ottawa, Toronto and Halifax, as well as branch companies in the United States. His title of "Photographer to the Queen" most likely resulted from his gift to Queen Victoria of over five hundred photographs of Canadian scenery housed in a silver gilded box of bird's eye maple. Notman also promoted photography as a fine art, producing two volumes of *Notman's Photographic Selections* in 1863 and 1865 that combined photographs with reproductions of paintings. His studio became famous for its elaborate interior sets of hunting and winter activities. The photograph from the Cariboo Hunting series "A Chance Shot" appeared in the May 1866 edition of *The Philadelphia Photographer* along with much adulation from the magazine's editor, Edward L. Wilson regarding its realism. Notman was also known for his large composite photographs of a variety of subject matter, the most famous being the "Victoria Rink skating carnival" (1870) which depicted a costume ball held in honour of Prince Arthur's visit to Canada in 1869. In the case of his Ottawa firm, William J. Topley opened the branch in 1867, bought the business five years later, and specialized in taking pictures of the city's well known personalities and politicians, in addition to the Parliament Buildings, monuments, and businesses. Notman's

Underwood & Underwood. Photographing New York City—on a slender support 18 stories above pavement of Fifth Avenue. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

younger brother, James, produced stereo views of St. John in the early 1870s. After Notman's death in 1891, his eldest son William MacFarlane Notman continued to run the business until his death in 1913 at which point his son Charles headed the firm until 1935, when the studio was finally sold.

Other large photographic firms of the time include James Inglis of Montreal whose work and reputation has been overshadowed by that of Notman. Inglis, who also created large composite photographs, found himself competing against Notman on a number occasions, the most controversial of which was the production of his version of the Victoria Skating Rink carnival in 1870. Jules Benoit *dit* Livernois produced daguerreotypes in Quebec City in the 1850s. Upon his death in 1865, his son Jules-Ernest took over the business and produced thousands of portraits and views of Quebec City, and its surrounding area for sale to tourists. Genre scenes depicting traditional but fast disappearing ways of Québécois life were also popular. The Livernois operated their photography business for over one hundred years, from 1854 to 1974. Also in Quebec City, Ellisson & Co. created dramatic portraits of local personages while the studio of Louis Parent Vallée specialized in views of the city and its surrounding area.

Another well-known commercial photographer, Napoleon Sarony, was born in Québec in 1821. He moved to New York around 1836 where he eventually established his famous studio several decades later.

In central Canada, James Esson operated a highly successful studio in Preston, Ontario. From the late 1870s to 1882, Esson took hundreds of stereo views of his travels throughout Canada and the United States. Other photographers who produced stereoscopic views of Canada include J.G. Parks of Montreal, W.J. Topley of Ottawa, and J.S. Climo and James McClure both of Saint John. Another important set of stereographs of Québec and Montreal were taken in 1867 by the American photographer B.W. Kilburn who, along with his brother Edward, ran the large stereoscopic firm of Kilburn Brothers of Littleton, N.H.

Commercial photography arrived on the west coast with the discovery of gold on the Fraser River in 1858. In 1859, George Robinson Fardon came to Victoria from San Francisco and produced a number of views of Vancouver Island. His panorama of Victoria was reproduced as an engraving in the 10 January 1863 edition of *The Illustrated London News*. Fardon is best known for his 1856 publication *San Francisco Album: Photographs of the Most Beautiful Views and Public Buildings*. He also specialized in pannotypes, or photographs reproduced on leather. Francis G. Claudet, the youngest son of Antoine François Claudet of London, England, pursued photography on an amateur basis while fulfilling his duties in the Assay Office in New Westminster in the 1860s. Richard Roche, a lieutenant on the survey ship HMS *Satellite*, was another amateur who took photographs while stationed in the area. Most notable are his views of aboriginal peoples, as well as American and British camps on San Juan Island taken shortly before the Americans occupied the island. Hannah Maynard settled in Victoria in 1862 where she operated her studio business for fifty years. Her husband, Richard learned photography from her and travelled extensively taking

landscape views. Charles Gentille was active in British Columbia between 1863 and 1866, taking carte-de-visite views of the Leech River gold rush of 1864, and landscape photographs of the Cariboo area a year later. In 1866, Frederick Dally opened a photographic studio in Victoria. That same year, he accompanied Vancouver Island Governor Arthur Kennedy on a trip around Vancouver Island where he obtained photographs of aboriginal villages and peoples and collected aboriginal artifacts. His best known works were produced between 1867–68 when he photographed the lives of gold miners along the Cariboo Road, many of which were reproduced for the pictorial press.

In the prairie provinces, Joseph Langevin opened his Photographic Gallery in Winnipeg in 1864. He was the first known photographer in the west to take carte-de-visite portraits. Nearly two decades later, in the same city, Rossetta E. Carr opened the American Art Gallery, a highly successful studio that specialized in the children's portraits. In the 1890s, Geraldine Moodie began her photographic career, taking pictures of the Cree Indians living near Battleford, Saskatchewan. Moodie is best known for her portraits of Inuit peoples taken while her husband was stationed in the Arctic from 1904-06, and in Dawson, Yukon from 1912–15. In Calgary, William Hanson Boorne, along with his cousin Ernest May, established a photography studio in 1886, and another in Edmonton in 1891. Boorne's most noted photographs are of the Blood Indian Sun Dance ceremony taken in 1887 and 1888 for which he received a gold medal in the 1893 Chicago World's Fair. The firm also built up a collection of scenes from across Canada that they sold to both workers and visitors along the newly constructed railway line.

The period's best-known amateur works were produced by Alexander Henderson of Montreal who created a number of artistic landscape views that he bound together and published as *Canadian Views and Studies by an Amateur* in 1865. Subsequent editions were titled differently and appear to have been personally assembled to suit the needs of the recipient. For those stationed in remote areas of the country, photography proved to be an important pastime, as well as a way of contributing to scientific pursuits. In the 1860s, Bernard Rogan Ross, a Fellow of the Anthropological Society of London, photographed the aboriginal peoples of the Mackenzie River District and the inhabitants and activities at Rupert House, a Hudson's Bay Co. trading post near James Bay. Moose Factory, located on the opposite side of the bay, also saw much amateur activity. From 1864 to 1869, Charles Horetzky produced a number of views of the area, perhaps learning the medium from Ross. In the 1870s, Horetzky joined the Canadian Pacific Railway survey teams under the direction of Sir Sandford Fleming, taking photographs of various routes proposed for the transcontinental railway. Another individual who became interested in photography while stationed at Moose Factory was James Cotter. He took numerous photographs of the Inuit, igloo building and kayaks, as well as landscape views some of which were reproduced in *The Illustrated London News*. George Simpson McTavish also photographed aspects of life in the north, as well as the hunting activities of the Inuit.

Surveyors and explorers hired by both British and Canadian Governments used photography to document their activities, and provide views of the largely unknown interior and its aboriginal peoples. Between 1858 and 1862, a corps of Royal Engineers was assigned to mark the boundary of the 49th parallel, or the border between the United States and Canada. Twenty-three photographs were taken around Victoria and Esquimalt between 1859 and 1860, and eighty-one were produced in the field between 1860 and 1861. The Royal Engineers continued their boundary survey in the 1870s. One set of photographs was used as evidence to settle a boundary dispute between Canada and the United States at the North West Angle of the Lake of the Woods in 1872. Other images depict the interior of the country, the surveying activities of the Engineers, and subject matter of particular fascination for Victorians such as views of aboriginal graves, burial sites, and the remains of aboriginals killed in tribal skirmishes. In 1871, Benjamin Baltzly, an employee of William Notman's firm, accompanied the Geological Survey of Canada expedition into the interior of British Columbia. Notman retained the negatives and sold the photographs through his studios. Such views were a novelty, as individuals living in the east knew little of the west and were curious about the area and the type of landscape found there.

George Mercer Dawson, a geologist with the Geological Survey, also took photographs in British Columbia during the 1870s and 1880s. Some of his most important historic and ethnographic pictures were taken of the Haida Indians of the Queen Charlotte Islands, which included views of their dwellings and totem poles. Edward Dossetter produced another important set of photographs of this area in 1881. The Canada-Alaska boundary, and topographical surveys of the west were achieved through photogrammetry, a photographic surveying technique which the Surveyor-General, Edouard Deville, employed on a large scale and for which he gained an international reputation. Views of Yukon and Dawson City were taken by William Ogilvie in 1895 and 1896, and depict the north prior to the immense increase in both population and mining activities that occurred as a result of the Klondike gold rush.

Photographs generated by the Geological Survey, and other government projects, were used by the Canadian government and the Canadian Pacific Railway Company (CPR) to encourage immigration. In terms of

the former, in the west, James B. Tyrell of the Geological Survey took pictures of the prairies, and the forts, aboriginal peoples, and settlers that occupied the area. In 1881, Frank Jay Haynes, a photographer of American railroads, was hired by the CPR to create photographs to entice immigrants to the country. With the completion of the CPR in 1885, William Cornelius Van Horne, then General Manager of the company, was especially eager to provide free passage on the railway to artists and photographers wishing to render views along the route. Between 1887 and 1889, Notman's son, William MacFarlane Notman, traveled along the newly build transcontinental railway to photograph scenes along the route. In the mid-1880s, Alexander Henderson also journeyed along the railway line, taking pictures of scenic areas that would later be bought by the company in order to encourage travel along the line. This was not Henderson's first project along a railway route. From 1872 to 1874 he had been hired by Sir Sandford Fleming to take photographs along the Intercolonial Railway Line, which linked, sometimes through already established lines, the Maritime provinces to the St. Lawrence River near Quebec City. In 1886, Oliver Buell took photographs along the western end of the railway line, specializing in views one would see while traveling along the route. The Canadian Pacific Railway reproduced a number of his photographs in their advertising literature, and included four works in its 1895 portfolio of photogravures entitled *Glimpses Along the Canadian Pacific Railway: Mountain Series*. Buell used his photographic views mainly for his "entertainments" or stereopticon and lantern slide shows in which he starred as the main narrator. He later traveled throughout the east, taking numerous landscape photographs in the Maritimes and New England states.

The public had access to photographic imagery not only through commercial establishments and lantern slide shows, but also through a number of technological developments that occurred in the latter part of the century. Dissemination of photographic imagery was substantially increased when, in 1869, two Canadians, William Augustus Leggo and George Edward Desbarats, reproduced the first letterpress halftone reproduction of William Notman's photographic portrait of HRH Prince Arthur for the 30 October 1869 edition of the *Canadian Illustrated News.* By the early 1880s, individuals could take their own photographs with relative ease as a result of improvements in dry plate photography. Amateur involvement in the medium increased and photographic societies and camera clubs became established across the country, beginning with the Quebec Amateur Photographers' Association in 1884. New types of cameras were manufactured which took advantage of the "instantaneous" photography the dry plate afforded. One such device was the detective camera that was employed by Captain James Peters of the Regiment of Canadian Artillery to photograph the Riel Rebellion of 1885.

The Arctic, a place of continued fascination for scientists, explorers and artists, first saw the appearance of photography in the early 1850s. Photographs were made during expeditions sent out in search of Sir John Franklin, and it is possible that the medium was included in the Sir John Richardson search expedition of 1847–49. William Henry Fox Talbot had donated a calotype apparatus to the expedition, but it is unknown whether or not the equipment ever left England. It is known, however, that attempts were made to produce daguerreotypes during Dr. Elisha Kent Kane's 1853 rescue expedition, which journeyed in the area north of Smith Sound. Francis Leopold McClintock successfully created calotypes in 1854 on Beechey Island as part of the Edward Belcher expedition. Two years later, McClintock headed his own expedition funded by Lady Franklin, which was successful in discovering the fate of the noted explorer. For the expedition, Dr. David Walker, who had been hired as surgeon and official photographer, used the wet collodion method to produce photographs of the Baffin Bay area. In 1869, William Bradford, artist, organized a cruise to the Arctic and employed two photographers, John Dunmore and George Critcherson of Boston to take photographs of areas visited. One hundred thirty five of these photographs were included in Bradford's 1873 publication, *The Arctic Regions*. Sir Allen Young headed north by steamer in 1875 along with George de Wilde, artist and photographer, some of whose work was used in the 1876 publication *Cruise of the 'Pandora.'* Young made a second trip that same year with William Grant as photographer. The British polar expedition of 1875/76, headed by Sir George Strong Nares, engaged two ships each supplied with a photographer, George White and Thomas Mitchell. In 1876, the expedition made a failed attempt to reach the pole, which, nonetheless resulted in the production of one hundred twenty one photographs. In 1884, the Canadian government committed expeditions to Hudson Bay and Hudson Strait, mainly for the reason of investigating the navigability of the waters. Robert Bell of the Geological Survey of Canada took photographs in the area from 1884 to 1885. Albert P. Low, another employee of the Survey, photographed in the Ungava Bay, northern Labrador, and Hudson Bay areas throughout the 1890s. Graham Drinkwater also produced views of Hudson Bay and Strait in 1897 while engaged on the William Wakeham expedition. By the end of the nineteenth century, photography had proved its usefulness to scientists and government officials who would continue to employ the medium in the following century as a means to establish Canadian presence, and thus sovereignty in the north.

CANEVA, GIACOMO (1813–1865)
Italian photographer and painter

Giacomo Caneva was born at Padua in 1813. In 1834 he went to Venice to attend the *Accademia di Belle Arti*, where, in particular, he followed the School of the Perspective of Tranquillo Orsi. Here he qualified as a "perspective painter," and widened his knowledge of the camera obscura, which he used in his paintings. Some of his paintings survive from this period: two canvases painted at Rome, which today are in the Museo Civico at Padua (a view of the Pantheon, commissioned by Jacopo Treves in 1843, and a view of the temple of Vesta in 1844), and a canvas in a private collection representing the Prato della Valle of Padua. He went to Rome to paint just before daguerreotypes came out. In 1840 and 1841 he superintended the works carried out at the Villa Torlonia after the project of Giuseppe Jappelli, and obtained a modest success. A couple of contemporary chronicles attest his presence at Rome and mention him as being ingenious, enterprising, and interested in new things (N. Pietrucci, 1858; N. Roncalli, 1844–1870). On the 14th of February 1847 he went up in a balloon with François Arban, who had come to Rome that year after making several ascents in Italy and other parts of Europe. In a letter to friends Caneva recounts his ascent and gives a marvellous description of the panorama of Rome and the surrounding countryside (A. Ganot, 1864). He went up again two months latter from the Villa Borghese with Arban and the Venetian painter Ippolito Caffi. His innate inclination for novelty awakened an interest in photography immediately after its invention. He began his photographic career as a daguerreotypist, according to notes left by his friend Tommaso Cuccioni, who later became a photographer himself. However, as things stand at present, his daguerreotypes cannot be individualized. He is recorded in the famous list of artists' addresses which was begun at the Caffè Greco in 1845: "G. Caneva, Painter and Photographer, Via Sistina 100," and then, "Via del Corso 446, near S. Carlo."

Quite early on, Caneva combined practice with theory, and in 1855 wrote *"Della fotografia, trattato pratico di Giacomo Caneva, Pittore prospettico" (A practical Treatise on Photography by Giacomo Caneva, Perspective Painter"),* in which he reveals a detailed knowledge of techniques such as the calotype process. The daguerreotype process now seemed to him to be obsolete, indeed superseded by the superior calotype process, by which many positive copies could be printed from just one negative. Paper photography is then described in all its variations: the method of W.H. Fox-Talbot, the improvements of Blanquart-Evrard, Gustave Le Gray, Humbert de Molard, Ghillon Saguez, and those of S.Geoffray. The greater part of Caneva's photographs that have survived are calotypes. In Italy there is the Caneva collection of the ICCD, the *Istituto Centrale per il Catalogo e la Documentazione* at Rome and that belonging to the Museo della Fotografia Fratelli Alinari at Florence; in Spain there is the Bernardino Montanés collection at Saragossa. In his treatise of 1855 Caneva shows his acquaintance with the albumen process on glass invented by A. Niépce de Saint Victor, and the damp collodion process on glass invented

by F. Scott Archer. In the same year he published the album *Vedute di Roma e dei contorni in fotografia (Photographic Views of Rome and Surroundings)*. He also took many important photographs around Naples, which show stupendous panoramas of the sea, Vesuvius and the ruins at Pompeii.

The magazine *L'Artista,* published in Milan in 1859 by Luigi Sacchi, one of the foremost photographers from the beginning, gives details of a grand enterprise inwhich Caneva took part, a journey to India and China. The "famous Caneva of Rome," was the photographer chosen by the silk firm of Castellani and Freschi to participate in an expedition to seek new silkworms untouched by disease. Of the pictures he took on this expedition there remain only a few engravings taken from the photographs, (G.B. Castellani, 1860), a salted paper in the collection of Piero Becchetti at Rome, and the relative calotype in the ICCD at Rome.

In 1864 Caneva was paid to revise the inventory of the photograhic material in the studio of his friend Tommaso Cuccioni, who had died a short time before. Caneva himself died in the following year and is buried in cemetery at Campo Verano.

His activities at Rome are bound up with those of many other artists and photographers who frequented the photographic circle that emerged at the Caffè Greco in Via Condotti shortly before 1850, the so-called "Roman School of Photography." Other members were the sculptor and medalist Frédéric Flachéron, Eugéne Costant and, for a short time, the goldsmith Augusto Castellani and Ludovico Tuminello. The earliest photographs of the "Roman School" are those of Costant and Flachéron datable to 1848, except for one view of the piazza Bocca della Verità, which is signed and dated "G. Caneva 1847." Thus Caneva has the merit of having taken the first calotype to attest the activity of this Roman circle, which was very important for the diffusion of calotypes in Italy. From the beginning he and other Roman friends devoted themselves to taking photographs of the monuments of Rome, using the knowledge they had acquired in their studies of design and perspective. These views reveal their confident mastery of the calotype technique, after the method of Gustav Le Gray, their strict attention to illumination, the relationship between light and shade, and the correct angle for perspective. As well as these pictures of the most important places in Rome, he took photographs of events such as religious and popular festivals, and scenes of everyday life. For the Vatican he took important photographs of statues, of which the most outstanding are those of the Laocoon and the Torso of the Belvedere. He also took several views of the Musei Capitolini, the Museo Albani and the Museo Ludovisi at Rome. His views of the surroundings of Rome and those taken at Tivoli are splendid. These exalt different parts of the beauties of nature, such as trees, ruins, rocks, peasants' huts, and rivers, views that were certainly in demand by many painters working in Rome. From 1852 he systematically took photographs for artists, using the calotype process precisely because it was able to reproduce to whole range of lighting effects of the countryside with delicate gradations of tone. His studies of nature are the first examples of the genre and thus precede the later popularity of such views, which spread throughout Europe. The extremely high quality that he achieved is due to the use of very large apparatus instead of the daguerreotype machines that he had at the beginning of his career. The continuing refinement of expression, obtained through his increasing mastery of the medium, and his continual updating of technical equipment gave him at the height of his career results of great originality, in which the determining role was played by his own creative gifts and his previous train-

ing as an artist. None of his photographs taken after 1860 remain, and nothing is known of his last years. However, his surviving photographs are the work of one of the greatest Italian photographers from the inception of photography in Italy.

SILVIA PAOLI

Biography

Giacomo Caneva was born at Padua on the 4th of July 1813 of Giuseppe Caneva and Anna Pavan. There were four other children, Antonio, Giovanni, Camillo and Teresa, who died as a child. The father was well-to-do, and was the owner of the "Albergo al Principe Carlo" in Prato della Valle. Caneva left Padua on the 12th of November 1834 to register at the Regia Accademia di Belle Arti at Venice (Royal Academy of Fine Arts). Here he took courses in perspective, ornamentation and decoration, and developed his knowledge of perspective, which played such a large part in his work as a painter and photographer. After he had finished his studies he went to Rome, perhaps with the help of a grant, to perfect his technique. Here he soon achieved recognition for his works at Villa Torlonia which were carried out in 1840 and 1841 by the architect Giuseppe Jappelli. With the discovery of the dagueurreotype process Caneva began his career as a photographer, but then decided to use mainly the calotype process. He became one of the leading members of the "Roman School of Photography"; his studio was first in Via Sistina 100 and then in Via del Corso 446, near S. Carlo. Among his preferred subjects were the statues in the Musei Vaticani, the monuments of Rome and surroundings, and the countryside in Lazio and Campania. In 1859 he went to China and India, and there remain some engravings taken from his photographs of that journey. He died in Rome on the 29th of March 1865.

CAPEL-CURE, ALFRED (1826–1896)
English photographer

Colonel Alfred Capel-Cure was born in 1826, a soldier and gentleman who was among the first generation of amateur photographers. He owned Blake Hall in Essex, and later inherited Badger Hall, Shropshire, in 1884 from his uncle Edward Cheney, whose brother, Robert Henry Cheney, was also an amateur photographer. He worked with paper negatives and salted paper prints in the 1850s. His subject matter included his home, Blake Hall, medieval architecture and ruins in England, Wales, and Scotland, as well as France. Additionally he photographed soldiers in the 55th Regiment at Templemore and Athlone in Ireland. He also made prints from the negatives of his uncle, Robert Cheney, in 1859–60, which are in the Horblit Collection at the Houghton Library, Harvard University and the Center for Canadian Architecture, Montreal. Examples of his work can be found in the collections at the Getty Museum, Los Angeles, and the Center for Canadian Architecture, Montreal. He died in 1896.

DIANE WAGGONER

CARABIN, FRANÇOIS-RUPERT (1862–1932)

François-Rupert Carabin, sculptor and cabinetmaker, first worked as craftsman for a sculptor within the Faubourg Saint-Antoine in Paris. He was then familiar to Montmartre, its cafes and cabarets. In the *Chat Noir* he met Henri Toulouse-Lautrec and Adolphe Willette. Along with Toulouse-Lautrec he became a close observer of Montmartre brothels looking at "fallen women" with both tenderness and acuteness. He chose all his models among them. Most of his sculptures and pieces of furniture had been inspired by the female body (see for instance the bookcase designed in 1890 for Henry Montandon, now kept at the Musée d'Orsay). He went beyond mere realism; under his chisel women became mermaids, sphinx. As a critic wrote on Carabin's works, his sculptures show a "daring perversity."

Carabin made from 1895 many photographs of his nude models in his studio. The albumen prints are closely related to the artist's work in decorating furniture. Their poses are charged with some erotic crudeness. The many girls who posed for Carabin did not always have the charm of his sculpted women or they voluptuous curves. Anyhow, with no doubt put at ease by the sculptor and full of the banter of young models in Montmartre, they freely strike the same poses with a naturalness that shines trough the photographs.

> The whole collection is kept at the Musée d'Orsay. They came there through the Fondation Le Corbusier as the artist's heirs had given them to the architect—who met Carabin just before World War 1—in 1953. Carabin's photographs make a rare set that gives insight into the use of photographs not only as models but as preliminary sketches for other works. Most of the view were not taken any further, but remained as projects or ideas.

CARBON PRINTS

Carbon printing developed from the need for a permanent photographic positive process, and derived from principles established by Gustav Suckow. In 1832, he noted that an alkaline chromate (potassium dichromate) reacted with sunlight to harden organic matter. Potassium dichromate is a bivalent chromium compound, which is reduced by exposure to light to a trivalent chromium compound. This in turn acts on organic colloids, producing a kind of polymerisation. In 1839, Mungo Ponton identified the photo-sensitivity of potassium dichromate, and in 1840, Edmond Alexandre Becquerel observed a greater photo-sensitivity when paper was sized with plant starch. This work established that an organic, water-soluble colloid (such as starch, gum arabic, gelatin, or albumen), when sensitised with potassium dichromate and exposed to actinic light, becomes insoluble in water. The discovery was first applied to photomechanical printing, as William Henry Fox Talbot's photoglyphic engraving process (patented 1852) and Alphonse Poitevin's photolithography process (patented 1855). In 1855, Poitevin also patented a direct pigment process using dichromated gelatin. By 1858, John Pouncy, J. C. Burnett, and Charles Cowper had all produced modifications, and in 1859, Emma Heineken achieved better tonal gradation by substituting finer pigments.

Poitevin's process used a mixture of lamp black pigment and gelatin coated onto paper (often called the carbon 'tissue'), and sensitised with potassium dichromate. The unexposed gelatin dissolved in water, leaving the hardened exposed areas as a pigmented gelatin layer that could be dried *in situ* or transferred onto another support surface.

In 1864, Joseph Wilson Swan patented a transfer method of processing the carbon tissue, allowing the removal of the top layer of hardened gelatin to give a finer tonal gradation. Adolphe Fargier had already patented a double-transfer process in 1860, but Swan attained his patent, and by 1866 was offering carbon prints through Mawson and Swan (see Mawson & Co.). Swan later sold the rights to Adolphe Braun, Edgar Hanfstaengl (see Franz Hanfstaengl), and T. and R. Annan (see Thomas Annan), among others.

In 1878, a new carbon paper was produced by Frédéric Artigue. As 'Artigue papier velours,' it had limited use from 1884. It was modified by Artigue's son and reintroduced in 1893 as 'Charbon-Velours' paper. Artigue paper was sensitised, exposed, and developed from the front surface, without the need for transfer onto a secondary support paper. The 'development' was effected by sawdust suspended in water, which abraded the pigmented gelatin coating, removing unexposed areas and leaving a velvety matt surface. The same method of development was later used for the Fresson process.

In 1868, Louis Ducos du Hauron patented a subtractive colour system from separation negatives, producing three-colour photographs with superimposed layers of pigmented gelatin. With the introduction of panchromatic materials in 1906, carbon was adapted for trichrome prints, and combined with Thomas Manly's ozobrome process as carbro, a dye imbibition process (1919).

Carbon was largely directed towards the commercial market of art reproductions and professional portraits. The main British supplier of materials and finished prints was the Autotype Fine Art Company, which acquired Swan's patent rights in 1868. Other firms included John Pouncy's Dorchester establishment, Liesegang (see Paul Eduard Liesegang), Goupil et Cie., the Woodbury Permanent Photographic Printing Company (see Walter Bentley Woodbury), the Scovill Manufacturing Com-

pany (see Scovill and Adams), and Hanfstaengl, which, as Hanfstaengl-McGraw, continues to produce carbon, carbro and photomechanical materials.

Carbon prints were made to look very like silver photographs; the tissues were made in brown and purple pigments to mimic the hues of albumen prints. In the late 1880s and 1890s, when silver prints were increasingly neutral black in colour, tissues were available in 'engraving black.' The process produces a fine, continuous tone image without a grain structure, for the tonal gradations are produced by the varying thickness of the pigmented gelatin layer, visible as a slight surface relief. Prints usually have a satin finish, although those made by single-transfer show a glossier appearance (especially in the shadows) than do double-transfer versions. The smooth surface more successfully reproduced image detail, but an increasing preference for a matt finish encouraged the adoption of Artigue carbon paper, although the crude half-tones limited its use until the 1890s, when roughness of image definition was more appreciated.

By 1875, selective development was being proposed for modifying half-tones. Because the 'development' of a carbon print consisted of soaking it in warm water to dissolve the unexposed areas of pigmented gelatin, longer soaking and local manipulation would remove some of the areas of tone and detail. In the 1890s, pictorial photographers used this method to produce a more 'painterly' effect.

Permanent, non-silver photographs were advantageous at a time when albumen silver photographs were notorious for their instability. As a pigment, rather than chemical, imaging process, the colour and density of the carbon print were highly predictable and not dependent on vagaries of exposure, development, toning, etc.. Carbon was a superior process for reproduction, as it transcribed images without intrusive grain. However, it was time-consuming and labour-intensive, being only practical in commercial production when economies of scale could be realised, as at Adolphe Braun's pigment printing works, which were the largest in Europe. Braun published art reproductions from 1866, and improved the process, using finer pigments in a wider range of colours to approximate more closely the hue and tonal range of the original works of art.

Few photographers had the time or space to make their own carbon prints, but a number of companies printed to order. In 1867, Mawson & Swan advertised carbon prints of photographs by Francis Bedford and Valentine Blanchard, and by 1874, P. & D. Colnaghi were selling carbon editions of Julia Margaret Cameron's photographs. Exceptionally, James Craig Annan produced carbon prints of his own photographs (exhibited 1896), an endeavour facilitated by his family's printing works (his father, Thomas Annan, established T. and R. Annan).

CARBUTT, JOHN (1832–1905)

American photographer and manufacturer

John Carbutt, landscape photographer and Philadelphia photographic manufacturer, was born to mason Robert Carbutt and wife Ann on 2 December 1832 in Sheffield, England. Pioneer photographer of the American West, inventor, and innovative manufacturer of dry plate and X-ray technology, Carbutt began his trade as a field photographer for the Grand Trunk Railway in Canada during the mid 1850s. From 1861 to 1868 he operated a photographic studio in Chicago where he issued stereographs of the frontier and newly constructed railroad infrastructure between the Mississippi River and the Rocky Mountains. In the 1860s he experimented with magnesium light, the portable dark tent, the solar camera, and woodburytypes, which he manufactured

commercially as the Superintendent of the American Photo-Relief Company in Philadelphia in 1870. Beginning in the 1870s Carbutt became the president of professional photographic organizations including the Photographic Society of Philadelphia (1875), the Photographer's Association of America (ca. 1879), and the Dry Plate Manufacturing Association (1884). In 1879 he introduced the first commercially successful dry plates in America, followed by the first orthochromatic dry plates in 1886. In 1895, Carbutt began to experiment with and manufacture X-ray plates to reduce the exposure time for radiography. On 26 July 1905 Carbutt died, following several years of poor health, possibly as a result of his X-ray experiments.

LINDA WISNIEWSKI

CARD PHOTOGRAPHS: MINOR FORMATS

Card photographs are comprised of paper photographic prints pasted to a larger sheet of cardboard, often called a card or mount. The majority of 19th century paper photographs were card photographs, and they were popular into early 20th century. Card photographs come in a variety of formats. The different formats often resemble each other, but differ in size of mount. There is wide variety of lesser known and often obscure formats. Some of the most obscure formats were marketing gimmicks. Many card photographs come with the photographer's stamp on the back and/or front. The majority of 19th century card photographs used albumen prints, though other types of prints will be found. Most 20th century card photographs were gelatin-silver prints. Most of these were standard commercial formats, marketed to photographic studios.

The United States Library of Congress catalogs the following listing as some of the more common card photographs. Many other formats can be found, including unique designs made by a photographer. The listed size is for the card and not the photographic print which usually will be smaller.

- Cigarette card—2¾ × 2¾ in.; 7 × 7cm. Popular era, 1885–1895. To promote sales, cigarette cards were inserted in boxes of cigarettes and other tobacco products. The photographic print was albumen and usually is the same size as the mount and depicts popular subjects including actors, athletes and other celebrities. They will also contain advertisement for the tobacco brand. In addition, there were cigarette cards that were non-photographic, most often printed with colorful lithography.
- Kodak card—4¼ × 5¼ in.; 10.8 × 13.3 cm; 1880's (photograph is circular). These were the first Kodak 'snapshots'
- Boudoir card—5½ × 8½ in.; 14 × 21.06 cm; 1890's
- Swiss card—6½ × 2.85 in.; 16.5 × 7.3 cm
- Imperial Cabinet Card—7 × 10in.; 17.8 × 25.4 cm; 1890's. The Imperial Cabinet Card became most popular in the early 20th century.
- Promenade card—7½ × 4 in.; 19 × 10.2 cm
- Paris card—9¾ × 6¾ in.; 24.8 × 17.1 cm
- Panel card—13 × 7½ in.; 33 × 19 cm

After 1906 mounted photographs were still made and were in a variety of sizes, but there was no longer the standardization of sizes or names.

CARJAT, ETIENNE (1828–1906)

Like numerous other photographers, Etienne Carjat's (1828–1906) entry into photography was through caricature. A fascination with celebrities and physiognomy in nineteenth-century France greatly contributed to the overwhelming popularity of the art of caricature. Daily and monthly journals were filled with portraits of political and cultural leaders, often with enlarged heads and small bodies. Though altered, these figures were recognizable by the humorous emphasis on carefully selected, exaggerated physical attributes. Carjat began creating caricatures of the actors of the Parisian theaters in the 1850s, turning his passion for the theater into a lucrative enterprise. In 1854 he published a series of lithographic caricatures representing the principal actors of Paris. The first installment appeared under the name *Le Théâtre à la Ville*. Each image was accompanied by an amusing quatrain. Carjat later reproduced these caricatures as cartes-de-viste and the photographer Pierre Petit reproduced the same images in a larger format.

Experiencing a good deal of success with his caricatures, Carjat chose to abandon industrial design. He began to create illustrations for *Presse Théâtrale* and founded the journal *Diogène Portrait et Biographies Satiriques des Hommes du XIXième siècle* with his friend Amédée Rolland. Appearing each Sunday from August 20, 1856 to April 26, 1857, the double-paged sheet was illustrated with a portrait which was accompanied by a biography. He often used the photographs

of A.A.E. Disdéri and Mayer & Pierson as study tools for his caricatures. Carjat established a solid reputation as a caricaturist after spending extended periods of time between 1855 and 1861 in the south of France in Lyon, St. Etienne, Marseille, and Eaux de Bade. Many of his caricatures were published in the Marseille newspaper *Phocéen* as well as in the revived *Diogène.* Despite his success, he was often in financial trouble, consistently losing his money at the roulettes.

Carjat returned to Paris in 1861 and on December 1, 1861 he published the first issue of a weekly journal called *Le Boulevard*. With a more literary formula than *Diogène*, it included a Parisian column, an ongoing story in installments, a musical column, and a gossip column. The journal was in a folio format of eight pages illustrated by two large portraits. Collaborators on *Le Boulevard* included many of the luminaries of Parisian culture including Charles Baudelaire, Gustave Flaubert, Victor Hugo, Champfleury, Jules Verne, Léon Claudel, and Honoré Daumier. *Le Boulevard* challenged the government's tolerance for criticism, particularly when it published extracts of Victor Hugo's *Les Misérables* between April 6 and July 6, 1862. The last issue came out on June 14, 1863 covered in black, a symbol of mourning. Carjat was financially ruined by the demise of *Le Boulevard*.

Around the same time that he founded *Le Boulevard* Carjat also opened a photographic studio at 56, rue Laffitte where he was to remain until 1865. He had previously apprenticed in Pierre Petit's studio in his branch in Stephanienbad and had practiced photography in Baden. Focused entirely on portraiture, Carjat broke with several established photographic practices of the time. Firstly, he worked on his own without the aid of assistants. He sought to show his subjects in natural poses and did not use numerous props such as tables, columns, ottomans, or prayer stools. He did make some exceptions for women who he would often show leaning on a table or seated in a chair, but with very few accessories. Carjat, along with Nadar, was one of the first photographers to use collodion before the process became massively commercialized. Producing cartes-de-visite and larger format portraits, he stuck to a rigorous composition for his photographs. The image would stop at the knees in order to highlight the subject's face and expression. The sitter generally faced the camera directly adding to the intensity of the image. Carjat's various enterprises were frequently interrelated. For example, he began advertising his photographs at special prices to subscribers of *Le Boulevard* in its very first issue.

Carjat chose not to photograph the bourgeoisie which was a very powerful and willing market for photography. Rather, he photographed painters (Gustave Courbet, Jean Baptiste Camille Corot), sculptors (David D'Angers), poets (Charles Baudelaire, Paul Verlaine, Arthur Rimbaud), writers, (Victor Hugo, Emile Zola)) politicians (Léon Gambetta, Jules Grévy), doctors, journalists, actors (Frédérick Lemaître, Rossini, Dubureau fils) and actresses (Adélaide, Sarah Bernhardt), as well as members of the *demi-monde.* Many of his subjects were his friends who frequented his studio, a favorite social gathering place known for its momentous parties. A number of Carjat's portraits were published in *La Galerie contemporaine*, a publication that focused on the most celebrated personalities of the time. Another aspect of his body of work were a series of the Communards of 1870 in their uniforms. Though Carjat does not seem to have participated in the 1870 Commune, he does appear to have aligned his sympathies with the Communards, helping a number of them and their families after the uprising.

Carjat enjoyed some public recognition through the exhibition of his photographic work. He submitted works to the Marseille Photographic Society exihibition of 1861 as well as to the London 1862 International Exhibition where he was awarded an honorable mention. His work at the 1867 Paris Universal Exposition was awarded a bronze medal. He also exhibited in London in 1861, in Paris in 1863 and 1864, and in Berlin in 1865.

Like his journalistic endeavors his photographic business had great ups and downs. His business at 56, rue Laffitte was dissolved on March 1, 1864 and reconstituted on July 14, 1864. He was forced to declare bankruptcy in June 1865 and sold the business. He perservered nonetheless and set up new studios at 62, rue Pigalle (formed in 1866 and dissolved in 1869) and then at 10, rue Notre Dame de Lorette (from early 1870 until the late 1870s). Carjat continued to write articles and poetry which were published in *La Gazette de Paris*, *Le Figaro*, *L'Evènement*, and *Le Nain jaune*, among others in the last decades of his life. He published a book of poetry entitled *Artiste et citoyen.* He died in 1906. A large body of his work was inherited by his daughter who bequeathed it to a Mr. Lemary who sold it to a Mr. Roth in 1923. Much of his work, the glass plate negatives, in particular, have been lost or destroyed.

CAROLYN PETER

Biography

Etienne Carjat was born on 1 April 1828 in L'Ain in the village of Fareins. The son of a concierge and an employee at a silk factory, Carjat moved with his family at age ten to Paris. His artistic education was comprised of three years as an apprentice for industrial designers of carpet and wallpaper under the direction of a Mr. Henri at the Cartier silk factory where his mother worked. As a young man Carjat took a great interest in the theater often spending his Sundays frequenting the

Parisian theaters. He performed in comedies at l'École Lyrique de la Tour d'Auvergne, but reportedly did not show a great deal of talent. He also wrote two dramas, *Le Pêcheur d'Amalfi* and *Les Martyrs de l'Autriche*. He took up caricature in the 1850s, illustrating figures of the Parisian theater world at first. His reputation grew and he enjoyed enough success that he was inspired to found several journals including *Diogène* and *Le Boulevard* which combined caricature with literature and cultural and political gossip. His interest and involvement with photography was a natural evolution from caricature. He opened his first studio in the early 1860s. His photographic work was exclusively portraiture in carte-de-visite and larger formats, focusing on figures in his circle such as writers, artists, and actors. He also photographed well-known political figures as well as the Communards of 1871. Though he gave up photography in the late 1870s, he continued to write articles and poetry until the end of his life. He died in 1906. The location of much of his photography is untraceable after being sold to a Mr. Roth in 1923.

CARRICK, WILLIAM (1827–1878)

Professional photographer

William Carrick, known in Russia as Vasiliy Andreevich Carrick, was born on the 31st of December in 1827 in Edinburgh, Scotland, into the family of a merchant. His father purchased wood from Russia and so due to business necessities, the family moved to Kronshtadt in 1828. Carrick spent nearly all his life, from his childhood, in Russia. Upon finishing school in St. Petersburg he entered St. Petersburg Academy of Art. He graduated from the academy in 1850 with and art degree. Among his teachers in the academy one could name Alexander Broullov, Karl Broullov's brother, and other outstanding Russian artists.

In 1853 he left Russia for Rome to continue his artistic education. In 1856 Carrick returned to Russia. This was the moment of strained circumstances for his family due to his father's death and because of some unsuccessful financial plans the family carried out in the course of Crimean War. Carrick was faced with the problem of having to choose the field of work that would allow him to provide for his family.

In the 1850s there were a lot of photographic studios in St. Petersburg as well as in other towns all over Russia. It was caused by Andre Disderi, a French photographer, who started to make cartes de visite, and since then demand for the photographs soared. Photography became not only a fashionable but also a profitable business.

Carrick made up his mind to become a professional photographer and in 1857 he left for Edinburgh to study the technology of photography. There he became acquainted with the photographer John McGregor, who became his associate.

In 1859 they open a photo-studio on the upper-floor of a building in Malya Morskaya street in the center of St.Petersburg. Carrick started by making photographic portraits and thus gained experience with the technology of studio photography. In 1860, Carrick started to make photo-reproductions of works of art. He worked out a unique technology of a more exact reproduction of a coloured image in black and white. For that he used specially developed photographic emulsion. He made reproductions of paintings by the Academy of Arts graduates, which were then sold in St. Petersburg.

After a while he became interested in making photographs of village and city inhabitants especially those belonging to the lower social classes. For the traditional, patriarchal society of Russia where serfdom was abolished only as recently as 1861, the topic of peasantry had a key position in the works of prominent and progressive men of art. The image of a peasant could be found in literature, music, and painting. One would encounter the peasant in the works by Alexander Pushkin, Ivan Turgenev, Mikchail Glinka, Alexei Koltsov and many other outstanding figures in Russian culture. The image of common people was tackled by a Russian artist Alexei Venetsianov who looked for the harmony in the beauty of traditional ways of living and the beauty of Russian nature. The followers of Venetsianov even formed a trend in the Russian paintings of 1830–40s; they introduced into painting the characters of town handicraftsmen, peasants, etc., by providing the viewer with an insight into the way such people lived.

The technical restrictions of wet collodion outdoor

photographic process at first made Carrick confine himself to working in a studio. He made photographs of various city types, staging scenes of folksy lives in St. Petersburg. In particular, since 1860 he made photographs of water-carriers, haberdashery salesmen, carriers, etc. As time passed, Carrick started to work in the streets of St. Petersburg and its suburbs, which turned out to be a rehearsal for future trips abroad. In 1862 he made a series of ethnographic cartes de visite "Russian Types." He received for this series, as a present from Tsarevitch Nikolai, the son of emperor Alexander II, a diamond ring. This success made him and his studio very popular.

Carrick never stopped making ethnographic photographs as he saw in such kind of works an independent artistic value. In 1871 he made a trip to Samara, Simbirsk and the Saratov regions where he concentrated on life scenes of the peasantry. There he carried out a large-scale ethnographic photographic session. 1872 was a year of hard blows to Carrick for in this year McGregor, his associate died.

In 1875 however he already made another long trip with his new assistant. He traveled over Yaroslavl, Tver, Kostroma, and the Kazan regions all the way down the Volga river, and up to Nizhni Novgorod. Carrick's photographs reflected the way of life for Russian peasants in their natural setting however, Carrick always remained an artist in his work. He created artistic compositions by means of choosing the landscape, vantage point, and arranging the ethnographic groups. Carrick recorded not the dramatic social conflicts, but the true poetry of the Russian village and the Russian nature. Still, his staged scenes contain the traits of peasant's life, which makes his material a valuable source of ethnographic and social information.

In the course of his trip Carrick made over 800 photographs. The bulk of these works were purchased by the Public library following the initiative of a prominent art critic and historian Vladimir Stasov. The latter distinguished in these works a most valuable source of culture-specific material. Stasov created a collection of photographs by different photographers, including Carrick, in the Public library and then he gave the genre-specific photographs to artists for them to use as images to paint.

In 1872 Carrick's works won a silver medal at the Polytechnic exhibition in Moscow, and in 1873 Carrick exhibited his works at an international exhibition in London through the first appearance of the fifth department of the RETS. In 1876 Carrick was awarded the title of Academy of Arts photographer. Then in 1878, he died suddenly in St. Petersburg.

Creative works by Carrick were highly regarded by his contemporaries. It was written in his obituary that one of the most outstanding Russian photographers had died. Even the outstanding figure in photography, Vyacheslav Sreznevsky, believed that Carrick's works were there to prove the true meaning and the true idea of photography. Today we can say that he was one of the first to begin the development of the ethnographic fundamentals of photography through his images of the life within Russian villages. His creative legacy laid the basis for publicist reports on rural life, similar to those of Maxim Dmitriev's.

Today it is obvious that the main interest and theme of the Russian peasant in the Russian culture is being revived. In 2005 the State Russian Museum organized important exhibitions in Moscow and in Saint-Petersburg entitled the Peasant World in Russian Art, where the objects of painting, sculpture and decorative arts were presented. Carrick's work was an integral part of this cultural heritage of Russia.

ALEXEY LOGINOV

Biography

William Carrick was born on the 31st of December in 1827 in Edinburgh, Scotland. In 1828 the family moved to Kronshtadt. He graduated from the academy in 1850 on receiving an art degree. Since 1853 and up to 1856 continued his artistic education in Rome. In 1857 he left for Edinburgh to study the technology of photography. There he became acquainted with a photographer John McGregor, who later became his associate. In 1859 they opened a photo studio in St. Petersburg. Carrick made reproductions of paintings by the Academy of Arts graduates.

From1860 Carrick made studio portraits of city types staging some scenes from the life of the peasants in St. Petersburg, often photographing water-carriers, haberdashery salesmen and others. In 1862 he made a series of ethnographic photographs "Russian Types" the size of a business card. In 1871 he made a trip to Samara, Simbirsk and Saratov regions where he conducted a large-scale ethnographic photographic tour. In 1872 Carrick's works won silver at a Polytechnic exhibition in Moscow. In 1876 Carrick was awarded the title of Academy of Arts photographer. He died suddenly in St. Petersburg in 1878.

CARTE-DE-VISITE

The *carte-de-visite* was one of the most popular photographic formats of the nineteenth century. It consisted of small portrait photograph, around 9cm by 6cm, pasted onto a slightly larger piece of card. *Carte-de-visites* derived their name from the fact that their size gave them the appearance of a visiting card, a purpose for which it was rarely, if ever, used.

The advent of the *carte-de-visite* in the late 1850s was keyed into photography becoming a public and a commercial media. It was a format ideally suited for the dissemination of celebrity images and for the collection of pictures of friends and family in photograph albums.

There is no single origin for the *carte-de-visite*. Sir David Brewster claimed that the idea originated with the Duke of Parma in 1857, who had his portrait gummed onto his visiting cards. However, as early as 24 August 1851, a humorous article in *La Lumiere* included a suggestion by Louis Dodero, an enterprising Marseilles photographer, that photographs could be placed on engraving calling cards. A similar suggestion also appeared in the American *Practical Mechanics Journal* in 1855, while Hugh Welch Diamond claimed that he used a comparable format to present an equestrian photograph to Queen Victoria in October 1852.

The *carte-de-visite* was patented by the French photographer, André Adolphe Eugéne Disdéri, on 27 November 1854. The terms of his patent emphasise the commercial impetus driving the invention of the *carte*; "In order to render photographic prints practical to commercial needs, it would be necessary to diminish greatly the cost of production, a result which I have obtained by my improvements" (Patent no. 21502). Instead of one large collodion plate being used for a single photograph, the ingenuity of Disdéri's design was that it he exposed ten images on one plate. Each individual *carte* was hence reproduced at a fraction of the cost previously incurred for one full-plate picture. Having ten pictures upon one plate also dramatically increased the potential to reproduce a large number of pictures in a short space of time, a significant factor in being able to supply a large consumer market.

Disderi's original patent was slightly modified after eight images was found to be a more practical number. In March 1860, a Parisian optician, Hyacinthe Hermagis, constructed a four lens camera that became the standard equipment used for *carte* portraits. The common rate charged in France was 30F for 25 cartes with two poses, 50F for 50 cartes with three poses, and 70F for 100 cartes with four poses. In Britain, top quality celebrity *cartes* during the 1860s sold for around 1s6d.

Deveria, Jacques-Jean-Marie-Achille or Charles-Theodule. Portrait of a Boy.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

The rise of the *carte* was instrumental in turning photography into a mass medium. It also helped to dramatically increase the number of photographic studios. A rage for cartes caught on in late 1858 in France and quickly spread to the rest of Europe. With the pleasure of seeing photographs of family, friends and celebrities, often for the first time, collecting cartes became the latest social fashion. In October 1861, the *Art Journal* compared the collection of *cartes* to an *ad infinitum* multiplication of national portrait galleries because they were able to be collected in "an unlimited range and in every possible variety—family-friends, collections of the portraits of friends, and of celebrities of every rank and order, both foreign and of our own country." Cartes constituted and expressed a collective identity, integrating public figures into the intimate arena of individual subjectivity.

The format of the *carte* was important in conditioning its appeal and ensuring its assimilation into everyday life. Small, ephemeral commodities which were widely available, easy to hold, easy to pass around, easy to look over by the dozen within a drawing-room, *cartes* possessed little distinction in themselves. They were

literally "touchy-feely" artefacts; not to be looked at with deferential awe or revered from a distance but catalogued and collected, gossiped and commented upon. The carte-de-visite had a distinctly egalitarian aesthetic. As the *Reader* put it in its edition of 9 August 1862, "Here there is no barrier of rank, no chancel end; the poorest carries his three inches of cardboard, and the richest can claim no more."

One of the most notable features of *carte* portraits is their uniformity of representation. Most contain a full-length single figure, posed inside a studio using a number of stock props and gestures. This uniformity stems from the fact that the artistic conventions initially used for picturing aristocratic sitters were imitated endlessly. Studios serving high society sitters were often sumptuously decorated, using genuine *objet d'art* for their props. Alongside such ornateness, however, a whole industry grew up in order to provide the majority of studios with cheap wooden balustrades and papier-mache adornments.

The expansion in the number of photographic studios resulted in numerous articles satirising the social performance of carte portraits. For some critics, there was a disjunction between the working-class class status of those sitting for their carte and the fine art conventions that were being used to represent them. The most notorious of these was the stereotyped false background:

> There is Mrs Jones, for instance, who does the honours of her little semi-detached villa so well: how does she come to stand in that park-like pleasure-ground, when we know that her belongings and surroundings don't warrant more than a little back-garden big enough to grow a few crocuses? Or Miss Brown again, why should she shiver in a ball dress on a veranda, and why should we be called upon—instead of looking at her good honest face—to have our attention called away to the lake-like prospect at her back? (Andrew Wynter, "Photographic Portraiture," *Once a Week* 6 (1862) 148)

The carte studio was as much a space for fantasy as it was for unadorned realism. *Cartes* were a pleasurable opportunity for posing and theatricality. Signs of labour and occupation were often discarded in favour of refined bourgeois poses. For many sitters, the pleasure of the *carte* was not in its realism but in its ability to enact a magic-grotto like transformation.

Cartes were produced in immense volumes during the last four decades of the century. However, they were fashionable only until the mid 1860s, when they were superseded by the introduction of the larger cabinet portrait. After reputedly being the richest photographer in the world, making £48,000 in 1861, Disderi himself was declared bankrupt in 1872.

CASED OBJECTS

The cased portrait predates photography, and the adoption of the leather case for the presentation of early daguerreotype portraits may be seen as the infant photographic art seeking to present itself in a format traditionally associated with the miniature painting. Photography therefore exploited a case-making industry which was already established, albeit on a small scale, and adopted the sizes, formats and styles of the cased miniature portrait painting.

The cased photographic portrait enjoyed widespread popularity in the United States and Great Britain, with limited popularity in South America and mainland Europe, particularly France. The frame—the alternative to presentation in a case—enjoyed widespread popularity in Europe despite the difficulties associated with viewing a framed daguerreotype. The case enhanced the perceived value of the photographic portrait by emulating a miniature painting, and by preserving the intimacy of the portrait it contained.

The evolution of the case from being a bespoke item produced for a very small and exclusive market—the painted portrait miniature—to a mass-market commodity brought with it standardization, mass production, and the development of entirely new materials. Standardization of camera formats introduced the fractions of full plate sizes that became universal—from whole plate down to 1/16th plate—and case manufacturers followed suit. In addition to the traditional morocco leather coverings, fabric covered cases—especially velvets—achieved some popularity. As alternatives to covered wood-framed cases, papier maché, mother-of-pearl, pressed metal and thermoplastic were all widely used in case manufacture. In Japan and China, plain uncovered wooden cases were available. Portraits presented in

lockets, brooches, watch cases and other enclosures—often also containing a lock of the subject's hair—were also highly popular in America and Europe.

While the leather-covered cases used to house miniature paintings were traditionally plain, the growing market for photographic cases brought about additional case decoration. By the mid-1840s, embossed leather cases had been introduced in the United States—by John Plumbe Junior and others. The 1850s saw more heavily embossed case designs, often using lower grade hides, as market pressures drove down unit prices. Later, embossed paper-covered cases achieved widespread popularity at the lower end of the market.

While it is only to be expected in the later era of mass-production that many of the cheaper cases bore no maker identification, it is more surprising that the majority of early casemakers are also unknown. Some makers and engravers can be identified. In America the names of Matthew Brady, Benjamin True, Harold Eichmeyer, David Pretlove, John Smith, and others can all be found on labels or embossed discretely in corners of cases, and in Britain cases made by Thomas Wharton of Birmingham have also been identified. From contemporary advertisements several more makers are known, of whom Edward Anthony of New York wasprobably the largest. As most did not identify themselves on their cases, the scale of their operations cannot be estimated.

The brass mats which surrounded the image occasionally bear their makers' names, and were sometimes patented. Elisha Mander of Birmingham, England stamped his name even on low quality foil mats. The surrounding brass frame which held image, mat and cover glass together bear no maker identification.

Thomas Wharton's English design for a mat and preserver pan dates from the early 1840s enabled a small portrait image to be presented in a larger case. It was an early example of manufacturers using recently introduced design registration to protect their ideas. The back of Wharton's embossed metal preserver pan bears the British Royal Coat of Arms, registration No.791 and a date of August 24th, 1841.

Case manufacturers offered an embossing service which stamped the photographer's name and address in gold on to the outside of the case. Others impressed the information into the velvet cushion pad on the left side of the opened case, or stamped it on the bottom of the brass mat. Relatively few photographers availed themselves of this facility, and the majority of leather, paper and papier maché cased images remain as anonymous as the makers of the cases which contain them.

The portrait case represents the first and most significant attempt to market the photograph as a precious object by adding to its perceived value, and in so doing the nineteenth century casemakers were quick to recognize the potential of new materials. Foremost amongst these was the use of thermoplastic to mould elaborate decorative cases. Pioneered by onetime photographer Samuel Peck in the early 1850s, the thermoplastic case industry grew rapidly.

Unknown Maker, American. Herdsman with Cox.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

The world's first significant use of plastics, the union case married the Victorian industrial ingenuity to the presentation of the photographic portrait. Over one thousand different designs of thermoplastic case have been identified, and are as worthy of the historian's interest as the images they contain.

Union cases were predominantly American in origin, the majority of makers located in and around Connecticut. Major makers were Samuel Peck and Company, A P Critchlow, Holmes Booth and Hayden, and Wadhams Manufacturing Company. Amalgamations brought about larger groupings such as Littlefield Parsons and Company and the Scovill Manufacturing Company, the latter also being involved in the production of daguerreotype plates.

In Britain, thermoplastic button-maker John Smith produced a small range of cases, expanded by his successors James and Edwin Gyde. Available from whole plate down to 1/16th plate, the majority of union cases were produced in the popular 1/9th and 1/6th plate sizes. Most bear a maker's label, and several have the die-engraver identified within the design.

Union cases designs include geometric motifs, floral motifs, scenes from American history, from the Bible and legend, and reliefs based on popular art and sculpture. Die engravers included Frederick Seiler, Frederick Key, Smith and Hartmann, Hiram Hayden, but many examples of the engraver's art are not identified. In Britain, John Smith's cases were made from dies engraved by Brookes and Adams of Birmingham.

A small number of cases were produced for the paper carte-de-visite print, but the low cost of the image did not warrant the high cost of the case. By the mid-1860s, the cased portrait was in decline and the family album was in ascendancy.

CASLER, HERMAN (1867–1939)

Motion picture inventor, engineer

Born at Sandwich, Illinois, March 12, 1867. Married Fanny Ehle. 1893 patented the Photoret novelty camera. With Elias Koopman, Harry Marvin, and W. K.-L. Dickson, Casler founded the KMCD syndicate (an informal group), and later in 1895 the American Mutoscope and Biograph Company. Seeking to design a competitor to Edison's peepshow Kinetoscope, they developed the Mutoscope, the flip-photo coin-operated machine that would be a popular feature of amusement arcades for decades. Casler filed the Mutoscope patent November 21, 1894. A camera, the Mutograph, was also developed, and—as the peep-show business was unlikely to be sufficiently profitable—a film projector too; the Biograph. Casler was involved in the design and development of all of these machines. He was also patentee of a version of the kinora domestic flip-photo motion picture viewer, on which he had a patent agreement with the Lumières. In 1896 he formed, with Harry Marvin, the Marvin and Casler Company of Canastota for the production of motion picture, arcade, and drilling machines. He continued in engineering until 1926. Died Canastota, New York, July 20, 1939.

STEPHEN HERBERT

CELEBRITY AND ROYALTY

One of the most notable consequences of the commercialisation of photography during the late 1850s was the advent of the celebrity picture. In both Europe and North America, the *carte-de-visite* heralded an unprecedented dynamic between mass culture and photography. Favourite politicians and actresses, kings and queens, and, later, well-known sportsman; it was the advent of the *carte-de-visite* that made celebrity photographs available in large numbers. They created a popular broadening of the public sphere and exacerbated the expectation that well-known figures would have a publicised existence.

Celebrity photographs had both an individual and collective agency. They were notable for their collective agency because, through their widespread circulation, they went beyond the scope of other graphic media like wood-engraving and lithography. Their ubiquity helped to provide a collective experience of any one individual. Thus, for example, photography was instrumental in creating the familiar and iconic image of Queen Victoria in her widow's weeds. Significantly though, celebrity photographs were also notable for the intimate relationship they generated between individual consumers and well-known figures. The collection of celebrity photographs helped to reinforce an individual's sense of themselves as belonging to an imagined national community. Compared to existing graphic media, the lens of the camera proffered a more authentic and affective relationship with the distinguished sitters so depicted.

In Britain, the first attempts to publish photographs of famous figures took place in the second half of the 1850s. One notable venture was that by Maull and Polyblank, who published a series of *Photographic Portraits of Living Celebrities*. The first issue appeared in May 1856, and the series was subsequently published in monthly instalments up to October 1859. Each issue included a mounted albumen print, 19.5 cm × 14.5 cm, accompanied by a biographical notice. Maull and Polyblank's publication set the format for

many European publications. Other series include Ernest Edward's *Portraits of Men of Eminence in Literature, Science, and Art* (1863–67), Disdéri's *Gallerie Des Contemporains*, and the *Album der Zeitgenossen (Album of Contemporary Figures)*, which was started in 1860 by two Munich photographers, Alois Löcherer and Franz Hanfstaengl.

A second significant type of early celebrity pictures was the reproduction of portrait photographs as engravings. From the early 1850s, journals like the *Illustrated London News* regularly used daguerreotypes as the basis for portrait engravings. When the *Illustrated News of the World* commenced publication in January 1858, alongside its graphic news it printed the *Drawing Room Gallery of Eminent Personages*. These were portrait engravings by D.J. Pound after photographs by John Jabez Edwin Mayall, accompanied by short biographical sketches. Included in the series were Queen Victoria and Prince Albert, Lord Stanley and Charles Dickens. Celebrity images were thus photographic well before they were constituted wholly through photographs.

Celebrity portraiture in America followed a similar path in that the 1850s saw attempts to create national galleries and to utilize engravings of photographs. Matthew Brady was the key figure in these early efforts to promote the images of distinguished national personages. In 1844, Brady opened his Daguerrian Miniature Gallery at 205–207 Broadway, Fulton Street, with another studio opening in Washington in 1849. Despite the non-reproducibility of the daguerreotype, in 1850 Brady published his *Gallery of Illustrious Americans*, a series of twelve lithographs of famous Americans made after daguerreotypes. Subjects included Zachary Taylor and John James Audobon. Brady's portraits won a Gold Medal at the Great Exhibition of 1851, and he continued to take photographs of distinguished personages. In 1857 *Harper's Weekly* published its first engraving of a portrait taken by Brady. In 1860 Brady famously photographed the Republican presidential candidate Abraham Lincoln, a picture that *Harper's Weekly* subsequently translated into a full-page front-cover woodengraving. In the same year, Brady also photographed Edward, Prince of Wales, on his highly successful tour of Canada and the United States. With the advent of the fashion for *carte-de-visites* in the early 1860s, E. & H.T. Anthony began to distribute large numbers of Brady's photographs.

One reason that the *carte-de-visite* marked the meteoric rise of the celebrity photograph is that it was reputedly only when photography became sufficiently flattering that distinguished personages were prepared to let their pictures enter public circulation. In 1861, the *Saturday Review* claimed that, prior to the *carte,* photography had distorted and exaggerated the prominent features of the face to the extent that celebrities had not been prepared to let themselves be revealed in such unflattering guises. As an article in the *Quarterly Review* put it in 1864, "it gives you a kind of panoramic view of your friend, and gives a prominence to his best coat and trousers, which cast his features into the shade"("Photography," *Quarterly Review* 116 (1864, 516).

A key figure in the popularisation of celebrity photographs in Europe is the Parisian photographer André Adolphe Eugéne Disdéri. By 1857, Disdéri had begun amassing portraits of the French royal family and its entourage. His photographs of Napoleon III and Empress Eugenie helped to start the fashion for celebrity *carte-de-visite*, which became cultural phenomena across Europe and North America. Between 1860 and 1862, Disdéri published two one franc instalments each week of a *carte-de-visite* portrait accompanied by four page biographical sketch.

Photographs of the various European monarchs and their families were amongst most successful celebrity pictures. Disdéri's published portraits of Napoleon III and Empress Eugenie may well have provided a reassuring model for the publication of photographs of the British royal family as, in August 1860, Mayall was permitted to publish his *Royal Album*. It was not until Manchester Art Treasures exhibition in 1857 that photographs of the British royal family had been officially shown in public for the first time. And, while royal photographs had been shown at subsequent exhibitions of the Photographic Society, these pictures had a singular existence and were neither for sale nor reproduction. Mayall's *Royal Album* was a wholly different kind of venture and was a phenomenal commercial success. Between 1860 and 1862, 3–4m copies of Queen Victoria's *cartes* were claimed to have been sold. Photographs of monarchs such as Napoleon III and Queen Victoria helped to promote the image of a patriotic and bourgeois royal family. A photograph of the young French Prince Imperial, for example, shows him dressed in a military outfit, wearing a hugely oversized busby and carrying a drum. These is a similarly loyal *carte* from 1860 of the future Kaiser Wilhelm II; a photograph by L. Haase, entitled "Little Willy's First Salute," shows the infant Prince saluting the camera.

With the pleasure of seeing photographs of well-known personages for the first time, collecting celebrity *cartes* became the latest European fashion. In October 1861, the British *Art Journal* compared the collection of diverse *cartes* to an *ad infinitum* multiplication of national portrait galleries. Celebrity photographs integrated well-known figures into the intimate arena of individual subjectivity. The *Art Journal* specifically drew attention to the importance of the *cartes* of the British royal family through their creation of a shared pattern of experience:

> The production and the reproduction and the diffusion of the *carte-de-visite* portraits of Her Majesty the Queen, and of the various members of the Royal Family, would furnish materials for no ordinary chapter in the history of popular Art. . .Without a doubt they will be required in tens of thousands. They will have to find a way into every quarter of our sovereign's wide dominions, and into every city and town, both at home and in the colonies. . .These royal *cartes-de-visite* leave far behind all other agencies for enshrining our Sovereign's person and her family in the homes of her people. They do for everybody, as much as Winterhalter can do for the Prince Consort himself.
>
> "Cartes-de-visite," *Art Journal* (1861) 306.

By equating the possession of a royal *carte* with Franz Winterhalter's court portraits, the *Art Journal* is eulogising the intimacy of the personal insight that photography offered.

From the early 1860s, the celebrity *carte-de-visite* was an industry with its own London wholesale house, Marion & Co., which stocked thousands of celebrity photographs of every kind. In 1862, their manager claimed that 50,000 *cartes* passed through the firm's hands every month. Forgeries of the celebrity photographs became commonplace and large profits were made out of an immense number of quasi-illegal pictures. Prosecutions took place regularly in the years following the introduction of a revised Copyright Bill in July 1862. Reported cases in the 1860s involved photographs of the Princes of Wales and the Duke of Cambridge. In France, there was a similarly thriving trade in illegal celebrity photographs. Mayer et Pierson, one of most successful Parisian studio of the 1850s, sued Ledot and six other photographers in 1862 for marketing counterfeit *cartes* of the emperor, empress and other notables.

Copyright records of British photographs, which were registered at Stationer's Hall, are a quantitative index to the celebrity photographs in circulation after 1862. Although they cannot reveal the volumes sold of any one photograph, they do record the number of portrait photographs registered of any one sitter. The copyright records emphasise that, especially during the 1860s and 1870s, the supply of celebrity *cartes* was dominated by those of royalty, politicians, artists and the leading clergy. Out of the first 2000 photographs that were registered, between 29 July 1862 and 11 September 1863, 317 contained one or more members of the British royal family, a proportion of just over 15%. Between 1862 and 1900, the two sitters who had by far the largest number of photographs registered for copyright were the Prince and Princess of Wales. Only theatrical figures like Lillie Langtry and Ellen Terry come close to the total number of royal photographs registered.

The prominence of pictures of the various European royal families emphasises the way that the first celebrity photographs were keyed into the existing social

Unknown. Frederick Douglass.

hierarchies. Conversely though, the celebrity *carte* was perceived to be democratic artefact, characterised by an aesthetic of demythologising equality. Partly, this was due to the changing status of photography: a counterpoint to the concern that photography had been debased into a vulgar medium was the claim that it had been democratised into a universal one. Moreover, whereas it was the traditional role of the portrait painter to search after the ideal—and in so doing judiciously flatter the well-heeled sitter—the lens of the camera was lauded for truthfully seeing alike all who sat before it. In an article in *Once a Week* on the superseding of the miniature portrait by the photograph, one commentator sardonically commented that, "Tompkins of Hopkins may submit to go down to posterity as livid, corpse-like personages; but the Lady Blanche or the fair Geraldine forbid it, Oh heavens!" In imposing the unadorned realism of its technological format upon its sitters, the camera had a demythologising effect upon its celebrity sitters.

The equalising nature of the celebrity photograph also stemmed from its status as a circulating commodity. In a second article in *Once a Week*, Andrew Wynter compared the National Portrait Gallery, with its reclusive opening hours of only three days a week, to the accessibility of the street-portrait galleries of any photographic establishment:

> Certainly our street portrait galleries are a great success: no solemn flight of stairs tends to pompous rooms in which pompous attendants preside with a severe air over pompous portraits; no committee of selection decide on the propriety of hanging certain portraits. Here, on the contrary, social equality is carried to its utmost limit, and Tom Sayers is to be found cheek-by-jowl with Lord Derby, or Mrs Fry is hung as a pendant to Agnes Willoughby. The only principle governing the selection of the *carte-de-visite* portraits is their commercial value, and that depends upon the notability of the person represented.
>
> (Andrew Wynter, "Cartes de Visite," *Once a Week* 6 (1861–1862): 135)

For many reviewers, the democracy of the celebrity photographs was constituted by their unfettered exhibition and circulation. Celebrity *cartes* broadened, albeit slowly, the scope of the public sphere. Photographs of the Queen could be placed side-by-side with working-class icons. The celebrity photograph created a new marker of cultural visibility, one less connected to traditional notions of status and wealth. Thus, at the same time as Disdéri was busy photographing the imperial court, Nadar was taking celebrity portraits of the members of bohemian Paris, many of them friends and acquaintances, including Baudelaire, Gautier, Dore, Dumas, and Sarah Bernhardt.

In Britain, one of the earliest examples of a working-class figure being turned into a celebrity through the aid of his photographs is Tom Sayers. In April 1860, Sayers fought the American champion, John Heenan, in what was effectively a fight for the undisputed championship of the world. Before the fight, Sayers was beset with photographers claiming the honour of paying for his sitting. However, his reported answer was "It's no good, gentlemen, I've been and sold my mug to Mr Newbold" (Newbold was a publisher of one of the sporting papers). 50,000 *cartes* of Sayers were reportedly sold around the time of his fight. Newbold's treatment of Sayers is an early example of how photography was used to allow a working-class figure like Sayers to achieve a populist prominence.

The case of Tom Sayers is paralleled by the situation of General Tom Thumb in America. In the 1860s, in addition to their Civil War work, Brady and his studio photographers continued to take many distinguished figures. One celebrity subject was General Tom Thumb: numerous *carte-de-visites* were taken by Brady's studio to both commemorate and commercially exploit his lavish wedding in 1863. The diminutive Tom Thumb, born Charles Stratton in Connecticut, had been initially discovered and exhibited by P.T. Barnum. However by the early 1860s, Thumb had split with Barnum and organised his own tours and exhibitions, consequently also taking control of the lucrative trade in his *carte-de-visites*. Thumb's decision, like that of Sayers,' epitomizes the growing self-consciousness towards the value of celebrity portraiture.

If the celebrity *carte* was characterised by its proliferation into the drawing room through the photographic album, a corresponding effect of such insinuation was a heightened awareness of the intrusive properties of the camera. The camera was already disreputably associated with a more intrusive form of celebrity. A series of engagement *cartes* of the Prince of Wales and Princess Alexandra, taken in November 1862 by the Belgian photographers, the Ghemàr Frères, exemplify the tension aroused by the camera's double form of permeability. Frères's engagement *cartes* depict the affections of the affianced couple and several of the photographs show Edward or Alexandra standing with their arms resting lovingly on the shoulders of the other. These displays of intimacy were far removed from the formality of a state portrait and were found to be distasteful by some commentators. There was discomfort over having the life of the monarchy constituted to such an extent through the camera. As the *London Review* put it "whether it be joy or grief affecting the royal family, in some way the lens of the camera appears to spy into it in the most offensive manner . . .these sacred feelings are turned to commercial account" ("The Medley of Portrait Cards," *London Review* 20 June 1863: 658).

Although the rage for *carte-de-visite* lasted only until the mid 1860s, photography played an increasingly dominant role in the constitution of celebrity. The advent of photo-journalism helped to exacerbate the spectacle of large public occasions. Increasingly high prices were paid for the rights to photograph celebrities. In 1880, Napoleon Sarony, probably the second most notable American celebrity photographer after Brady, famously paid Sarah Bernhardt $1500 for permission to shoot her while on her tour of America. Sarony was renowned for his portraits of theatrical performers working on the New York stage, and in 1882 was involved in a landmark legal case involving the piracy of a photograph he had taken of Oscar Wilde. By the end of the nineteenth-century, the growth of the popular entertainment industry, in both Europe and America, meant that the celebrity photograph was well-established. The growing ability to reproduce photographs in periodicals and newspapers also meant that these pictures received greater circulation. In the 1890s, for example, the *Strand* had a regular article on "Photographs of Celebrities at Different Times of their Lives." By the time of Queen Victoria's Diamond Jubilee in 1897, the ability of photography to disseminate images of public figures was even officially recognised. An official photographic portrait, taken by W & D Downey, was sanctioned for the first time. The key point about the Diamond Jubilee photograph is that it was deliberately

not registered for copyright, a decision that allowed it to be reproduced on biscuit tins, commemorative plates, mugs and souvenir artefacts of every description. In the Diamond Jubilee photograph, the very lack of official control over the photograph was the way that the iconic figure of Victoria was constituted. In a defining moment for celebrity photography, the media image took over the role of the traditional court portrait.

CENTRAL AMERICA AND THE CARIBBEAN (EXCLUDING MEXICO AND CUBA)

During the first two decades of photography, the daguerreotype and other procedures were employed by explorers and adventurers, most of them Americans and European, who had crossed nearly all political and geographical boundaries in their travels.

They were generally influenced by Alexander von Humboldt, the most relevant scientist devoted to the study of the New World, who encouraged the use of photography as a tool for naturalists and scientists.

Several explorers repeated Humboldt's travels, reaching the places visited by him and Bonpland some years ago, as did the Austrian citizen Emanuel von Friedenthal (1809–1842), who daguerreotyped along the Yucatán peninsula between 1839 and 1841. An exhibition of 25 images from this travel took place in London and Paris in 1841; all of them are today considered lost.

Also noteworthy is the North American archaeologist John Lloyd Stephens (1805–1852) and the English engineer Frederick Catherwood (1799–1854), who explored the maya cities in Guatemala and Honduras. In their second trip, between 1841 and 1842, they took daguerreian views of the extant ruins of the palaces of Copan, acheiving success with only few of their images.

Robert M. J. Douglass (1809–1887), an African American itinerant daguerreotypist, visited the main Antillian islands in 1847. Afterwards he made trips through several countries of Central America, and finally settled in the Bahamas in the 70's. Another daguerreotypist, but one of Canadian origin, Thomas Coffin Doane (1814–1896) travelled along the Antillian region between 1844 and 1846. The legendary brothers Ward -Charles and Jacob- from Bloomfield, New Jersey, US, frequented the Caribbean islands between 1841 and 1846, as well as did the Hungarian prince Pal Rosti, who in a private photographic tour visited the U.S., Mexico, Venezuela and Cuba, between 1856 and 1858.

An early photographic documentalist, Claude Joseph Desirée Charnay (1828–1909), who in 1857 visited several countries of Central America and Mexico, recorded in large size plates the ruins of Chichen Itzá and Güija lake (El Salvador), empoying both salt print and albumen techniques.

The French painter and photographer Ernest Charton arrived to Guatemala, Nicaragua and El Salvador from Panamá in 1852, on his way to California. The North American William Buchanan visited the same region, including Costa Rica, first in 1853 and then between 1857 and 1862, recording the ruins of Cartago monastery, the parochial church of Heredia, and the church of Orosí.

Charles DeForrest Fredricks, an American photographer (1823–1894) started his long career in 1846, in Angostura (Venezuela), continuing to Tobago, Saint Vincent, and then Trinidad. After this first voyage he returned sick and without money to the U.S. After recovering, he returned in the pursuit of a destiny of adventure and success.

In 1858 John H. Fitzgibbon another American photographyer (1816–1882) departed for a voyage along Central and South America. He visited El Salvador and Nicaragua, and in 1859 arrived to Guatemala, photographing the just opened Teatro Carrera.

Emil Herbruger, a German Photographer (1820–1890) settled in the U.S. in 1841 and received, in 1843, a prize for his daguerreotypes. He visited the Antilles, El Salvador, Nicaragua, Honduras (Tegucigalpa) and then remained in Guatemala.

A native from the Antilles, Paul-Emile Miot, joined the French Navy and in 1857 organized a photographic lab for the processing of plates taken in several naval expeditions, in Terranova, Senegal, Perú, Chile, Oceanía, Tahiti and the Marquis islands.

Eadweard Muybridge, a North American of multiple interests, travelled to Costa Rica, El Salvador, Guatemala, Nicaragua and Panamá. The result was an exhaustive photographic collection, particularly from Guatemala, where he remained longer.

By the sixties, photography was so popular that all social classes could recognize photographs as identificatory elements. At the same time, albums of views emerged, because of their exotic aspects or documentary value.

Additionally, railroad development often attracted numerous foreigners looking for work in the region, and often carried photographic equipment. Also, engineer workers were documented by their constructors, tus finding a new role for descriptive photography.

In the market of exotic places and images, in which Central America was included, it is worthwhile to mention stereographs. Anthony & Co. sent photographers to several places in the world, and specially to this region. In 1860 George N. Barnard (1819–1902) was comissioned to make a series of stereoscopic views of Cuba.

Later, thousands of stereographs from the region were made, mostly by photographers belonging to American companies. At the turn of the century, however, Brown & Dawson visited the same area, and made views of Martinica, Barbados, Puerto Rico and St. Thomas.

Bahamas

The English photographer Henri Louis Duperly (1840–1908) owned a studio in Nassau in the 70s, under the name "Duperly Brothers."

Bermudas

N.E. Luscher was an itinerant photographer active in the 90s and made views of the main streets in Hamilton. Several publishing houses produced stereoviews of the island, for instance Balch, J.B. Heyl, H.L. Chase, T. Frith and the Kilburn Brothers.

Costa Rica

Santiago Páramo (1841–1915), was an arquitect, painter, sculptor and amateur photographer, and left behind many graphic records of San José and Puerto Limón. Masters of the stereoscopy like F. Albar, L. Fortino and A.S. Taylor produced views by the 70's, which are now extremely scarce. H.N. Rudd and the studio Paynter Bros. were active by the turn of the century and left views of Alajuela and San José as well, and recorded the activities of the United Fruit Co. and the banana and coffee crops.

Curaçao

The daguerreotype period was represented by Frederico Guttich and Senior Hartman, this last one being based in Martinique.

Several travelers were active in this Dutch colony, like Epifanio Bellini (1823–1892) from the Dominican Republic; and the Bostoniano: Thomas Gray, M. Hofman, L.A. Leavitt, Gabriel Salom Landaeta; and the partners Velez & Serralle, who later too moved to Cuba.

Alva Pearsall (1837–1898) visited not only Curaçao but also Jamaica, Guyana and Surinam, as well as John L. Ricker from New York.

El Salvador

Emil Herbruger was based in Guatemala and made periodical trips to the capital city of El Salvador. Between 1870 and 1900, Henri Louis Duperly from England (1840–1908), the French citizen Félix Morin, and the African American photographer Robert M. J. Douglass (1809–1887) were active.

Guatemala

Like in all the entire region, daguerreian pioneers were foreigners. In 1843 the arrival of the French León de Pontelle from México city was recorded. He established a studio in Calle del Colegio. After him, in 1846, Emilio Herbruger arrived, but he soon left the country. Nicolás Fuchs settled around 1847, and then went left, finally returning from 1853 to 1858, to take ambrotypes, melanotypes and photographs.

In 1861 and 1862, the botanist Osbert Salvin recorded indigenous indian groups.

In 1866 Emilio Herbruger returned, as the owner of Hawley & Buchanan studio. Photographer and piano teacher, in 1868 he dedicated his polka *La Unión* to the guatemaltec ladies. The musical score's front page includes a mounted photomosaic of 68 photographic portraits of his pupils. By 1871 he established his studio "*Fotografía Imperial*" in Guatemala.

After Emilio Herbruger passed away (1890), his son Emilio Herbruger junior took charge of the studio, until the beginnings of the 20th century.

During the 60s, the photographers G.A. Hawley and Enrique Seeligman, were active, making stereoscopics as well.

Between 1882 and 1888, travelers such as Sanfred Robinson made photographic registers of remote places, industries, crops, and indian huts.

In 1882 Juan José de Jesús Yas (Japan 1844–1917) opened his studio "Fotografía Japonesa," and then visited Mexico and Peru, returning to Guatemala in 1890. This photographer acted as an interpreter of the Mexican Commision that travelled in 1874, to Japan, in order to observe and take photographs of the transit of Venus in front of the Sun. This visit preceeded a second visit to Mexico, probably during the next transit of Venus, in 1882 and afterwards, he settled in Guatemala.

In 1880 the photographer Emilio Eichenberger was active in 129th Oriente Street. Legrand & Co. was another renown studio at the end of the century.

Haití

The photographer Joseph Henri Besse (Haití 1810–1871), who was sent young to study in Paris, returned mastering the art of photography.

Edmond Laforestiére (1837–1894) also traveled from Haití to Paris, where he became a photographer. Once back to his country, he became an active professional. Barón Colbert de Lochard, from St. Marc, made photographic portraits in the 50s, and J. Wheeler actively produced stereoviews during the 60s, as well as W. Watson in the 70s.

Honduras

Typical itinerant photographers, were Alva Pearsall, active in 1865, J.W. Newland and the German citizen Federico Lessman. All of these photographers were headquartered in Venezuela. In 1883, Alfred P. Maudslay left traces of his work documenting the ruins of Copán.

By the turn of the century, Juan T. Aguirre worked in Tegucigalpa taking views for commercial purposes, and later devoted himself to photomechanical reproductions.

Jamaica

Installed in Kensington near 1878, Ernesto Bavastro made portraits of important Cuban patriots, like the hero Máximo Gómez and some other well known people like Rafael Rodríguez, Enrique Collazo, and Enrique Canals, who moved to Jamaica after the Ten Years War. Bavastro's studio was located in 67 King Street, Kingston. Great quantities of stereoviews were made by several studios, like A. Duperly & Sons, George W. Davis y P. Sarthou, particularly between 1860 and 1870.

Martinique

François Gouraud (1812–1848), from Martinique, studied with Jacques Mandé Daguerre and became a representative of Alphonse Giroux in the island. Senior Hartman was active also in the early daguerrian years, and travelled along the Antilles.

Panamá

Thimothy O´Sullivan, the American photographer (?–1882), participated in the expedition to Darién in 1870, and intended to study a proper location for digging a channel through the istm. He was hired out as an official photographer of the expedition on January 11, 1870, and returned five months after. O´Sullivan did not take enough photographs of the area, due to the adverse climate and the cumbersome operation in the jungle, but nevertheless succeded in documenting the expedition and getting anthropological records of the indians and their huts, as well as in taking views of San Lorenzo y Cartagena. He gathered more than 200 stereos and over 100 glass negatives about the region. In 1871, John Moran followed his steps, getting a larger quantity of stereoviews. When the French engineer Ferdinand de Lesseps was appointed as director of the channel works, professional photographers were sent to document the whole operation, including the landscapes and natives.

Puerto Rico

The French photographer H. Gautier was active in San Juan in the 1870s. He was devoted intensively to the *carte-de-visite* format. His publicity consisted of a curious round label with nice engravings. By the 1890s, in the location of Ponce, worked a photographer named M.C. Gray.

By the end of the 19th century, the vernacular photographer Eduardo López Cepero documented the city of San Juan and its fortresses. The most outstanding photographer during that period however was Feliciano Alonso (?–1901). In 1882 he received a prize in an exhibition that took place in Ponce and in 1893 he was in charge of recording the buildings and activities of the Great Exhibition at San Juan de Puerto Rico. He made two albums of views, which were the *Álbum de Puerto Rico* and *Álbum de vistas fotográficas de Puerto Rico*. He started producing stereoviews when the American occupation occured in 1898.

República Dominicana

The painter Epifanio Billini (1823–1892) was considered the first photographer in the island. Although another outstanding photographer was David Benjamín Benzo (1840–1896), who moved later to Caracas (Venezuela). At the end of the 19th century Abelardo Rodríguez Urdaneta (1870–1933) was active as well.

Trinidad

The French photographer Félix Morin worked in Port Spain during the 1870s.

The "Eureka Art Studio," of J.E. Marshall, at 20 Frederick Street, was active near the end of the 19th century, making portraits and recording popular types and public markets. Later, at the beginning of the 20th century he merged with the new enterprise "Muir, Marshall & Co." This studio produced albums with photomechanical reproductions that were intended as souvenirs from the island.

Conclusions

It is evident that most of the early activity in the region was made by travellers or foreign photographers. Many of them settled down in the different cities, building stronger traditions in each place.

The discovery of exotic places via adventurers was a *primum mobile,* that slowly was replaced by a second wave of photographers who pursued the search for a place that World foster a successful comercial business.

Portraits, as usual, were the main production of these artists, mainly in carte-de-visite and portrait-cabinet formats. Likewise, extant views were mostly in stereoscopic format.

CEYLON (SRI LANKA)

Evidence of photographic activity in Sri Lanka during the first decade of photography is sparse, and it is now unlikely that we will learn when the first photographs were taken on the island. It is known, however, that one S. J. (or possibly S. F.) Barrow, whom the commercial directories place in the island from 1844–49, was active as a daguerreotypist for a period in the mid-1840s. While no examples of his work are known to have survived (perhaps unsurprising in view of the context in which his name appears), an 1850 advertisement placed by John Vanderstraaten in the periodical *Young Ceylon*, claimed to be able to restore the now 'defaced and obscure' daguerreotypes that Barrow had taken (at a cost of between £4 and £10 each) in studios in Colombo and Kandy in around 1844. The high cost of these portraits and their evidently inferior quality, may go some way to explaining the lack of enthusiasm for photography which seems to have characterised these years.

The earliest extant photographs from Sri Lanka are now almost certainly those taken by Frederick Fiebig, a German lithographer turned calotypist based in Calcutta from the mid-1840s. Fiebig appears to have visited the island during a trip to South India in 1852 and some 70 hand-coloured salted paper prints of the island were purchased by the East India Company in 1856. These indicate that he photographed only in Galle (then the island's principal port), Colombo and Kandy, taking architectural views, landscapes, coffee estate studies and portraits of representative 'native types,' a choice of material which was to become a staple for succeeding generations of commercial photographers on the island.

Apart from this body of work—produced by a temporary visitor rather than a resident photographer—the 1850s appears almost as barren of photographic activity as the previous decade. Only one commercial photographer, James Parting, appears to have remained in business for any substantial period. Parting traded as a watchmaker, but from 1855–59 he operated a daguerreotype and latterly a wet collodion photographic studio. Although a few crude wood engravings copied from his work were published, none of his original photographs has been identified. But Parting retains some importance as a direct link with the founding of the most successful 19th-century studio in the island, for before leaving Ceylon in June 1860, his business and equipment was purchased by the Government Printer William Skeen, who placed it under the management of his son William Louis Henry Skeen (1847–?1903).

The developments in photographic technology and a growing market of European residents made the early 1860s a propitious period for commercial studios and for the next forty years Skeen and Co exercised a largely unchallenged supremacy in the island. The studio (which until 1868 traded as Slinn and Co., presumably in reference to another family member, S. Slinn Skeen) established itself quickly and by the late 1860s its catalogue listed over 400 stock images, providing a comprehensive coverage of the architecture and scenery of the island's main economic centres of Colombo, Nuwera Eliya, Rambodda and Kandy. A major speciality of the firm was the very detailed documentation of the island's plantation industries, particularly tea, cocoa, cinnamon and other spices. The fact that little attention was paid to the north of island reflects the way in which the photographic market was rigidly determined by the location of the main centres of European population and economic activity. With the growth of the tea and other industries and a swiftly developing rail network (the latter also extensively documented by the firm), this deficit too was corrected in the last decades of the century. Views were also collected from as far afield as northern India, and in 1887 Frederick Albert Edward Skeen, who had worked for his brother since 1878, opened the Burma branch of Watts and Skeen in Rangoon. The firm survived (in a somewhat attenuated condition in the latter years) until the early 1920s.

While the late1860s and 1870s saw a steady if unremarkable increase in commercial studios, only Joseph Lawton, who opened his Kandy studio in 1866, offered any substantial competition to Skeen and Co. Contemporary reviews (such as an account of photographs of the newly-opened Colombo-Kandy railway in 1868) repeatedly compared their work, often in Lawton's favour, and it was Lawton who was selected by the island's Archaeological Committee to document the ruined medieval cities of Anuradhapura, Polonnaruwa and Sigiriya. This work, undertaken in 1870–71, was Lawton's most important achievement and constitutes a remarkably powerful record—both from a documentary and aesthetic viewpoint—of these sites at the very beginning of their modern archaeological history. Sadly, it was also to be his memorial, since he died in 1872 as a result of overwork and illness contracted while working in the jungle. His studio continued to trade under the management of his widow, but closed its doors within a few years.

Unlike India, which from the earliest years of photography had supported an enthusiastic amateur community, the professional studios appear to have supplied almost all the island's photographic requirements. While there is scattered evidence of amateur activity—the civil servant James Birch and the Royal Engineer Richard Warren, for instance, had preceded Lawton in photographing at Polonnaruwa in the late 1860s—no photographic society was formed which might have channelled and developed such work, and notwithstanding the residence of Julia Margaret Cameron (from 1875 until her death in 1879), few non-professional Europeans appear to have been inspired to take up the camera.

With the opening of the Suez Canal in 1869, the island became an increasingly attainable and popular tourist destination and the number of photographic studios increased in response to the demand for visual souvenirs. Among the most distinguished of these was the studio of Charles T. Scowen, who opened his first studio in Kandy in around 1875, with a Colombo studio by 1883. While Scowen's choice of subjects was generally comparable to that of Skeen and Co, early work from his studio is characterised by the particularly fine quality of his printing: this is particularly evident in the very beautiful flower and plant studies which appear to have been a speciality of the firm (appropriately, given the proximity of the great botanical garden at Peradeniya to his Kandy studio). Scowen's stock appears to have been acquired by the Colombo Apothecaries Company in the early 1890s, and continued to be marketed by them, but by the last decade of the century the majority of commercial firms were producing standard tourist views and postcards of little freshness or originality. While a number of these studios—such as A. W. A. Plâté & Co, founded in Colombo in 1890 and surviving up to the present—remained successful commercial enterprises, the photographic vision of the small group of early photographers who had documented the island's landscapes, archaeological heritage and economic development had by the turn of the century become largely exhausted.

CHARCOT, JEAN-MARTIN (1825–1893)
French physician and patron

Jean-Martin Charcot was born in Paris on November 29, 1825 and grew up in a middle-class home as the son of an artisan. He completed his secondary schooling at the Lycée Bonaparte and began his medical training in 1844, completing his doctorate at the Faculty of Medicine in Paris in 1853. His primary interest was in disorders of the brain and spinal cord. He became senior physician at the Salpêtrière Hospital for women in 1862, where he began to employ medical photography as a visual aid and diagnostic tool. In 1882 he became the first Chair of Diseases of the Nervous System at the Paris School of Medicine. During the final period of his career, Charcot became interested in hysterias and used photography to further his research. Charcot did not take photographs himself, but employed professional photographers to run the Salpêtrière's photographic studio. The photographs taken at the hospital under Charcot's direction were published in three volumes under the title *Iconographie photographique de la Salpêtrière* in the years 1877, 1878 and 1879. Charcot married Madame Augustine Victoire Durvis in 1864, with whom he had two children. He died in Paris on August 15, 1893.

Andrea Korda

CHARNAY, CLAUDE-JOSEPH-DÉSIRÉ (1828–1915)
French itinerant photographer

Claude-Joseph-Désiré Charnay was born near Lyon, France, in 1828 and died in Paris in 1915. After completing his education in Paris and travelling in Europe he moved to the United States, where he started teaching in 1850, in New Orleans, though yearning to become an explorer. Fascinated by John Lloyd Stephens's accounts of travels in Central America, he embarked on his own expedition in 1857, with a commission of the French government, to visit and photograph ruins in the Yucatán. This Mexican trip, which lasted until 1861, was the first of a long series of travels that took him to Madagascar (1863), Chile and Argentina (1875), Java and Australia (1878–79), and back to Mexico in 1880–82 and 1886. On all of these various expeditions he took photographs, most of them large-size glass negatives. Although on his first Mexican trip he concentrated on pre-Columbian architecture, the subject of his superb and widely acclaimed book *Cités et ruines américaine*s (1863), in later travels Charnay turned to a rather cold and even voyeuristic anthropological photography of native populations (especially in Java and Australia, and then in Mexico in the 1880s). His many illustrated books and publications, translated into English and Spanish, made him, in his lifetime, one of the day's famous explorers.

François Brunet

CHAUFFOURIER, GUSTAVO EUGENIO (1845–1919)
French photographer

Before 1869, Chauffourier, born Paris, turned up in Palermo taking photographs along with Perron as *Photographie Parisienne* and published an album of views, monuments and works of art with a text in French and Italian. In 1870 he obtained a permit to photograph from the collections of Naples Museum. In 1871 moved to Rome (although there is still reference to a studio in Palermo). He then became, along with his wife, Filomena Foschi, a travelling photographer and visited Austria, Serbia, Romania, Bulgaria, Turkey, Russia while changing his business address in Rome several times. After his death in 1919, his sons, Pietro and Emilio, continued to expand the business by the Spanish Steps, becoming 'Pietro—Emilio Chauffourier, photographer editors.' He is noted for documenting (including taking official buildings) the last years of the decline of Papal Rome before the Unification of Italy 1870. In 1953, 300 glass plate negatives of Rome and some positives were acquired by the Museo di Roma, 5,000 others passed to Alinari in Florence in 1960 but in the flood of 1969 were partly destroyed. Only a few images of his Italian views have ever been published. Yet his work can often be identified by strong characteristics: his love of an empty foreground, a nondescript street, an apparently lesser viewpoint in the cityscape, a personal angle of view, all of which contemporary trade photographers (and no doubt his sons or others the business might have used) would not have seen. All the more remarkable then that he still awaits the study he deserves.

Alistair Crawford

CHEVALIER, VINCENT (1770–1841) & CHARLES LOUIS (1804–1859)
Companies

Jacques Louis-Vincent Chevalier and his son Charles Louis Chevalier were Parisian opticians descended

from a family of opticians established along the quai de l'Horloge, île de la Cité. After ten years spent in the Napoleonic army, Vincent returned to Paris in 1803 to find his father had died, taking the family business with him. As a result, Vincent worked for other opticians before opening his own shop at 21 *bis*, quai de l'Horloge in 1805. His business a success, in 1810 he moved to a larger location at 67, quai de l'Horloge. In 1818, he expanded his shop into the neighboring 69, quai de l'Horloge. His son Charles also began working for him at this time.

Since glass was not made in his father's shop, from 1819–1821 Charles enrolled as an apprentice to an optician named Godelar. Charles's health started to decline and he began to suffer from bouts of depression, characterized by a series of persecution crises that were to plague him throughout his life. The first concerned Vincent's 1819 invention of a camera obscura with a meniscus prism lens, whereupon the reflecting surface normally located in the camera was reincorporated as part of the lens. Charles believed that the idea was his, and became angry that his father received exclusive credit for its invention.

From 1822–1824, the Chevaliers concentrated on the production of microscopes. During this time, Charles succeeded in constructing uncemented, achromatic lenses made from two crown bi-convex lenses and one flint bi-concave lens. In this, he followed the theories of Leonhard Euler (1707–1783).

By 1824, the painter Louis Jacques Mandé Daguerre had become a weekly visitor to the Chevaliers' shop. On one occasion, Daguerre informed them that he had succeeded in fixing an image using a camera obscura. This was followed, in 1826, by the visit of Colonel David Niépce, who wanted to buy a meniscus prism lens for his cousin, Nicéphore Niépce. The colonel informed the Chevaliers that his cousin had succeeded in fixing an image created by photosensitive means, and showed them an example. Two weeks later, an anonymous visitor arrived in their shop, and showed Charles an image that he obtained with a camera obscura. The man never returned, but the event reminded Charles of Daguerre's earlier claim. As a result, he informed Daguerre about the work of Niépce, suggesting that they contact each other.

Throughout 1826–1829, the Chevaliers sent Niépce a number of lenses, ranging from a prism meniscus, to a Wollaston-type periscopic meniscus, to an uncemented, achromatic bi-convex lens adapted from their microscopes.

In 1831–1832, Charles had series of quarrels with his father, with Charles claiming that he was poorly paid. This lead to a final break with his father's business in 1832, whereupon Charles set up shop in another part of Paris, at 163, galerie de Valois, Palais-Royal.

From 1832–1839, little is known about Vincent's activities. Charles, however, specialized in achromatic binoculars and telescopes, and relocated his business to 153, galerie de Valois, Palais-Royal. He also made lenses for Daguerre, who continued Niépce's research following Niépce's death in 1833. In particular, one lens consisted of a bi-convex crown glass element and flint glass bi-concave element cemented together, forming an achromatic, positive meniscus arrangement along the lines of a Wollaston periscopic lens. This would constitute the first lens sold in daguerreotype camera outfits in 1839.

Upon the announcement of the daguerreotype process in 1839, the demand for camera lenses was so great that Charles was unable to keep up with the demand. Consequently, production was taken over by a rival firm headed by Noël-Paymal Lerebours, who supplied the majority of the Daguerre-Giroux camera outfits with an inferior achromatic, plano-convex lens. Another problem was that the single achromatic lens was found to be impracticable for portraits, due to the necessity of using a stop in making the exposure.

Returning to an 1834 telescope design, the *Lunette à verres combinés* [Telescope made from combined glass], involving two achromatic lens elements separated in a tube, Charles modified the design so that it could be used at full aperture as a photographic lens. This was marketed in early 1840 as the *Photographe à verres combinés*, along with a folding camera design named the *Grande Photographe*. In addition to its being the first double, or portrait lens made for photography, the *Photographe à verres combinés* was also the first convertible, or variable focal length lens, consisting of lens components that could be taken apart and reassembled to obtain different lens formations with different focal lengths.

By early 1841, Charles's portrait lens was threatened by a rival, the Petzval portrait lens, marketed by the Viennese firm, Voigtländer. Adding to Charles's frustration was that the Petzval lens proved to be more popular with daguerreotype portraitists, since it allowed for shorter exposure times and a higher resolution at the center of the image.

On 29 November 1841, Vincent died, and the two estranged family businesses were reunited at Charles's Palais-Royal address.

Largely at Charles's instigation, in 1842, the Parisian *Société d'Encouragement* [Encouragement Society] began a comparative analysis of the relative merits of the *Photographe à verres combinés* and Petzval lens, to determine which one was the best. Not surprisingly, since Charles was a board member, the society sided with his *Photographe à verres combinées*, stating that its circle of definition covered a whole-plate, whereas the Petzval lens only covered a quarter-plate.

Still frustrated by the continued success of the Petzval

lens, and convinced that it was of similar construction, Charles entered a protest to the Parisian *Académie des sciences* [Academy of Sciences] claiming that the lens was an infringement upon his original, 1834 telescope design. A closer inspection proved that it was of independent design, consisting of an air-spaced rear component.

Also in 1842, Charles met Edmund de Valicourt for the first time. Valicourt, a photographer and technical writer, would become an important defender of the *Photographe à verres combinés*.

Up and until his death in 1859, Charles continued to make and sell the *Photographe à verres combinées*. He also published a number of catalogues and technical manuals during the period 1841–1854, on an almost annual basis. These provide a wealth of information about photographic equipment and processes of the period; however, they were also characterized by a continual need to justify and defend the primacy of his lens, whereupon he publishers letters by noted photographers attesting to their preference for his lens above all others. During the mid-1840s, Charles also become embroiled in a bitter dispute with his Parisian rival Lerebours, and the two sides traded lengthy insults in their respective publications. Upon his death in 1859, his son Louis-Marie Arthur Chevalier continued the business, which ultimately terminated with Arthur's death in 1872.

CHEVREUL, MICHEL-EUGÈNE (1786–1889)

French scientist/color theorist

In 1806, after studying chemistry at the Collége de France, Chevreul devoted his interests to organic substances at the Muséum National d'Histoire Naturelle Paris. By 1810, he was chosen as an assistant naturalist in the department of Garden Plants, a position which led to his appointment as chemistry chair, and a long affiliation as an instructor and administrator with the Muséum. He served as director from 1864–1879. His scientific discoveries included the development of margarine and stearine. Chevreul's findings revolutionized the production of soap and candles.

As director of dyeing at the Manufacture des Gobelins in 1824, Chevreul developed his color theories which were then publicly introduced in *The Principles of Harmony and Contrast of Colors and Their Applications to the Arts,* first published in France in 1839. His concept, the "law of simultaneous contrast of colors," in which complementary colors placed next to each other on a canvas are seen mixed in the eye of the observer inspired painters: Eugène Delacroix, Camille Pissarro, Claude Monet, George Seurat, and Robert Delaunay.

On October 25, 1847, at the Academy of Science, Chevreul's paper, "Considerations on the Reproductions by M. Niépce de Saint Victor's Process of Images that are Engraved, Drawn, or Printed," encouraged Abel Niépce, a cousin of Nicéphore Niépce, to work on new photographic processes and emulsions.

The Art of Living a Hundred Years; Three Interviews with Monsieur Chevreul…on the Eve of his 101st Year is considered the first photo interview. On September 5, 1886, *Le Journal Illustré* published a series of photographs (taken by Paul Nadar) documenting conversations between his father Nadar and the centenarian Chevreul. Each picture is captioned with Chevreul's witty response to Nadar's questions on the subject of being 100.

Margaret Denny

CHILD, THOMAS (1841–1898)

British engineer and photographer in China

Thomas Child was born in Shropshire, England in 1841to John (a mechanic) and Elizabeth. By 1851 his parents had moved to Greenwich in south London. He married Ellen in the mid 1860's and went on to work as a gas engineer with the Chinese Maritime Customs in Peking, China.

China had only been open to the West since the early 1860's and Child was in the second wave of pho-

tographers, following pioneers Felice Beato and John Thomson.

Child, who largely concentrated on photographing Peking and the north of China, produced around 200 images depicting the architecture of the city, along with some portrait studies. They formed a series entitled "In and Around Peking" and were largely made between 1875–77.

Child appears to have combined his photography with his position an engineer. His pictures were produced commercially, mounted on card with printed descriptive labels on the reverse and his name often appears marked in the negative, along with a date. His 10x8 inch albumen prints were well-composed and full of detail but lacked the visual quality of Thomson's work. His documentation of Peking was probably the most complete of any Far Eastern city in the mid 1870's.

He returned to London with his family in the early 1880's.

Ian Charles Sumner

CHILE

In 1840, the ship *L'Orientale* docked in Valparaiso, Chile. Aboard were French and Belgian students on a worldwide tour. Also aboard was daguerreotype equipment, belonging to Louis Compte, the ship's chaplain. A propós of the arrival of *L'Orientale*, a Valparaiso newspaper reprinted an article that had previously appeared in a Montevideo newspaper, on the subject of the daguerreotype process. Unfortunately, the *L'Orientale* sank shortly after its arrival and it was several years before Chileans became acquainted with this new marvel.

By the mid-1840s both foreign and native-born photographers were active in Chile. In 1845 the Helsby brothers (William, Thomas and John), two of whom were born in Argentina and one in England, arrived in Chile and operated successful studios in both Valparaiso and Santiago until the 1860s. William also traveled and photographed in other Latin American countries, including Uruguay and Argentina. Due to the quality and quantity of his daguerreotypes, he is considered the "grand old man" of the daguerreotype in Chile. The Helsby studio location was eventually owned by Carlos Rowsell, who for a time was engaged in a business collaboration with the famed Courret Hermanos studio in Perú. In 1854 Victor Deroche a Frenchman, opened a studio in Santiago. Several years later, Deroche and photographer Augusto Beauboef, traveled throughout Chile with the goal of producing the country's first photographic survey. Their work was published as *Viaje Pintoresco a Través de la República* (1856).

The first native-born Chilean photographer José Dolores Fuenzalida, began working in 1844 in partnership with Philogone Daviette and a Mr. Hulliel, and later opened his own studios in Valparaiso and Santiago. In the midst of a commercially successful career, Fuenzalida bought the famed Helsby brothers studio. This purchase led to an acrimonious legal battle with one of the Helsby brothers. Possibly weary of the protracted litigation, Fuenzalida died in 1857 at the age of forty-seven, after which his studio was managed for a time by his son Manuel Fuenzalida.

North American photographers active in Chile included Charles and Jacob Ward who arrived in Valparaiso in 1844, and were commercially successful due to the quality of their portraits. Their studio location was later occupied by compatriot Robert Vance who had studios in Santiago and Valparaiso between 1847–1850. Vance was one of the first daguerreotypists to work in the silver mining district of Copiapó in the Atacama Desert, and this experience may have influenced his decision to later leave Chile and sail north to photograph the California gold rush. The silver boom in Copiapó attracted a number of photographers including Esteban Adaro and Jorge Inchaurrandieta, as well as Enrique Dohrn who also owned a studio in Lima, Perú.

Arthur Terry arrived from New York via Perú in 1853 and several years later announced the availability of photographs on paper and "metal." Terry was an associate of Chilean photographer Cipriano Clavijo. The latter also worked with Jacinto Pedevill (or Pedevilla) and Ricardo Tosell. Among those who pioneered in the area of ethnic photography in Chile were the Frenchman Gustavo Milet (Millet) and the Canadian Obder Heffer. While managing studios in other locations, they also photographed the Mapuche people in the south of Chile. Salomón Adolfo Alexander, a German immigrant and his compatriot a Mr. Boehme, pioneered in the production of images on paper. He also recorded panoramic views of Valparaiso and Copiapó. He later relocated to Argentina where he and his descendants operated several prominent studios.

The Frenchman Pedro Emilio Garreaud, arrived in Chile via Perú in the early 1860s and managed a number of commercially successful studios. In association with Pedro Adams, Garreaud produced photo albums of Patagonia (1874) and Santa Lucia (1875). After Garreaud's death in 1875, his brother-in-law, Félix Leblanc operated the Garreaud studio with Esteban Adaro as his partner. In 1890, Leblanc sold his studio to Obder Heffer. Leblanc went on to publish his photographs as lithographs and photogravures and is remembered for his images of the Valparaiso earthquake (1906).

The Guerra del Pacífico (1879–82) between Chile against Perú and Bolivia was ably recorded by North American photographer Edward Spencer and his associate Carlos Díaz Escudero. Their work during the war, marks them as pioneers in the area of photojournalism

and their images of the conflict were widely circulated in photo albums. Díaz along with Carlos Renard and Federico Leiva, also pioneered in the production of cartes de visite in Chile.

Images of progress symbolized by railroads were recorded by Emilio Chaigneau and E. Cachoirs. Their work appeared in a book on the subject of the Santiago to Valparaiso Railway (1863). Thomas William Oliver, a Chilean of English descent who was trained as an engineer, photographed industrial locations and projects, including the Santiago to Quillota railway whose construction was supervised by famed railroad builder, Henry Meiggs. Oliver later immigrated to the United States and worked for the Kodak Company in the area of research and development.

Several women are known to have worked in the field of photography in nineteenth-century Chile. The most notable was Carolina B. de Poirie, who owned studios in Valparaiso and San Felipe in the 1870s and specialized in cartes de visite. Photo historian Eugenio Pereira Salas mentions one Mercedes Quiroga as active in La Serena at the turn of the twentieth century. Both Salas and photohistorian Hernán Rodríguez Villegas note that during the 1860s, Isabel Lagremoire, wife of photographer Ernest Charton was at times behind the camera. In the 1850s, artist Clara Filleul was responsible for "illuminating" photographic images in the studio of Victor Deroche.

Research on the history of photography in Chile is well underway. The extant literature on the subject includes Eugenio Pereira Salas's pioneer study of Chilean photography (1942). More recently, architect Hernán Rodríguez Villegas completed a substantial and years-long investigation on photographers active in Chile during the 19th century. His directory was published by the Centro Nacional del Patrimonio Fotográfico in 2001. The Centro under the Directorship of Ilonka Csillag, is dedicated to preserving the photographic heritage of Chile. It is also collaborating with six other South American countries to create a union catalogue of photographic archives and collections.

CHINA

The earliest recorded reference to photography in China is contained in the Journal of Harry Parkes, quoted in Lane-Poole and Dickins's *The Life of Sir Harry Parkes* (1894, Vol. 1, 31). In his entry for July 16th, 1842, the fourteen-year-old Parkes writes: "Major Malcolm and Dr. Woosnam took a sketch of the place to-day on their daguerreotype. I cannot understand it at all: but on exposing a highly polished steel plate to the sun by the aid of some glass or other it takes the scene before you on to the plate and by some solution it will stay on the plate for years. It is no use me trying to describe it, it is quite a mystery." The photograph taken was of an unnamed town on the banks of the Yang-tse Kiang River, up which the British Expeditionary Force was making its way in order to obtain a treaty at Nanking. [Parkes and the amateur daguerreotypists were on board HMS *Queen,* and Major Malcolm was private secretary to Sir Henry Pottinger (HBM Plenipotentiary and Hong Kong's first governor) and was subsequently tasked with taking the signed Treaty to England]. Even if the daguerreotypes were successful, no trace of them appears in the British foreign office archives.

By way of background, Britain had just defeated China in the First Opium War (1839–42), and the Treaty of Nanking forced the opening of the five ports of Amoy, Canton, Foochow, Ningpo, and Shanghai for both trade and residence. Hong Kong island was also ceded to Britain, although it is worth remembering that Portugal had been in *de facto* control of Macau since the mid-sixteenth century.

The next earliest reference to photography appears in *Journal d'un voyage en Chine* (1848) where the author, Jules Itier (1802–77), described taking some thirty-seven daguerreotypes in Macau and Canton in 1844. These are now held by the *Musee Francais de la Photographie* and one example is illustrated in John Wood's *The Scenic Daguerreotype* (1995).

The first mention of a photo-studio in China that the writer has been able to find, is that of a Mr West, whose Hong Kong establishment was advertised in the *China Mail* on March 6th, 1845:

> Mr. West begs leave to inform the inhabitants of Victoria that he has opened a Photographic or Daguerreotype Room in Peel Street, near Queen's Road. His room will be open from 10am until 4pm. Single miniatures $3. $2 charged for each additional head in a group.

Another early studio is that of Hugh MacKay's, a Scotsman who took over an existing, but so far un-

identified, daguerreotype and lithographic Hong Kong business in 1846. His advertisements start to appear in the *China Mail* from October of that year. The earliest dated photograph taken by a Chinese is a daguerreotype portrait of General Ko-Lin which was auctioned in Christie's London on 19 October, 1994**.** The studio's printed label on this 1853 image carries the name of a Shanghai photographer, Lai Chong. The ships of Commodore Perry's 1852–54 Expedition to Japan spent some time in Macau in 1853. Eliphalet Brown Jr., the official photographer, was known to have taken photographs there but, to date, none has appeared. Another early view in the writer's collection is an 1857 photograph of the town of Canton, just prior to the allied bombardment in December of that year.

In Shanghai, the Frenchman Louis Legrand advertised his watch and clock-making business which also contained a photo-studio. The *North China Herald* issue of 15 August, 1857 carried the following:

> L. LEGRAND WATCH & CLOCK MAKER, near Mr. Smith's market. N.B.—PHOTOGRAPHS taken in the most elegant style.

By September, 1858 Legrand was advertising stereo portraits. He is also the photographer behind a commercial series of Shanghai-scenery stereo views issued in 1859 under the imprint of Legrand Freres & Cie. However, these are not the first commercial photographs of China to be published. That honour goes to the Swiss photographer, Pierre Rossier (1829–18??), who had been commissioned by Negretti and Zambra, a successful London-based firm specializing in the manufacture and sale of photographic and scientific equipment, to travel to the Far East and send back views for publication in Europe and America. Without naming either photographer, the periodical *La Lumiere,* in its 17 March 1860 issue, reviews the work of both artists. Rossier started putting together his Chinese stereo portfolio sometime in 1858; this consisted of approximately eighty-five views and portraits. Apart from two Hong Kong views, all the scenes were taken in Canton.

The American, Orrin Freeman (1830–66), arrived in Shanghai from Boston with his ambrotype camera and equipment in March 1859. His first decision was to open a studio inland at Soochow, rather than Shanghai. However, after a few months he was back in Shanghai issuing the following advertisement in the *North China Herald*:

> AMBROTYPES-AMBROTYPES. The undersigned respectfully begs to intimate to the Community that he is prepared to take the Ambrotype likeness in a style superior to anything hitherto offered in Shanghai. Charges low and satisfaction guaranteed. Yang-king Pang Road, next door to Messrs. H. Fogg & Co. ORRIN E. FREEMAN. Shanghai, 21st July, 1859.

But by December that year, Freeman had closed his studio and moved on to Japan. Commercial photography in China in the 1840s and 1850s does not seem to have been a very profitable enterprise.

William Nassau Jocelyn (1832–92) was an amateur photographer who was attached to Lord Elgin's suite during the latter's 1857–59 diplomatic missions to China and Japan. Jocelyn arrived in Shanghai in July 1858, taking up the post of assistant secretary and official photographer. He was replacing one Robert Morrison, who had been temporarily attached to Elgin's staff in China from April 1857. Very little is known of Morrison, incidentally, and his work may not have survived. A few of Jocelyn's Chinese photographs, however, can be found at the *Victoria and Albert Museum*, London.

Very little pre-1860 photography of China survives today. Apart from a handful of missionaries and foreign consuls, residents at the recently opened treaty ports and in Hong Kong and Macau were focused on making money, not on wielding cameras or patronizing studios. There were really no foreign tourists, and access to the interior of China was prohibited to all except a small band of foreign diplomats and those on official business. No doubt there was some demand for portrait photography, but those few foreign studios which did operate had to work very hard to make a living. And photography in China was never easy: The hot and humid summers played havoc with chemicals, and supplies of fresh water were not always easy to secure. Travelling inland over unmade roads meant risking damage to glass plates and equipment. Many Chinese were hostile to foreigners and there was a general superstition about photography's ability to conjure up evil spirits. Photographers and/or their equipment were, as a result, sometimes attacked. Nevertheless, by the 1860s the population in the various China coast settlements was increasing steadily and the demand for photography was consequently rising —albeit slowly.

Felix Beato (1834/5–ca.1907) arrived in Hong Kong in early 1860, intending to photograph the climax to the Second Opium War (1858–60). He was a seasoned and competent professional, used to overcoming the practical and technical difficulties of photography in intemperate climates. At Hong Kong he photographed the military build-up of the Anglo-French forces and produced some memorable panoramas. He moved on to Canton and photographed the city whilst waiting for the expedition to move north. In June and July more than 200 allied warships sailed north, and in August Beato photographed the aftermath of the storming of the Taku forts, south of Peking. Beato also photographed Peking itself, after the city was occupied, and he also captured views of the Summer Palace, just before it was destroyed and looted by the allied forces. These appear to be the earliest

photographic images of Peking so far discovered, and are of the utmost historical and cultural importance.

In Hong Kong, a succession of photographers opened and closed studios, often buying and selling their predecessors' stock and negatives. As a result, attribution of Hong Kong studio photographs from the 1860s and 1870s is often problematical. In 1860, Messrs. Weed and Howard set up a studio together, having travelled from California to do so. Charles Leander Weed (1824–1903) is remembered more for his California landscape photography and use of his mammoth-plate camera in various parts of the world. Weed and Howard (about whom little is known) were accompanied by Milton Miller, who initially went along as assistant. Weed and Howard didn't stay long in Hong Kong and moved to Shanghai and then to Canton, opening studios in both places. Miller had taken over the Hong Kong studio by January 1861, and he subsequently acquired Canton in September at which time Weed returned to America. Miller managed the Hong Kong studio until 1864, after which he also probably returned home.

Miller is becoming increasingly recognised as one of the key figures in early Chinese photography, even though almost nothing is known about him or his career. Although little of his landscape work has yet been identified, the *genre* portraits he took are celebrated for their often jarring intensity and also for the apparent empathy he felt for his Chinese sitters—be they coolie, mandarin, aristocratic lady or concubine. Miller also produced an interesting series of stereoviews of China and Japan, published by the American firm E. & H. Anthony.

John Thomson (1837–1921) is also fêted as one of the finest photographers of nineteenth-century China. He left his native Scotland in 1862, and travelled to Singapore where he began his photographic career. After moving his studio to Hong Kong in 1868, he used that as a base and embarked on a number of photographic tours in China. He photographed, amongst other places, Swatow, Amoy, and Foochow and sailed up the River Min to the city of Yenping. In 1870–72 he visited Peking and travelled up the mighty Yangtze Kiang River from Shanghai, stopping at Nanking and then on further upstream beyond Wuchang. His work was immortalized in a number of his books, principal amongst which were *Foochow and the River Min* (1873) and *Illustrations of China and its People* (1873–74). Thomson, like Miller before him, had respect and understanding for most of the Chinese he encountered, and this is reflected in his portfolio of sympathetic and sensitive portraits. Thomson was an exceptionally gifted photographer—equally adept at portraiture and landscape. He was the first to introduce the beauty of China's inland scenery to the West—a wonderful example being his work in and around Foochow. Thomson left China in 1872 and returned home.

At about this time the Chinese photographer, Lai Afong, was establishing his reputation. Thomson himself was impressed: "There is one China-man in Hong Kong, of the name Afong, who has exquisite taste, and produces work that would enable him to make a living even in London." Afong assiduously and successfully cultivated contacts amongst the foreigners in Hong Kong. As a result, many of his photographs were brought back to the West; they survive today and stand testimony to an extraordinary talent in both landscape and portraiture. He was active from ca.1859–ca.1900, and proprietor of the longest-lived studio in the Colony. Unfortunately, very little is known about his life, and his work has hardly been assessed.

A contemporary of Afong's was Tung Hing, about whom even less is known. Like Afong and Thomson, he produced some stunning landscape work around Foochow and the River Min. Again, his work has yet to be properly documented and appraised. Another major Chinese photographer based in Hong Kong was Cheung Mee (1890s–1920s). His work was of a very high standard, and he was also successful in attracting foreign patronage. His work was of a very high standard. Numerous other Chinese operated studios predominantly in the Queen's Road area; most of these, however, seem to have restricted their photographic activities to portraiture.

In Shanghai the Englishman, William Saunders (1832–92), ran a very successful studio. Opened in 1861 or 1862, it operated until at least 1887 producing quality *souvenir albums* of *genre* portraits and views—often finely handcolored. His only serious competition came from an L.F. Fisler, about whom little is known. In the 1880s, a Chinese photographer by the name of Tai Kung established a reputation by taking multi-plate panoramas of the Shanghai Bund.

We should also mention two expert photographers who spent very little time in China but who nevertheless made important contributions to Chinese photo history. The talented French amateur photographer and chemist, Paul Champion (1838–??), visited China in 1865–66 in order to collect zoological specimens. In the process, he put together a fine portfolio of scenes in Shanghai and Peking and these were published in large format and as a stereo series immediately on his return to Paris. Wilhelm Burger (1844–1920) was the official photographer to the Austria-Hungary Far East trade and diplomatic mission which arrived in China in 1869. The Austrian took a series of superb views and portraits, mainly in Hong Kong and Shanghai. Many of these are illustrated in Gert Rosenberg's *Wilhelm Burger* (1984).

One noted commercial photographer was St. John Edwards who operated out of Amoy from 1872 until at least the end of the 1880s. All that is known about him is that he produced a series of local views and also

photographed the Chinese and aborigines of Formosa. The Englishman, Thomas Child (1841–1898), was a gas engineer attached to the Chinese Maritime Customs in Peking. In his spare time he compiled a series of some 200 views of the capital, together with *genre* studies of local Chinese. His albums were very popular and a number have found their way into institutional holdings.

In closing, it is worth making the point that, in reality, relatively little is yet known about the history of Chinese photography, and the work of the key Western and Chinese photographers has yet to be properly researched and chronicled. In twenty years from now, however, we will surely still be celebrating the work of Louis Legrand, Pierre Rossier, Felix Beato, Milton Miller, John Thomson, William Saunders, Lai Afong, Tung Hing and Cheung Mee. It will be interesting, however, to see who else is added to this list.

CHIT, FRANCIS [KHUN SUNTHONSATHITLAK] (1830–1891)

Thai photographer

Francis Chit, a Thai-Christian born in Bangkok in 1830, learnt the daguerreotype process c.1847, from French Bishop Jean-Baptiste Pallegoix (1841–1862) changing to the collodion wet plate a decade later. In 1863 he opened his first studio on a houseboat at Kradee Cheen village in front of the old Portuguese Santa Cruz church, then the heart of international affairs in Bangkok. He was appointed court photographer firstly to King Rama IV, and promoted *Khoon Soondr Sadis Lacks* (officer for fine likeness image) by King Rama V in 1866.

Images based on Chit's early works appeared—uncredited—in the 1883 edition of naturalist Henri Mouhout's classic "Voyage dans les royaumes de Siam, de Cambodge, de Laos et autres parties centrales de l'Indo-Chine 1858–1860." (*Tour du Monde*, v. 111, nos. 196–204, Paris, 1863). His works were widely reproduced, being invariably claimed by—or misattributed to—other photographers including; Wilhelm Burger, John Thomson and W. K. Loftus. Francis Chit died of cholera in 1891.

Chit's work constitutes the major photographic record of Thailand in the second half of the 19th century, and includes portraits of royalty and royal events, views throughout Thailand, including his great 6-part panorama of Bangkok of 1863/4, and astronomical photographs of the solar eclipse in 1868. His 1877 catalogue lists over 9,000 images. There are over 2000 glass plate and large format negatives preserved in the National Archives of Thailand.

PHIPHAT PHONGRAPHIPHON

CHOISELAT, MARIE-CHARLES-ISIDORE (1815–1858) AND RATEL, FREDERIC PATRICE CLEMENT STANISLAS (1824–1904)

French daguerreotypists

Choiselat and Ratel were born in Paris ten years apart: the first, Charles Marie Isidore Choiselat, on February 13, 1815, to a family of bronze manufacturers, who specialized in religious articles (the Choiselat house); the second, Frederic Patrice Clement Stanislas Ratel, was born on March 20, 1824.

Little is known of their backgrounds. Their first writings and communications reveal, from 1840, solid scientific knowledge. Stanislas Ratel for his part was a

Choiselat, Marie-Charles-Isidore; Stanislas Ratel. The Pavillon de Flore and the Tuileries Gardens.
T*he Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 (2005.100.29) Image © The Metropolitan Museum of Art.*

pupil of the School of mining engineering in Paris, between 1842 and 1846, the year he received his diploma. In addition it is likely that Choiselat had knowledge in chemistry. The two men undertook research in the field of alchemy, on the transformation of metals into gold. It is not impossible that the two men came to photography by the means of alchemy.

The various communications, which they addressed to the Academy of Science in the first half of the 1840s, remains the principal source used to reconstruct their direction and work. March 16, 1840, Arago presented in front of the Academy two daguerreotypes; Arago would have praised them as admirable images taken by Choiselat. On this date, it would seem that the latter had taken some tests in the field of the daguerreotype with the chemist Paul Pretsch and later started his collaboration with Ratel. According to Choiselat these images were fixed by means of a particular process.

In this period, following the contest launched by the *Société d'encouragement à l'industrie nationale*, the two men endeavored to solve various technical problems preventing the industrial and commercial rise of daguerreotype. In 1841 they conducted engravings according to the process recommended by Fizeau. Their works, submitted at the end of 1842 to the *Société d'encouragement pour l'industrie*, won them a medal and a prize the following year. The first known plates of the views of the beaches of Tréport remain from this period.

In 1843, the two men developed an accelerating liquid of bromoforme, combining bromine with hydrogen, carbon and other substances similar to the alcohol which, according to their statements, created images "in less than two seconds." They presented three papers on this subject in front of the Academy of Science and ensured the diffusion of their invention by the means of *Soleil et Chevalier*.

The same year, these two men presented plates at the *l'Exposition des Produits de l'Industrie de Paris*, even if their names did not appear among the official exhibitors. The essentials of their work were published in the summer as an anonymous work, *Essai de théorie daguerrienne et résultats pratiques par un professeur de Sciences,* and Charles Chevalier included one their communications with the Academy of Science in its *Mélanges photographiques*.

The following year, in the summer and the beginning of the autumn 1845, Choiselat accompanied Ratel on a voyage at the end of their completed studies, along with two of their colleagues on behalf of the School of the Mines. Their tour, in the form of loop, led them from Auvergne to the Cantal, through the Alps (Grenoble, Gap), and to the South and the western south of France (Toulon, Marseilles, Nimes, Arles, Montpellier, Sète). It was during the three and a half months of this voyage that they took the majority of their pictures now known as views of the valley, (sight of the town of Die, panorama in 3 plates July 21, 1845) and of the Alps, as well as images of the various ports (Marseilles, Sète and Toulon (panorama in five plates of the roads of September 15, 1845) and monuments of Provence (arenas of Nimes, amphitheatre of Arles, cathedral of Rodez). The collection manifests a predilection for the

panoramic format carried out in juxtaposition to the format of plates sized 12,5 × to approximately 18,5 cm. Some images testify, in addition to the views of Dié and of the roads of Toulon, a view of the arenas of Nimes and amphitheatre of Arles as well. In January 1846 Arago, presented in front of the unquestionable Academy of Science the images taken during this period, which again were considered "very admirable ones."

Their last known work, "La Grande galerie du Louvre et les quais de la Seine" and "Le Pavillon de Flore et les Tuileries" were dated 1849. Currently, it is difficult to say if they continued to practise photography beyond this point. The complete absence of their names in critical reviews by the Academy of Science, the press, as well as their separate personal accounts, especially after this date, would imply that their collaboration stopped at this time.

In 1848, Ratel left Paris for Tours and joined the company of the railroads Paris-Orléans as an engineer. Two years later he married Marie-Angel Zoe Choiselat, the sister of Charles. The latter died on December 20, 1858 in Paris, 34 street Cassette. Ratel survived him for nearly the fifty years.

In 1847, the daguerreotypist Thierry in his shortened *Histoire générale abrégée de la photographie,* (general History of photography), placed them in fifth position among the "remarkable daguerreotypists," behind Fizeau, Séguier, Claudet and Gaudin. Since then, their names have become forgotten. Their production that is now known is made up of only approximately thirty images, mostly of landscapes and images of architecture of South-east and South of France and images of Paris. It is necessary to add that some plates were erroneously attributed to one of their parents who moved away, François Adolphe Certes. Of their talent as portraitists and hired by their contemporaries, one knows today of only two examples which are two extraordinary self-portraits. Among the collections of institutions, one finds examples at the musée Carnavalet among them, with the museum of Orsay, the musée français de la photographie de Bièvres, with the musée Réattu à Arles, l'Agfa-foto Historama de Cologne, the Cana Centre canadien d'architecture de Montréal like in Getty Museum, and Metropolitan Museum of New York.

CHRONOPHOTOGRAPHY

The term chronophotography applies to a loosely constituted group of photographers who used the medium to freeze rapid action for analysis and study. Emerging from the instantaneous photography movement, chronophotography is distinguished by the use of various measurement systems to quantify distance travelled in a short period of time. Although it is occasionally used to describe twentieth-century practitioners such as the time photographers Harold Edgerton (1903–90), the term is mainly used to describe those who worked shortly after stop-action photography first became possible. The term appears to have been coined by the French scientist and photographer Etienne-Jules Marey and consequently it is sometimes wrongly asserted that chronophotography began with his time photography experiments on the 1880s. However, Marey was just one of a number of practitioners who worked around the same time in a similar vein. No precise dates can be established for the existence of chronophotography; however, it can be said to have flourished from the 1870s to the turn of the twentieth century. The photographers most often associated with chronophotography are Eadweard Muybridge, Etienne-Jules Marey, Georges Demeny, Albert Londe, Thomas Eakins, and Ottomar Anschütz.

Chronophotography depended on two separate technological developments: instantaneity and automatic exposure. Photographic materials common in photography's first four decades, including Daguerreotype, paper negative, waxed paper negative, and wet-plate collodion, required substantial exposure times to register a sharp image. Photographers struggled to capture even slow-moving objects such as ocean waves or flags flapping in a breeze. Hundreds of minor advances in chemistry and optics during these years gradually reduced exposure times, but it was not until the introduction of gelatine dry-plate negatives (commercially introduced around 1880) and bromide chemistry (invented 1879) that exposures exceeding the capacity of the unassisted eye became commonplace. One notable exception to this is in the area of flash photography. Even with slow materials, phenomena briefly bathed in extremely bright light such as a spark or thunderbolt will still register on the plate; William Henry Fox Talbot demonstrated this principle at a lecture before the Royal Institution in 1851.

There is some foreshadowing of the chronophotography

movement in the fields of astronomical and anthropological photography. In astronomy, photographers including John Herschel, Samuel D. Humphrey (active 1850s), John Adams Whipple (1822–91), and Warren de la Rue (1815–89) photographed the progression of heavenly bodies through the night sky in the 1850s and 60s. Although the subjects of their research were comparatively slow moving, they were also dimly illuminated, which made them especially challenging subjects. The French photographer Jules Janssen (1824–1907) devised a machine called a photographic revolver in 1873, which famously enabled him to photograph the transit of Venus across the face of the Sun while in Japan in December 1874. The design of the device, which recorded a series of images in succession on a circular glass plate, was influential to later chronophotographers, especially Etienne-Jules Marey. Although anthropological photographers were not as interested in sequential imagery, throughout the 1850s and 60s they created systems for recording comparative measurements photographically. Such photographs have been described as photometric, or anthropometric. In Britain, Thomas Henry Huxley (1825–95) and Lord Granville Leveson-Gower (1815–91) spearheaded a project to photograph the peoples of the British Empire through the offices of the Colonial Office beginning in 1869. Huxley's protocol for making these photographs involved placing a clearly marked measuring stick of uniform size and distance next to a nude subject and parallel to the picture plane, so that precise dimensions of skeletal and muscle size could be calculated. The anthropologist J. Lamprey (active 1860s) introduced an alternative system in a meeting before the Ethnological Society of London in 1869. Lamprey advocated the use of a gridded backdrop with both horizontal and vertical markings so that measurements could be obtained easily in any direction. Though this system was flawed in that the sitter could skew the results by standing relatively close or far away from the camera, it gained currency and was applied by Eadweard Muybridge in his *Animal Locomotion* photographs of 1884–5.

The inclusion of Muybridge in the ranks of chronophotographers is somewhat problematic. His contributions to stop-action photography are indisputable, and he arguably exerted more influence over the rise of chronophotography than any other figure. However, unlike most of his colleagues he lacked scientific training and never achieved the rigor of his contemporaries. Muybridge's photographs of moving horses and other animals began in California in the 1870s in the purpose-built laboratory funded by railway magnate and politician Leland Stanford and constructed by a team of engineers. While he was ideally equipped to conduct locomotion experiments and often presented his findings in a scientific context, in fact the power of his images lay in their visual appeal, refined by his acute artistic sense. This became increasingly apparent with his work at the University of Pennsylvania from 1884–5, in which he occasionally inserted or deleted plates to create more compelling grids. Muybridge was criticised in scientific circles for his superficial understanding of biomechanics, and his invariable tendency to emphasise style over substance. Still, his photographs did contain metric grids intended to permit the recovery of photometric data, and were executed at carefully timed intervals. Interestingly, Muybridge's initial approach may have been inspired partly by Oscar Rejlander, who published a paper outlining a strategy for photographing moving horses in the *British Journal of Photography* in 1873.

The French scientist Etienne-Jules Marey was the central figure around whom chronophotography coalesced. Starting in the late 1850s, Marey had been working to devise mechanical means to record human and animal activities. At first he contrived non-photographic methods to accomplish this, beginning with his sphygmograph (a kind of heart monitor) in 1860. In the ensuing decade he perfected numerous related devices which enabled him to automatically record physiological effects; most involved marks registered on paper attached to a revolving drum resembling a seismograph or hydrothermograph. He described these techniques as 'chronography.' As his investigations expanded into the field of human and animal locomotion he eventually adopted photography as a recording device. In a play on his earlier term he described these experiments as 'photochronography' and ultimately 'chronophotography.' Marey developed several techniques for making chronophotographs, including his 'photographic gun,' based on the photographic revolver of Jules Janssen. Marey's photographs were invariably exposed on a single plate, with images either separate or superimposed on each other. This prevented the kind of photomanipulation of which Muybridge was accused. Working at the College de France, Marey's laboratory thrived. It launched the careers of a number of students who became prolific chronophotographers in their own right, including Georges Demeny, Albert Londe, and Lucien Bull (1876–1972).

The Prussian photographer Ottomar Anschütz worked contemporaneously to Marey, using animals as his main subjects. Because he was interested in photographing natural interactions between animals, Anschütz did not include measuring grids in the frame as Marey and Muybridge did. His skill and equipment were unsurpassed; his photographs are the sharpest and most detailed of any chronophotographer. Whereas Muybridge was often reduced to photographing mere silhouettes, Anschütz produced images of striking beauty, delineating exact areas of muscular tension and even individual hairs in an animal's fur. His electrotachyscope of 1887 was a

stroboscopic projection device for animated loops of photographs and represented a considerable advance over Muybridge's zoopraxiscope.

Best known as a painter, Thomas Eakins is sometimes also identified as a chronophotographer. A direct associate of Muybridge, Eakins lobbied for him to move his researches to the University of Pennsylvania in 1884 and was assigned to supervise him during his residency. However, Eakins preferred Marey's more scientific techniques, and distanced himself from Muybridge's laboratory. Eakins was not as prolific as other chronophotographers, and those images that do exist closely resemble Marey's. However, Eakins used fine photographic papers including platinum prints to give his pictures added visual impact.

A number of other photographers who worked principally at the turn of the twentieth century are often associated with chronophotography. Peter Salcher (1848–1928) was an Austrian photographer worked with the physicist Ernst Mach (1838–1916) to take photographs of airwaves created by bullets in flight. British photographer Charles Vernon Boys (1855–1944) made similar photographs of speeding bullets breaking glass and other objects. In the 1890s John William Strutt (1842–1919, known as Lord Rayleigh) photographed a stream of water emerging from a tap and breaking into drops. Arthur Mason Worthington (1852–1916) photographed splashes at the Royal Naval Engineering College, including a drop of water falling into milk.

CHUTE AND BROOKS

Chute and Brooks is the commercial name of an association of two American photographers: Charles Wallace Chute (1846–1923) and Thomas Brooks. Chute arrived in Montevideo from Boston (Massachusetts) in 1865 and started the company with Brooks in 1868. They had studios both in Argentina (Buenos Aires and Rosario) and Uruguay (Montevideo), and become famous for the quality of their portraits.

They used the standard formats, mostly carte-de-visite, portrait-cabinet, and also made stereoviews. They published views of several cities, such as Montevideo, Rosario, and Buenos Aires. At the beginning of the twentieth century, they installed studios in Rio de Janeiro, Brazil; New York,USA; and La Havana, Cuba.

In Chile (1875) and France (1878), they received medals for the quality of their works exhibited in international fairs.

Early views from Montevideo in carte-de-visite by Chute and Brooks are preserved in the Biblioteca Histórico-Científica, Buenos Aires.

ROBERTO FERRARI

CIFKA, WENCESLAU (1815–1883)

Born in Prague in 1815 came to Portugal in 1836 when Ferdinand of Saxe-Coburg-Gotha married the Portuguese queen Mary. He became known as a painter, drawer, potter, collector and patron of the arts. He was one of the pioneers of Portuguese photography, making daguerreotypes since the 1840's. He settled in a permanent studio in Lisbon, in 1848, just after the Portuguese Civil War, where he portrayed, using the daguerreotype process, an important part of Portugal's highest society. Among his sitters was his friend the King Ferdinand, photographed in an armor and helmet. He was the official photographer for the King.

The daguerreotype was still in use in Portugal, during

the 1850s when other process where replacing it in other parts of Europe. Portuguese society was just starting its modernization, made possible by the consolidation of liberal government. Cifka was, most likely, the publisher of the first stereoscopic views of Portugal and participated in the mid nineteenth century most important exhibitions: The 1849 *Exposição Industrial de Lisboa*, the 1851 *Exposição Filantrópica,* the 1867 *Exposition Universelle de Paris*, among others. He also made an album with the major sculpture works of the Mafra National Palace, one of 18th Century's major monuments.

Cifka had a major role in the popularization of photography in Portugal; he had many students, including the King Ferdinand and (according to Portuguese culture and art historian, José Augusto França) Carlos Relvas, the best known 19th century Portuguese amateur photographer. His images were mostly lost and few are known today.

NUNO PINHEIRO

CIVIALE, AIME (1821–1893)

Aimé Civiale was born in Paris, in 1821 and was not a professional photographer, but a geologist. He studied sciences in the famous French Polytechnique School.

In 1857–1858, he began to photograph the Pyrénées. The same year he became a member of the Société française de photographie. Civiale regularly presented his research at the French Academy of Sciences. But he is especially known as the photographer of the Alps that he studied between 1859 and 1868.

As an engineer, he did not use his photography practice only as a proof of his geological research, but also as a way to show new landscapes and to keep traces of them before erosion makes them change. In these extreme conditions, photographs were particularly difficult to realize. Despite using aluminum for the lens's frame instead of copper, he had to bring with him up to 550 lbs. of photographic devices.

In this environment he could not use the wet collodion plates. He then decided to choose Gustave Le Gray's technique, using waxed paper for the negatives, technique that he later improved by adding beeswax to paraffin. He also built a camera able to represent the 360 degrees view in forteen panoramic images.

Aimé Civiale died in Paris, in 1893.

CLAINE, GUILLAUME (1811–1869)

Belgian photographer

Guillaume Claine was born in the small southern Belgian town of Marche-en-Famenne on 12 January 1811. An obscure provincial upbringing was followed by a two-year stint as an editor on the liberal Brussels daily *L'Observateur* around 1841. Several attempts to promote his career within the Belgian administration came to naught, and, suffering from ill health (the nature of which was never specified), he gave up journalism. Together with his wife, Augusta Van Buggenhoudt (1810–1871), Claine moved from the centre of Brussels to the outlying commune of Saint Gilles on 10 July 1845, where he was registered as a law student, and then to nearby Molenbeek on 19 May 1847, where their only child Auguste Emile was born on 10 June 1847. Claine earned his living as a court stenographer, while referring to himself as a man of letters.

By this time, Claine was devoting his leisure time to the calotype. He entered into collaboration with Louis Jacopssen (1797–1877), an artistically inclined arboriculturist and landowner who ran the domaine de Bloemendael, a rural estate near Bruges. They made excursions together, to Bruges, Ghent and Brussels, view-taking and print-making as dedicated amateurs. Their most notable achievement was a series including views of the royal palace at Laeken, to the north of Brussels, the resultant salt prints characteristically retouched to suggest billowing clouds. Claine wrote: "nous avons vécu des mois entiers dans la chambre noire… la phot[ographie] nous a fait dépenser en deux années quelque chose comme trois à quatre mille francs" [we have lived whole months in the dark room… phot[ography] has made us spend in two years something like three to four thousand francs] (letter to Joseph-Ernest Buschmann dated 24 December 1849).

Claine, ambitious and impecunious, had become a competent landscape photographer, and cast around for a way to profit from his skills. Rather than opening a studio, at a period when the daguerreotype was still the only widely accepted process in Belgium and portraiture its sole commercially viable application, Claine began lobbying the Belgian government for a subsidy. He addressed a formal request to the Interior Minister, Charles Rogier (1800–1885) in October 1849, and in parallel publicized his efforts in the Brussels press, not least *L'Observateur*, which praised the quality of the prints: "Entre autres

perfectionnements ingénieux découverts par ces deux habiles photographes, ils ont trouvé le moyen de prendre, avec un objectif ordinaire, des images de toute grandeur et sans déviations" [Among other ingenious improvements discovered by these two skilled photographers, they have found a means of taking, with an ordinary lens, images of all sizes and without distortion] (*L'Observateur*, 29 October 1849). Large prints were a speciality, as attested by one surviving example, featuring the Brussels town hall, which measures 77 × 66.5 cm.

Rogier referred Claine's request to the Académie royale de Belgique [Royal Academy of Belgium], which set up a commission to investigate the matter. While Adolphe Quetelet (1796–1872), the influential secretary of the Academy, expressed his scepticism, Claine found a staunch defender in Joseph-Ernest Buschmann (1814–1853), man of letters, publisher and himself an experimenter in photography. Buschmann's intervention in Claine's favour was decisive in persuading the Academy to adopt a motion that "la photographie sur papier peut devenir une auxiliaire des plus utiles pour les sciences et pour les arts, et qu'elle mérite en conséquence de recevoir les encouragements du gouvernement" [photography on paper can become a most useful aid for the sciences and the arts, and consequently deserves to receive the government's support] (*Le Moniteur belge*, 12 January 1850).

Unable to fix a fee per print, the Interior Ministry awarded Claine the lump sum of 1,250 francs. Claine used the award in part to finance a study trip to Paris, where he spent most of May 1850 familiarising himself with the latest innovations, selecting a lens for field work more efficient than any obtainable in Brussels, and meeting leading practitioners including Gustave Le Gray. Abel Niépce de Saint-Victor initiated Claine into his albumen-on-glass process, which led Claine, on his return to Brussels, to make a somewhat hasty pronouncement: "Jetez la photographie sur papier au feu! Le verre a triomphé!" [Throw paper photography onto the fire! Glass has triumphed!] (letter to Joseph-Ernest Buschmann dated 8 August 1850).

Claine's championing of this new process would have fateful consequences. Following their initial contacts the previous year, Buschmann had entered into a prolific correspondence with Claine and Jacopssen on their shared interest. He now began an intense practical collaboration with Claine, the purpose of which was to commercialise the albumen process. Their attempt to construct a machine for albumenizing glass plates failed, and further experiments were brutally curtailed in November 1850 when Buschmann was committed to a mental asylum. Among the reasons advanced by his family for his medical state was "…une idée fixe, mal fondée du reste, de gagner des millions par de nouvelles découvertes dans cette science" […a quite baseless obsession with making millions through new discoveries in this science, i.e. photography].

Bereft of his collaborator, Claine completed the assignment for the Interior Ministry in 1851, the first state commission granted to a photographer for drawing up an inventory of Belgium's cultural heritage. This landmark achievement was repeated the following year when Claine made a further series of 44 views of monuments and sites for the municipality of Brussels, at 60 francs per print. Claine's final legacy is a series of ten plates published by L.-D. Blanquart-Evrard in 1854, under the title *Bruxelles Photographique*. Measuring up to 48 × 36 cm each and priced at 10 francs apiece, they were the largest and most expensive prints produced by the Lille establishment.

On 31 August 1853, Claine moved back into Brussels. Abandoning photography along with his freelance status, he was appointed a municipal clerk. Photography had outgrown the opportunistic enthusiast fortunate enough to benefit from public subsidy. Guillaume Claine ended his days as a museum caretaker, dying in Brussels on 1 March 1869.

No comprehensive set of the Interior Ministry commission of 1851 has been located, but the Bibliothèque Royale Albert Ier, Brussels, owns several prints, as does the Musée de la Photographie, Charleroi. The Brussels municipal archives possess the full series of views commissioned in 1852, and the Bibliothèque municipale, Lille, has a complete copy of *Bruxelles Photographique*. The Museum voor Fotografie, Antwerp, owns Buschmann's surviving salt prints, as well as the manuscripts composing Claine and Jacopssen's correspondence with him, along with an annotated transcription in typescript.

Steven F. Joseph

Biography

Evrard-Guillaume Claine was born in Marche-en-Famenne, province of Luxembourg, Belgium, on 12 January 1811. A failed journalist, he was working as a court stenographer when he began practising the calotype around 1847. Specialising in landscape work, he entered into two significant collaborations, firstly with Louis Jacopssen (1797–1877), an artistically inclined landowner from Bruges. Claine's correspondence with Joseph-Ernest Buschmann (1814–1853), man of letters and publisher in Antwerp, plots their joint experiments and pivotal steps in the introduction of glass-plate photography to Belgium in 1850. Claine's series for the Interior Ministry completed in 1851 constitutes the first state commission granted to a photographer for drawing up an inventory of Belgium's cultural heritage. In 1852 Claine made a series of 44 views of monuments and sites for the Brussels municipality. Claine abandoned

photography by 1855 and ended his days as a museum caretaker, dying in Brussels on 1 March 1869.

CLAUDET, ANTOINE FRANCOIS JEAN (1797–1867)

Henry Snelling, editor of *The American Photographic Art Journal* March 1868, 47, wrote of Claudet:

> 'M.Claudet is not only one of the most theoretical but practical daguerreotypists of Europe. His whole soul seems wrapped up in the study of his art; instead of making it a mechanical business, he raised it to its proper sphere amongst the arts and sciences.'

Antoine Claudet was born at the *Chateau de Rosay, Lyon*, France in August 1797 at the end of the France Revolution. The second child in a family of six, he was brought up mainly by his mother from the age of 10, as his father died in 1807.

When he was 21, Claudet moved to Paris to work as a banker for his uncle, M. Vital Roux. In Paris Claudet married Julie Bourdelain, a French girl whose family had moved to England. In 1825, Claudet was appointed co-director with George Bontemps (his wife's nephew), of M. Ponces Grimblot's glass works outside Paris. Following on from this, in 1828 Claudet moved to 89 high Holborn, London to import shades and sheet glass manufactured in Choisy le Roi. It was through this introduction to glass thatClaudet first showed his creative skills as an inventor, when in 1833 he invented a machine for cutting cylindrical glass, which was later to be awarded a medal from the *Society of Arts*.

In 1837. George Houghton joined with Claudet to set up Claudet and Houghton, an importing company for the wholesale and retail of glass.

In the autumn of 1839 on hearing about Louis Jacque Mande Daguerre's photographic discovery, Claudet went straight to Paris on the advice of the optician, Noel Marie Paymal Lerebours. Claudet took lesson from Daguerre himself, learning the complete daguerreotype process before buying a licence from him for £200, which enabled him to perform the process in England.

In 1840 Claudet and Houghton were the sole importers of camera equipment and daguerreotypes in England. They began selling daguerreotypes imported from Paris for one to four guineas. In April of that year Claudet sent a selection of daguerreotypes of European cities and other scenes to Queen Victoria and Prince Albert. They bought the best of them and the remaining pictures were put in an exhibition at the Royal Society. In July of 1840 Claudet took pictures of some of the first daguerreotype views of London.

In 1841 Claudet opened his first portrait studio on the roof of the Adelaide Gallery in London and began taking portrsits for the first time. The glass house was constructed from blue glass to improve the lighting. Later in life, Claudet described to Thomas Sutton what was required to be a photographer:

> 'To achieve success in photography requires the chemical knowledge of a Faraday, the optical knowledge of a Herschel, the artistic talent of a Reynolds or a Rembrandt, and the indomitable pluck and energy of a Hannibal.' *The British Journal of Photography*, 30 August, 1867, 413–414.

At the time when Claudet first practised photography, the long exposure times required, made it difficult to achieve good and natural portraits. Often sitters looked serious and uncomfortable. Sittings could be hard to endure. Claudet endeavoured to speed up the process of photography and in May 1841, he discovered that by combining chlorine and iodine vapours the sensitivity of the plate was increased. By using this process, he was able to reduce the exposure time from two minutes to a few seconds. Claudet may not have been the first to discover this, he was however the first the publish the findings in a report to the *Academie des Sciences* in Paris and communicated them to the *Royal Society* on the 10th of June. Priority of publication was of all importance and throughout his life, Claudet was eager to make his discoveries known.

It is thought that Claudet could not afford the entire patent for the use of the daguerreotype process in England, which would have cost £900. Instead an English

entrepreneur Richard Beard, purchased the patent and then offered Claudet £200 to cease practising. Claudet refused and on 15 July 1841, Beard issued a court injunction against him. But the law was on Claudet's side and stated that although the patentee had to buy the licence, the licencee was not obliged to sell it. The injunction was dissolved. This loophole, fortunately for Claudet, allowed him to continue producing daguerreotype s freely with no obligation to Beard.

At the end 1841, Claudet took out patents for the use of painted backdrops, the red light in the dark room and artificial light. By this time Claudet was considered both technically and artistically, the most skilful portrait photographer in London. And in the same year, Claudet took what are considered the first instantaneous photographs ever taken. The subject was the members of the Italian Opera in ballet poses.

In October Claudet was approached by William Henry Fox Talbot to use Talbot's *calotype* process. He adopted it for a short time but soon returned to the daguerreotype as he was not happy with the inferior quality that the paper *calotype* image produced.

With official permission, in 1842 Claudet climbed to the summit of the Duke of York's column, between St. James Park and Pall Mall and produced a series of daguerreotypes of the panorama of London. A wood engraving of these was printed in *The Illustrated London News January 1843* to promote the publications first six months in operation. Six wood blocks were used to produce the print, which measured three by four feet.

In 1843, Claudet spent several months in Paris, where he bought a *Petzval lens* which had a wider aperture to reduce exposure times.

In 1844 Claudet exhibited his 'multiple portraits' at the *Exposition de Produits de l'Industrie Francaise*. Claudet had out grown his studio at the Adelaide Gallery, so he moved across to 18 King William St, at the adjoining corner of the Adelaide Gallery. At this new studio in 1845, Claudet employed the miniaturist painter L.Mansion to colour daguerreotypes. Two years later, Claudet opened another studio, The Colosseum, Regents Park, London.

In 1848 Claudet invented the *photographometer* to measure the sensitivity of light. This was the first light meter. Following on from this in 1849, he invented the focimeter, an instrument used to aid focusing.

In 1850 Claudet invented the *dynactometer*, a device used to compare the speed of different lenses.

Claudet opened what was to be his last studio in 1851. He called it the "Temple of Photography," and it was one of the grandest studios of its time situated at 107 Regent's Street, London. The French artist Herrien described the interior as the most elegant in London. Renovations were carried out by Banks and Barry, architects, who had designed the Houses of Parliament. The interior was designed in an Italian style, the reception rooms with a series of murals showing the history of photography and stereoscopy. This included fourteen medallion portraits of photography inventors.

After the invention of the *lenticular stereoscope* in 1849 by Sir David Brewster (1781–1868) many of the leading photographers of the time turned their attentions to the stereoscope which was a device for viewing photographs which gave an illusion of depth. Claudet was one of the most enthusiastic of its followers and before the invention of the *binocular camera*, Claudet developed a way of achieving the desired effect with two cameras side by side. In 1851 at the Great Exhibition in Crystal Palace, Claudet exhibited a selection of stereo daguerreotypes alongside Dubosq's stereoscopes. Queen Victoria was greatly impressed by the novel effect given by this new invention and Claudet sent a selection of these pictures to her as well as to the Czar of Russia. As a pioneering scientist Claudet devoted himself to the improvement and the advancement of stereoscopy and was largely responsible for the extent of its popularity.

Among some of Claudet's most prestigious sitters at this time were, Queen Victoria, the Prince of Wales, Charles Dickens, Charles Babbage and he also produced one of the only known portraits of the first Duke of Wellington.

In 1852, Claudet began his exploration into moving image when he put pictures of himself taking off a hat, and he put these on a *pneumatoscope* to give an illusion of motion.

In 1853 Claudet was appointed *Photographer in Ordinary to Queen Victoria*. In the same year he became a member of the *Royal Society of London for the advancement of science* after his entry *"The Application of the Stereoscope to Photography.*" In March 1853 Claudet patented a *folding pocket stereoscope* and in 1855 he patented a stereoscope with adjustible tubes to suit different eye widths. This patent also covered the invention of a *large revolving stereoscope* where 100 stereoscopic slides could be rotated on a band. Claudet's fascination with three-dimensional reality continued throughout his life and for many years he worked on combining the stereoscope with the *zoetrope* to create *'moving photographic figures'* providing an important step towards the creation of moving pictures. In April 1858, at the Royal Society, Claudet presented his *stereomonoscope* where two stereo pictures could be brought together in one image enabling several people to view the pictures on a large screen.

In 1865 Claudet was made the *Chevalier de la Legion d'honneur*.

Towards the end of his life Claudet worked with John Henry Dallmayer on differential focusing and was also involved in producing *Photosculptures*.

Even late in life Claudet was an ardent promoter of photography, a focused scientist and artist and valued Photography as a fine art. He wrote that being a photographer:

> …requires thought, taste, judgement and refinement, to use with success the apparatus and the process, I consider that there is as much art in the result as in any of the so-called 3fine arts… *The Photographic Journal* August 1861

Claudet died in 1867. Sadly a year after his death there was a huge fire at his studio, which destroyed around 20.000 negatives, daguerreotypes and prints.

In August 1868, Basil Montague Pickering wrote 'A. Claudet FRS-A Memoir'.

LAURA CLAUDET

Biography

Born at the Chateau de Rosay, Lyon, France in 1797. Claudet moved to Paris to work as a banker in 1818 and then to England in1827, to import glass. Established manufacturing and wholesale company of glass *'Claudet and Houghton'* in 1834. Visited Daguerre in Paris and bought a licence to practice Daguerreotype Photography in 1839. 'Claudet and Houghton' sold photographs and photographic equipment in their shop in 1840. In the same year Claudet took some of the first photos of London. Opened daguerreotype portrait studio, *'The Adelaide Gallery'* in 1841. In the same year, Claudet read his *'Acceleration'* paper to the *Academie des Sciences*, discussing his process which reduced exposure times and Beard brought out court injunction against Claudet which was dismissed. Claudet also patented painted backgrounds, artificial lighting and the use of the red light in the dark room. Invented the photographometer in 1848. Invented the dynactometer in 1850. Opened 'Temple of photography' studio and exhibited daguerreotypes and stereo daguerreotypes at the Great Exhibition in 1851. In 1853 was made 'Photographer in Ordinary' to Queen Victoria, became member of the *Royal Society of London for the Advancement of Science* and *patented the folding pocket stereoscope and the stereoscope with adjustable tubes*. Patented the revolving stereoscope in 1855. Presented the stereomonoscope to the Royal Society in 1858. Delivered *lecture 'On Photography in its Relations to the Fine Arts'* at the Photographic Society of Scotland in 1860. Made *Chevalier de la Legion d'honneur* in France in 1865. Died in 1867.

Selected Works

Individual Exhibitions

1844, Palais de l'Industrie, Paris,(F).
1847, John Scott Russell's Industrial Exhibition, the Society of Arts (GB).
1851, Great Exhibition, The Crystal Palace, London (GB).
1855, Amsterdam Photographic exhibition, Received 'Tentoonstelling van photographie' prize.
1855, Exposition Universelle, Paris, First Class Medal.
1856, Photographic exhibition, Brussels.
1859, Exposition S.F.P.,Paris (F).
1861, Exposition S.F.P., Paris (F).
1861, Birmingham exhibition.
1862, London International exhibition (on Jury).
1863, London photographic exhibition.
1865, Dublin International exhibition (on Jury).

CLAUDET, FRANCIS GEORGE (1837–1906)

Canadian photographer

Francis George Claudet, the youngest son of photographer-inventor Antoine Francois-Jean Claudet, was born

on February 15, 1837, in London, England. Assumed to have received his photographic education from his father, Francis studied mining and metallurgy in London and Germany from the mid to late 1850s in preparation for his career as an assayer. In 1859 the Master of the Royal Mint appointed him the Assayer for the Colony of British Columbia, Canada. Due to the cost, Claudet's photographic equipment followed him to British Columbia, which he reached on February 10, 1860. While awaiting the completion of his work buildings and living quarters in New Westminster, he lived in Victoria (Colony of Vancouver Island) and traveled to various points in both colonies, partly on board HMS *Satellite*, the vessel on which Lieutenant Richard Roche served. After Claudet received his photographic kit by the end of summer 1860, he busied himself, in his spare time, with taking photographs of New Westminster and its residents, as well as various points he visited on official duties. He knew other professional photographers, including Frederick Dally (Victoria), David Withrow (New Westminster and Moodyville), and possibly Richard and Hannah Maynard, who were on the same crowded vessel Claudet took back from San Francisco in 1862 when he purchased coin-minting equipment. Claudet competed with George Robinson Fardon at the London International Exhibition (1862). At least two of Claudet's photographs were used for engravings published in the *Illustrated London News* (May 12, 1866). Claudet worked in a variety of other civil service and judicial capacities until he was laid off in January 1873. He returned to England with his family, bitterly disappointed at his treatment after 13 years service. He continued to work in the assay business, but does not appear to have pursued his interest in photography. He died in London, England, on March 13, 1906. Although Claudet's wet plate negatives have not been located, family papers, including photograph albums, were purchased by the British Columbia Archives in 1946 from a son who had returned to settle in the province. The University of British Columbia Library also preserves a number of Francis George Claudet photographs.

DAVID MATTISON

CLICHÉ-VERRE

Essentially a hybrid of printmaking and photography, cliché verre technique uses neither ink nor camera to produce, through photographic chemistry, hand-drawn or composed images on paper. The process involves two basic steps. First, a transparent glass plate (or other transparent surface) is coated with an opaque substance such as collodion, ink dusted with powdered white lead or an oil-based pigment. Using a sharp instrument, the artist draws a design into this matrix. The plate, which acts as a hand-drawn negative, is placed into contact

Carot, Jean Baptiste Camille. L'Embuscade.
The Metropolitan Museum of Art, Purchase, The Horace W. Goldsmith Foundation Gift, 1991 (1991.1072) Image © The Metropolitan Museum of Art.

with a light sensitive sheet of paper and exposed to light, which passes through the drawn areas of the glass plate but is absorbed by the opaque areas. The paper, darkening in proportion to the amount of light received, forms a positive, laterally reversed print. The print is then washed, fixed, and dried. Modern cliché-verre are often made using transparent plastic or film, rather than glass. Nineteenth-century cliché-verres, usually made with either salted or albumen paper, generally exhibit light brown tones while twentieth-century prints can exhibit a range of tones and colors. Cliché-verre ("glass negative") is the most common term for the process. Other terms include *cliché-glace, dessin héliographique, autographie photographique,* photogenic etching, etching on glass, autograph etching, and glass print.

The cliché-verre process was introduced to the public in 1839 by three English artists, James Tibbits Willmore, William Havell and his brother James Frederick Havell. Experienced printmakers, the trio was inspired by William Henry Fox Talbot's experiments with the cameraless "photogenic drawing" process in which objects or designs were placed in direct contact with a sensitized paper and exposed to light to produce a negative image. In March 1839, two months after Talbot gave his report

on his photogenic drawing process to the Royal Society, Willmore and the Havell brothers exhibited cliché-verre prints at the Royal Society in London. Their prints were made by covering a sheet of glass with etching ground and smoking it to create an opaque surface. Using a sharp instrument, they drew designs into the opaque ground, placed the glass in contact with light-sensitive paper (made using Talbot's salted paper process) and exposed it to light to produce a positive print. Countering Talbot's protestation of prior invention, Havell stressed that unlike Talbot's process, which sought to faithfully reproduce the external world, the aim of the cliché-verre was "to delineate the work of the artist's pencil by the Photographic process" (Glassman and Symes, 1980).

By 1841, the cliché-verre technique had been included in two technical manuals: Robert Hunt's *A Popular Treatise on the Art of Photography,* and T.H. Fielding's *The Art of Engraving.* Though none of the earliest cliché-verres appear to have survived, a print by the English. A fairly simple reproductive process that required neither the manual skill of engraving nor the complicated equipment of etching, the cliché-verre process was nevertheless used only intermittently in the 1840s and few cliché-verre from this period are extant. The development of cliché verre as a significant artistic practice did not occur until 1853, when the medium was independently discovered by the amateur photographer Adalbert Cuvelier, in collaboration with Léandre Grandguillaume, a professor of drawing in Arras, in northeast France. Together, they introduced the cliché-verre process to the circle of artists living and working in Arras in the 1850s and 1860s that included the landscape painter and lithographer Constant Dutilleux, lithographer and photographer Charles Desavary, photographer Eugène Cuvelier (son of Adalbert), and, most notably, the painter Camille Corot, who would eventually produce over 65 clichés-verres that ranged from rapid, bold sketches to more monumental, fully worked compositions.

The period from the early 1850s through the 1870s was the golden age of cliché-verre in France. Along with Corot, a number of artists working in and near the town Barbizon adopted the technique, including Théodore Rousseau, Charles Daubigny, Charles Jaque, François Millet, Paul Huet and others. Sometimes the process involved collaboration between photographers who prepared the plate and made the print and painters who drew the design. The most common subjects of nineteenth-century cliché-verre prints are landscape and rural motifs; as in the case of Corot, cliché-verres sometimes functioned as studies for a larger painting.

During this fruitful period, artists expanded both the range and vocabulary of cliché-verre technique in a number of ways. While the glass plate was most often coated with collodion to make it opaque, other techniques included covering the glass with printer's ink dusted with white lead powder or with an oil-based pigment which could be applied onto the plate in varying thickness to allow for a more subtle modulation of tone and transparency. Other modifications of the process included placing the emulsion side of the sensitized sheet onto the bare (unworked) side of glass, rather than directly onto the hand-drawn surface, before exposure to light. Because the light traveling through the glass is refracted before reaching the sensitized paper, it creates an effect of halation and produces a softer, less linear print. Another technique for creating a softer, more impressionistic image involved interposing a second plate of glass between the hand-drawn glass negative and the sensitized paper. The surface of the print could also be given a dotted or patterned texture by using a roulette wheel (a toothed wheel used in etching) or lightly tapping the coated plate with a steel brush or other instrument. Although cliché-verre prints were most often made on either salted or albumenized paper, some nineteenth-century artists employed the cyanotype, gelatin silver or other processes. Varnishing and toning cliché-verre prints was not uncommon.

Although never a widely popular technique, the cliché-verre has continued to interest artists and viewers. In 1921, the Parisian publisher and art dealer Maurice Le Garrec published *Quarante Clichés-Glace,* a portfolio of reprints of cliché-verre plates by Corot, Millet, Rousseau, Daubigny, and Delacroix. Among twentieth-century artists who have explored the technique, mostly using gelatin-silver paper, are Picasso, Brassaï, Max Ernst, Paul Klee, Man Ray, and Frederick Sommer. Artists continue to make clichés-verre prints today, and have greatly expanded the medium's technical and artistic range by using a variety of supports, including glass and plastic-based films, as well as by experimenting with different photographic processes, such as dye transfer to make color.

CLIFFORD, CHARLES (1819–1863)

Although he was British-born in South Wales, Charles Clifford became one of the finest photographers in Spain. His work combined the highest technical standards with a sympathetic eye towards the architecture of Spain.

Little if known of Clifford before he arrived in Spain in 1850, although it is apparent that he was already skilled in photography. Several accounts of his life suggest that he went to Spain to work as a balloon pilot—or 'aeronaut of aerostatic balloons' as one source describes him. And shortly after arriving in Spain he is believed to have attempted to make daguerreotype aerial views from a balloon, together with the French lithographer Alfred Guesdon. The success or otherwise of this venture is unclear, as none of these experimental images is known to have survived.

However, it is his work after 1852, when he moved to Madrid, which marks him out as one of the country's finest photographers. Working with calotype, waxed paper, and wet collodion, he produced an enormous output within a relatively few years, exhibiting and publishing widely. His control of light and space marked his work out as exceptional, although he was less concerned with architectural and geometric accuracy than many of his contemporaries. Working with a very direct and visually engaging style, much of his work—especially those images of the regeneration and modernisation of Madrid has a surprisingly fresh documentary feel to it.

Portfolios such as his 1856 *Vistas del Capricho,* containing fifty five views of the 15th century palace at Guadalahara and the 18th century summer house of the Dukes of Infantado at Capricho were well received. *Voyages en Espagne* (Journeys through Spain) produced in the same year, contained four hundred large format (35cm × 45cm) images, and was widely acclaimed when exhibited in Paris. A project on this scale would, of course, have taken some considerable time to complete. Some of the photographs which would eventually form part of *Voyages en Espagne* were displayed at a meeting of the Photographic Society in London in April 1854. Having progressed from calotype to le Gray's Waxed Paper process, these images portrayed the great churches, palace, monuments and landscape of Spain. Gernsheim suggests that Clifford was working towards a much wider publication of *Voyages en Espagne* but that his death in early 1863 brought the project to a halt.

In Spain the calibre of his work was recognised at government level, and resulted in several important civic commissions. Thus, from 1856 he photographed many of the city improvement projects in Madrid.

Clifford's photographs of the construction between, 1856 and 1859, of Queen Isabella's canal and aquaduct system to bring fresh water to Madrid are fascinating and important historical documents. Images showing the apparent chaos of the construction site for the *Pontón de la Oliva*, reservoir-dam, and the long snaking route of the *Sifón del Gualix,* contrast vividly with the stark simplicity of his views of the partially completed tall arches which would eventually carry one of the major aquaducts into Madrid. A significant number of fine salted paper prints from collodion negatives survive from this project.

Clifford's photographs brought him to the attention of Queen Isabella II, who was known to give albums of his architectural and landscape photography to visiting heads of state, and in September 1860 he accompanied her and her entourage on a journey to eastern Spain and the Balearics, arriving back in October. The albums of images which he produced on his return revealed all the places they had visited en route. By this time he was using collodion glass plates and printing on albumen paper.

On November 14th 1861, at Windsor Castle, Clifford made an exceptionally fine portrait of Queen Victoria, dressed in a long evening dress and wearing a coronet. The portrait was well received, and critics in Britain praised it for the regal quality it gave to the Queen, in sharp contrast to the rather less formal views of her and her family which were being published at the time by Mayall and others.

Historians disagree about the genesis of this royal 'sitting,' and indeed about Clifford's relationship with both the Spanish and British monarchs. It has long been held that the idea for the portrait was instigated by Queen Isabella, with several sources claiming that she sent Clifford to Windsor to take the picture. Those same sources claim that Clifford enjoyed some sort of official status as court photographer to Isabella. Others suggest that the portrait was at the request of Queen Victoria. Further research on this is clearly needed.

It would, however, appear that both Clifford and Juan Laurent did enjoy significant royal patronage from Isabella, and the selection of Clifford to accompany the Queen on two of her journeys suggests that he was, indeed, a favourite. Henisch & Henisch (1994) remark that "Isabella was an unhappy woman and an incompetent queen, but she was blessed with one stroke of good fortune: the inspiration to appoint Charles Clifford. No one could have been better fitted than he for the unenviable

task of creating an image of dignity and progress from the disorder and corruption of her reign."

The resulting portraits, whoever instigated them, were published widely. They were available in large print format (275mm × 215mm) and as *carte-de-visite*. Two versions of the carte-de-visite are in the collection of London's National Portrait Gallery, one published by Clifford himself, the other, hand tinted, published by Cundall and Downes.

Clifford's work featured in several exhibitions of the Société française de photographie—of which he was a member—while he only contributed work to the 1854 exhibition of the Photographic Society in London. He offered forty-six images for sale in the 1858 exhibition of the Architectural Photographers Association in London—four shillings and nine pence un-mounted, five shillings and sixpence mounted.

After his death in early 1863, and in the face of stiff commercial competition, his wife Jane attempted for a time to keep the business operating.

COBURN, ALVIN LANGDON (1882–1966)

American photographer

Alvin Langdon Coburn was born in Boston on June 11, 1882. He was given his first camera, a 4" × 5" Kodak, on his eighth birthday. Coburn's interest in photography was further nourished by his distant cousin F. Holland Day, who in 1899 encouraged the young Coburn and his mother to travel to London. While in England, Coburn had his work exhibited at the Royal Photographic Society and with the Linked Ring. In 1902, he opened a studio in New York City and became a member of the Photo-Secession.

Coburn moved back to England in 1904 and took classes in the photogravure process in 1906, and in 1909 used his own copperplate press to print his photographs which were published in his books *London* (1909), *New York* (1910), and *Men of Mark* (1913). Coburn was a champion of photography as an art form and helped to organize exhibitions of contemporary photographers along side the prints he made from Julia Margaret Cameron's and Hill & Adamson's original negatives. In 1916–17 Coburn created abstract prismatic portraits which the poet Ezra Pound named Vortographs. After 1923 Coburn showed less interest in the art of photography and devoted his time to mysticism. He was residing in Wales when he died on November 23, 1966.

Diane E. Forsberg

COLE, HENRY SIR (1808–1882)

Henry Cole was born in Bath, England, on 15 July 1808 to Laetitia (née Dormer) and Captain Henry Robert Cole, an army officer. Educated at Christ's Hospital School, London, in 1823 he gained employment as a civil servant, embarking on what was to be a highly influential career in public service and more specifically, in the world of art education and museums. Cole chiefly organized the Great Exhibition of 1851, which introduced an unprecedented gathering of European and American photographs to huge audiences, and, under his supervision, was itself photographically documented. In 1856 Cole became the founding Director of the South Kensington (later Victoria and Albert) Museum where he worked until 1873. An amateur photographer Cole, was a pioneer in the appreciation of photography. He collected for the museum photographs both *of* and *as* art and purchased and exhibited work by radical contemporary photographers, such as Julia Margaret Cameron (1815–1879). He also established the museum's photographic service for copying works of art for educational purposes, and enabled Royal Engineers to be trained in photography by the museum's first staff photographer Charles Thurston Thompson (1816–1868). No other museum in the world did so much for photography or collected so well at this time. Knighted in 1875, Sir Henry Cole died in London on 18 April 1882.

Anne-Marie Eze

COLLARD, AUGUSTE-HIPPOLYTE (1812–c. 1897)

French photographer

Auguste-Hippolyte Collard was born in Valençay, Indre, France, on February 1, 1812. After marrying in Paris in 1838, he settled in Poitiers. There, for 10 years, he prospered as a wood frame gilder. The year 1850 marked a turn in his career, henceforth dedicated to photography.

Helped by his two younger brothers Jules and Victor Brutus, he set up his own workshop in Paris in 1855 and created in 1856 the "Collard and Cie" company—which went bankrupt two years later. He produced numerous portraits, and built up a reputation in the reproduction of works of art. Today most of these prints have disappeared.

Towards the end of the 1850s, mostly through commissions, he began using photography for civil engi-

neering applications. His most important patron was the Ministry of Agriculture, Commerce, and Public Works. With Edouard Baldus, by commission of the Emperor, he also documented the expansion of the railroad in France. A first album (1857), dedicated to the re-building of the Pont St Michel, marked the beginning of a 25-year-long collaboration with the 'Administration des Ponts et Chaussées,' the last outcome of which is an illustrated report on the reservoir of Noisel (1885). The process and outcomes of architectural construction have by then become the focus of the 'Atelier Collard.' Its prints span the major urban upheavals of these times, throughout the territory and not the least in Paris.

Always conscious of the quality of his prints, displayed notably at the universal exhibitions, Collard designed in 1860 a proprietary solution known as "bain de virage (toning bath) Collard."

Luce Lebart

COLLECTORS

If twentieth-century collectors of photographs are just recently becoming well known, then those of the previous period were mostly unknown. A very few studies have been conducted in the domain of 19th century collectors and photographic market. This gap can also be explained by the fact that the idea of a large disinterest for old photography, which marked the first half of the 20th century, and has been extended to the second part of the 19th century. However, everything indicates that many people during this period were able to distinguish between photographic prints of a work of art, a document, an industrial production or a scientific archive.

To study this complex topic, one must not only ask who collected photography, but also which types of images were collected and where one could find photography. The advancement of the history of photography and the studies of contemporary documents illuminated the first clues which established the parameters for this type of research.

The figure of collector has changed throughout time and in accordance with the type of objects collected. Photography is one of the subjects which considerably changed the traditional ideal of the collector. Since the beginning of photography collecting images was made possible because it was democratic, available, and easy to archive. Photography also produced collectors of various types who were more diversified than before. If the first collectors were aristocrats and rich bourgeois, at the end of the century, then a new type of collector appeared. The average man in the street became a collector too. This new medium had begun to democratised the collector as art enthusiast.

Since the end of the 1830s, the art market was in full expansion. It extended rapidly and the number of collectors in general increased constantly with the rise of middle class. Galleries opened and showed various exhibitions as the Beaux-Arts Salon did. The engraving market was particularly flourishing and the dealer as the collector became an emblematic figure of the art world. At the same time, linked to the engraving market, a photographic market began to appear. Photographic prints could be found in traditional places for engraving amateurs: book shops, shops of engravings and drawings, but also in studios and shops of photographers, in editor's places (Colnaghi in London, Gide & Baudry, Gosselin, Pellion, Legoupy in Paris), paper-makers, camera manufacturer places (Susse and Giroux in Paris) and in auction rooms.

This context shows that during this period there existed several kinds of collectors: princes and princesses, aristocrats, artists, architects, industrialists, rich amateurs of art and tourists, but also public institutions, museums, libraries and schools dedicated to art and science education. Those institutional collections were held by curators and the collection itself was related to the public institution's history and policy, to the state's will. Several academic collections were established in universities and libraries throughout Europe. In the United States, the Library of Congress was established in Washington, D.C. The collection started in 1870, contains photographs of Fenton and 12 millions of photographs of the country's history. The Victoria and Albert Museum (VAM), the Bibliothèque Nationale de France (BNF) and the Institut de France have all been collecting since 1850, which thanks to the "dépôt légal" and the royal sponsor, consists of a large number of prints of all kind from landscapes, to portraits and official patrimonial missions like Mission heliographic in 1851, commissioned by the young Commission of historical monument. The Société française de photographie (SFP) and the Photographic Society of London both pioneered the collection of photographs and specifically stated that the assembly of the collection was a part of their raison d'etre.

However, the focus rather was put on private collections, because as collectors are defined in the Pierre Larousse, *Grand dictionnaire universel du XIX^{e} siècle,* "they are those jumble sales apostles, who had learned the state of forming archives, museums, deposits of all kinds." At first, an outline on the emergence of the photograph collectors appeared, and was followed by the various types of collectors there could be.

In France, the organisation of photography auction sales is not well known, but several elements indicate that a photograph market did exist. Helène Bocart's studies of the SFP exhibitions in the 19th century and the examination of contemporary art magazines give partial answers. The first photographic sale known in Paris was organised in 1857 by the SFP, from its

collection, in order to solve financial problems. The sale took place in June 5th 1857 at the Drouot's hotel, the exhibition of the prints was the day before and it counted 58 names. A public noticeboard announced "Sale of photographs. Prints of amateurs and artists." The 1857 sale was successful, several photographs exceeded the double of their initial price, which was the first time in photographic history. In the *Revue photographique* of July 5th 1857 one can find an interesting commentary about collectors :

> "The ones [photographs] which had reached exceptional value were perfect in every respect, and it has been demonstrated then, that collectors taste was already formed, which we were far from expecting. […] A reproduction of Leonard de Vinci *Cene*, by M. Sacchi, even if it was still not up to the mark, has been pushed up to 125 francs."

The 1857 SFP sale indicates then that at this time there were a certain number of photographs collectors, certainly since the paper process expansion, whose tastes were already formed, which assumes the existence of a photographic market more or less officially since 1855, out of which the critic emerges as a new phenomenon. Photography on paper certainly attracted more people than the daguerreotype which was unique and difficult to look at. The 1850s were also the golden age of calotype during which, following the example of painting, photography required schools.

This new situation was confirmed during the second sale of the SFP on May 18 and 19, 1858. It was announced in the journal *Cosmos* in December 1857 and took place in the Drouot Hotel in Paris. 441 photographs were sold, 10 to 20 per photographers amongst whom one could mention Olympe Aguado, Gustave Le Gray, Camille Silvy, Mailand, Paul Gaillard, Pierre Richebourg, Alphonse Davanne and Paul Perier. A commentary by Robert de Lasteyrie in the journal *Le Siècle* in June 25th 1858 indicated the increased numbers of collectors interested in photography:

> "Each year, we make a sale of it. […] the preceding exhibition, unfortunately too short, had attracted a lot of [the] curious. The sale itself had proved that the number of true amateurs, [and] collectors of photographs, had regularly increased amongst us, and that their taste is developing more each day. Such pieces that one finds in every dealer at 5 francs are sold 25, 30 and up to 40 francs. Isn't it the best evidence that, in a beautiful photograph, there are some very artistic qualities, which can't escape to the connoisseur eye? The only work doesn't produce such differences in the results."

This second success confirmed the cause of photographic art and the concept of the collector with a high degree of knowledge of photography. Two other sales were organised during this period, the first in Brussels, from August 15th to October 31st, 1857, and the second in Amsterdam in 1858. As underlined by Robert de Laysterie, the development of the collector's taste was directly linked to the emergence of photographic schools.

> "Little by little schools are formed and are distinguished, thus, right now, the slightest trained amateur eye will recognise without pain the English or Italian photographs from those made in France."

What gave to the 1858 sale a particular appeal, was that it gathered a great number of works by foreign amateurs and artists which couldn't be found in the shops. The striking matter of fact, according to Robert de Lasteyrie, was the "discernment, the uncluttered taste of the public buyer." Most of the big monumental plates of Baldus and Bisson sold for twice their price. Landscapes were largely represented in this sale, and "the public seems to have keenly tasted their work." The portraits were less appreciated, while reproductions of works of art had stronger success. The buyers were mainly photographers and collectors like Adolphe Moreau, Dupuy Montbrun and Hulot. The average print price was between 2 and 6 francs (6 and 12 euros today).

This context seemed to be the same in England. As underlined by Mark Haworth-Booth, the fact that the 1858 exhibitions of the Photographic Society of London were staged and opened by Queen Victoria and Prince Albert indicates that photography "had gained a fashionability year by year during the 1850s. Photographs were not only exhibited in important art context but acquired by collectors."

This fashionability first influenced princes and princesses of European courts who encouraged, bought and commissioned photographs. Napoleon III in France, Victoria and Albert in England, Pedro II in Brasilia, were important collectors of photographs as well. The Napoleon III collection was shown in an exhibition at the Bibliothèque nationale de France in Paris in 2004, under Sylvie Aubenas direction. The collection consisted of various major works containing historical themes, and were presented in luxuriously bound albums, that came from the libraries of the state residencies. Those images had originally come from public commissions, photographic campaigns encouraged by Napoleon III or by his ministries, or as gifts made to the prince with the hope of attracting his favour and some subsidy. Far from trying to support this new art, seen above all as a technical progress, the prince's ambition was to constitute, by the means of photography, a "historical gallery of the reign." The veracity of the photographic image, with the modernity that it symbolised, made it the ideal auxiliary of the reign great realisation.

The Victoria and Albert collection was also exhibited within an exhibition and a catalogue in 1998, *The Museum and the Photograph. Collecting Photography at the*

Victoria and Albert Museum, 1853–1900, at the Sterling and Francine Clark Art Institute. It is preserved in the Windsor castle and counts 25,000 prints. Since 1842, the Queen had inaugurated the accumulation of private souvenirs of family photographs, such as her trips and the outstanding events of her reign (1837–1901). The queen's interest for photography was more personal, and precocious and followed than Napoleon III's. Her husband, Prince Albert, had the same taste for the new medium: he became member of the Royal Photographic Society and collected Le Gray marines and numerous reproductions of works of art.

A comparison can be made with Pedro II, Brazil's emperor from 1831 to 1889. Like Queen Victoria, the emperor had acquired since 1840, at the age of fourteen, a daguerreotype camera. His collection, mostly protected, is preserved to the Print Department of the National Library of Rio of Janeiro. By its nature, it is situated between Napoleon III's and Victoria's. One can find albums commissioned by Pedro II on Brazil major themes, scientific albums in particular ethnographic, some other offered by European commercial companies as advertisement, family portraits, celebrities in visit, and travel and exploration albums on Egypt, Italy, Persia, France, Madagascar. Pedro II, who didn't leave his country until 1871, when he was 45, largely took knowledge of the world through the photographic prism. Moreover, by commissioning adventurous photographers and businessmen installed in his country, he gave to Brazilian photography an unexpected importance.

Those princely collections are certainly the most important ones of that period, containing various subjects. The princely figure as aesthete and art protector invited the others to follow this model. Aristocrats, rich amateurs but also architects and artists bought photographs for aesthetic and documentary interest. In France, Duke of Aumale, Dollfus-Ausset (industrialist), Ignace Chauffour and Alfred Bruyas can be taken as example to show the diversity, the taste and the destination of their collections.

In 1886, Henri d'Orléans, duke of Aumale (1822–1897), fifth son of king Louis-Philippe, gave the Chantilly castle and collections he had gathered therein to the France Institute. Known for his very important paintings collection (Raphaël, Poussin, Watteau, Ingres, Delacroix…) and painted manuscripts dating back to the middle age, the castle also preserves an important collection of old photographs. This collection counts almost 1.400 photographs from the second part of the 19th Century. Firstly, photography was a means for the prince, who lived exiled in Britain from 1848 to 1871, then from 1886 to 1889, to see places he had known or lived during his youth and where he couldn't go anymore. For instance, the Louvre and Tuileries, photographed by Baldus and Bisson brothers, and more generally, Napoleon III Paris then in transformation. His collection also contains family portraits, views of his castle and reportage on the Crimean War. But the other purchases can only be explained by a real taste of the prince for the new art that photography constituted. The collection is composed of all the photographic movements from 1855 to 1897, except Pictorialism. For instance, he bought views of Great Eastern by Howlett, five marines by Le Gray, some views of Switzerland by Adolphe Braun, purchases which can be explained like "love at first sight" buys. In 2001, an exhibition and a catalogue of this photographic collection had been set up in the Chantilly castle.

Daniel Dollfus-Ausset (Paris 1797–Riedisheim 1870) is an important collector figure, really out of common. A great textile industrialist in Mulhouse (Alsace, France), passionate by mountain, he ordered an important series of daguerreotypes of high mountain in 1849 and 1850. Looking for bigger images, he ordered a new series to the Bisson brothers. After the Bisson success with a big panorama of the Aar glacier, Dollfus-Ausset became their patron in 1855. But from that time on, he had already gathered an important photographic collection. In December 1856, the Society of Art friends of Strasbourg organized an exhibition of more than 250 photographs from the private collection of the Mulhousian industrialist. This contained lots of Bisson prints, made in Paris, landscapes and views of architecture from Heidelberg, Strasbourg and Basel. Other important photographs were presented: a *marine* of Gustave Le Gray, two countryside views and a portrait of the empress Eugenia by count Olympe Aguado, a view of Rome by Ferrier, flowers of Adolphe Braun, views of Pyrenees by count de Vigier, an *effect of water and sky* by Alphonse Giroux, a fountain by Edouard Baldus and an incunabulum of photography, the *Pencil of Nature* of Fox Talbot of 1844, publication illustrated by original calotypes. Unfortunately, it doesn't exist anymore.

A contemporary and without doubts a friend of his, Ignace Chauffour, an intellectual, member of Scientific society, member of the Martin Schongauer Society in Alsace, is one of the earliest photographs collectors. His curiosity for the new medium was precocious: he began to buy prints from the "second birth of photography," the expand of paper process. Ignace Chauffour collection counted almost 550 prints and proposed significant examples, beginning with a series of nine photographs by Henri Le Secq, a rare print on salt paper of François Renard (view of Notre-Dame of Paris), and views of Fortuné Joseph Petiot-Groffier, Edouard Baldus, Olympe Aguado, Bisson brothers. Ignoring the development of the Dollfus-Ausset collection after 1856, one can't maintain the comparison with the one of Chauffour, which continued with Adolphe Braun and James Anderson (ten views of Italian architecture.) But the most important part of Ignace Chauffour collection

is constituted by reproduction of works of art. Intending to build his own "imaginary museum," Chauffour gathered about 350 reproductions (representing 63% of his collection.) He bought photographs as well as engravings or lithographs reproductions. Photography was in this respect most of the time considered superior to the traditional graphic arts for the copy of works of art, because it was a difficult and delicate task. Some photographers like Robert Bingham for contemporary art and Adolphe Braun for old masters were the best in this domain and Chauffour, looking for quality, supplied to them. Thanks to the extraordinary fidelity to the original and the rapidity of execution, photography was attractive and stimulated appropriation instinct: one had the work of art under their eyes, one could possess it. With photographs of reproduction, Chauffour completed his fac-simile collection, aiming to create for him and in the spirit of the Schongauer Society, a true collection of reference. Chauffour became very early conscious of the importance of photography for art knowledge and diffusion. In 1879, he bequeathed his photographic collection to Colmar museum that he dedicated to art education. The Dollfus-Ausset and Chauffour collections clearly assume the capacity of both to approach photography as a proper artistic medium, above all the only technical curiosity or the documentary interest.

Another kind of collector, free from any consideration, was the art amateur. Alfred Bruyas (1821–1877) from Montpellier, a rich art collector of contemporary paintings (Courbet, Delacroix, Millet, Ingres…), collected photographs for his pleasure and his documentation. Travelling in Rome in 1848, he brought back six daguerreotypes by Eugene Constant and three calotypes by Flachéron that he included in the catalogue of his collection edited in 1851. This catalogue also mentioned an album reproducing his gallery counting 35 paintings and drawings. Bruyas largely commented this album, encouraging photographic progress notably for the reproduction of works of art which were for him synonym to education, truth and modernity. But unhappily his photographic collection disappeared. The Fabre museum only preserves his photographic portraits by Disderi, Mayer & Pierson, Cairol, d'Albenas and Baldus.

From 1870 and 1880, the progress of the photomechanical process gave the possibility of mass producing images of quality at low cost. Framed more or less luxuriously, the images published by the firm Goupil & Cie for instance were above all destined to decorate the middle-class home walls or more modest classes. It did exist folding screen-frames used to put photographs, one hangs on the wall a photography frame as a painting, as well as family albums began to decorate the living-room.

All these elements confirm the importance of art photography and photographs collectors during the second part of the 19th Century. They deserve to be taken into account now, to go further in for a better knowledge of history of collectionism and a fairly approach of photography history.

COLLEN, HENRY (1800–1879)

Henry Collen was a painter of miniatures who later became the first professional calotypist. He trained under Sir George Hayter and was a Royal Academy Silver Medal winner in 1821. Collen became interested in photography in 1841 and in August of that year obtained a license from Talbot to practice calotype portraiture commercially. He enjoyed some success although his technical skills were limited and he complained of a lack of support from Talbot. Despite the problems, relations with Talbot remained cordial. When his studio closed in August 1844 he had produced around a thousand portraits. Collen's artistic training influenced his photography. He criticised Talbot's use of light and backgrounds and extensively retouched his portraits. Collen's photographic interests extended beyond simple portraiture. In 1840 he was involved in experiments to

electrotype daguerreotype plates, in 1841 he made portraits for Charles Wheatstone's stereoscope and in 1842 put photography to practical use by making calotype copies of part of the Treaty of Nanking. He considered the possibility of exploiting Herschel's glass negative process and in the 1860's proposed a system of colour photography. The collections at the National Museum of Photography, Bradford and George Eastman House include examples of Collen's work.

JOHN WARD

COLLIE, WILLIAM (1810–1896)

Scottish photographer, worked in Jersey, Channel Islands

William Collie was born in Skene, Aberdeenshire, Scotland in October 1810 and like many other early photographers, started his professional life as a portrait painter. He moved south and is recorded as living at St. Helier on Jersey in the Channel Islands before 1841, where he had a portrait business. He became one of the earliest photographers working in the Channel Isles, operating from Belmont House, St. Helier until 1872. Another photographer (J. Collie) is recorded at the same address between 1861–64, this was probably his wife or other relation.

Collie was not merely a provincial studio portrait photographer. In the late 1840s he made a series of genre calotype portraits depicting "French and Jersey Marketwomen" which were well received by the photography critic of the Art Union (June 1, 1847), who compared them to the work of David Octavius Hill (1802–1870). The studies were later exhibited at the London Great Exhibition of 1851.

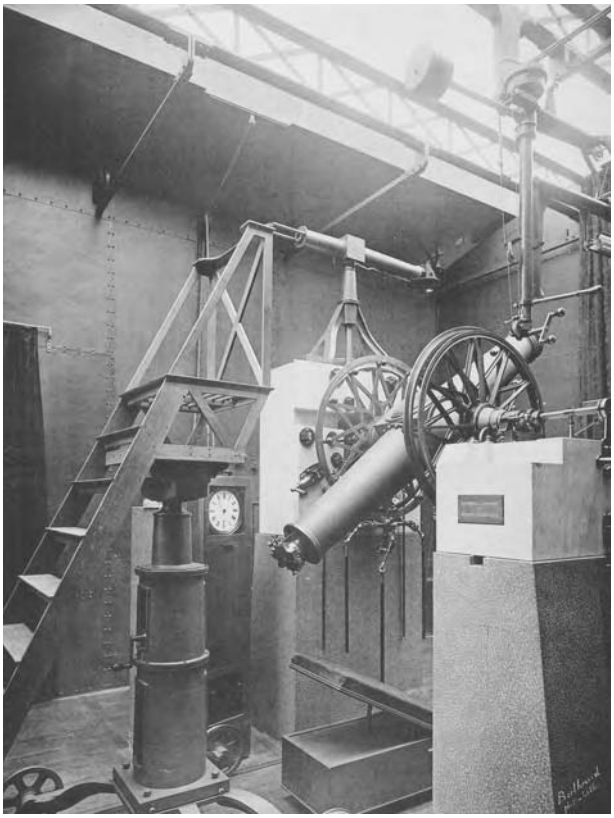
In 1860 Collie is known to have made a photograph of the total eclipse of the sun, which occurred on July 18th.

The Société Jersaise has a collection of his work, as does the National Museum of Photography Film and Television, Bradford, England.

IAN SUMNER

COLLOTYPE

Not to be confused with calotype, this dichromated colloid process uses the tanning effect of light on dichromated gelatin, whereby the hardened parts retain greasy ink that can be transferred onto paper, porcelain, or a variety of other supports. This planographic process was invented by Alphonse Poitevin (1819–1882) in 1855 (Fr. Pat. 24,592, Aug. 27; the Engl. Pat. 2,816 of Dec. 13, 1855 is not as complete) and can be considered the first practical process of photolithography.



Berthaud, Michel. Observatoire de Paris. Cours d'Astronomie. Ecole Polytechnique. Portefeuille des eleves. Cercle Meridien. Collimateur zenithal. Diametre de l'Objectif 0m. 19. Distance focale 2m. 325 (donne par Mr. Bishoccsheim).
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

Poitevin's original invention made use of a light-sensitive emulsion that consisted of a mixture of colloids such as albumin, gelatin, gum arabic, etc., coated on the surface of a regular lithographic stone. After exposure, the resulting matrix was washed with cold water and printed much the same way as an ordinary lithographic stone. On October 27, 1857, Poitevin sold his French and foreign patents to Deraine, who, the following day, sold them to Lemercier, the well-known Paris lithographer. Lemercier, who had been using a primitive form of photolithography, preferred Poitevin's process as it could provide up to 700 impressions from a stone. Poitevin was keeping five percent (5%) of all net profits between Aug. 27, 1863 and Aug. 27, 1870.

Once improved, this new technology was commercialized in France in 1857 by Lemercier and in 1860, by Ferdinand Joubert, under the name phototype. Although successful, the process was apparently seldom used but was revived in 1867 by MM. Tessié du Motay, and Maréchal (de Metz) under the name phototypie. Joseph Albert, of Munich, significantly improved the process in 1868 under the name Albertype. Albert's improvements

consisted of utilizing a glass plate as the base for the sensitized emulsion, instead of a stone, and also using an intermediary layer of hardened gelatin to support the gelatin matrix. It is interesting to note that early collotypes examined under a magnifying glass do not exhibit a reticulation pattern that is commonly seen in variants printed after ca. 1880. The reason for this was the introduction of accelerated drying in a stove which caused reticulation at the last moment of drying.

Jakob Husnik of Prague introduced a process very similar to Albert's and was bought out by the latter to reduce competition. The first Albertype to be made in America was produced by David Bachrach in the winter of 1868. The following year, Edward Bierstadt made his first Albertypes and exhibited them in January 1870. Autotype, of England, introduced collotype in 1872, although "Autotype reproduction" may also have meant this company's own use of the carbon transfer process which they were also exploiting at the time. Autotype was the largest English collotype operation by the late 1880s.

Collotype became very popular for the production of both, cheap quality postcards and high quality art reproductions. It gradually displaced woodburytype, although as the latter, it could not print text at the same time as a picture. One of the advantages of the collotype however was the ability to print an illustration on paper with any desired amount of white margin.

In 1873, Albert introduced the first rotary collotype press. In the early 1900s a combination of collotype and half-tone was introduced in the U.S.A. under the Aquatone trademark. This was later renamed Optak. About 1940, the offset press and gelatin coatings on thin, flexible metal sheets were adapted to collotype printing. The patent literature mentions improvements until at least the 1960s.

As of today, with the exception of screenless-lithography, aquatint photogravure and processes that use stochastic screening, collotype is still the only photomechanical process which uses a screenless matrix. High quality monochrome collotypes are practically indistinguishable from original photographs, especially if they are varnished, or if they have received a coat of gelatin (rare). The lack of a screen allows multiple impressions without the risk of moiré patterns. Collotype printing requires high skills and the nature of the matrix (reticulated dichromated gelatin) makes it suitable for only a limited number of impressions, e.g., 100 to 5,000. In England, ca. 1890, the most successful variations of the collotype were Autotype, heliotype, phototint and Humphrey's processes.

Fine colored collotypes can be seen in many books, including J.J. Tyler's "Wall Drawings and Monuments of El Kab: the Tomb of Paheri," 1895. Also, F. Rathbone's "Old Wedgwood, 1893–1898." One of the most impressive contemporary examples may be a facsimile reproduction of the illuminated manuscript "Le livre d'heures de Louis d'Orléans," Paris, Ed. Seefeld, ca. 1980, which used ten colors. Contemporary artists, like American photographer Todd Walker (1917–1998), have used collotype to print their work.

The last collotype plant in England, the Cotswold Collotype Company, closed in 1985.

The oldest and possibly the largest collotype plant, was Max Jaffé in Vienna, owned by Gerhard Habarta. It ceased operation in the 1990s. In America, a sister company, owned by Thomas Reardon, operated on a smaller scale under the name of The Arthur Jaffé Heliochrome Press, in Dalton, Massachusetts.

The premier collotype operation in the United States was Nicholas G. Jannes' Black Box Collotype, in Chicago, which had Michael Intrator as a technical director. Jannes, who was president of Black Box, donated the company's collotype presses to Arizona State University in 2001, under the condition that they remain in use.

There are about a half-dozen printing plants in the world producing collotypes today. Small operations are reported active in France (Item, Paris), Germany (Lichtdruck Kunst, Leipzig and Lichtdruck Werkstatt, Dresden), Italy (Fratelli Alinari, Florence), and in the former member countries of the USSR.

Among the many people who worked on the development of the collotype, we mention: Bolinetto, P.A. Despaquis (Engl. Pat. 3947, Nov. 17, 1874), E. Edwards (Engl. Pat. 3543, Dec. 8, 1869), Gemser, Geymet, Husnig, Jacobsen, Murray, Obernetter, Thiel, Van Monckhoven, Léon Vidal, Voigt, Waterhouse, F.R. Window (Engl. Pat. 3049, Oct. 19, 1869), etc.

The history of the invention of the collotype process and its variants are treated exhaustively in the brochure by August Albert, "Die verschiedenen Methoden des Lichtdruckes," 1900.

COLLS, LEBBEUS (active 1840–1860s)

Lebbeus Colls and his brother Richard were art dealers in London with premises at 168 New Bond Street. They commissioned work from many contemporary painters, including Samuel Palmer and John Linnell.

Colls became interested in photography before 1850, using Talbot's calotype process, and with his brother, exhibited 'sun pictures' at the 1851 Crystal Palace exhibition.

When Linnell expressed an enthusiasm for photography in spring 1852, Colls offered to sell him a 12 × 8 inch calotype camera, with lens and stand, and this transaction may mark Colls' transition from calotype to collodion.

He later sold his own photographs through his gallery, including several calotypes to Linnell. Prices ranged from 10/- to £1 per print. He also exchanged photographs with Linnell for sketches and paintings.

The Colls brothers photographed widely together, but while Richard exhibited collodion images in Glasgow in 1855, Lebbeus seems to have eschewed the exhibition circuit.

His subjects included landscapes, cloud and sunset studies, and locations in Chepstow, Raglan and Tintern, His view of Lynmouth in Devon, published in January 1857, was one of two which appeared in Paul Pretsch's *Photographic Art Treasures*. With two other images, 'Lynmouth' also appeared in *The Sunbeam*, published by Philip Delamotte in 1859.

Colls was still supplying photographs—'printed by Mr Cundall'—to Linnell in 1868.

JOHN HANNAVY

COLNAGHI, PAUL (1751–1833) AND DOMINIC (1790–1879)

The imprint of P & D Colnaghi is synonymous with the publishing and distribution of high quality photography from the mid 1850s. The company entered the photographic arena when they became the commercial distributors of Roger Fenton's images from the British Museum in 1854. In 1856, they became joint British publishers—along with Thomas Agnew of Manchester—of Fenton's images from the Crimean War.

The partnership with Agnew was an enduring one, as the two business co-published the five volume illustrated *Photographs of the Gems of the Art Treasures Exhibition, Manchester*, in 1857, with photographs by Caldesi and Montecchi.

Paul Colnaghi entered the employment of art dealer Anthony Torre 1783, eventually taking control of Torre's business. By developing strong relationship with artists, he ensured that the gallery exhibited the best of contemporary art. Paul was joined in the business by his son Dominic, and the name P & D Colnaghi was adopted.

In the 1850s, in addition to the Fenton material, Colnaghi published war artist William Simpson's works *The Campaign in the Crimea*, and in the 1860s, acquired exclusive commercial rights to market the photography of Julia Margaret Cameron.

The company withdrew from the photographic market at the outbreak of the First World War, returning to it in the mid-1970s.

JOHN HANNAVY

COLOR THEORY AND PRACTICE: 1800–1860

Color photography, both theory and practice, has a history as long as black and white photography, but one rather more full of disappointments. From the beginning of photography as an enterprise in 1839 with the publication of Daguerre's and Talbot's results, commentators noted color's absence and experimenters sought to invent a process for it. Richard Beard, the holder of the British rights to the Daguerreotype process wrote in 1843:

> "It was color that was wanting to crown all the other improvements and give perfection to the whole."

Sir John Herschel, perhaps the greatest physicist of his time, and a close friend of Fox Talbot's, famously gave Talbot his 1819 discovery of sodium thiosulfite as a solvent for unexposed silver halides to use as a photographic fixer in 1839. He then began immediately to experiment on Talbot's and other photochemistries, and by 1840 and for the next several years tried many experiments aimed at recording color. Some of these were reported to the Royal Society, while others were recorded only in his notebooks and in letters to Talbot. Herschel tried experiments with vegetable extracts, some of which gave quite beautiful and permanent colors, but like his well known invention based on iron salts, the

cyanotype (the "blueprint"), these were unrelated to the colors of the subjects. He also experimented repeatedly with silver chloride (see below). As shown below, until well after 1860 all such attempts by all experimenters failed to create a permanent color photographic process. The first hints of a direction for research, however, predate photography by 60 years.

In 1777 Carl Scheele published an account that showed that silver salts would darken most rapidly when exposed to the violet and blue parts of the spectrum, and that the blackened areas were due to the reduction of the silver salt to metallic silver. Jean Senebier shortly after, in 1782, published work that showed that it took red light 80 times longer to darken silver salts than violet light. He also noted a hint of color in the results for different parts of the spectrum, which foreshadowed Seebeck.

In 1800 Sir William Herschel (John's father), while studying the energy distribution in the solar spectrum, discovered significant heat energy beyond the red end of the spectrum, later christened the infrared. Spurred by this result, in 1801 Johann Ritter examined the violet end by exposing silver chloride ("hornsilber") to it and discovered energy beyond the violet, now called the ultraviolet. He too observed some hints of color at the blue end of his recording. (Wollaston independently discovered the ultraviolet shortly thereafter.) Both these results stimulated awareness of the energetic and chemical effects differences of different parts of the luminous spectrum and suggested a way of recording color.

Slightly later Johann Seebeck became interested in the problem and corresponded with J. W. Goethe who was then writing his well known book on the theory of color (*Zur Farbenlehre*), in which the results of Seebeck's experiments were published in 1810 and thereafter. Seebeck discovered that the solar spectrum, projected from a prism onto silver chloride sensitized paper (this was essentially Ritter's technique), gave rise to a rough copy of the color at most locations in the spectrum. Seebeck reported that in the violet he got red-brown; in the blue, blue, which spread into the green; he got black or yellowish in the yellow; and in the red a rose red or hortensia red. But these were of very unequal quality and could not be fixed. In a spectrum attributed to Seebeck in a private collection purple and violet currently remain visible, though weakly.

In 1839 Sir John Herschel was well aware of Seebeck's work with silver chloride and in addition to trying to use light to bleach out plant dyes he attempted to make direct positive images by exposing silver chloride on paper. By adjusting the concentration of his solutions, the dampness of the paper and exposure times, he achieved the following results on exposure to the colors of the solar spectrum in 1840: in the "deep red and mean red," no color; orange and orange-yellow, brick red; yellow, red passing into green; yellow-green and green, dull bottle green; blue-green, very somber blue; blue and violet, black, except metallic yellow with long exposure (which would blacken the rest of the spectrum); beyond violet, violet–black. These colors did not appear simultaneously and could not be fixed. A bath in sodium thiosulfite, Herschel's fixer, destroyed the colors.

The *prehistory* of color photography is much older than that of black and white, if one counts observations of dye colors fading in sunlight that undoubtedly go back to ancient times. This process, by itself, is capable in principle of yielding a color photographic image. Such processes were tried by Sir John Herschel (his vegetable dye experiments) and again in the late 19th century, then called bleaching-out processes. Start with a range of light sensitive dyes, in cyan , yellow and magenta. Generally each dye will fade most quickly when exposed to light which is its color complement, as this is the color it absorbs most. In this case the complementary colors to those above are the primary colors, red, green and blue. Two problems bedeviled this scheme: the most "fugitive" dyes that were tried were too insensitive to result in fading at reasonable camera exposure times. Secondly, some were too fugitive: no means was found to prevent their continued fading; the image could not be fixed. Image impermanence is still a problem for color photography (including modern digital printed images), though progress has been made. A form of bleaching out is used in some modern color print processes.

Color *theory* also had a considerable pre-history by the early 1800s. Newton had (mid-1600s) broken white light into its spectrum of colors and had shown that recombining just three colors, red, yellow and blue, would reconstruct white. Jakob le Blon used those three colors to do the first practical 3-color printing in 1667, having also concluded that they were sufficient to reproduce all the colors of the spectrum. Mixing red, green and violet light also gave white, and suggested (around 1800) to Thomas Young that the human eye is sensitive to just these three bands of color. This theory was elaborated by Helmholtz, Maxwell and others in the middle 1800s.

At the beginnings of photography in the 1820s the gentleman farmer-scientist Joseph Nicéphore Niépce (later linked to Daguerre) systematically tried a range of photo processes that included using various resin and other coatings on metal plates. It is well known that this eventually resulted in the first photographs, using a modified *camera obscura*, in 1827 and 1829. Less well known is that some of the other processes he tried did perhaps yield color images. Their potential has recently been demonstrated by J-L Marignier at Orsay and Marc Kereun of Paris, in trials using Niepce's original recipes. Exposure times were very long.

However, neither Daguerre's process nor Talbot's

process of 1839 recorded natural colors. Overexposure of the sky could lead to solarized daguerreotypes in which the sky, appropriately, looked blue, but otherwise there was no color. This was a disappointment to the general public, but did not really slow down the arrival of the new market in photographic images. It exploded.

The appeal of color was very strong. The failure of photography to provide it left a hole in the market. Soon, artists who had specialized in painted miniature color portraits stepped in by learning to hand-color daguerreotypes, and later also Talbotypes, ambrotypes, tintypes and other black and white processes that soon appeared. The images by the latter processes were hand colored up to about 1900. For daguerreotypes, beautiful results were achieved, but they required great skill. The colors were applied as powdered pigments by brush onto the Daguerreotype surface. The image layer, a thin surface film, could be marred or removed by the slightest misapplication.

In the 1840s Edmond Becquerel, a member of the Becquerel physics "dynasty" at the National Museum of Natural History in Paris, experimented with variations of the daguerreotype process, and found that he could create a color-sensitive coating by dipping the standard polished silver plate into a solution of chlorinated water and sending a current through the solution, using the plate as an electrode. He observed the plate go through color changes and stopped the process when a certain color was achieved. This succession of colors was almost certainly due to light waves reflected off the mirror[-]like plate interfering with incoming waves in the thin films he created during sensitization. These were analogous to colors seen in thin films of gasoline floating on puddles of water. He exposed these plates to the solar spectrum and recorded the spectrum colors relatively faithfully, according to his 1848 paper and contemporary accounts. However, these images were fugitive in light. A few remain, kept in the dark, at the Centre National des Arts et Metiers in Paris, at the Musée Niépce at Chalon-sur-Saône, and at the Science Museum in London.

At almost the same time the Reverend Levi Hill of New York explored the same problem. He announced his success in making colored daguerreotypes prematurely, which created a market stoppage for black and white portraits and a considerable controversy. When he finally published his technique in 1851 it was so complicated that no one repeated it, even though the well known inventor Samuel Morse testified favorably as to the results. This process was widely labeled a fraud, but recent reconsideration suggests otherwise. William Becker published articles which carefully examined the controversy and reproduced some of Hill's images. He concluded that Hill had succeeded. Then Joseph Boudreau tried Hill's recipe, and published his experiments in 1987. More recently Arron Miller also repeated the process with unspecified modifications and essentially equal success.

Examination of the surviving Hillotypes and Becquerels shows that there is no question that each man recorded color, but of a peculiar and perhaps related sort. The prevalent color in each case is now a deep aubergine. On the Hillotypes one can make out just two instances of another reasonably saturated color, yellow. On the Boudreau image at the Smithsonian there is a wider variety of colors, including blue and green as well as yellow and a faint red, but none saturated, all dark, and underlain by aubergine. Its wider color range may well be the result of its lower age. The colors probably fade, at least in light, though the Hillotype colors seen recently at the Smithsonian look similar to those published by Becker 20 years ago.

The Becquerel images in Chalon, like the Hillotypes, can be viewed briefly in dim light. The colors orange and red at one end of the spectrum are clearly visible, and the other colors are very faint if present, along with the aubergine. Because there are no notes or marks on the plates, it is impossible to say what parts of the spectrum these correspond to.

In 1849–52 Niépce St. Victor (Niépce's cousin) did an all-chemical version of Becquerel's process, for which just a few examples survive. It was recently reprised by David Burder, and consisted of subjecting a metal plate to several metal salt solutions resulting in a silver chloride sensitive layer. Burder's exposure time to contact print a color transparency was several hours. The colors were initially essentially correct as to hue, but not well saturated. Exposure to light causes them to fade. Their surface, like Becquerel process images (and unlike daguerreotypes), is quite durable. Their color can be restored somewhat by rubbing.

Alphonse Poitevin, working into the 1860s, repeated and extended the earlier work with silver chloride on paper by Sir John Herschel and others. After pre-exposure to light, he bathed the paper in metal salt solutions (also various plant extracts) and exposed it while damp. He achieved some color by contact printing through stained glass (never in camera). The images were not stable. In the Exposition Universelle, Paris, 1867 his images and those of Niépce de St. Victor were shown in locked albums only opened briefly and upon request. No examples of Poitevin's images are known to survive.

Very recently John Hurlock of Chicago made daguerreotypes sensitized with silver chloride that show a strong yellow image of a yellow house. They seem to be permanent.

The physical explanation for these (in some cases poor) colors is still to be determined. Zenker, in 1868, maintained that they were entirely interference colors. Wiener, who reconstructed Becquerel's process in the 1890s and conducted various tests on the resulting

plates concluded the same. Recent observations suggest they were not. Rather, they were some form of scattering color related to grain size. The verdict relates to Lippmann's color process and awaits electron microscopic examination and other tests.

In any case, no practical color processes were conceived until the decade of the 1860s and none succeeded until almost 1900.

COLOR THEORY AND PRACTICE: 1860–1910

Processes (positive)

The 1860s was a decade of great conceptual advances in color photography, which laid the foundations for ultimate success, yet no practical results flowed from these advances for almost 30 years.

In that decade James Clerk Maxwell (1831–1879) was working on both the theory of color and on the electromagnetic wave theory of light, the last great triumph of classical (pre-Einsteinian) physics. At a public lecture in 1861 he showed that full color images could be made from a combination of 3 separate color photographs. He chose a tartan ribbon as a subject, and made black and white photographs through a red, a green and a blue filter. These were developed into negatives and then reversed into positives. The three transparencies were then each projected through the filters they were taken with, mounted in three lantern slide projectors of a conventional sort. The images were carefully superimposed on the projection screen and a full color image resulted (of modest color quality). This three-color separation process was not immediately commercialized in photography (but see Frederick Ives below).

There is one curious thing about this famous experiment: it should not have worked! In 1861 there were no films sensitive to red or yellow light and most were barely sensitive to green light. So how did the three colors record to give a true color image? In 1961 Ralph M. Evans showed that the red filter Maxwell used also transmitted light in the ultraviolet, to which the film was sensitive, and which was well reflected by the ribbon. The film was exposed until the negative was usable and

by chance its contribution to the colors gave a "red" which was about right.

In 1862 Louis Ducos du Hauron (1837–1920) sent one of his friends a letter, to be read at the French Academy of Sciences. It described several ideas for color photography based on color separation. The paper was never presented. du Hauron continued his work, making some early images which combined photographs and carbon-based pigment prints, which still exist and are rather beautiful. By 1867 he had refined and expanded his ideas. He received a French patent on them in 1868. In that patent and one received in England in 1876 du Hauron laid out *all* color processes, save one, attempted since.

In 1869 he submitted a paper on his ideas to the Société française de photographie. Completely independently and unbeknownst to du Hauron, Charles Cros (1842–1888), a French poet and dilettante who among other things, invented the disk phonograph before Edison, submitted a detailed proposal for one of these ideas to the Society within days of du Hauron. The papers were opened and read at the same session. It turned out Cros had also sent a sealed letter describing his ideas to the French Academy of Sciences in 1867. A potential priority dispute was fairly quickly squelched by the actions of both men, who quickly became friends.

Their common idea was that of sandwiching three layers of emulsion, each absorbing one of the 3 primary colors, each containing a dye that passed its color complement. This process is the basis of every successful modern color process, and is usually termed a "subtractive" process.

The other main classes of ideas outlined in du Hauron's patents, termed "additive," included the color separation processes, as first demonstrated by Maxwell (see above), and the color screen processes. The latter included various schemes to filter the picture plane into small regions of the three fundamental colors, for taking and viewing.

All these ideas were initially impossible to implement, because the emulsions of the day were only sensitive to blue light (termed isochromatic), whereas every proposed color process required making images which included the whole of the spectrum. In the early 1870s the German chemist H. W. Vogel (1834–1898) discovered by chance that adding dyes to the silver halide-based collodion and gelatine emulsions could extend their sensitivity out into the green, and orthochromatic emulsions resulted. His discovery was not immediately accepted as, for a short time, others failed to duplicate his results. When he pointed out that they had used such high dye concentrations that all light was absorbed before reaching the silver halides, and lower concentrations would do the trick, he was ridiculed. One critic reasoned (falsely) that following Vogel's suggestion, it was logical to expect that the dye would work best at zero concentration, not realizing that Vogel was correct and that there was an intermediate optimum concentration.

In the 1880s and 90s Vogel and others systematically extended this idea into the yellow and red, as well as showed that dyes could enhance the emulsions' original sensitivity in the blue. This advance created increasingly sensitive black and white emulsions. By the 1880s this improvement, coupled with advances in the speed of photographic lenses, permitted photographers routinely to take exposures at speeds greater than 1/30th of a second, allowing the making of what were called "instant" images that could freeze ordinary motion. This created a rage for motion capture, as well as the possibility of making sequences of moving images. It also made possible the creation of panchromatic emulsions for color (and black and white) films, and the possibility of stable dyes to use in the resulting final colored images.

The separation processes were pursued by du Hauron and others. In the 1860s and 1870s he built cameras, camera backs and viewers (Chromographoscopes), designed to take and display three color-separated plates in sequence or simultaneously, and tried to commercialize them. He was not successful, though as mentioned above, some of his carbon-based prints, which required no viewer, survive, as do some of his Chromographoscopes.

The 1870s and 1880s saw attempts to make practical use of du Hauron's ideas, but with little success. In the early 1890s the situation changed. In the U.S., Frederick Ives (1856–1937), already known for his inventions in color printing processes, turned to color photography and made a range of cameras, viewers and projectors to employ the 3-color separation process, using the new panchromatic plates and films. He called his equipment Kromscops, riding the commercial coattails of the letter "K" which resulted from George Eastman's success with his *K*oda*k* cameras. In some versions the images were made in succession, for which the equipment was a sliding back, and optically straightforward. In others, using a more complicated arrangement of internally mounted color-separating ("dichroic") partially reflecting mirrors, the images were made simultaneously. The latter arrangement was bulky, but avoided the problem of color fringing due to subject movement between exposures, which images by the other method suffered from. He lectured frequently and widely, disputed the importance of du Hauron's and Cros' ideas, and tried to sell his equipment on the Continent as well as the U.S. He was modestly successful.

Also in the 1890s the first screen processes hit the market. McDonough in the U.S. in 1892 and Joly in Ireland in 1894 each patented and began to sell film and screen filters for making color photos by this general

scheme. It was described by du Hauron in his 1868 patent: "Finally there is another method by which the triple operation may be effected on one surface. The separation of three elementary colors may be effected no longer by three colored glasses, but by means of one translucid sheet covered mechanically by a grain of three colors." McDonough's patent refers to this grain idea, later used successfully by the Lumieres, but he gave up on it and adopted the ruled overlapping line-screen approach, as used by Joly and a number of others. These screens consisted of fine lines alternating red, green and blue. The layout varied, in some cases they were interleaved parallel colored stripes, in others the screens crossed each other at right angles, yielding color patches which were square. The image was recorded through the screen on black and white film, developed and either redeveloped to a positive or a positive copy was made. In most of these processes the final positive was mated with a color screen identical in layout to the taking screen, and in other versions the screen was bound to the emulsion from start to finish. (The former version suffered from color fringing and Moire patterns if the screen and image were not perfectly aligned. The Paget process in England, and the Dufay color and Omnicolor (du Hauron's last hurrah) processes in France, came on the market in the early 1900s and the latter two enjoyed reasonable success. All these processes were slow compared to black and white, and required exposures of several seconds in bright sunlight, even with the fastest films. A particular disadvantage of the regular line screens was that, though their patterns at 200 to 400 lines per inch were invisible to the naked eye on the originals, modest enlargement would reveal the pattern, which was annoying.

In 1891 a radically different color process, the interference process, the one not predicted by du Hauron, was announced by Gabriel Lippmann, professor of physics at the Sorbonne. He was motivated to invent it in order to confirm the wave nature of light, and according to several of his accounts it took him 12 years to achieve a fine-enough grained emulsion for the purpose. He realized light could be made to record itself, color by color, if a way could be found to let each color (wavelength) interfere with itself, and to capture that standing wave pattern of nodes and vibrations on film. Each layer created would be a half wavelength from the next, throughout the depth of the emulsion. He completed a full mathematical theory based on Fourier analysis, employed in the same way as it was used to analyze complex sounds, before he achieved any experimental results.

To record blue, which has the shortest wavelength, required resolution better than 10,000 lines per mm, a factor of 100 better than most commercial films today, and as good as the best current holographic films. He imagined the pattern could be created by reflecting the image's light back on itself using a mirror, but due to the impurity of ordinary light the pattern would exist in a layer of space in front of the mirror only about 2 microns (0.002 mm) thick. To provide the required perfect contact between mirror and emulsion, he ingeniously employed a special plateholder with a thin pocket behind the plate into which he poured mercury. The emulsion faced the mercury and away from the camera lens and light entered through the plate's glass surface. He first demonstrated the recording of a spectrum, a 12-hour exposure, on silver halide albumen emulsion. He also pointed out that any panchromatic black and white emulsion of sufficient resolution would work and he demonstrated this by showing images on collodion, silver halide gelatine and dichromated gelatine. St. Florent made Lippmann images using iron salts in gelatine. Recently Hans Bjelkhagen and Jean-Marc Fournier have produced Lippmann images in photopolymers.

There was controversy at the beginning over whether this process gave good color. But after the Lumiere brothers tried it, along with Eduard Valenta and Dr. Richard Neuhauss who improved on Lippmann's emulsions, there was no doubt of its potential. Eduard Steichen commented in a Camerawork issue of 1908: "The rendering of white tones was astonishing, and a slide made by one of the Lumiere brothers.. a slide of a girl.. was simply dazzling, and one would have to go to a good Renoir to find its equal in color luminosity." Altogether perhaps 8 to 10 professionals and about twice as many amateurs tried the process. Around 1900 Penrose in England produced the special plates and plateholders required, as did Cheron and Mackenstein in Paris and Jahr and Zeiss in Germany. More than 500 images exist by the Lippmann process, and some of these, including portraits, still lifes and landscapes, have truly spectacular color.

Over the next decade Krone and then Rothe showed that Lippmann pictures could be made without the mercury mirror, relying solely on the slight reflection of light at the gelatine-air interface. The colors were less saturated. Today a few people are trying to improve on this approach, including the author, and the abovementioned Mr.'s Bjelkhagen and Fournier.

Lippmann's process provided amazing color, color permanence (no dyes were needed for the final image, and the emulsion was sealed from the air under a prism used to improve viewing contrast), and superb resolution that allowed immense grainless projections. Nevertheless, the process was never commercialized. Perhaps one reason was that Lippmann did not patent it, which lowered the incentive for a manufacturer. Nonetheless, the Lumieres tried hard to industrialize it from 1891 to about 1895. They were not able to achieve reliable results. This was likely the decisive factor, though others were

undoubtedly contributory, including the long exposures (a minute or more in sun), lack of direct duplicability (like daguerreotypes before), and somewhat awkward viewing arrangements.

Having given up on the Lippmann process, the Lumieres next tried a wash-off dichromated gelatine process, which they called the Chroma process (trademark written in Greek). It resulted in rather garishly colored transparencies, examples of which can be seen in the Lumiere collection in Lyon). As their efforts in this area drew to a close in about 1897 they started work on a screen process based on randomly colored tiny grains of potato starch. This they industrialized brilliantly well. They devised a flotation method to sort the grains by size, and optimized the grain size by exposure test. They tested hundreds of dyes both for coloring the grains and for sensitizing the emulsions (their notebooks still exist in Lyon). They ended up using orange, green and blue-violet dyes for the grains. They produced a sticky varnish to coat their glass plates, sprinkled the mixed dyed grains onto it. They used a self-invented rolling machine to squash the grains as flat as possible and then sprinkled on powdered charcoal to fill in the interstices between the grains to block unfiltered light from reaching the emulsion. The final step was to add a sensitized black and white gelatine layer. The photographer shot the picture, and exposure times were several seconds in sunlight, then developed and reversed the negative to a positive, and mounted a second piece of glass to protect the emulsion. Viewers were made by others. The resulting transparencies were often lovely, easily viewed, and the process straightforward. The randomness of the grains gave a more pleasing effect than any of the line screen processes. Their grain gives them a visual quality like that of a pointilist painting.

The Lumieres patented the process in 1904 and marketed it starting in 1907 as the Autochrome process. It was the first successful, and for almost 30 years, the dominant color process. It brought color photography to amateurs as well as well known photographers. Some really beautiful images by Stieglitz, Steichen de Meyer, Genthe and others still exist. Millions of plates were sold world-wide. From about 1908 to perhaps 1912 they manufactured them in a plant in Vermont, as well as in Lyon. They were supplied as quarter and half-plates, and also as stereo plates. The Lumieres gave a number of public presentations of their images in both Europe and the U.S. Recently, Prof. Jean-Paul Gandolfo of the Ecole Louis Lumiere and Bertrand Lavedrine of the CNRS excavated the Lumiere's rolling press and had it hauled to Paris. They are in the process of restoring it to the making of Autochromes.

In 1909 Albert Kahn, a financier, created a project, *les Archives de la Planete*, to document the whole world in color photos. He under wrote travel and the cost of buying and processing Autochrome plates for a select group of well known photographers. The result was a compilation of more than 100,000 images, now housed, displayed and published at the Musee Albert Kahn, near Paris. Shortly after, the National Geographic magazine started using Autochromes for its color photos. The Society now holds a collection of nearly 60,000 images in its Washington D.C. headquarters.

Eventually the Lumieres came up with a film version, called Filmcolor. They eventually made faster versions, including Filmcolor Ultrarapide and Lumicolor Ultrarapide. By the late 1920s there was competition, chiefly Agfacolor, a similar random grain process using droplets of shellac as the colored grains.

In about 1935, after years of intense effort, two musicians with a fierce interest in color photography, Leopold Mannes and Leopold Godowsky, working alongside the laboratory experts at Eastman Kodak, succeeded in realizing du Hauron's dream of a 3-layer-in-one process. The result was Kodachrome, and with its higher speed and more saturated color it drove Autochromes out of the market in about 5 years, though Autochromes were produced for many more. The Lumiere Company never recovered, and eventually Ilford bought their operations and closed them down. The modern era of color began. Today digital color, based on electronic cameras, is invading the market.

COLOURING BY HAND

When the first daguerreotype images were produced, many people were disappointed that the photographs did not reflect the true colours of nature. The cold appearance of the monochrome metal plate could be unflattering for portraiture. Lines and blemishes were often emphasised by the process. Some colours in nature did not respond well on the daguerreotype and the photographer and entrepreneur, Richard Beard (1802–88) warned against black, white and violet clothing as these colours did not represent themselves well. He promoted silk and satin due to the play of light on these surfaces. The introduction of hand colouring helped to hide these discrepancies and added warmth and natural flesh tones to a portrait, complementing the sitter.

Not all photographers agreed with the introduction of hand tinting, however, the renowned American photographers Southworth and Hawes believed it unnecessary. Francois Arago, the scientist and secretary of the Academie des Sciences believed hand colouring ruined the natural daguerreotype image. He stated that:

> 'to hand-tint a lovely image, even by the hand of an artist of repute, is as if one should set a sign painter to retouch the wings of a butterfly.'

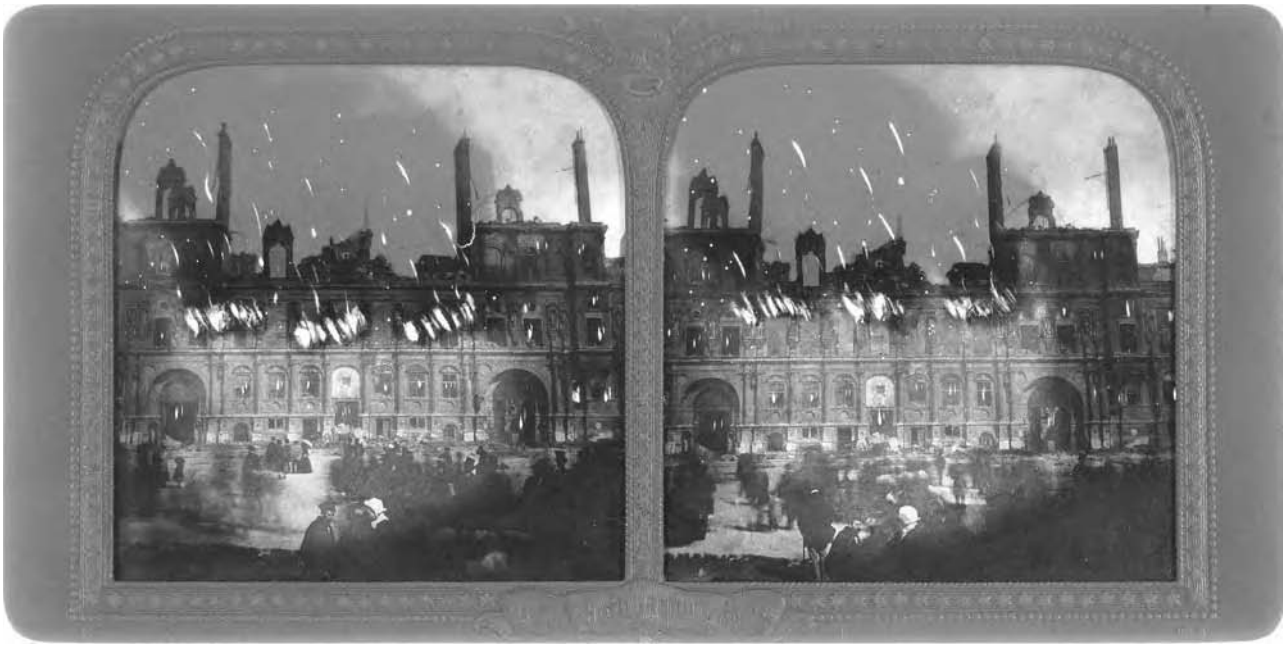
Despite these criticisms, hand-tinting soon caught on with the public and provided extra income for photographers. Most photographic studios charged extra for a tinting service. In 1853 Hay and Wilson of Aberdeen charged from12/6d to one guinea extra for this service. Hand colouring was an extremely skilled task and was carried out by a colourist. Most colourists were former miniaturist painters, many of whom had lost their previous career with the introduction of portrait photography. As reported here in *The Photographic News* Feb, 1859, 255:

> 'There can be no doubt whatever that the miniature painter's 'vocation' is gone…By the old system of miniature painting about a score of sittings were necessary…while now by means of photography, only one sitting of half an hour is necessary in order to produce the most elaborate and finished miniature.'

Colourists would make a tracing of the portrait on glass and then a paper stencil was made for each colour. The dry powder colour with gum arabic was shaken over the stencil or applied with a fine camel-hair brush. By breathing on the plate, the gum arabic was thus fixed to the plate. Alternatively, the plate would be painted with a thin layer of gum arabic, then breathed on to make it sticky. With a fine brush the powder pigment was applied carefully. There were occasionally mistakes, but most colourists were masters of their art. Later with the introduction of paper prints, albumen paper was tinted in various colours, some of which have now faded.

Daguerreotype portraits where the sitter is wearing jewelery were often highlighted with real gold, or the plate was scratched away to reveal the silver underneath. This was highlighted and glimmered when it caught the light. Richard Beard patented colouring Daguerreotypes in 1842. He had opened the first photographic portrait studio in London in 1841 on hearing of the success of the first studio in New York. Beard produced fine hand tinted examples such as "Portrait of Fanny and Henry Mason." C. 1852 7.5 × 10 cm (quarter Plate). The delicate quality of the lace is beautifully emulated, as are the subtle flesh tones. The sitter is placed in front of a painted backdrop of a stormy dark blue sky and a column to give depth to the composition. The gold is brought out of the necklace and ring.

Antoine Francois Jean Claudet (1797–1867), a French born photographer who moved to England, was one of the earliest photographers to use hand-colouring and his technique was one of the first to be used in the manuals on photography. As early as 1844, he was colour tinting his daguerreotypes and using painted backdrops to give added depth to the composition. As the idea caught on, there were soon several photographers using the hand colouring technique. Claudet's was however, considered one of the best in Europe. Even his French rival Alexis Gouin praised Claudet for his beautifully coloured portraits. It was thanks to Claudet's skillful colourist that he was able to achieve



Elliott, Joseph John. Hotel de Ville, Paris.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum

such hand tinted masterpieces. Whilst working in the Regents Street Studio, Claudet employed Andre Leon Larue, known as Mansion as his colourist. Mansion was a miniaturist painter born in 1785, the son of *Jacque Larue*, a portrait painter. Mansion wrote at least two books on miniaturist painting. The second of which was *'The Principles and Practice of Harmonious Colouring in Oil, Water and Photographic Colours on Paper, Glass and Silver Plate.'*

Critics were very impressed by Mansion's skill and in the *Art Union* 1845,1st June, p. 171, it was written that:

> '...no human had ever obtained such brilliant effects as these which result from the combined labours of nature and art.'

Mansion had his own technique of colouring plates, using a palette made up of fifteen colours which he had learned as a miniaturist. Hand tinting kits were eventually on sale such as the Newman kit dated 1850 which had thirty-six colours.

A beautiful example of a tinted photograph taken by A. Claudet and tinted by Mansion was the portrait of Mrs Andrew Pritchard 1847, Victoria and Albert Museum, London. The subtle beige of Mrs. Pritchard's dress is complemented by the painted landscape backdrop and her jewellery is highlighted in gold.

Claudet was aware that it would never be possible to produce daguerreotypes in natural colours. Despite this, he continued to carry out research into the solar spectrum. At the Great Exhibition in the Crystal Palace in 1851, Claudet exhibited a daguerreotype showing the spectrum and illustrated the different refrangible rays. Claudet delivered a paper discussing the sensitivity of the photographic surface to colour media to the Royal Society but never had the opportunity to follow this concept through to its full conclusion.

It was not until 1861 that James Clark Maxwell was the first to demonstrate the additive colour process. He superimposed three photos through red green and blue filters, then projected the original in full colour. In 1869 Louis Ducos du Hauron discussed the possibilities of natural colour in photography in his book *Les Couleurs en Photographie Solution du Probleme.* In 1895 Professor John Joly of Dublin presented the first additive screen plate colour process and finally, in 1904 Auguste and Louis Lumière patented the autochrome process, which was to dominate the world of photography for the next thirty years and made orthochromatic photography possible.

LAURA CLAUDET

Biography

In 1839 the daguerreotype was presented by Daguerre. There was disappointment that daguerreotype images were not in colour. Richard Beard patented the colour tinting process in 1842. Critics such as Francois Arago were against the hand tinting of daguerreotypes. Many of the colourists were former miniaturist painters. The hand tinting process involved coating the plate with gum arabic, then brushing on powdered pigment with a very fine brush. Andre Leon Larue, known as

Mansion a renowned colourist worked for A. Claudet during 1840s and1850s. Auguste and Louis Lumiere patented the autochrome process of colour photography in 1904.

COMPOSITION

Before the invention of the calotype (and the daguerreotype), artists and amateurs used various drawing devices. The *camera obscura* became the camera. Instead of tracing a drawing of what was seen, the 'camera' could now impregnate a description of what was seen onto a piece of paper. The use of this instrument which could be the size of the palm of a hand or a table, was designed as an *aid*, that is, its function was already prescribed before it came into existence—such instruments go back at least to the 15th century, to Durer's woodcuts of 1525–38 of drawing machines, or even before. It is only post the invention of photography that their use became dislocated and, until the 1960s almost entirely forgotten, so that, post the invention of photography, during the 19th century Romantic period, artists took flight; as the French artist Ingres commented, "It is to this exactitude that I would like to attain, it is admirable—but one must not say so." Instead artists were now to be deemed to be good draughtsman solely by their individual dexterity, their talent of genius. This was a historical lie, told because it suited the culture of the day to think it so. But today we can acknowledge the debt that artists such Durer, Mantegna, Vermeer *et al* owed to such aids. Indeed it may well be that often those Renaissance 'mysterious' constructions in paint, including their compositions, are probably only mysterious to our eyes because we no longer know exactly how such devices contributed to the end results.

When William Henry Fox Talbot, on his honeymoon in 1833 to Bellagio, Italy, using his little Wollaston's *camera lucida* in his hand and tracing tentatively a description of Lake Como, thought about the possibilities of fixing nature's image permanently onto the paper to obviate his necessity for continuing to draw badly, artists and some scientists had already thought about this possibility for around four centuries. What he produced in drawing was a good example of how the aid was used, that is, its use was limited to the perception of how it 'could' be used. In the amateur results of the use of such instruments we can see clearly that, in spite of what was seen on the ground glass screen, the view in front of the *camera obscura* had still to be translated into a 'good' composition; that is, one that followed a known and accepted formula of that time of what constituted a 'beautiful picture.' Similarly, in the first place, the view chosen for study, particularly amongst amateur users, would be selected if it conformed to that which was acceptable, fashionable. In Britain, around the time of the invention of photography in the 1840s, that conformity would be to produce images that accorded with the tradition of the Picturesque, of William Gilpin's *Three Essays* (1792). Gilpin (amateur artist) argued that it is the artist's task to supply 'composition' to the raw, inadequate, nature, and that while looking at nature, this task is to recognise when it behaves itself; supplies that which is agreeable to the art of making a picture. In other words it was a known quantity. This has continued to our time, for example, the accepted criteria *applied* to photography in some quarters resulted in 'rules' of

engagement, such as, the use of the golden section, the third to two thirds; that the tree should always be placed at the left hand side, a third of the way into the picture, and that the sun should be always behind and over the left shoulder; that the horizon should be lower than the middle and never higher.

Of course, artists were more knowledgeable than Gilpin and were well versed, if not verbally articulate, in the various histories of composition and its fundamental importance in the creation of meaning. That book has still to be written for it would need to trace the subject back to at least the Greeks; to Aristotle's *Poetics*, "If any of the parts be either transposed or taken away, the whole will be destroyed or changed"; back to the importance the Renaissance attached to *composito*, to the 17th century European Academies with their 5 elements: Invention, Proportion, Colour, Motion, Disposition. All knew that in order to convince the audience of the reality depicted in the image, the *truth* of it, firstly a process of observation of reality, of 'nature,' had to take place, followed by an analysis, then a distillation, then re-invention. All had to be put together within the structures of composition; the classical Greeks called it: *synthesis*, Plato's 'organic whole.' Fox Talbot, in his *The Pencil of Nature* (1844–46), the first ever publication to include photographs, acknowledges this with his 'air of reality':

> "I have observed that family groups are especial favourites: and the same five or six individuals may be combined in so many varying attitudes, as to give much interest and a great air of reality to a series of such pictures."

It was inevitable therefore when the new toy appeared, as is the case today, it would firstly be used to imitate that which it sought to replace. Fox Talbot, it is suspected, did want to make images 'drawn by the sun,' but he would have wanted them to be translated into Picturesque images, of acceptable beauty, that accorded with all the values of why, culturally, pictures were wanted at that time. And, as can be seen in his publication, *The Pencil of Nature*, concerning his photograph of 'Articles of China,' he marvels at the extraordinary detail and accuracy but then he adds perceptively, "It may be said to make a picture of *whatever it sees*." This explains much of the cultural revolution that would now take place as a result of the invention of the photograph, that is, by its own influence, *by its very nature*, unrelated to the user or the users' abilities.

In the *Pencil of Nature* Fox Talbot conducts a scientific and aesthetic analysis of what his new invention, his aid—for that must have been how he envisaged its purpose originally, was for, could do, then he noticed that it did not behave according to his preconceptions and instead opened up a large new terrain, one without answers attached. In spite of the Industrial Revolution and all its progress in the mechanical field, it was this new invention of photography that ushered in our age of technology. Talbot noticed it, but many photographers never did and others only a long time later, in the next century. For the most part his perceptive observations went unnoticed. The audience remained simple mesmerised.

Some photographers took the need to conform to the accepted conventions of picture making much further with compositions that imitated the 'best in painting,' from Renaissance triangles (originally used to produce the hierarchy of kings or Madonna's), to compositions which turned everything into the centre of the image; to be complete within the picture frame, that is: to create a complete world within the two dimensional space that had no references to anything outside it. In many cases such images were arranged in accordance with the best practice of Victorian painting. However an audience cannot read Oscar Rejlander's *The Head of John the Baptist in a Charger*, c. 1857–58, as a severed head simple because, unlike the painting, the over riding attribute of the photograph is that it records, for better or for worse, for real or fiction, an actual moment in time. When the photograph was used to imitate the conventional compositions of painting, past and present, for the most part, it actually failed to convince unlike the paintings they imitated.

Even when photographers noticed that this new machine could interrupt actual time which they had never been able to do before, for the most part it was just the detail that mesmerised; the advocacy of the verisimilitude of the photograph by John Ruskin (1819–1900) which legitimised the use of photographs as painting aids by the new Pre-Raphaelite painters, of Holman Hunt and Thomas Seddon, resulted in the painstaking imitation of its ability to record detail but missed the many characteristics of the new medium.

Fox Talbot observed first hand the waywardness of nature, that it went about its business completely outside the concerns of man, that it did not seek perfection and that it had no regard for human values. Put another way: the camera gave credibility to Charles Darwin's *Origin of the Species* (1858). He also noticed that man simply interrupts nature, that the photograph of the bridge traversing the ravine, unlike all that history of painting such subjects, looks and is profoundly man made and apart from nature. He also noticed that for *order* in a picture to exist, it must first be placed there, created in front of the lens by various means of controlling composition. He further observed that the description of reality, instead of being simply applied, could now be created solely by his machine, and he touched upon the observation that by recognising this new phenomenon, a different world appeared.

As we have noted, the use of composition to create

meaning in the observer was fundamental to the Western tradition, indeed, well known to the Roman and Greeks before the Renaissance: that projected 'reality' has to be the product of astute re-creation and that composition is one device used to create the illusion of that reality. Some photographers did notice something different about photography—that, when controlled, it could create *precise meanings* especially if composition was used effectively. While photography, like etching, is a subtle art, it can nevertheless be impregnated with intended meanings. To give one example: of all the photographs of the *Equestrian bronze statue of Marcus Aurelius standing in the square of the Capitol, Rome* taken in the 19th century, not many are found by the Scottish photographer Robert Macpherson (1814–1872), which relates the object, the statue, to its surroundings and locates the head of Marcus Aurelius within the window pediment of the Capitoline Museum behind it and, with equally exact mathematical precision, lines up the horse's front leg and tail to fit within the boundary of the two columns of the window. This produces, within the confines of the use of photography as a two dimensional graphic art, a perfect harmony between the sculpture and its stage set, resulting in a picture of supreme nobility. Technically, in order to achieve such a line up, it had to be taken from a point suspended above the normal eye level, probably from a ladder and/or by the use of a tilt lens. All other photographers of this sculpture, and there were many, ignore the surrounding building which nevertheless becomes part of the image, thus forgetting that *everything* that occurs in the picture must be constructed for a purpose, that if meaning is to be created, it is created from a knowledge of composition, from the ability to compose.

There was an exception to Fox Talbot who fooled many into thinking that it was his individual genius that was able to create an entirely new language; one that pushed art forward. Later he was to 'fool' many art historians who seemed to prefer to give, as explanation of his imagery, the influence to the more intellectually acceptable Japanese woodcut that entered Europe for the first time in the mid-nineteenth century and which had became much loved, particularly in France. That artist was Edgar Degas (1834–1917), painter, sculptor, printmaker, draughtsman (and photographer) who had been trained in the Renaissance tradition, well placed, therefore, to notice a new and different visualisation. He, more than most, had observed, perhaps early on even unconsciously, what happened to 'reality' when it was interrupted by photographers who were *not* part of the visual tradition; who used it, in comparison, crudely, badly; allowing it to be itself. Degas then *re-translated* this new vocabulary by applying the same principles as the Renaissance/Academy, exactly as he had been trained to do: observe, analyse, distil, re-invent. Those who praised his new way of 'seeing,' his unique genius, never noticed that it was rooted in an astute perception and understanding of how photography actually works. Those who labelled it as unworthy as a snap-shot had entirely missed the point. Degas was able to articulate in paint many of the observations of Fox Talbot that had gone ignored. Such was the incomprehension of fellow artists and critics that, ironically, Degas' paintings began to influence photographers and fellow artists so that, for example, the young Edward Steichen, photographing the races and street scenes in Paris at the end of the century, interrupts time consciously when he observes a similarity of composition to that of the radical painter, Edgar Degas. All art, as Oscar Wilde observed, influences art. We can add to that: knowingly or unknowingly.

Most of the characteristics of photography, the workings of the camera and its lenses, are to be found in Degas' paintings: the blurred, out of focus, differential focused image; scientific movement (not seen by the eye); the specifics of camera angle, camera view point, lens perspective (especially distinct from Renaissance perspective); distortion and the acceptance of *none* information conveyed by the photograph for this never existed in visual art prior to photography, such as the absence of specific tones in order to explain light and shade as volume as hitherto all artists had been taught Renaissance formulas for drawing three dimensionally onto a two dimensional surface; asymmetric composition (certainly to be seen in Japanese prints); cut-off composition (hardly ever to be seen in Japanese prints made prior to the invention of photography, more likely if found to be a folded page or torn out print); use of height and distance as acceptable subject matter in their own right; giving more prominence to other matter at the expense of the apparent subject of the picture, for example, in Degas' 'The Rehearsal,' 1873–1874, a spiral staircase takes over and obliterates most of the dancers, meanwhile the Ballet Master nearly disappears, stage right; placing subjects against the light so as to be hardly seen; the depiction of (apparent) spontaneity, the accidental, the unplanned; including the incongruous and inexplicable to the point of looking unreal: consider the seated girl in Degas' 'Bellelli Family,' c. 1860: where is her other leg?

Degas' perception and use of photography was profoundly intellectual. In his painting of the 'The Cotton Office, New Orleans,' 1873, (*Portraits dans un bureau*), he depicts a strange interior which rushes to the back of the room, the perspective has not been made according to the accepted norms, it is more probable the result of lens perspective. While there has been much written on the influence of Japanese prints and their use of asymmetric composition, correctly so, they may have legitimised the acceptance of similar compositional structures now seen in photographs, a natural result of

Thompson, Stephen. Satyr, British Museum.

the camera interrupting space, but the Japanese prints did not enter Europe until mid-nineteenth century. If Degas was only influenced by things Japanese then he would not have cut the man legs off at the knee (sitting stage front), nor would he have cut the hands off the man at the table stage right. To our eyes now we see such works as 'real' because we see photographically, but pre-photography this painting would merely look crude, inexplicable, badly composed, unnatural. It has a channel of nothing running between the man with no hands and the main group examining the cotton. There is a channel of windows running stage left to the back which directs your eye to the back of the room to find nothing of importance. It has a cupboard door sticking out, top right and a wood doorpost running down the entire left hand side. Put against the Renaissance tradition that had lasted nearly 400 years this is all a revolution. However the most important aspect is the meaning produced from this range of compositional, photographically-derived devices. Unlike virtually any other painting before its time nearly every participant, '*portrait*,' is going about his business without any regard for the other persons in the image. This is no longer a complete world, one of order and harmony, a *composito*, quite the opposite. The man at the desk has no interest in the man sitting in the chair with no legs who has no interest in the man reading the newspaper who has no interest in the man leaning up against the window who would appear to be equally disinterested in the two engaged in examining the cotton in front of him who have no interest in the two men walking through the room behind them. It is a profound image that heralds a new world, the industrial city with its money-making preoccupations, a dislocated community of self interest; while they are all busy at their tasks, they are profoundly lonely, nobody really connects. This picture tells of what we in the 'economic developed countries' were to become. While Degas' world foretold the coming of narrative cinema, many

painters and sculptors continued to seek refuge away from the camera and moved further and further towards none representational and finally abstract art.

Photographers in the next century were to probe endlessly, and still are, Degas' vision of that city life; think of Walker Evans, Henri Cartier-Bresson, Robert Frank, and they were to do it using the same compositional devices, that life's continuum could be interrupted by the camera and, if the photographer wished to place meaning into the image, then the means to do so, along with light and shade, would be to choose, recognise, how exactly the world, the chaos, had to be interrupted, composed now by photographic means, in order to do so. Although Degas and others similarly influenced had come up with a new vocabulary, a new way of seeing, he was nevertheless still operating in the tradition of Western realism. This tradition had brought into being the camera but, as a result, had also brought into being a new way of looking at the world, new ways of composing, which would be used to try and explain what our human condition might mean.

By the end of the 19th century the discipline of the tripod, the heavy plate camera, gave way to the hand-held camera with its instantaneous interruption, as foreseen by Fox Talbot, and was accepted as standard; the world was now to be described verbally and visually as if it were a photograph; little children brought up in the new age describe reality as if it is the product of the camera, later the movie, now, with us, alarmingly, the computer play game. While 'reality' had become the capturing of the images of light from that little hand-held *camera lucida,* it had also become freed from the art conventions of the past. Soon, by the end of the 19th century, the street could be interrupted in all its chaos, and, in the interruption, made meaningful by the static residue captured in an instantaneous photograph. It heralded 'The Decisive Moment,' essentially the 'photography of the street,' which was still to be rooted, albeit sometimes skilfully camouflaged, in that previous formula; that if meaning is *also* to be transmitted (as distinct from only providing documents), then precise composition is still required, just as William Henry Fox Talbot had quietly observed in his *Pencil of Nature.* When the middle of the 20th century eventually came, both photographers and artists, and a few art historians, suddenly began to observe that what some visual artists were now doing had already been observed by Fox Talbot and had been articulated brilliantly in the paintings of Edgar Degas whose eyesight was so bad that he found it difficult to go too much into the sunlight.

The creation of 'meaning,' in the end, be it in the photograph or the painting, is not arbitrary, irrational, by chance, but the product of careful thought. As Degas said, "Even when working from nature, one has to compose" and he added (what many photographers also know), "No art was ever less spontaneous than mine."

COMPTES RENDUS HEBDOMADAIRES DES SÉANCES DE L'ACADÉMIE DES SCIENCES

The *Comptes rendus hebdomadaires des séances de l'Académie des sciences* [Weekly reports on the sessions of the Academy of Sciences] was founded in 1835 by physicist François Arago, then Secretary of the French Academy of Sciences, to serve as a regular and complete chronicle of the proceedings of the scientific body, which until then had only sporadically published memoirs; it is still in existence, albeit with a different format and title. In scope and frequency, it was a novel kind of publication, which answered not only the needs of scientific communication but also, and perhaps more importantly, the emerging social demand for vulgarization. As it was widely distributed in Europe and North America, it quickly became an international reference in science and technology. In the mind of the buoyant Arago, who was also a leading left-wing Parliament member, the purpose was as clearly social as it was scientific: the new periodical was intended to publicize the progress and social utility of science, in accordance with a broader agenda that enlisted the Academy itself into scientific education and even the promotion of inventions and inventors, as happened with the daguerreotype. From the first disclosure of "Daguerre's discovery" on 7 January 1839 to the famed announcement of photography to the world on 19 August 1839, the *Comptes rendus* reported week after week on the lengthy procedure of publication of the daguerreotype. Starting in early 1839, the periodical continually printed reports by physicists (especially Arago and his arch-enemy Jean-Baptiste Biot), as well as claims from inventors and scientists who, in France and abroad, had designed alternative methods of photography (such as William Henry Fox

Talbot, letters by whom appeared in several issues, and Hippolyte Bayard) or simply submitted improvements and observations. Photography was reported on in nearly fifteen different issues in the second half of 1839, and in about thirty in the first half of 1840; many of these papers, which described methodology rather than theory, were taken up by other publications throughout the world. The *Comptes rendus* was indeed the major scientific publication involved in the initial development of photography, and a quasi-official channel for its announcement. Remarkably, a method of picture-making that was hailed as a revolutionary and radically simple alternative to every known craft of depiction was thus given a fairly abstract and scientific definition, rather than a technical or visual one (actual practice was not discussed in the *Comptes rendus*, and there were no illustrations). Although passions surrounding the invention abated after 1840, the topic of photographic technology remained prominent in the *Comptes rendus*, with publications by Louis Daguerre, Alfred Donné, Léon Foucault, Hippolyte Fizeau, among others, on various processes of microphotography, astronomical photography, photographic printing and reproduction. With regard to photography on paper and glass, the French periodical advocated Louis-Désiré Blanquart-Evrard's process as opposed to the English collodion process, until Arago's death in 1853. Later on in the century, the *Comptes rendus* published important contributions on color photography and permanent printing techniques.

CONSERVATION AND PRESERVATION

The history of photography has become a well-established and respectable scientific aspect of art history. It is a highly productive field that produces much scholarly work on the lives and works of photographers as well as the impact of photography on art and society. The preservation of photographs has become a matter of concern for societies that appreciate and continue to enjoy photography. Over the past few decades, scientific research has advanced considerably in its efforts to understand the deterioration of early photographs and to find more effective methods of preserving them.

In the United States, the principles of archival processing seem to have been applied at an early stage by the majority of photographers. In Europe, and the rest of the world, the situation has evolved more slowly, perhaps by a lack of information and resources.

World wide however many conservationists such as James Reilly in the United States and Bertrand Lavédrine in Europe have incorporated their scientific interest in photographic conservation, restoration, and preservation. Important museums such as The Getty Conservation Institute; The National Media Museum in Bradford; the Centre de Recherches sur la Conservation des Documents Graphiques (CRCDG) in Paris; the Images Permanence Institute (IPI); a part of the Rochester Institute of Technology; The Harry Ransom Humanities Research Center in the University of Texas at Austin, Texas, USA all provide a foundation for the development of new tools to address the causes of deterioration of photographic materials. Their work also includes the development of new treatment and preventive conservation strategies for these materials. Because of their work in preservation, photographic collections with images from the nineteenth century can be appreciated today, serving as an integral part of our collective heritage and memory.

Individual pioneers of conservation were Ian L. Moor and Angela H. Moor from the Centre for Photographic Conservation (London), Etsuo Fujii and Hideko Fujii (Tokyo) and Roger Kockaerts (pH7 Center, Brussels). The foundation pH7 was establsihed in the early 1980s to educate European photographers and museum staff on existing photographic conservation techniques. At that time photo conservation, as seen by the majority of the photographic community, was still in its infancy although its principles referred to the findings of the scientific committees of the 1850s, organized by the Photographic Society of London and the Société française de photographie in Paris.

Fortunately much of this pioneering work was published in photographic journals such as the early issues of the *Photographic News*, *Photographic Journal,* and the *British Journal of Photography*, and their

counterparts in other European countries and the USA. The Photographic Society (precursor to the Royal Photographic Society) was dominated by photographic scientists who found it a vital forum for mutual exchange of information and constructive criticism. Of the many photographic issues discussed by this group and the Linked Ring, the Société française de photographie in Paris and Secessionist Movements was the issue of conservation and preservation.

A brief inspection of nineteenth century scientific work proves that many scientists were interested in photography and made significant contributions in conservation or other related fields as a means to solve the problem of deterioration. It is unfortunate for the present day researcher in these fields that few of the actual photographs exist to serve as scientific records. The fading of prints was one of the key problems of early photography, with the Photographic Society of London setting up a committee on the subject in 1855. Surprisingly the committee came up with some highly pertinent recommendations, suggesting the prints be thoroughly washed with gold toning. Two French investigators, Alphonse Davanne and Jules Girard, conducted detailed and exhaustive scientific investigation of the process, and their study, published the same year, emphasized the importance of using fresh (sodium thiosulphate) fixer. Albumen prints however created new problems. Their thicker coating was relatively impermeable, and it proved difficult to completely wash out the chemicals. One of the favorite methods used in the early years for gold toning—the sel d'or (gold salt) method—mixed an acidic gold solution with the fixer, but often caused the decomposition of some of the fixer, which produced sulphur that could not be washed out. This was a major cause of print fading. A move to separate toning in alkaline gold solutions (first introduced by James Waterhouse around 1855) before fixing in fresh hypo produced significantly more stable prints. The kind of rapid fading that had often been a problem with the earlier salt prints and albumen prints largely became a thing of the past as Alkali gold toners deposited more gold, helping to protect the image. All nineteenth century albumen prints show some evidence of yellowing, but in a few cases it is relatively slight and only noticeable if the print is compared to a white paper surface.

As photography entered an age of more sophisticated and comprehensive knowledge about collections of photographs, the need for specialists in both curators and conservationists increased. Attention was paid to the methodology for the isolation and evaluation of problems with deterioration and specialists focused their analyses and prioritization on determining the eventual solutions, which were applied or adapted to them.

The issues concerned with the conservation and preservation of nineteenth century photographs are still not fully understood, and this remains an important area of scientific research. In addition to ensuring the long-term survival of the originals, the challenge of digitising early photography so that it remains available for study, are huge.

Photography had to wait almost a century and a half before scientific studies on complex chemistry of early materials, and the effect on them of environmental conditions, had advanced to a level where the inter-relationship of many diverse factors involved in image deterioration where understood. In recent years, many important research projects have identified the very different chemical processes involved in apparently similar materials. This has resulted in a much sounder understanding of the effects of time and environmental impact on different papers, films, and plates. Only relatively recently have conservators been able to establish and create optimum storage conditions.

It was not until 1989, exactly 150 years after the invention of the medium that, in addition to the many albums that were titled "the world history" of photography, excellent monographs emerged resulting from patient research in often difficult circumstances. Remarkable essays studied development, revealing little known or concealed facts. The history of photographic representation, however, was a controversial field that played an important role in the scope of photographic records. Today, conservationists see themselves confronted with a shift regarding the conditions of traditional historical research. Because photography captures a moment in time, that moment will exist as an artifact of the time it was taken. This image then functions as a tool for referencing that time period thus shaping our understanding of that time period. Historians though, can only access this history if the image exists and therein is the fact that its history is only possible as a result of future interest in the medium and the conservation and preservation of the image. Walter Benjamin stated that we should rethink photography and history altogether, because what transforms an event into a historical event is its technical reproducibility (the photographic recording of it). The language of photography memorializes history and at the same time expands the significance of photography. More than ever though, this history of photography remains ambiguous.

To help establish a comprehensive history of photography, conservationists and preservationists address the primary issues of: modes of decomposition of photographic materials; carriers, binders, image forming materials, the effects of specific pollutants and moisture in decomposition and biological attack; enclosures; advantage/disadvantages of various types of construction materials, and selecting specific materials for specific purpose such as cracked glass plates; storage; relative humidity and temperature, freezing, acclimatization,

rack systems, airflow, and desiccants. Secondarily are the issues like photographic identification, repairs and consolidation, compensating for loss, surface cleaning, humidification, and flattening of the image.

Important also in conservation and preservation of are the contemporary photographers who have revived the nineteenth century photography processes in trying to make photographs like them. Many of these alternative processes are historical methods of photographic printing based on the light-sensitivity of certain salts of iron, rather than silver which is the industry standard. Iron based processes are named according to the substance of the image, which may be a noble metal such as platinum (platinotype), palladium (palladiotype), gold (chrysotype) or silver (argentotype), or a pigment such as Prussian Blue (cyanotype). These alternative processes require hand-sensitized papers instead of any commercial photographic product, and are noted for their tonal beauty, individuality, and archival permanence. Their practice is therefore now of value chiefly to fine artists using photography, who through the use of these processes gain aesthetic control over important visual characteristics like color and texture of the paper surface. These photographers who revived these processes in the 1970s were obliged to use formulae from the nineteenth century, as there had been little progress in improving them since their invention. Michael John Ware is representative as an independent researcher, author and photographic artist who has been researching, teaching and improving these processes whenever possible to understand their underlying photochemical science, to improve their technology with modern materials, to publish his findings, to impart skills through practical workshops and to assemble a body of work for exhibition in order to highlight the special qualities of these early media for a wider public. The updating of the analogue photochemical science of the historic iron-based processes and re-creation of photographic methods establishes this vital art as contemporary and keeps its rich heritage from being lost or forgotten. Such innovative work also helps the professional restorers with their work in museums and other facilities.

One of the nineteenth entury's approaches is characterized by a departure from reality that renders an alternative reality from a very specific angle/perspective as a result of the photographic technique and design it employed. For instance there are myriad photographs from the nineteenth century of people with stern expressions, however to discern a historical reality from these images would be in fact a mere a assumption based upon the circumstances of photography. In particular, the processes that are typical of the medium of photography such as repetition, paradox and the gap between actual reality and its representation often reoccur. This emphatically visually oriented photography is characterized by a certain degree of alienation from reality as the latter can be perceived and often stands out by its markedly illusory character.

A photograph may be historical, academic, research, curatorial or administrative, but does not function exclusively as one or another. We tend to overlook the fact that photographs, which support scientific experimentation, may also be historically important images, or may represent the first use of an innovative photographic technique. If presented in a manner, which strips away prejudice for an exclusive use and function, photographs can provide a rich resource for all kinds of users with all types of needs.

Another goal, which digitisation and the development of comprehensive illustrated catalogues are designed to establish, is the widening of access to early photographs. One of the most pressing issues in photographic collections management is the paradoxical desire for increased use on one hand, and preservation of the objects on the other. Every reference aid reduces the need to handle multiple images and acts to preserve individual items and collections. Directories assist researchers in their assessment of a collection before locating the images themselves, and thus to preserve those unneeded photographs from unnecessary handling.

Directories also provide the information gathered about each collection details its purpose, organization, storage facilities, procedures, and current use and allows a thorough, easy and efficient investigation of the collection function.

There is perhaps another basic reason that the wide spread of conservation and preservation (imaging technology) have been delayed. In addition to the needed scientific knowledge in chemistry and optics, preservationists and conservationists need an understanding of commercial and business practices of the times in order to fully understand the importance of certain images. Needed as well is an ability to sift through and evaluate patent information for significant details that are not specifically referred to, but only suggested. Research as well may be difficult and require pairs or teams of workers to complete. Without a comprehensive understanding and appreciation for nineteenth century photography, not only as an art, an artifact, but also as a science critically limits its potential for growth.

Those interested in creating unified collections of nineteenth century images are doing more than protecting photographs. Conservationists and preservationists all attempt to:

- keep together the original collection with a international value, making it available to the public by means of commercial and non-commercial use;
- expand its contents by collecting documentary photo collections which otherwise would not be kept in

record in the originating country and which in that case probably would be lost and/or which are supplementary tot the original collection;
- preserve a historical document which formed a part of the cultural-historic memory, not only of the own country, but also of the rest of the world:
- bring forward and emphasize the photo historic value, which during the days as company archives hardly played a role.

Keeping the collection together as a whole has increased the value of the photographs, which goes beyond the value of the individual photo. The collection is a source of information on mass culture in the nineteenth and 20th century as seen by well-known photographers as well as an even greater number of anonymous photographers. This enables future generations to understand how people saw at their surroundings. Such collections have been preserved and can now be accessed and used in quite different ways than originally intended. The versatility of such collections allows photography to expand its application than in the days the photos originally were published and shown. Institutions and museum use their collections as a source of inspiration for many.

The conservation of the photographs has developed from not existing to the present standard of being critically needed due to the cooperation of experts and photographic conservationists. This conservation runs parallel to the increase in knowledge of photo-conservation in the past decades. It is also due to our culture's vast interest in these the collections, which have required specific solutions for conservation on a mass scale.

During recent years initiatives like the ICOM-conference has made an important contributions to the preservation of the photographic memory. The ICOM committee for conservation held the 14th Triennial Meeting in 2005 in The Hague (the Netherlands).Without its vast collections and many unique photographs the photographic collection of the world would be less saturated. In response to the regional need for training professionals in the field of photographic conservation, a series of mid-career photographic conservation training workshops were organized in Australia. These workshops were funded by the Getty Grant Program and organized by PHOTON, the photographic special interest group of the Australian Institute for Conservation of Cultural Materials (AICCM). These workshops targeted conservationists and cultural heritage professionals in Australia and the surrounding region.

Archives, museum and institutions are contributing to make the public aware of the values of the photographic memory to the community. Its collections are not only of interest to (photo)historians, but are used to stimulate students, artists, designers and serve educational purposes. With this in mind more and more conservationists and restorers are working together with researchers in the field of photo history and with culture, state, and municipal archives, as well as with other institutions, professional and amateur photographers, social organizations, the business community, designers artists and teachers.

Many archives consider the production of temporary exhibitions as an important part of its activities. It enables the public to see photography from constantly changing perspectives. This may range from creating a feeling of recognition of portraits of landscapes, to public debates about the use of photography and its impact as well.

By making photographic collection available in so many ways, institutes have made archives into dynamic experiences. By the daily use and growth of digital photography, reproductions have been easily made in recent years for (photo)historic research, exhibitions, and publications like books, newspapers, magazines, cd-roms, DVDs, commercials and advertisements, school materials, television and film, and the institute's wide and various audience. The expansive use of archives makes nineteenth and twentieth century photographs part of the twenty-first century. The collections also contain international pictures, help establishing an international concept of the world in earlier centuries.

In 1992 a conference on photographic conservation was held at Windemere, Cumbria, England. More than 150 delegates representing 15 different countries from all over the world attended the Conference The Imperfect Image—Photographs, their Past, Present and Future. It was organized by the Centre for Photographic Conservation based in London and directed by Angela and Ian Moor, two of the most influential conservators in the field.

This Conference 92 was divided into five sections, and there was an accompanying poster exhibit. Section one was Photographic history, processes and applications; section two was Photographic collection management; section three: preservation and conservation research; section four: conservation and restoration and section five: photographic conservation training. This conference was an important meeting for scholars that celebrated surviving images while drawing attention to the degradation of countless others.

Many institutes, archives and their researchers/restorers as well as artists have contributed to the proliferation of knowledge about photographic conservation and preservation. Members of these institutions share their experiences with other conservationists, allowing free exchange of information. Focused on as well are the great number of photographs that stimulate the debate about more efficient ways of conservation. These institutions cooperate with the scientific centers also concerned

with photographic conservation and preservation like the Getty Conservation Institute.

CONSTABLE, WILLIAM (1783–1861)

William Constable, a man of many talents who opened one of the first provincial daguerreotype studios in England. Constable was born in Horley, Surrey, the son of a flour miller. After a brief formal education, he began working life with a draper, Henry Browne, who encouraged Constable's artistic and scientific interests. Following a tour of North America with his brother (1806–1808), he returned to Horley Mill, which he helped restore and operate. By 1816 when he married he was an established surveyor and Civil Engineer. He embarked on further visits to America in 1837, returning in 1839 when he became interested in the 'New Art' of photography. Now based in Brighton, he began negotiations with Richard Beard who owned the English patent rights to practise daguerreotype photography. Constable's `Photographic Institution,' opened on the 8th November 1841, was one of the first daguerreotype studios outside of London. Constable's reputation was firmly established following a visit from Queen Victoria's consort, Prince Albert, in March 1842. Members of the court and aristocracy flocked to his studio. In all, he worked as a photographer for twenty years. Constable died in Brighton and was buried in Horley, the place of his birth.

CONSTANT, EUGÈNE (1848–1855)
French Photographer

Eugène Constant was a brilliant and innovative French photographer who produced views of Rome that are unique, particularly with regard to their manufacture. As early as 1848 Eugène Constant sent to Paris some excellent positives printed from albumen negatives taken by him personally in Rome. Yet he still remains a mystery. He used the calotype, then became one of the first in Rome, if not the first, to use the new albumen on glass negative. He lived Rome 1848–1855, then disappeared. He exhibited Society of Arts, London 1852, Paris 1857.

No one of the period seems to have produced so consistently the same texture, the precise quality of the printed mark, not simply with regard to tone, often a soft pink, but in relation to the specific *granular* construction of the printed silver solution, which resembled an etching as distinct from the soft, often blurred tones that were characteristic of the early albumen experiments. As such Constant was able to bring out the quality of the Roman ruin majestically, such as his 'Temple of Castor, Rome, from the West' or 'The Arch of Titus,' or 'The Arch of Septimus Severus.' These prints were probably made from albumen glass negatives as distinct from wet collodion. They are comparable with some early prints by the Scottish photographer Robert Macpherson who was to eventually use the rarely used collodio-albumen dry plate negative, invented 1855. He had commenced with the albumen negative in 1851. Constant's work displays perfect composition, a delicacy; small, petite, exquisitely refined—all photographs display some aspects of the photographer's character. They are decidedly French. He controls the light perfectly, as if it were paint; the light alternating precisely with the shadows.

Eugène Constant was part of the foreigners art scene in Rome that congregated round the Caffè Greco where many visitors also came to talk to the artists and obtain invitations to visit their studios. The French would appear to have formed the first significant group of photographers: along with Constant were Jean-François-Charles André (1813–83), known as Count Frédéric Flachéron, sculptor, lived Rome 1839-1867, originally as a Prix de Rome at the French Academy. He commenced with the calotype in 1847, Prince Giron des Anglonnes, lived Rome 1850–52, perhaps also Alfred-Nicolas Normand (1822–1909), a Prix de Rome architect arrived 1847 took up the calotype, producing prints dated 1850–52, and Louis-Alphonse Davanne (1824–1912). It is probable that the interest in photography began as a gentleman's pursuit, a side show originally to painting, during the daguerreotype and calotype processes, and although they produced excellent work, mostly using Louis-Désiré Blanquart-Evrard's (1802–72) improved calotype formula and his new albumen paper, and then the albumen on glass negative, they did not become successful commercial exponents.

Some did try to make photography pay, just as in painting, but how much of a business is still difficult to tell. Count Flachéron, as Flachéron-Hayard, using his married name, attempted to run a business and also sold work by Robert Macpherson (c. 1856), Eugène Constant sold his prints, mounted on card, inscribed with an embossed stamp of 'Eugene Constant,' and on the mount the monogram EC, at the shop of Edouard Mauche, Via del Corso 174, along with other French photographers.

One reason for the fading of such as Constant's brilliance was the political and economic blight in the 1840s to 1870 which drove the collectors from Rome. The artists' studios gradually began to disappear. They no longer came for several years at a time; the migration to Paris had begun. In later years the abandoned artists' studios made excellent photographic studios and darkrooms for the thriving trade that catered, post-1870, for a different kind of tourist. All were never to be heard of again in their time. The new formula for success in the mass market was to be the denial of the photographer as personality; companies could now employ many photographers and few would notice the difference between one photographer's product and another.

CONSTANTINOU, DIMITRIOS (active 1850s–1870s)

Dimitrios Constantinou was known as the second pro-

fessional Greek photographer of the nineteenth century. He set up, his first studio, in 1858, in a central road of Athens (Aiolou Street 925), only to move it some years later, between 1865 and 1875, a few blocks closer to the New York Hotel. In 1859, Constantinou participated in the 1st Olympiad (held in Athens) where he was awarded a silver medal for his excellent depictions of classical Greek antiquities; after this distinction followed many others as he took part in numerous exhibitions in Greece and abroad such as the International Exhibition in London (1862) and the Exposition Universelle in Paris (1867).

Constantinou was also known as the first photographer to have collaborated with the Greek Archaeological Society; his task was to document the archaeological work that Greece had undergone during the last two decades of the nineteenth century. For this purpose, he photographed the most important monuments of Athens such as the Acropolis, the temple of the Olympian Zeus, the Tower of the Winds and the Theseion. One could characterize Constantinous' images as beautiful, but at the same time conventional, satisfying the taste of the eager market of the nineteenth century. A closer examination of his photographic work will reveal his austere and scholarly approach to the sites produced by the photographer's interest in the archaeological as opposed to the picturesque details of the antiquities.

ALIKI TSIRGIALOU

CONTACT PRINTING AND PRINTING FRAMES

Contact printing is a method of making a photographic print in which the negative emulsion is placed into direct contact with the sensitised material (usually paper) and exposed to either daylight or artificial light. Contact printing was the principal means to make multiple copies from either paper or glass negatives until the development of and widespread use of solar enlargers from the early 1860s and reliable artificial light sources allowed for more convenient enlarging to be undertaken.

The most basic form of contact printing pre-dates photography with objects being placed into direct contact with a piece of silver-sensitised paper. Talbot's photogenic drawing process was essentially a contact process as was Herschel's cyanotype process of 1842. The salted paper prints were also made by placing a negative directly into contact with a piece of sensitised paper. These processes and many other processes all made use of daylight to create the image.

Contact prints were made on albumen paper with daylight as the exposing light source which gradually gave way to gelatine printing-out papers, usually silver chloride based. Ilford Ltd coined the word printing out paper (POP) and introduced it in 1891 and Kodak produced their own version under the name Solio from 1892. The introduction of silver chloride papers under the colloquial name of gaslight papers which came in a variety of contrast grades (Kodak produced their version under the name Velox) could be handled under subdued illumination and exposed by use of gas or electric illumination which made them eminently suitable for amateur use. As a consequence the printing frame saw a resurgence of use from the 1880s onwards.

To facilitate contact printing the photographic printing frame was an early feature of photographic darkrooms and outfits from the 1840s onwards. The printing frame allowed the negative and receiving sensitised material to be held tightly together often with some means of inspection without disturbing the register of the two during exposure.

The printing frame was also called the reversing frame or pressure frame. All contemporary writers stated that two sheets of glass clipped together would act as a printing frame but recommended the French form of pressure frame that "opens at the back, in order that the progress of work may be examined from time to time. It is rather expensive, but very convenient, and many blunders will at first be avoided by the use of it." (Thornthwaite,1853). Frederick Cox his *Compendium of Photography* (1866) stated: "After taking the Negative on glass, a pressure Frame is required to produce the paper copies: they are made of various sizes, one sufficiently large to take the Negative with a small margin around it, is recommended; and the back-board should be jointed." Photographers using printing frames were cautioned about over-tightening pressure screws which could cracked the cover glass or more disastrously the glass negative.

There were variations in design. Frame for printing from paper negatives, Calotype or waxed-paper, generally had a glass plate behind which the two pieces of paper were mounted. Those for printing from smaller glass negatives did not and the glass plate set into a rebate in the frame acted against the sprung back to maintain close contact. Some frames were designed to hold two or more negatives with the cheaper models holding just one. In 1860 a superior pressure frame with pressure board hinged in two places was sold for 2s for a 6½ × 4¾ inch model and 16s for a 12 × 10 inch model. Frames were available in oak or mahogany with the latter being slightly more expensive. Bland & Co. in 1863 were offering an Improved Pressure Frame in mahogany in nine sizes from 13s 6d for a 9 × 7 inch model to £2.15s.6d for a 25 × 23 inch model and altogether offered thirty-three different styles in their catalogue.

The basic design of printing frames changed little through the century. The earlier back pressure screws gave way to spring metal clips and the sizes of frames,

at both ends of the scale, expanded to cope with printing from the various sizes of roll film negatives available by the end of the century. Specialised frames were also introduced to cope with particular processes.

In 1900 Houghtons Ltd., one of Britain's largest photographic manufacturers and retailers, carried seven pages of printing frames plus one of printing frame accessories listing over eight-five different types of frame. These ranged from pine models, ordinary teak frames in 'good' and 'best' quality in sizes from 3½ × 2½ inches to 15 × 12 inches plus Continental sizes; white wood frames, and a series of frames for roll film negatives from 2 1/8 × 1 5/8 inches to 3½ × 3½ inches. Specialised printing frames for stereoscopic negatives had been available in the 1850s and remained so in 1900 (sometimes called transposing frames). Frames were also available for printing opals and lantern slides and for making Bromide prints on to rolls of sensitised paper. Accessories included rubber and felt pads for the frames—some flexibility of the frame back was important so ensure perfect register between the two photographic emulsions and to ensure that glass plates did not crack when pressure was applied. Spare springs could be purchased and a print indicator that could be attached to a printing frame which recorded the number of prints taken from a negative.

From the later 1880s and especially into the 1890s patents were granted for a range of more specialised designs some of which saw commercial development. Other designs were registered or offered in manufacturer's catalogues. A very basic design relied on metal clips to hold the glass negative against the sensitised paper and being light weight were intended for touring. Lancaster of Birmingham produced the Triple Pressure Frame that allowed a print to be inspected from both ends without disturbing registration. The Birmingham Photo Co made a Full View Frame that allowed the whole print to be inspected and also allowed for vignetting and other masks to be attached. Pickard's printing frame was made solely of metal. Specialist opalotype frames reflecting the popularity process in the early 1890s were designed to accommodate dif-

ferent thicknesses of opal glass and glass plates and to keep them in register during inspection. The increased use of vignetting and the growth of the postcard in the 1890s also led to manufacturers producing specialist printing frames. The production of the 3¼ inch square photographic lantern slides from the late 1880s well into the twentieth century was also undertaken by contact printing on to glass where the negative was of the same size as the intended slide, once the glass slide had been exposed, usually in daylight, developed and toned the emulsion side was protected with a cover glass and the edged taped with passé partout.

The printing frame remained an essential part of the photographer's darkroom throughout the nineteenth century. Photographers studios or printing works from the bigger studios such as Elliott and Fry such would often employ large rows of printing frames to produce the volume of prints they required. For the amateur the contact print offered a convenient way of producing prints used limited equipment.

The development of the practice of enlarging negatives and smaller roll film formats did little to dampen their use right through to the 1960s when the rise of low-priced photo-finishing saw a reduced need for amateur photographers to undertake this task. In the later part of the nineteenth century professionals would use them to make proofs and amateurs would use them to make their final prints. Their basic design remained largely unaltered throughout the century with an increasing variety of designs reflecting the rise in the number of photographic processes.

COPYRIGHT

For twelve years after Daguerre and Talbot announced the invention of photography, its products were of relatively limited application and difficult to reproduce. With the invention, though, of the wet plate collodion process it became much easier to produce multiple copies of images, and commercial exploitation through such media as *carte-de-visite*, stereo cards and cabinet prints rapidly followed. Photography became a profitable business, but competition was fierce and the product needed protection from illicit copying by those wishing to have a share but unwilling or unable to make the necessary investment. Photographers needed the protection of the law, and the answer lay in copyright.

In the United Kingdom, limited protection was available, it is true, through the common law, but only to the photographer himself and only while the work remained unpublished. That was of little practical use to commercial firms. Statutory copyright protection was given to sculptures, to maps, charts and plans (as books) and to engravings and prints (including lithographs), but none of this was apt for the protection of photographs. In 1857 the Society of Arts, which four years earlier had helped the foundation of the Photographic Society, drew attention to the serious defects in the law which left painting, drawing and photography largely unprotected. The Society began lobbying for a new statute, with active support (directly through the Society's Artistic Copyright Committee, or indirectly through articles in the artistic press) from notable figures such as Roger Fenton, Henry Cole and Francis Frith. It faced fierce opposition to the proposal to cover photographs notably on the grounds that they were mere mechanical reproductions, not true art, but ultimately commercial and diplomatic imperatives led the government to act.

In 1862, with a new Great Exhibition looming at which it was hoped that overseas photographers would exhibit, Parliament passed the Fine Arts Copyright Act. This gave protection against copying to the authors of paintings, drawings and photographs, whether published or not, with a requirement that they be registered at Stationers' Hall before the protection was enforceable. The statute as it dealt with photographs was not tested until 1883. That first case remains, even in the twenty-first century, of importance because it defined as the author of a photograph the person who was 'the inventive or master mind' behind it. In subsequent cases commercial photographic companies were found to own copyright in portraits they took only if they had solicited the sitting and the sitter had not paid for the pictures taken.

In America, Congress was not far behind. Since 1790, acts had given copyright protection to 'the author or authors' of books, maps, prints, engravings and musical works, so long as works were registered in district courts (from 1870 in the Library of Congress). In 1865, an amendment Act was passed to extend these provisions to photographs, 'upon the same conditions as to the authors of prints and engravings.' Unlike in the United Kingdom, though, the American provisions had to conform with a written constitution, which allowed protection only for 'writings,' so the act faced a challenge. The Supreme Court concluded in 1884 that

a photograph was a writing, and so could be protected, but only if the photographer had created an original intellectual conception of which he could be considered the 'author.' Napoleon Sarony's images of Oscar Wilde passed the test with ease but some photographic circus posters later failed. One further problem remained: the United States approach was heavily protectionist, and until 1891 works by non-resident authors, including photographers, could be pirated with impunity.

In the United Kingdom and America, statutes explicitly gave copyright to photographs. Countries in the civil law tradition followed a different route. By the law of July 1793, the National Assembly of France gave exclusive rights to 'les auteurs d'écrits en tout genre, les compositeurs de musique, les peintres' and others to sell and distribute their works in the Republic. Following this lead, albeit slowly, other countries gave authors of at least some artistic works varying degrees of protection against copying: Prussia in 1837 for drawings and paintings, Austria in 1840 for unspecified works of art, Spain in 1847 for paintings and sculptures. No-one knew though whether these laws applied to photographs: was a photograph a work of art? It was not until November 1862 that the courts in France concluded, in a case brought by the *carte de visite* company Mayer and Pierson, that it could be, so long as the author had invested his own personality in the work and had not merely used a machine to reproduce nature. The Belgian courts followed a similar route, but many European states, notably in Germany and Scandinavia, regarded photographs as purely mechanical products deserving only very limited protection.

Protection in countries other than the photographer's own was provided until 1886 by bilateral treaties. This caused problems for trade, since provisions varied so widely and protection was available only if a treaty had been agreed. The Berne Convention brought an international system of protection, though its value was much reduced by the absence of the United States which continued to rely on bilateral treaties. Moreover there was no agreement on photographs, which were not mentioned in the main text at all but only in a protocol. Some countries (such as the United Kingdom and France) accorded photographs the status of artistic works, while others (led by Germany) declined to do so. The solution to these differences was a compromise which permitted both approaches, but it was inequitable in its effect. A state that recognised photographs as artistic works was obliged to follow the basic Berne principle of granting protection under its national law to works created by citizens of any member state of the Berne Union, but no reciprocal protection was available for their citizens in countries which did not treat photographs as artistic. This problem was not finally resolved until well into the twentieth century.

The Berne Convention was signed by only ten countries, Belgium, France, Germany, Great Britain, Haiti, Italy, Liberia, Spain, Switzerland and Tunisia, but its effects were more widespread than this small membership implies. Japan, for instance, recognised photographs as artistic works the year after it was signed and the colonies of Britain and France mostly adopted the copyright laws of their mother countries. By the end of the century, most commercially active photographers knew where they stood in the countries with which they dealt, even though the protection they were able to enjoy varied hugely.

CORNELIUS, ROBERT (1809–1893)
Pioneer daguerreotypist and businessman

Robert Cornelius was born in Philadelphia on 1 March 1809, the only son of Christian Cornelius to live to adulthood. Christian had worked as a silversmith before establishing himself as a successful lamp and chandelier manufacturer. Robert's name first appeared in a 1835 Philadelphia business directory listing his occupation as

a brass founder. Shortly thereafter he joined his father in the lamp business. Cornelius & Co. became one of the largest importers of gas lamps in the country, providing fixtures for the U.S. Capitol in Washington, DC, as well as other state capitols and public buildings.

Robert Cornelius was one of the first Americans to experiment with the daguerreotype process. Details of the process were available in the United States one month after Louis Jacques Mandé Daguerre's announcement of his invention to the public in Paris on 19 August 1839. Already a center for scientific research, Philadelphia was home to many people who experimented with the daguerreotype process. Cornelius adapted skills from the lighting business—polishing metal and plating silver—to the practice of making daguerreotypes. His interest in the daguerreotype may have been stimulated by the hard economic times of the early 1840s that followed the financial panic of 1837 when a lag in business would have afforded Cornelius time to experiment with this new photographic process.

In September or October of 1839, Joseph Saxton, an employee of the U. S. Mint and pioneer photographer, asked Cornelius to produce silver-coated copper plates for his daguerreotype experiments. After this request, Cornelius began to make his own daguerreotypes, fashioning a camera from a tin box and an opera lens. In October or November of 1839, he made a self-portrait that is considered one of the marvels of early photography. Working outdoors in sunlight to minimize exposure time, Cornelius placed his camera on a sturdy support, removed the lens cover, sat still for several minutes, and then replaced the lens cover. The resulting daguerreotype shows Cornelius slightly off-center with his hair askew, eyeing the camera warily. Considered the earliest extant photographic portrait in America, it is in the collection of the Library of Congress.

Cornelius set the earliest standard for daguerreotype portraiture in America. In May 1840, he opened one of the first daguerreotype studios in Philadelphia, along with his partner Paul Beck Goddard, a chemist at the University of Pennsylvania. At a time when many people thought daguerreotype portraiture was impossible, Cornelius produced sixth-plate daguerreotypes with a camera that used a short, fast lens. Goddard improved the daguerreotype process by using bromine in addition to iodine to sensitize the plates, which allowed portraits to be made in a matter of seconds rather than minutes.

The Cornelius studio, on Eighth Street, above Chestnut, Philadelphia, had a southern exposure. A large mirror attached horizontally to one of the windows reflected light onto another mirror set at an angle to illuminate the sitter's face. A piece of light purple glass suspended from the ceiling softened the light. Typically, Cornelius's sitters faced the camera directly. Using this system, he produced evenly lit, bust-length portraits. An article in the 5 September 1840 *Botanico-Medical Recorder* provides a description of a portrait sitting in the Cornelius studio:

> "... as it is only necessary to sit about a minute; till the sun has, by his powerful pencil, transfixed every lineament of your features, with all their beauties and blemishes, in imperishable lines upon the plate of silver." Cornelius's early portraits were devoid of props, but later sittings include a small table used by sitters as an arm rest.

Leading Philadelphia businessmen and scientists patronized the Cornelius studio, paying five dollars per portrait. Cornelius photographed the scientist Martin Hans Boye several times over a two-year period producing unusual studies, including two portraits of Boye reading a book, and images showing Boye conducting scientific experiments. These portraits show a mastery of the daguerreotype medium.

In addition to portraits, one street scene by Cornelius is known to exist. His view of Eighth and Market Streets, Philadelphia, made circa 1840 is remarkable for its early use of a mirror or reversing prism to present a laterally correct image. (Early daguerreotypes produced mirror images of their subjects.)

Early Cornelius daguerreotypes can be identified by their atypical heavy, brass frames that may have been made in his family's lamp factory. These pieces frequently have a paper label with Cornelius's name and address attached to the back of the object. Cornelius developed a metal support for his plates which was recessed to hold the daguerreotype plate and had a rim to hold the cover glass above the plate. Later Cornelius daguerreotypes are housed in traditional cases, usually with an overall floral design, and brass mats stamped with his name.

Cornelius, along with fellow Philadelphia daguerreotypists Paul Beck Goddard, Joseph Saxton, and Walter Rogers Johnson, received recognition for their achievements with the daguerreotype process in local newspapers and at the meetings of the American Philosophical Society and the Franklin Institute. As early as 6 December 1839, Cornelius showed his daguerreotypes at a meeting of the American Philosophical Society in Philadelphia. Knowledge of Cornelius's daguerreotypes was not limited to the United States. Writing from England in 1843, John Egerton's preface to the translation of Noël Marie Paymal Lerebours *A Treatise on Photography* states that "he remembers seeing, about two years ago, the most beautiful specimens of the Daguerreotype then in existence, produced by Mr. Cornelius, of Philadelphia, ..." The plates Egerton saw were most likely portraits of Philadelphia wigmaker Augustus Gallet that were sent to France to demonstrate America's prowess with the process.

Although Cornelius closed his daguerreotype studio

in 1842, he made a few portraits after this date. After the use of residential gas lights had become popular, Cornelius returned to the family lamp business where he continued until he retired in 1877 and turned the business over to his sons. During retirement, Cornelius operated a fruit farm near Frankford, Pennsylvania.

In 1876, Marcus Aurelius Root, a former pupil of Cornelius's organized a historical display of photography for the Centennial Exposition. The Cornelius self-portrait was included in this exhibition. Cornelius exhibited his lighting fixtures at the Centennial, and most likely saw the photography exhibition.

Fewer than fifty daguerreotypes by Robert Cornelius are extant. Among the institutions that hold his work are the Library of Congress, the International Museum of Photography and Film at the George Eastman House, the Library Company (Philadelphia), and the American Philosophical Society, as well as several private collections.

Carol Johnson

Biography

Genealogical information about Robert Cornelius's mother is very limited. According to a family member, Christian Cornelius was married three times, first to Anna Buck, then Sarah Jackson. He was survived by Sarah McGowan. Robert Cornelius was born on 1 March 1809 in Philadelphia. He married Harriet Comly (spelled Comeley in *History of the Cornelius Family in America*) in 1832. They had eight children, three sons and five daughters. Cornelius spent most of his career working in his family's lamp business. He was awarded several patents for improvements to gas lighting. Cornelius operated one of the first daguerreotype studios in Philadelphia between 1840 and 1842. His studio attracted both portrait sitters and people interested in viewing the daguerreotypes that were on display in his gallery. His rare portraits are celebrated for their mastery of the daguerreotype process. Cornelius died on 10 August 1893 at the age of 85.

COROT, JEAN-BAPTISTE CAMILLE (1796–1875)

An accomplished landscape painter and draughtsman

Jean-Baptiste Camille Corot was also the most important practitioner of cliché-verre in the nineteenth century. Introduced to technique in Arras in 1853 by the painter/lithographer Constant Dutilleux, Corot created at least fifty clichés-verre between 1853 and 1861 and produced another sixteen in the early 1870s. He experimented with several techniques, including *tamponnage* (tapping the glass negative with a stiff brush to create texture). Most of Corot's clichés-verre are rapidly sketched landscapes, some with figures, although he also completed several large, complex works that exist in several states, such as *Le Songeur* (illus.).

Drawn to the fluidity and relative freedom of the technique, Corot left the complex chemical manipulations of printing from the negative to his colleagues in Arras, including Dutilleux, Adalbert Cuvelier, Léandre Grandguillaume, and Charles Desavary, who printed most of Corot's clichés-verre after 1858. Though he generally made salt prints, in the 1870s Desavary made some prints on albumen paper. Desavary also experimented with making reductions and countertype impressions from Corot's glass negatives. Between 1911–1913, the amateur photographer Albert Bouasse-Lebel attempted to make prints from about fifteen of Corot's negatives acquired from Cuvelier; most are characterized by untrimmed edges. These negatives were then acquired by Parisian editor Maurice le Garrec, who reprinted them in 1921 in an edition entitled *Quarante Clichés-Glace.*

COSMES DE COSSÍO, ANTONIO L. (b. 1820s)

Antonio was the son of Antonio Cosmes, a Spanish officer, and Guadalupe de Cossío, his well-connected Mexican wife, was one of a number of daguerreotypists active in Mexico during the Mexican War (1846–1848), and is considered to be the first native Mexican to have practiced the trade. Cosmes was initially associated with the American C.S. Betts who had a studio in Mexico City. In January 1848 Cosmes announced his break from Betts and the opening of his own studio at calle San José Real #5, and advertised his specialties as a miniaturist and colorist. One of Cosmes' first commis-

sions was to document the estate of Hernán Cortés for its current heir. By 1852 Cosmes had moved to Spain and opened a studio in Cádiz, where he had a versatile practice, specializing in miniatures, ambrotypes, and stereographs. He colored the portraits himself, and, in 1859, announced his discovery of a new method of tinting them via chemical baths.

In May of 1858 Cosmes partnered with José Martínez Sánchez, a Madrid photographer, to record the arrival of Queen Isabel II at the port of Valencia, en route to Alicante for the opening of the new railway. Their views of the historic occasion are considered to be the first instance of narrative photographic reportage of an individual news event. As official photographers of the event, Cosmes and Martínez Sánchez were situated at the port well in advance of the queen's arrival, and were thus able to record the entire event from the preparations for her reception and the crowds awaiting her arrival to the appearance of her accompanying squadron, the royal's trip to shore, and their return to their ship for lunch the following day. While waiting for the Queen, who had been expected early in the morning, the photographers made was is believed to be the first photograph of dawn taken in Spain.

Beth Ann Guynn

COURBET, GUSTAVE (1819–1877)
French photographer

As it was the case for most artists, the relationship between Gustave Courbet and photography was two-fold. He used it as a model for his paintings and to promote his work. Contrary to others, Courbet made no secret of it. Those practices were directly related to his art conception, according to which, art is democratic. For thirty years, it was known that Courbet used Vallou de Villeneuve's photography as a model for his feminine figures. Realism art critics accused him of dirtiness and of photographic truthfulness. Théophile Gautier, for instance, trashed "the ugliness of [the] daguerreotype" (Salon of 1850–1851). It was with Realism and a realistic representation that Courbet felt he was most able to effectively object to the academic model of both photography and painting.

Photography also helped him to promote his work. From 1850 to 1883, when was published an album of his posthumous retrospective exhibition at the Ecole des Beaux-Arts, Courbet made regularly his painting reproduced by photography with the object of selling and distributing the prints. He knew by the way some of the famous photographers of his time, Etienne Carjat and Gilbert Radoux who became his friends, Victor Laisné, Nadar, Robert Bingham, Pierre Richebourg and Charles Michelez. Thereby, the new democratic medium also served his art ideology.

Laure Boyer

COURT CASES AND PHOTOGRAPHY

Photography's first century was riddled with court cases. Many of them sought to identify photography's role as either an art or a science. If a case centered on photography as an art, then copyright laws were applicable to an image's content. If photography was a science, then its original inventor could patent the process used to obtain the image. Some early photographic inventors choose not to patent their processes to allow the growth of photography; Fredrick Scott Archer was one of these photographers. His wet plate collodion process led to one of photography's first high profile cases: *Talbot vs. Laroche*. William Henry Fox Talbot held the patent for the calotype process, which he patented in 1839 in England. The process required a license in England, whereas the new wet collodion process did not require a license and produced a clearer picture; therefore, it became very popular with photographers. Talbot felt that this new process infringed on his patent.

Talbot's original calotype patent, number 8842, had been granted and sealed in 1841 and was set to expire in 1855. Then in 1851 Archer published his wet collodion process. Talbot asserted that because this process, like his own, involved creation of a negative to make a positive on paper that it infringed on his rights. The threat of litigation hindered many photographers of the time from fully embracing the improved process.

Under pressure from the photographic community, Talbot did relinquish his patent rights for amateur photographers, but did not extend it to professional photographers**.** Talbot still contended his rights included all photographic processes that produced a positive paper print as its finished product. This act brought the ire of professional photographers, who believed that Talbot was standing in the way of photographic progress. On December 18th 1854, the trial of Talbot *vs. Laroche* began. Talbot was seeking damages of 5000 pounds for violation of the calotype patent. In his defense Laroche's contended that, instead of Talbot, Rev. J.B. Reade first published the calotype and that the calotype process was not the same as Archer's process. On December 20th the jury found that Talbot was the true inventor of the calotype process, but that Laroche had not infringed on the calotype patent by using the wet plate collodion process. This decision opened up the new collodion process to photographers, which quickly surpassed its predecessors, the calotype and the daguerreotype. Archer's process also became central to another set of court battles in the United States.

This second court battle tested the validity of the patent process. In July of 1854 James A. Cutting patented three elements of a collodion process called the ambrotype. The patents covered the use of camphor with collodion (No. 11,213), Canada balsam to hermetically seal the image (No. 11,267), and the use of potassium bromide in addition to potassium iodide to make collodion more sensitive to light (No. 11,266). This last patent affected not only the ambrotype process but also the wet plate collodion process. Photographers at the time did not believe that Cutting had originally invented the ambrotype process and instead credited Archer with its invention. As a result, they assaulted his claims and blatantly infringed upon the patents. Many of the photographers who had purchased the right to practice the process legally from Cutting brought litigation against the patent infringers. The most zealous of the patent men was William Tomlinson of New York. He was involved in litigation with many photographers. Most of the cases were settled by the infringer paying a fine rather than having to be involved in a lengthy trial. Included in this group were notable photographers Brady, Gurney, and Bogardus. The photographic community eventually joined together to form a committee whose sole purpose was to fight the Cutting patents. The committee set up a fund to help Charles A. Fredrickson to fight the suit brought by Tomlinson in 1859. The case would last until 1865 when Fredrickson finally decided to no longer legally oppose the Cutting patents.

In the end the patents were not revoked but instead expired. An extension to the patent was applied for, but the patent office denied the application stating that an error had be made in its original issuance.

Copyright protection, as opposed to patent rights, was the issue in the case of *Sarony vs. Burrow-Giles Lithographic Company,* which began in April 1883. In this case the photographer Napoleon Sarony was asking the courts to uphold his copyright protection for an image entitled "Oscar Wilde, No. 18." The Burrow-Giles Lithographic Company contended that photographs were not written works and therefore there was no author to claim copyright. Additionally, the defense stated Sarony's copyright notice, as it appeared on the image, "Copyright, 1882, by N. Sarony," was not valid because it did not state his Christian name. Sarony countered the defense by asserting the photograph was a work of art because the he had directed the pose, costume, and expression of the subject to produce an original image despite the fact the process was mechanical. Painting had been protected under copyright by the law of 1793. In 1865, because of the case *Woods vs. Abbott,* Congress extended copyright protection to include photographs. The court found in favor of Sarony and set precedent for photography to be legally included as a means of artistic and original expression. The defense appealed the decision a year latter, but it was upheld. This case proved that photography could be legally copyrighted and patented and was therefore, both an art and science.

Towards the end of the nineteenth century there were many other court cases that would carry through well into the next century. Especially notable were the court battles involving Eastman Kodak Company. In 1889 George Eastman and Henry Reichenbach filed a patent for cellulose film. The patent was not approved at first because of a patent application for a similar invention by Reverend Hannibal Goodwin. Eastman and Reichenbach were eventually granted the patent in December of 1889. The use of this technology by Kodak led to many court cases between Goodwin and Kodak and later Ansco and Kodak. The cases were not finished until 1913 when the court ruled against Kodak.

17 F.591

111 U.S. 53, 4 S.Ct.279

COUTINHO BROTHERS (active 1870s–c. 1905)

The Coutinho brothers established one of the first commercial photographic enterprises on the island of Zanzibar, some time in the 1870s. Probably of Portugese origin, little is known of their lives, and one brother is referred to in records only as J. B. Coutinho. The other

was Felix. A studio in Dar es Salaam in Tanganyika (Tanzania today) was opened a few years later, possibly operated by Felix.

The initial partnership between the two brothers lasted little over a decade, before J. B. Coutinho entered into partnership with A C Gomes & Sons c.1890. Gomes had opened his first studio in Aden before 1869, moving to Zanzibar in the early 1870s, establishing what was probably the first studio on the island. That arrangement was dissolved on 31st July 1897, when the Countinho Brothers started trading together once again.

Their photographs of life in fin-de-siecle Zanzibar were sold singly and in albums, and form an important visual account of the period. When the photographic picture postcard started to gain popularity in the 1890s, Coutinho Brothers cards were produced in great numbers, showing tribal characters and cultures, local fishermen and traders, and the architecture of Zanzibar, all clearly aimed at a tourist market.

At some point c.1905, the brothers went their separate ways, Felix moving to Mombasa in Kenya, and opening a photographic company there, once again producing tourist images and postcards, but this time trading as Coutinho & Sons.

JOHN HANNAVY

COX, JAMES (1849–1901)
Scottish painter and photographer

Particularly noted for his realist depiction of the fisherfolk of Auchmithie and West Haven, Carnoustie, on the east coast of Angus, Scotland. While they are in the tradition of Hill and Adamson's calotypes of Newhaven of the 1840s, (and pay homage to the importance of the French painter Jules Bastien-Lepage 1848–1884), Cox's naturalist approach forgoes sentimentality and the transference of the aesthetics of painting, rather he displays the Scottish characteristic of directness. Cox was contemporary with the emergence of the 19th Century Scottish realist painters, such as The Glasgow Boys (1875–1895), themselves influenced by such stark photographs of the hard life of the working class, particularly the fishing and farming communities. Born Dundee 1849, the eldest of 7 children of George Cox, one of the millionaire Jute barons of Dundee, James Cox took up painting then changed to photography and was active c. 1870s–1880s. Founder member and chair of the Dundee and East Scotland Photographic Association, Cox was particularly interested in process and technique, using albumen, gelatine, carbon and platinum processes, the latter he seems to have preferred. His portraits of fellow artists and his photographs in the current fashion for costume and frivolous fancy dress sit awkwardly with the expressions of poverty and exhaustion of his fisherfolk images. There are four albums in the Scottish National Portrait Gallery's collection dated between 1879–1888.

ALISTAIR CRAWFORD

CRADDOCK AND CO., JAMES
(active 1860s–1890s)

Little is known of the antecedents or background of James Craddock, who maintained a successful and prolific studio in Simla from around 1864–90. He is known to have been one of the photographers involved in recording the durbar held at Ambala in 1869 between the Viceroy Lord Mayo and the Amir of Afghanistan, but is best known for the wide range of topographical and architectural subjects from all over Northern India, produced for the European market. In addition to his photographic studio, Craddock also had business interests in banking, building and printing and appears to have lived in retirement in Simla until at least 1896. His son George Craddock (c. 1859–1934) continued the business, with studios at Simla, Kasauli and Lahore. From about 1890 he appears to have concentrated his activities on Lahore, where he died at the age of 75 and is buried in the Roman Catholic Cathedral.

JOHN FALCONER

CRAVEN, WILLIAM (1809–1866)
English

William Craven 2nd Earl of Craven was born on 18th July 1809 and became the Second Earl of Craven on the death of his father in 1825. He was educated at Eton College and Oxford University and in 1835 married Lady Emily Grimston, the second daughter of the 1st Earl of Verulam. They went on to have a family of nine children.

Craven was a wealthy landowner known to be keen on country pursuits as well as an accomplished craftsman. He took up photography in the early 1850's, making studies on his estate at Ashdown in Berkshire. Ashdown provided Craven with plenty of photographic subject matter and he made many studies on the estate, along with portraits of his young family. He also produced an unique series of high-contrast images of the ornate, geometric parterre that graced the garden of Ashdown House. Craven's photographic output was virtually unknown until a large body of his work came to auction in 2000 and 2001 when his large studies of trees, some in the snow, family portraits, garden views and the impressive "Craven Memorial Album," containing almost 100 images, were seen by historians for the first time. Craven's personal collection included many studies by fellow photographers including Gustave Le Gray, Roger Fenton and Frederick Scott Archer.

Craven used an elegant horse-drawn photographic caravan which, uniquely, served as a portable camera as well as darkroom to prepare his wet-collodion negatives. His photographic activities appear to have been terminated by 1858 due to a stroke and he died in Scarborough, Yorkshire on 25th August 1866.

IAN SUMNER

CRÉMIÈRE, LÉON (1831–1872)

French photographer

Born in 1831, Léon Crémière learned photography as an assistant to the most important photographer of his time, Disdéri. Crémière opened his first studio at 28 rue Laval and 2 rue Frochot in 1861 collaborating with Erwin Hanfstaengl, a German photogapher working in Paris for the aristocracy and people of high society. The same year, he became involved as a member of the Société française de Photographie and was a member until 1864. There he displayed official portraits and also Opéra sets "obtained with electrical light" and animals, "study for rapid photography" (from *Catalogue des exposition organisées par la Société française de Photographie, 1857–1876*, Paris: Jean-Michel Place éditions, 1987).

The publication of the "Album militaire de l'Empereur" in 1961, photographed with Hanfstaengl, portrayed the different military corps, a project from which earned him official acknowledgement and recognition. One year later, he photographied Napoléon III hunting with hounds as well as the imperial farms and became involved with animal photography. His work with animals was exhibited at the Société française de photographie between 1861 and 1865 and the "Exposition canine" of the Tuileries.

As a scientific editor, he released several magazines during the 1860s, specifically "Le Centaure" in 1866 which specialized in sports and "Le Petit Sportsman" in 1868 which focused on hunting. He also contributed to the illustration of works, the most important of which was "La Vénerie française à l'Exposition de 1865." He stopped working at his studio in 1871, and died later probably in 1913.

MARION PERCEVAL

CRIME, FORENSIC, AND POLICE PHOTOGRAPHY

Photographers and criminals exploited the photograph for illegal activities well before public authorities incorporated the photograph successfully into criminal investigations and legal proceedings in the last two decades of the 19th century. By the late 1840s, for example, there was an established international market for pornographic daguerreotypes violating obscenity laws in most countries. Similarly, as paper-based photography improved in the 1850s, there was an increase in currency counterfeiting by photographic means, though the lack of colour and loss of surface details precluded any widespread activity.

Forensic photography—primarily to identify suspects and convicts, but also to survey crime scenes and document clues—did not come into systematic use until the 1880s, despite numerous isolated efforts dating back to mid-century. The relatively slow appropriation of photography for criminalistic and forensic ends, despite photography's rampant popularity and rapid growth in other sectors of society, can be attributed to at least two important factors. The first was the practical difficulty of establishing systemic and standardized photographic methods across jurisdictions given the significant costs and complicated processes that the medium entailed before the availability of factory-prepared photographic plates. The second was a prevailing uncertainty concerning the legitimacy of the photograph as a convincing legal document bearing reliable scientific content. As Western legal tradition was primarily text-based, the new visual language of photography entailed a fundamental shift in the approach to the image as evidence, requiring subsequent changes in jurisprudence, before the photograph would circulate freely within police departments and courtrooms.

As early as 1844, inventor William Henry Fox Talbot suggested that photographs could be used to catalog valuable objects and recuperate stolen property. "If the mute testimony of the picture were to be produced against [the suspect] in court—it would certainly be evidence of a novel kind," he wrote in *The Pencil of Nature.* In a more far-fetched application, scientific and popular journals throughout the second half of the 19th century recounted experiments photographing the retinae of murder victims in the hope of obtaining an afterimage of the culprit.

Despite these examples, however, the principal forensic use of photography in the 19th century was in documenting and tracking suspects. The mid-century fascination with physiognomy and phrenology, both of which entailed the study of facial features and other physical attributes as indicators of an individual's moral character, fuelled an interest in photographing the "criminal type" as a scientific, rather than sociological, subject. To this end, in 1846 Marmaduke Sampson's *The Rationale of Crime and its Appropriate Treatment* included an appendix of engraved portraits of New York state prisoners, made from daguerreotypes by Matthew Brady.

By the 1850s, police and prison officials in communities in the United States and Europe began photographing prisoners for "rogues' galleries" to track repeat

offenders. The practice was highly localized, thereby limiting the usefulness of the photograph as a regular investigative tool or legal document. Often made by professional portrait galleries, the arbitrary approach to these photographs diminished their scientific value, and those made as daguerreotypes or ambrotypes had an additional physical fragility and uniqueness that prevented widespread circulation.

Photography's role in two high-profile investigations of the 1860s and 1870s helped establish its place as a practical tool in police work. The first was the hunt for suspects in the aftermath of U.S. president Abraham Lincoln's assassination in 1865. Government-issued wanted posters included albumen carte-de-visite format photographs of the principal suspects, while the Secret Service called upon Alexander Gardner to photograph the crime scene, the convicted conspirators and their subsequent execution. The other instance was the round-up of suspected insurgents after the fall of the Paris Commune in 1871, when government officials relied on photographs of Commune crowds as evidence linking individuals to the events. Officials compiled albums of suspected Communards and hired photographer Eugene Appert to photograph suspects as they were apprehended.

In 1870 the British government required all prisoners to be photographed, with additional prints sent to Scotland Yard for a national archive, but after the Commune, Paris became the leader in forensic photography for much of the rest of the century. Its Prefecture of Police established a photographic service in 1874 and criminal identification photography came into regular use. Two competing methods for documenting criminals arose in Europe at this time, one devised in England by the statistician Francis Galton, the other developed in France by Alphonse Bertillon, a physical anthropologist. Galton's system was meant to be a preventive measure, furthering the argument of the biological causes of crime by producing photographic composites of known criminals to aid authorities in building criminal stereotypes. Italian psychiatrist Cesare Lombroso applied Galton's method to his own research in eugenics, and used photographic composites in *Criminal Man* (1876) to argue the genetic inferiority of criminals.

Conversely, Bertillon's system—first suggested by Ernest Lacan in 1854—sought to solve specific crimes rather than the roots of criminality. It involved documenting suspects by coupling standardized full-face and profile bust photographs (eventually called a "mug shot") with a set of precise anthropometric measurements. Appointed Chief of Judicial Identity in 1879, Bertillon created a huge photographic and statistical archive for the Paris police, and by 1893 he claimed that it had helped identify over 4,500 recidivists. Bertillon also compiled tables of sectional photographs of facial features to aid police in piecing together a suspect's appearance from witness testimony. His methods, known as "bertillonage," quickly spread as far as Russia and the U.S., aided by his numerous books on the subject.

Despite occasional examples reaching as far back as the 1860s, crime scene photography only became standard practice in the closing years of the 19th century, as police departments hired staff photographers and the invention of flash photography made on-the-spot field work practical. Metric photography became fundamental to such activities, employing wide-angle lenses and large plates to capture fine details while photographing at precise angles (often directly overhead) with measuring scales that permitted accurate computation of distances. Similarly, stereometric photography documented individual articles of evidence with carefully measured front and side views. In these fields as well, Bertillon took the lead, promoting them through displays at the 1889 Universal Exposition in Paris and the 1893 World Columbian Exposition in Chicago. By the early 20th century, such photography would commonly appear as evidence in courthouses around the world.

CRITICISM

Most photography criticism in the nineteenth century attempted to identify photography's applications and areas of expertise; a smaller group of texts also included de-

scription and critique of individual photographs. There was much of both kinds of writing in the 1850s and '60s, when the medium was growing into its technical and commercial potential. After that, photography criticism appeared intermittently (and on the model of painting criticism), as a necessary feature of art photography movements. Those movements and their twentieth-century equivalents singled out certain early practitioners as exemplary forebears; but nineteenth-century photographers and photographs received unprecedented critical attention in the last quarter of the twentieth century, when debates about the nature and quality of early photography sprung from two intertwined developments: the maturity of photographic theory, and the medium's new presence in the art market.

Early criticism was centered around photographic societies and the exhibition venues they created. The greatest number of texts are French, reflecting the role Paris played as the first modern art capital, with a developing market for painting *avant-gardes* and much attention to the industry of art reproductions. Some of the best French criticism has to do with photography's relation to Realism and Naturalism, or with the medium's role vis à vis traditional printmaking media. Francis Wey's writing is the chief example, and also the earliest. In the course of 1851 Wey wrote twenty-three articles for *La Lumière*. His attention to the medium subsequently subsided, but Wey is the only figure in the nineteenth century who engaged in programmatic photography criticism: he attempted to identify photography's relationship to other mediums, and some of its particular qualities. Wey's writing affected the thinking of other writers for *La Lumière*, who often engaged in remarkable descriptions of individual photographs, making that journal the best source for early photo criticism. Henri de Lacretelle praised Gustave Le Gray's Mission Héliographique photographs of the cloisters at Moissac and Saint Trophime in these terms: "The arabesque unfurls, the trefoil cuts a relief, the ogive arch lets the daylight pass, the glass draws its legend with perfect transparency. M. Le Gray has a palette in photography: he varies his tints to infinity, clarity cannot go further. The page itself seems of stone or marble." Charles Gaudin, reviewing one of Ernest Lacan's photographic soirées, had this to say about Charles Marville's photograph *L'Ecole des beaux-arts sous la neige*:

> A thick layer of snow covers the ground, the statues of the facade, and the architectural fragments that adorn this courtyard. The effect of the snow is admirably rendered; but what is most striking is the effect of the perspective. The planes fade and withdraw in a vaporous atmosphere, and the background details draw themselves with charming delicacy. I wish I could better describe this remarkably beautiful work; it is one of the most surprising results that has yet been obtained.

Both descriptions are of architectural views, a subject singled out by Wey and agreed upon almost universally as apt to photography.

Wey's conviction that photography was also the best medium for artist's studies, especially those of landscape motifs with light and weather effects, found an echo in the writing of Sir William Newton, a British miniaturist and amateur photographer. In 1853 Newton delivered a paper to the newly formed Photographic Society, upon the topic of photography's relation to the arts. He suggested that when artists were making photographic studies for use in the studio, they should throw camera subjects a bit out of focus, to better record effects of light and atmosphere. Lady Elizabeth Eastlake concurred with Newton's observations, finding the accumulation of contrasting details in most photographs the quality that removed them from visual "truth." Eastlake praised the calotypes of David Octavius Hill and Robert Adamson for their Rembrandtesque chiaroscuro. However, for Eastlake, photography's value lay less in its relation to art than its ubiquitous social presence, and its ability to render present absent loved ones. She wrote about portraits of children: "the very shoes of the one, the inseparable toy of the other—are given with a strength of identity which art does not even seek." Eastlake's few observations about the intimate relationship possible between viewer and photograph resonate with pictures by her contemporaries Julia Margaret Cameron and Clementina, Lady Hawarden. The same critical predilection is widely elaborated in later photography and criticism, notably the writing of Roland Barthes (q.v.).

Many early critics delighted in photographs' masses of details, precisely for the surplus of information they brought. This is clear in reviews of another subject understood to be suited to the new medium, travel views, especially when they were produced as stereographs. The most interesting American voice from this period, Oliver Wendell Holmes, Sr., popularized photography in three essays for *The Atlantic Monthly*, between 1859 and 1863. His chief object was the stereoscope, but he informed his readers about the technical production of various kinds of photograph, and their possible applications, from criminal profiling to the stereographic exploration of great cathedrals. This is not criticism *per se*, but Holmes' passion for the medium makes him one of its best writers:

> "A painter shows us masses; the stereoscopic figure spares us nothing—all must be there, every stick, straw, scratch, as faithfully as the dome of St. Peter's, or the summit of Mont Blanc, or the ever-moving stillness of Niagra...Theoretically, a perfect photograph is absolutely inexhaustible."

Holmes marveled at the profound disruption photographs caused in the experience of the world. He

declared "Form is henceforth divorced from matter," and imagined great libraries of stereographs as future storehouses of knowledge.

Holmes embraced photography's technical potential, and, implicitly, its industrial possibilities. Other writers (all photographers) began to assert the medium's status as art. Paradoxically, this involved emphasis on the manual making of the photograph, and its uniqueness, in order to demonstrate the presence of the artist's imaginative intellect in the work. Henry Peach Robinson, inspired by the work of Oscar Gustav Rejlander, began making composite photographs in 1857, with a view to producing finished *tableaux* on a par with academic painting. Robinson wrote copiously on photography; his 1869 book *Pictorial Effect in Photography* is his definitive treatise. It is modeled on the *Discourses* of Sir Joshua Reynolds: Robinson largely co-opted Reynolds' precepts for painters, arguing that the "immutable laws" of art apply as well to photography as any other medium. He thus concentrated more on the compositional probity and completeness of a finished work than on the particularities of photography, although his chapter devoted to combination printing is a vivid blend of technical instruction and aesthetic opinion.

Robinson's book was translated into German and French, and survived for several editions. It satisfied a void in photographic literature: most art critics who mentioned photography did so dismissively, and their comments were generally aimed at painters and printmakers. Charles Baudelaire's famous tirade about the medium in his 1859 *Salon* is more substantive than most references to photography, as he proclaimed photography the antithesis of art *and* catalogued the good purposes he could find for the medium, but the passage was nonetheless written as a prod to painters. Similarly, Phillipe Burty's numerous references to photography were typically foils for his enthusiastic support of etching and engraving, especially during the etching revival of the 1860s, which arose in a distinctly anti-photography climate among painters and reproductive printmakers.

Baudelaire certainly had Robinson and Rejlander in mind when he mockingly wrote about the authors of photographic *tableaux* "committing a double sacrilege, and insulting, at one and the same time, the divine art of painting and the sublime art of the actor." But Robinson's staunchest critic was Peter Henry Emerson, his follower in the paired fields of pictorial photography and photo criticism. Emerson's brief advocacy of art photography stemmed from his preference for naturalistic art; Robinson's academic compositions and evenly sharp focus were anathema to him. In his book *Naturalistic Photography* (1889), Emerson based his arguments on modern optics: he contended that photography was the best medium to approximate actual visual experience, through its control over focus and tonal range. Differential focus, and even blurry photographs, were promoted as means to photographic art.

By 1891 Emerson retracted his claims about art photography, but his and Robinson's writings had contributed much to the Pictorialism movement. Art photography clubs sprang up in many cities and towns of the industrial world in the last decades of the nineteenth century. Groups communicated with each other through journals, and photographers met at regional and international exhibitions. Alfred Stieglitz won a medal—awarded by Emerson—at one such meeting, sponsored by the *British Amateur Photographic Society* in 1887. Stieglitz recognized that art photography's legitimacy would be attained as much through the paraphernalia of art movements—journals, exhibitions, criticism—as through photographs. Exhibition reviews became a staple of the movement, and Pictorialists sought artistic forebears from early photography. Three "old masters" emerged: Julia Margaret Cameron, David Octavius Hill, and Nadar. The critical fortunes of these three had to do with personal connections—Cameron and Nadar each had sons who were active photographers who promoted their parents' work (Nadar himself lived until 1910). Hill and Adamson calotypes (Adamson was forgotten at this time) were collected and disseminated by the Scots photographer James Craig Annan. The early work was praised for the primacy given to artistic effect: Annan wrote about the chiaroscuro in Hill's calotypes. Cameron was praised in *Camera Work* for "[realizing] what few could then appreciate, the difficulty of dealing with the critically sharp definition of the portrait lens."

Modern enthusiasm for nineteenth-century photography arose in several circles in the 1920s and '30s. Nadar, Cameron, and Hill remained the most widely-known figures from the past. The Surrealists went beyond them, and embraced virtually all forms of nineteenth-century photography, as touchstones to Surrealist sensibility. Pierre Mac Orlan wrote:

> Phonograph, photograph, all the graphs, after being thrown far from delicate, sensitive existences, are reinstated in the lives of those who marvel at seeing and hearing. They take a unique revenge in restoring to the things whose limits they mechanically reproduce the presence of that universal mystery of which everything possesses a part that confers on it both its personality and its interest in the world.

Man Ray discovered the photographs of his neighbor Eugène Atget (who came to be seen by all of his admirers as a holdover from the previous century), and published the most enigmatic of them—window reflections, crowds gazing at nothing in view—in *La Révolution Surréaliste*. Man Ray's studio assistant, Berenice Abbott, took Atget's work to the United States, and his reputation on a different trajectory. She promoted Atget as the great

"straight" photographer, free from the arty pretense of Pictorialism and its Stieglitzian afterlife. Abbott and Walker Evans both wrote short, influential articles which celebrated Atget's photographs. Abbott also mentioned the work of Mathew Brady, Timothy O'Sullivan, William Henry Jackson, and the U.S. Geological Surveys, as the epitome of clean, great photography.

Other *avant-garde* photography movements were not so preoccupied with nineteenth-century precursors. However, in Europe in the 1930s, several writers began to view photography as the most important visual medium of the era, and they sought ways to incorporate it into the history of art. Heinrich Schwarz and Walter Benjamin both turned to the model of Alois Riegl and the Vienna School of art history. Riegl had insisted on the importance of minor arts in any historical period: devotion to a given material or process must be studied seriously. Schwarz undertook a study of David Octavius Hill (1931), and argued that the photographer's use of the calotype process was the perfect expression of the bourgeois society of 1840s Edinburgh. Benjamin, whose 1931 essay "A Short History of Photography" is partly a review of Schwarz's book, took up the argument, and extended it to suggest that the wide photographic experimentation of the 1930s made photography yet again central to the culture. In his 1936 essay "The Work of Art in the Age of Mechanical Reproduction," Benjamin went further, and stated that the nineteenth-century debates over photography as art missed the point: "The primary question—whether the very invention of photography had not changed the entire nature of art—was not raised." Benjamin's point was that the conditions of photography swept away old notions of self-expression, genius, and craft, by which art had hitherto been defined. His model was Atget, who had systematically catalogued Paris without any evident interest in arguments about art or photography.

From the 1930s, historical and aesthetic interest in early photography grew. Many artists and critics took the medium seriously—whether as mode of expression or simply as the ubiquitous visual stuff of the age. A broad range of writers paid attention; by the 1970s there was a body of photographic theory to draw from, the history of the medium was better understood, and there was active interest in collecting work from all periods. The rise in values for vintage prints in the 1970s led to a hunt for old material: museums and libraries transferred whole bodies of work from archives and library shelves to exhibition spaces and art storage. The Museum of Modern Art acquired Berenice Abbott's vast holdings of Atget material in 1969, and between 1981 and 1985 celebrated him as a master of modern art, with major exhibitions and a four-volume publication. Other early practitioners, such as Gustave Le Gray and Henri Le Secq, also received monographic attention.

A divide in the critical community arose around these exhibitions: one group of curators and historians celebrated the over-due recognition of photography by the artworld establishment (Eugenia Parry Janis, John Szarkowski), while others loudly demanded at what cost to the understanding of nineteenth-century photography these objects were being fed into the system of gallery/museum/auction-house, as yet more examples of great modern art (Rosalind Krauss, Christopher Phillips, Allan Sekula, Abigail Solomon-Godeau). The latter writers invoked Benjamin, and they also turned to Roland Barthes, whose 1980 book *Camera Lucida* took up Benjamin's observations about photography's resistance to authorial intent. Barthes insisted on photographs' absolute, structural difference from all other kinds of visual image: the photograph always "carries" its referent with it, and the viewer's relationship to the referent can be intensely personal. Barthes included nineteenth-century images because they exacerbate one condition of all photographs: the presentation of a past moment in time, Barthes' "that-has-been." For Barthes, as for Benjamin, photography is more powerful than art.

These critical debates continue. Szarkowski has elaborated a lucid formal critique of the art of photography in many books. For him, the medium was "born whole": great photographs are generated when photographers learn their craft, and look at other photographs. No other training is necessary—any vernacular image might be a successful picture. Diverse authors have written against this position, insisting on the social role played by photographs, and writing material histories of nineteenth-century photography. Others have insisted upon the medium's persistent difference from all comparable categories of picture, and the consequent changes photography caused in modern experience.

CROMBIE, JOHN NICHOLS (1827–1878)

Scottish photographer

John Nichols Crombie (1827–1878) was a Scot who came to New Zealand from the gold-fields of Victoria, Australia, where he¹d worked for a time with the American firm of Meade Bros. During his initial stay in Auckland (1854 to 1856) he claimed he¹d made over a thousand portraits, with a further 450 in Nelson and the Southern Provinces. After this tour he traveled back to Australia where he acquired the skills of an ambrotype artist and collodion photographer. One of Crombie¹s endearing qualities was his constant ability to gain the attention in the newspapers with reports of his photographic activities. This echoed his rise to fame and fortune. With the money he made from photography, he invested wisely in property and gold mining shares. On September 4th, 1862 he returned to Scotland where he gave a talk to the Glasgow Photographic Association at the commencement of their 1862–1863 season. A report of this was published in the British Journal of Photography in 1863. It is one of the first reports of its kind which identifies some of the problems encountered by those who went to New Zealand with a camera. Crombie returned to New Zealand and expanded his business interests. When he and his wife finally departed for good in 1872, they entertained their friends on a grand scale by giving a ball. He died in Melbourne.

WILLIAM MAIN

CROOKES, SIR WILLIAM (1832–1919)

English scientist, photographer, and editor

Crookes was born in London in 1832 as the eldest of sixteen children of a tailor. As the son of a man of comparatively modest means, Crookes received irregular schooling until studying chemistry at the Royal College of Chemistry from 1848 until 1854. Displaying an early interest in photography, Crookes used it as a research tool. In 1852, he tried to photograph the colored rings shown by certain crystals between tourmaline plates in polarized light. He obtained the photographs by using either calcspar or nitro, but also traced certain abnormal figures due to rays beyond the visible spectrum that had never been seen by the naked eye. Crookes joined with another chemist, John Spiller in May 1854 in penning an article for the *Philosophical Magazine* that discussed the use of glycerin as a means of prolonging the moist and sensitive state of collodion film.

A physical chemist, Crookes suffered from taking a nontraditional route to the profession as most top scientists came from universities. Lacking superior qualifications, he scrambled to make a living. In May 1854, he was appointed superintendent of the meteorological department of the Radcliffe Observatory at Oxford. The position proved to be a short one, lasting only one year but Crookes again applied photography to his work. He made meteorological records at the observatory using the wax-paper process. In 1856 he took some photographs through a telescope of the moon that were one and one-fourth in diameter. His moon photographs were exhibited at the Crystal Palace. The photographs included great detail and Crookes obtained a grant from the Royal Society to enlarge them by twenty diameters, a scale that could not have been achieved if he had employed the gelatin process rather than the wax-paper one. He received an additional grant from the British government to defray the cost of experiments for finding a portable means of illuminating objects in dark places sufficiently to enable them to be photographed. In 1857, he produced a 60-page *Handbook to the Waxed-Paper Process in Photography*.

In 1856, Crookes moved to London, where he set up an analytical laboratory in his home and began to edit a number of scientific journals, including *Chemical News*. A patient and careful man who quickly earned renown for experimental ability, Crookes aimed to prove that pure scientific research could lead to financial rewards. Among his achievements are the Crookes Tube, a predecessor of the cathode-ray tube used in television sets; the spinthariscope, which registers radioactive decay as flashes on a phosphor screen; and the radiometer, which shows radiant energy.

In his London home, Crookes devoted his energies to the development of photography and edited the Liverpool Photographic Journal from November 1856 until March 1857. In March 1857 he also began to edit the Journal of the London Photographic Society and served as that organization's secretary. In 1857, after reading a paper entitled "The Albumen Process on Collodion,"

Crookes proposed to resolve one of the main problems with glass negatives. Glass easily picked up impurities and photographers found it difficult to produce clean negatives. Crookes advised coating glass with collodion then using it as a basis for the albumen process, which was already common knowledge. To aid photographers, he invented a box of tinplate that light could not enter and a bottle for pouring albumen free from froth. In 1858 he made a two-year commitment to supply articles on photography to the *Photographic News.* Crookes cemented his reputation as one of the leading scientists of his day by discovering a new metallic element, thallium, by means of spectrum analysis in 1861.

By the 1870s, Crookes' interests changed and he began to speculate about theoretical scientific matters, including spiritualism. Crookes' beloved younger brother Philip had died in 1867 and the scientist hoped that spiritualism could provide a reunion. Although warned of the risk of ridicule, Crookes announced his intent to investigate mediums. In the nineteenth century, mediums commonly communicated with the dead by entering a trance while alone in a room. The manifestation, which many observers noted looked exactly like the medium, would then mingle with guests as the medium purportedly remained behind in the other room with her face hidden under a blanket. Although he conducted inquiries about other spiritualists, Crookes achieved lasting fame for his photographs of Florence Cook, who summoned the manifestation "Katie King." To determine if the medium and the materialization were indeed two separate beings, Crookes proposed a series of séances to be held in his home. Convinced of the existence of genuine mediums, Crookes ruled out trickery as a possible explanation for the manifestations. He planned to obtain photographs of the two women. He took 44 photographs of King using five cameras from December 1873 to May 1874. Midway through the experiment, on 30 March 1874, he announced that he had obtained proof of Cook's innocence and of the actuality, paranormal nature, and separate existence of King. The results of Crookes' experiments were published in W. H. Harrison's paper *The Spiritualist* in the form of a series of letters that were afterward republished as part of the book *Researches in the Phenomena*. Nearly all of the photographs and negatives were later destroyed but one of published pictures depicts Crookes arm-in-arm with King. Only one photo depicted both the materialization and the medium, but unfortunately King sits in front of Cook thereby concealing her head. No photograph shows the faces of both women. Few scientists accepted Crookes' proof, but the certification of a noted man of science significantly bolstered Cook's fame and financial situation as well as aiding the cause of spiritualism. Charged with unscientific practice, Crookes seriously damaged his professional reputation and gave rise to speculation that he was protecting the medium because of romantic involvement with her. He dropped his spiritualist investigations in 1875 though his interest remained strong. Crookes belonged to the Society for Psychical Research from its 1883 founding and served as its president from 1896 to 1899. In later years, he served as president of the Royal Society (1913–1915) having been made a fellow of it in 1863. Knighted in 1897, he remained active until his 1919 death.

CARYN E. NEUMANN

Biography

Sir William Crookes was born at 143, Regent Street, London, England on 17 June 1832 to Joseph Crookes, a prosperous tailor, and his first wife, Mary Scott. Demonstrating an interest in photography while studying chemistry at the Royal College of Chemistry (1848–1854), Crookes and John Spiller co-wrote an article on the collodion process for the May 1854 *Philosophical Magazine.* In 1857, he produced a 60-page *Handbook to the Waxed-Paper Process in Photography*. He edited the *Liverpool Photographic Journal* (1856–1857) and served as the secretary of the London Photographic Society and the editor of the fourth volume of its *Journal* (1857–1858). While stressing photography as a means of livelihood, Crookes expanded his knowledge with the aim of qualifying as a consulting chemist. He studied a wide range of subjects and conducted experiments on a number of subjects. He also found time to marry Ellen Humphrey of Darlington on 10 April 1856 and the couple eventually produced ten children. On vacating the editorial chair of the Photographic Society's *Journal,* Crookes agreed to publish his photographic articles only in the *Photographic News* until 1860. In 1859, Crookes brought out a new chemical weekly, *Chemical News,* using it to make him one of the most important people in the English chemical world. Fascinated by spiritualism, Crookes published four articles on the subject. The first of these, "Spiritualism Viewed by the Light of Modern Science" appeared in July 1870 in the *Quarterly Journal of Science.* "Experimental Investigation of a New Force" appeared in the same journal in July 1871 and was reprinted in the *Chemical News*. "Some Further Experiments on Psychic Force" (October 1871) with a summary of Crookes' spiritual investigations printed in the January 1874 *Quarterly Journal of Science. Researches in the Phenomena of Spiritualism* summarized Crookes' experiments with mediums. An exceptionally prolific writer, Crookes' more notable later works include *Select Methods in Chemical Analysis* (1871), which gave information on the methods of isolating rare elements, and a paper read before the Royal Society on 11 December 1874 "Attraction and Repulsion Resulting from Radiation" which introduced Crookes' new inven-

tion, the radiometer. He received a number of honorary university degrees and distinctions in recognition of his outstanding scientific work, including a knighthood in 1897 and the Order of Merit in 1910. Widowed in 1916, Crookes died on 4 April 1919 at the age of 87 in Kensington Park Gardens.

CROS, CHARLES EMILE HORTENSIUS (1842–1888)

French physician and poet

Cros, a poet, was born in 1842. In photography, he is known for his early three-color photographic experiments. Cros had, like Ducos du Hauron, been working on a subtractive method to obtain full color prints. Cros did not have a studio of his own, instead he performed his photographic experiments in his friend's, Herzogs von Chaulness, photographic studio.

Cros made photographs through red, green and blue filters, which were converted to positives. However, rather than converting them into transparencies for projection he dyed each positive with the complementary color of its original filter. Precisely overlapped on white paper, the three sheets fused into a full color image of the original. Unfortunately, the color sensitivity of b/w negative emulsions at this time was rather poor. The film was mainly sensitive to blue and some parts of the green spectrum. There was virtually no red sensitivity at all. Therefore Cros' color prints were less than perfect. In a letter, sent to the Academy of Sciences in Paris, Cros described his color photography experiments. The letter was deposit on December 2, 1867 not to be opened until 1876.

Only two days after Ducos du Hauron was granted a patent on the same technique, Cros published the correct principle of the subtractive color method in *Les Mondes*, February 25, 1869.

Cros described a photochromoscope and how to set up the components within the camera to make three-color separated negatives. Later, on May 7, 1869, did Cros present his technique at the Société française de photographie. On the same day had Alphonse Davanne, the vice-president of the society read a report about Ducos du Hauron's similar work.

On 23 December 1878 a seminar by Cros was presented at the Academy of Sciences in Paris in which he described a photochromoscope which he referred to as a *Chromometre*.

Cros invented the *hydrotype* process in 1881, which is a reversed collotype process. It can be used in color printing. A gelatin image is made to absorb dyes in proportion to the action of light so that, when a paper is brought in contact with the stained plate, a color image can be transferred from the dye. The color image recorded in a camera is received on a chromo-sensitive surface composed of red, yellow and blue superimposed or juxtaposed, the color-sensitive material being so selected that each pigment is destroyed by light of complimentary color. Thus, the orange rays destroy the blue pigment, the green rays destroy the red pigment, and the violet rays destroy the yellow pigment. The glass plates were made by having collodion colored red by cartharnine, then gelatin colored blue by phyllocyanide, and finally collodion made yellow by curcuma.

Hans I. Bjelkhagen

Biography

Charles Emile Hortensius Cros was born on October 1, 1842, in Fabrezan, France (Department of Aude) After his baccalaureate in 1859 Cros started to study medicine which he never completed. Instead, he started to live a bohemian life, meeting with artist and writing poems.

Cros has published many poems, e.g., *Le coffret de santal*, for which he was awarded the Juglar Prize.

On December 2, 1867, Cros was granted a patent on his three-color helichromy method.

His book *Solution générale du problème de la Photographie des couleurs* was published in 1869. In April 1877 Cros described a device to record and replay acoustic waves. Instead of storing the sound on cylinders as was chosen by Edison, Cros suggested the used of a disc instead.

Cros married Mary Hjardemal in 1878 and they had two sons, Guy-Charles (1879–1956) and René (1880–1898). Cros died on August 9, 1888, in Paris.

CRUCES, ANTIOCO AND LUIS CAMPA (active 1862–1877)

Antioco Cruces and Luis G. Campa are credited with fomenting the carte de visite craze in Mexico City between 1862 and 1877. They both attended the Academy of San Carlos, a prestigious art school in Mexico City and may have received some professional support from photographer José Maria de la Torre who worked with them between 1863 and 1866, but like many photographers of the time period, they were self-taught. Their studio, Fotografia Artistica, located near the Cathedral, was considered one of the most important in a city where keen competition existed in the photography business.

In 1876 their work on "Mexican Popular types" ("tipos") received a bronze medal at the Philadelphia International Exhibition. The following year Campa, an engraver, who had been teaching at the Academy of San Carlos, left the partnership to teach full-time. Cruces continued alone for several decades and became known as the "dean of photographers" of Mexico City. Toward the end of his career, Cruces served as the official photographer for the Mexico City jail and later for the War Ministry.

The Cruces and Campa images depict the personages of Maximilian's short-lived Mexican empire; notables of Mexican society and those who could afford the studio's prices; as well as the popular ethnographic "occupationals" and "tipos." They also produced a number of stereoviews and "illuminated enlargements" (hand colored prints). Collections of their work are preserved at the Museo de Fotografía in Mexico City and at Tulane University in New Orleans.

Yolanda Retter Vargas

CRUICKSHANK, JOHN W. (1852–1918)

Scottish survey photographer

Born Aberdeen, of the famous Scottish Quaker family of world-famous shorthorn cattle breeders, John Cruickshank was sent at the age of 10 to Ackworth, Pontefract, and Kendal Quaker Schools, and after training as an engineer in Leeds, he returned to Scotland on the death of his father in order to help his uncle Amos Cruickshank (1808–1895) of Sittyton run his herd. His business interests become extensive, including banking, jute, and meal mills. In 1892, aged 50, he retired from business and moved to a specially built Art & Crafts mansion Coombe Head, Haslemere, Surrey. Ill health then determined a permanent move to Florence in 1912 where he and his wife, Alice Mary Henderson (1861–1920), also established a Quaker Meeting. Along with his wife, he wrote several guide books in the Grant Allen series, including *Umbrian Towns* (1901) and *The Small Tuscan Towns* (1912), illustrated with his direct and elegant photographs. Deeply religious and scholarly, Cruickshank was a lover of mediaeval manuscripts and Romanesque, Lombard and Gothic church architecture and sculpture, especially its symbolism. He made extensive and exceptional photographic surveys throughout Europe, in particular, Tuscany and Umbria. His photography has affinities with Frederick Evans (1853–1943). A collection of over 1,500 negatives is held at the Conway Library, Courtauld Institute, London, and over 3000 prints, using platinum and various rich sepia papers, together with 500 negatives and his library, are at the British School at Rome.

Alistair Crawford

CUBA

In March of 1839, a Havana newspaper reprinted an article on J. M. Daguerre's new "method of fixing images." A year later, Pedro Tellez de Girón took the first known daguerreotype on Cuban soil, an image of part of the Plaza de Armas in Havana. In early 1841, North American, George Halsey announced that he was ready to photograph people using a new admirable and "amazing invention." He stayed until June, after which his studio was acquired by one R. W. Hoit. In the same year, the Italian Antonio Rezzonico, newly arrived from New York, opened his studio and offered to produce not only studio portraits but also city and rural views. Two illustrations derived from daguerreotypes taken with his equipment, were published in the book *Picturesque Island of Cuba* (1841). Several years later, Cuban-born Esteban Arteaga returned from Paris and announced his ability to produce daguerreotypes "with color."

North Americans Charles and Jacob Ward arrived in Chile in 1848 after working as photographers also in Perú and Bolivia. They offered to photograph "squirming" children as well as individuals and groups in home settings. Hungarian Pal Rosti, arrived in 1857 and for three months recorded city views, coffee plantations and ethnographic subjects. By that time, Cuban-born Francisco Serrano and Esteban Mestre were producing ambrotypes and paper prints. Charles DeForest Fred-

ricks, owner of successful studios in New York and Paris, opened another in Havana in 1857.

In Cuba, Fredricks worked with several partners including George Penabert, Augusto Daries and Samuel Cohner. Fredricks had traveled and photographed widely in South America, and was known for his cartes de visite and his outdoor views. His images of modern buildings and public works were meant to reflect national progress and achievement. It was a method of dispelling negative stereotypes and encouraging foreign investment in Latin America. In the 1850s, increasing interest in travel created a market for the new stereoview format. New York photography publisher E. Anthony sent George Barnard to Cuba where he recorded numerous images of people and places. These later appeared in Anthony's stereoviews without photographer attribution.

As in other countries, the business of photography attracted an increasing number of practitioners. The *Havana Annual* of 1859 listed seventeen daguerreotypists including two women, Encarnación Irastegui and Francisca Madero. The 1860 *Havana Directory* included photographers L. Cabrera, Juan B. Fernández & Co., O.B. Loomis, as well as the studios of José Cotera and Carlos Serpa and a photographic museum managed by José López Molina. By 1884, twenty-seven photographers were listed in a directory of the island.

Growing interest in photography among Cubans led to the formation of associations, as well as to exhibitions and publications. One photograph made by Cohner shows the photographer Fredricks at a gathering of the Cuban Photographic Society c.1860. The first exhibition of Cuban photography was held in 1868 and in 1882 Domingo Figarola published *The Photographic Bulletin*, the first Cuban photography journal. The following year, The Association of Amateur Photographers was formed in Havana.

A second generation of Cuban photographers included Esteban Mestre's son Narciso, whose studio was prominent in Havana in the 1870s. Father and son left an important record of Cuban architecture and city views. In the provinces, Bavastro and Agüero photographed parts of Santiago in eastern Cuba; and Jacinto Cotera in the 1870s, and Salay y Roig toward the end of the century, were among those who had studios in Cienfuegos.

Between 1868 and 1898, Cubans fought to achieve independence from Spain. The main conflicts are remembered as the War of '68 and the War of '95. The first was recorded by numerous foreign and Cuban photographers including the firms of Fredricks y Daries; and individual photographers Elias Ibañez, Andres Oca, Leopoldo Varela y Suárez, José Robles and Esteban and Narciso Mestre. The war of 1895–1898 was documented by photographers such as José Gómez de la Carrera, Gegorio Casañas, Ramón Carreras, Luis López, and the firm of Otero y Colominas.

During the Cuban-Spanish War, publishers of stereoscopic views used that medium to both inform and propagandize to audiences eager for vivid images of events in Cuba and other Spanish territories involved in the conflict. Historian Sarmiento Ramírez notes that while many of the photographs from the '95 War were posed, they do provide valuable documentary evidence regarding the quotidian life of both warring sides as well as a record of people, places and events related to the conflict. In 1898, after the ship *Maine* was blown up by persons unknown, the United States entered the conflict. Spain surrendered to the U.S. in 1899 and the latter officially governed Cuba between 1899 and 1902. According to researcher James Swick, during that time U.S. stereoview publishers used the medium to "reinforce both the image of a 'benevolent' empire and the racial stereotypes that provided much of its ideological justification."

During the War of '95, cameras served a new purpose, recording not only battles, but also human rights abuses. When the Spanish general Valeriano Weyler placed Cuban families in "reconcentration" camps, the new Kodak cameras were smuggled in and used to make a dramatic record of dismal camp conditions and the inhumane treatment of the incarcerated. Both photoeditor Ramiro Fernández and curator Gary Libby, have noted that those images laid a cornerstone for photojournalism in Cuba. The images also contributed to the wide use of photography as a propaganda tool later in the twentieth century.

According to Rufino del Valle Valdés, president of the Fondo Cubano de la Imagen Fotográfica, the history of early Cuban photography is under-researched. In addition, United States foreign policy prevents what does exist from being widely distributed in the United States and economic conditions limit what can be published in Cuba. Cuban-born Ramiro Fernández, now living in New York, owns a significant collection of Cuban photographs from the daguerreotype era onward. His collection of photographs from 1860–1920, was exhibited at the Museum of Arts and Sciences in Daytona Beach, Florida in 1988. The catalogue of the exhibition includes a useful chronology of the history of photography in Cuba.

CUCCIONI, TOMMASO (1790–1864)

Italian, photographer, printmaker, publisher

Prior to taking up photography in the early 1850s, Tommaso Cuccioni trained as an artist engraver, working first with the government engraving office (1830–35) and then operating his own business engraving and selling *vedute* from his shop in central Rome. He began photographing the subjects of his engravings—views of Roman antiquities such as The Temple of Vesta, The Baths of Caraclla, The Column of Trajan, views of the forum, and the banks of the Tiber—which he offered for sale alongside traditional engraved views. The large format of his photographic prints established an equivalence with engraved views by approximating the dimensions of the engravings, a strategy employed by another Roman photographer, Robert MacPherson. He submitted his photographs to international exhibitions including the Paris Exposition of 1855, as well as London, Edinburgh, and Dublin. His work garnered favorable notice for the size, composition, and technical merit. After his death in Rome in 1864, the Cuccioni firm continued to produce photographic views and to reprint his negatives. In the 1880s, the firm offered a number of his negatives as photomechanical prints in very large format (1 meter x 1/3 meter).

KATHLEEN HOWE

CUNDALL, JOSEPH (1818–1895)

English painter, photographer, and publisher

Joseph Cundall first exhibited at the 1852 exhibition at the Society of Arts, London. From 1853-1858, he was an exhibitor under his own name. Thereafter, his work was successively illustrated under the names of the partnerships 'Cundall & Howlett,' 'Cundall, Howlett & Co.,' 'Cundall, Howlett & Downes,' 'Cundall & Downes,' and 'Cundall, Downes & Co.' He was both a photographer and a publisher.

Cundall trained as a painter, and experimented with the calotype in the 1840s, joining Robert Hunt, Hugh Diamond and others in the early grouping often referred to today as the 'Calotype Club.'

Robert Howlett joined Cundall in 1855, one of their first projects being the publication of *Crimean Heroes* a portfolio of animated studio portraits of heavily armed soldiers before embarking for war.

Cundall published many books outside photography. His 1845 *Booke of Christmas Carols*, was the first in a series of 'illuminated gift books' based on mediaeval illuminated manuscripts. *The Photographic Primer* (1854) was published through his 'Photographic Institute,' while the second edition (1856) was published by Sampson Low & Son. Several other illustrated books were published by the Photographic Institute, some with Cundall's own photographs, others with images co-credited to Cundall and Delamotte.

Delamotte's *Photographic Views of the Progress of the Crystal Palace* (1855) was also published by Cundall.

CUNDELL, GEORGE SMITH (1798–1882), AND BROTHERS

The Cundell family came from the port of Leith, near Edinburgh in Scotland

There were four Cundell brothers: George Smith Cundell (1798–1882), a photographer scientist and politician and the author of a treatise on the Calotype process published in 1844. Joseph Cundell (1802–?) was a photographer. Henry Cundell (1810–1886) was a landscape painter and photographer. Charles Edward Cundell (1805–1880) was a painter. Three of the brothers, George, Charles and Henry, moved to work in London though Joseph, who remained in Leith, visited his brothers and took a number of photographs of London, including a view of Hampton Court in around 1847.

Members of the Cundell family appear in several photos taken by the amateur photographer John Muir Wood (1805–1892) who played a key role in the social interchange of photographs and the sharing of knowledge on processes and techniques. Some twenty photographs by the Cundell brothers were in the collection of John Muir Wood.

The Cundell brothers played a significant role in the link between photography in Scotland and in England during the 1840s.

An album of 100 Salt paper photographs taken by George Smith Cundell between 1842 and 1847 is in the Harry Ransom Humanities Research Centre, University of Texas at Austin.

ANTHONY HAMBER

CURREY, FRANCIS EDMUND (1814–1896)

Irish

Francis was born on 15 March 1814 to William and Anna Currey (nee Tappenden). His father was an agent on the Duke of Devonshire's Irish estate at Lismore Castle, County Waterford. Francis graduated from Trinity College, Cambridge and in 1855 called to the bar at Lincoln's Inn. He took over from his father as Lismore's land steward in 1839, later he was known for his kindness to victims of the 1847 Irish famine.

Currey took up photography in the early 1850s and in 1855 joined both the Photographic Society and Photographic Exchange Club. He built a darkroom at Lismore Castle where firstly he used the calotype process and later wet-collodion. He exhibited 16 small studies at the 1856 Photographic Society exhibition. His photographic studies were mostly made around the Lismore estate and included still-lives of game, flowers and plants, landscapes and portraits. He was a prominent member of the Amateur Photographic Association and received at least two certificates of excellence from them in the early 1860s.

He carried on with his photography into the 1880's, re-printing some of his earlier pictures onto platinum paper. He was agent at Lismore until 1885 when he finally retired. He died on the 6th June 1896.

IAN SUMNER

CURTIS, EDWARD SHERIFF (1868–1952)

American photographer

Edward S. Curtis is known principally for his serial, *The North American Indian*, which was published between the years 1907 and 1930 in the form of twenty separate volumes of illustrated text and twenty accompanying portfolios of photogravures. Since the 1970s, the work has enjoyed a popular revival, rescuing Curtis' name from relative obscurity. However, the Project has often met with critical ambivalence and has altogether eclipsed other segments of his oeuvre, which include significant contributions to geographical surveys, award-winning portrait and landscape photography, independently produced documentary film, cinematography for Hollywood movies, and several popular books.

Curtis' photographic career began in the 1870s, when he worked as an assistant in a St. Paul, Minnesota studio. By 1891, after a forced hiatus from the trade in order to support his family after his father's death, he became a partner in a Seattle portrait studio with Rasmus Rothi, and later, in 1893 with Thomas Guptill. An 1896 issue of *Argus* gave special mention to the success of the Curtis-Guptill partnership, and their bronze medal from the Photographer's Association of America for excellence in posing and lighting was prominently noted. In 1897 Curtis continued his studio work alone, specializing in portraits and Northwestern landscapes.

Inspired by the romantic, nineteenth century- conception of the 'noble savage,' Curtis began photographing Seattle area Indians as early as 1895. His first Native American subject is said to have been Princess Angeline, Chief Seattle's daughter. In both 1898 and 1899, Curtis won first place in the National Photographic Convention's Genre Class for his images, *Evening on Puget Sound*, *The Clam Digger*, and *The Mussel Gatherer*, all of which featured images of Native Americans. However, it was his chance rescue on Mt. Rainier of C. Hart Merriam, Chief of the U.S. Biological Survey, Gifford Pinchot, Chief of the U.S. Forestry Department, and George Bird Grinnell, an eminent ethnologist that drew Curtis down the path ultimately leading to the North American Indian Project. In gratitude for his assistance, Grinnell asked Curtis to accompany him on the E.H. Harriman Expedition to Alaska, an outing for the wealthy Harriman family that would include over 30 natural scientists and closely resembled the federally supported Western geographical surveys of the 1870s. The expedition yielded a 10-volume publication, illustrated by Curtis' photographs, which numbered over 5,000 by trip's end.

Critics have generally described Curtis' earliest images of Native Americans as commercially driven, appealing more to aesthetics and to the late Victorian appetite for the exotic than concerned with ethnographic documentation. It was George Bird Grinnell's prediction that the Indian way of life would soon disappear, during a 1900 trip to view a Sun Dance gathering of Blackfoot, Bloods, and Algonquin on the Piegan reservation in Montana that prompted Curtis to approach his work with more scientific rigor. Disease, starvation, and forced assimilation into Anglo-American culture were slowly eradicating authentic Native American customs and way of life. Although Curtis began studying theories of ethnography, he was still obligated to fund his fieldwork with salable material. He therefore photographed only those tribes that confirmed popular notions of Indian identity.

Curtis soon found that funds generated by his studio and the small grant he received from Doubleday Publishers in 1904 were not enough to defray his fieldwork expenses. A 1905 exhibition of his photographs at the Waldorf-Astoria in New York brought his work to the attention of Theodore Roosevelt, who became a life-long Curtis admirer and wrote the introduction to the series' first volume. Through a laudatory letter written to Curtis about his work, Roosevelt indirectly facilitated a January 1906 meeting with railroad magnate J.P. Morgan, who agreed to finance Project-related fieldwork for

$15,000 per annum for five years. This allowed for the construction of a team of Native American guides and the recruitment of an on-staff ethnologist. However, Curtis was unable to find a publishing house for the serial, which sold for $3,000 a subscription, and he was subsequently forced to take on the publication and marketing of the series himself.

By the 1910s, Curtis found it necessary to raise money and renew enthusiasm for the project. Between 1912 and 1914, while only midway through the publication of the complete twenty volume series, he spent $75,000 producing a film about Kwakiutl culture, titled *In the Land of the Headhunters*. It was a commercial failure and left Curtis in debt. During this time, Curtis also wrote several books for the popular market, one of which was *Indian Days of Long Ago*, published in 1914. In 1920, after a financially ruinous divorce settlement, Curtis moved to Los Angeles and worked as a cameraman for Cecil B. de Mille on several films, including *The Ten Commandments* before returning to fieldwork in 1921.

Over the thirty years Curtis worked on the *North American Indian* project, he traveled 400,000 miles, made 40,000 photographs, studied nearly 80 tribes in the western United States, Canada and Alaska, and transcribed, with the help of his linguistically talented ethnologist, Seattle newspaper reporter, William E. Myers, 350 myths and legends, 75 languages, and some 10,000 pieces of music. The total cost of the Project ultimately ran to over $1.5 million dollars.

While lionized by the popular media for his aesthetic sensibility, technical prowess and the regality with which he captured an enervated and 'vanishing' culture, Curtis' work also met with a host of denunciations from ethnographers regarding its authenticity, casting him as a dubious figure in contemporary studies of photography and ethnography. Curtis believed that the most truthful depictions of Indians were those manifesting no vestiges of Anglo interference. He therefore manipulated his images through the process of photogravure or by burning or crosshatching away with the retouching stylus elements not commonly recognized as part of indigenous Native American culture. He also posed his sitters and provided them with props, which may not have been part of their tribe's customary dress or natural demeanor. With his knowledge of ethnology largely self-taught, Curtis still operated under a generic conception of Native American 'otherness,' which critics feel is evinced by the North American Indian representations.

By 1930, with the publication of volume XX, the *North American Indian* project was complete. With less than 300 subscriptions sold, the bankrupt North American Indian Corporation dissolved and the project, dubbed by the *New York Herald* in 1907 as "the most gigantic undertaking in the making of books since the King James edition of the Bible" ultimately met with little critical or public fanfare. The Moroccan leather, Japanese vellum and Van Gelder etching stock used for each volume made the cost of each set prohibitive, and America, mired in the depths of the Great Depression, had long since turned its gaze away from the romanticized conception of the West. Plagued by exhaustion and depression, Curtis landed in a Denver osteopathic clinic in 1932. Four years later, he returned to Los Angeles, where he worked for Cecil B. de Mille on *The Plainsman*, starring Gary Cooper. The 1940s brought a flush of enthusiasm for new projects, and Curtis began another mammoth historical chronology on gold mining, which was never completed. Although suffering from the bodily injuries sustained while conducting fieldwork, Curtis remained mentally active and productive until his death on 21 October 1952.

Savannah Schroll

Biography

Edward Sheriff Curtis was born in February 1868 in Whitewater, Wisconsin, the eldest son of Reverend Johnson Curtis. In 1887, after moving to the Washington territory, Curtis' father died and Curtis was forced to support the family through clam digging, farming, and odd jobs. He purchased his first photographic studio in Seattle in 1891 and married Clara Phillips one year later. In 1898, he rescued three scientist-explorers, Grinnell, Merriam, and Pinchot on Mt. Rainier and was consequently invited to join the Harriman Alaska Expedition as its official photographer. Using his own monetary resources, Curtis formally embarked on The North American Indian Project in 1901. Impressed with Curtis' work and the enthusiastic endorsement given Curtis by President Roosevelt, J.P. Morgan agreed to provide financial support for the Project for five years in January 1906. Volume I was published in 1907. Volumes II and III were published in 1908. Volumes IV and V were published in 1909. Volumes VI, VII, and VIII were issued in 1911. Volume IX was published in 1913. To generate capital and renew public interest in the Project, Curtis produced the film *In the Land of the Headhunters* between 1912 and 1914. In 1915, Volume X was published, and Volume XI was released in 1916. In the same year, Curtis' wife Clara filed for divorce, citing spousal neglect. The divorce settlement was final by 1919, and, as Clara was awarded Curtis' studio, Curtis and his daughter Beth smashed his glass-plate negatives so that she could not profit further from them. In 1920, Curtis moves to Los Angeles, opened a new photo studio, and worked briefly for Cecil B. de Mille on the *Ten Commandments*. In 1922, Volume XII was

Curtis, Edward Sheriff. Susie Little-Hoopa Medicine Woman. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

published. Volume XIII and XIV were issued in 1924. Volumes XV, XVI, and XVII were published in 1926. In 1927, accompanied by daughter Beth, Curtis made a perilous trip to Northern Alaska to obtain material for volume XX. Upon his return, he was arrested for failure to pay alimony for over seven years. In 1928 volume XVIII was published, and in 1930, volumes IXX and XX were issued. Curtis returned to work for Cecil B. de Mille on *The Plainsman* in 1936 and died of heart failure at the home of his daughter Beth in Los Angeles on 21 October 1952.

CUTTING, JAMES AMBROSE (1814–1867)

American inventor

The history behind the legend 'Cutting's Patent,' found embossed into the matte of several American ambrotype portraits, reveals a fascinating story of mid nineteenth century photography.

Cutting, born in Haverhill, Massachusetts, was a self-styled inventor, originally best known for his patent beehive which attracted a lot of publicity, and some considerable wealth. However, by the 1850s, the beehive business having failed, he had turned his attention to photography, originally taking daguerreotype portraits, but then, in 1854, opportunistically, took out American patents for collodion positive images. Tradition has it that the term 'ambrotype'—used in America as an alternative to Archer's 'collodion positive' derives from Cutting's middle name. 'Ambrotype' is now the universally recognised term.

The process was actually invented in England by Archer and Fry but not patented. Their decision allowed Cutting to submit three loosely worded patent applications (US Patent Numbers 11,213, 11,266 and 11,267) which offered only slight modifications of the original process. He quickly disposed of his patent rights, but his name remained associated with them.

One of his 'improvements' to the collodion positive involved sealing the image and its cover glass using Canada balsam as a means of eliminating oxidation. Ironically, the tendency of the balsam to attract moisture caused many of the images sealed in this way to develop fungal growths.

Cutting later opened a famous aquarium in Boston, and died in poverty in Worcester Massachusetts in 1867.

CUVELIER, ADALBERT-AUGUSTE (1812–1871) AND EUGÈNE-ADALBERT (1837–1900)

French photographers, father and son

Adalbert Cuvelier was a well-to-do merchant in the northern French city of Arras, a refiner of vegetable oils and sugar by profession, but also an amateur painter and photographer. Only a few dozen of his photographs survive (notably at the Bibliothèque nationale de France, Paris) but these give ample evidence of the technical proficiency and artistic vision that won him the respect of his fellow painters and that provided the foundation for the photographic work of his son, Eugène. Adalbert's surviving photographs were made in and around Arras in the early 1850s and include views of the town's main square, rustic huts, and farmyard still-lifes, as well as a series of portraits that are unusual in their celebration of the common man.

Because his impressive photographs have rarely been seen, Adalbert Cuvelier is better known to art historians for having introduced the cliché-verre process to the painter Camille Corot, whom he befriended in April 1852, and for having printed Corot's cliché-verre plates. In the early 1860s, Eugène Cuvelier in turn introduced cliché-verre to the principal painters of Barbizon, among them Charles-François Daubigny, Paul Huet, Jean-François Millet, and Théodore Rousseau, guided them through the process, and printed their compositions. Although the Cuveliers were thus the catalysts for a brief flowering of this hybrid technique of photographic printmaking, only a single cliché-verre by Eugène, and none by his father, survives. Rather, it is their extraordinary photographs that had a greater aesthetic influence on their fellow painters and that now constitute their more lasting artistic legacy.

Eugène was a teenager when his father first took up photography, and he undoubtedly learned to make pictures at his father's side. A few photographs are inscribed "E.C. 1852" suggesting that Eugène was already taking accomplished pictures by the age of fifteen, but these photographs appear, instead, to have been made by Adalbert, initialed "A.C.," and only later changed to bear the initials of the son; perhaps the two worked side-by-side and Eugène rightfully claimed a part of their creation. He also studied art with the period's two principal painters in Arras—Constant Dutilleux and Xavier Dourlens (although in truth, smoking, drinking, and singing seem to have been as common in Dourlens's atelier as artistic instruction). Despite Cuvelier's teenage ambition to be a painter, at twenty-one he described his trade as "mécanicien" (mechanic or engineer); he designed and built a small steamboat, a machine gun, and small working models of a steam-driven locomobile and a Crampton locomotive. In all these endeavors Cuvelier worked in a time when science and art were not opposed, and photography was the perfect medium to merge the two.

Most of Eugène's surviving photographs date from the early 1860s, shortly after his marriage in March 1859 to Louise Ganne, daughter of the Barbizon innkeeper whose establishment was a gathering place for the pre-Impressionists. Photography appears to have been a personal rather than a professional pursuit. Aside from exhibitions of the Société française de photographie, in which Cuvelier displayed views of Barbizon, Fontainebleau Forest, and the environs of Arras in 1864, 1869, and 1870, he rarely exhibited his photographs. No evidence exists that he ever sought government commissions, operated a studio, or offered his work to the public in published form. Finally, and perhaps most significantly, the rarity of his photographs suggests a very limited printing of his negatives.

Uncharacteristically for a photographer working in the 1860s, he used paper negatives and frequently made salted paper prints—processes that his father taught him in the early 1850s. Cuvelier must have employed these slightly antiquated materials by design rather than by default, for collodion-on-glass negatives and commercially prepared albumen paper (which he also used on many occasions) were the universal norm by 1860. In choosing the more difficult and time-consuming processes typical of a decade earlier he was surely motivated by a preference for their aesthetic qualities—notably the soft, fibrous texture of paper negatives, with their tendency to mass light and shadow, and the velvety mat surface and appealing color range of salted paper prints.

The vast majority of Eugène Cuvelier's photographs were made in Fontainebleau Forest—most within an easy walk of Barbizon. By the time he arrived in the area, the 40,000-acre wood surrounding the Palace of Fontainebleau—once the site of royal hunts and, more recently, the domain of highway robbers, hermits, and isolated woodsmen—was a destination for painters and photographers. Instead of cataloguing its points of interest, however, Cuvelier's photographs capture the experience of the forest. He more often pictured a fern-edged path *leading to* the "Sully" or a lichen-covered rock *near* the "Reine Blanche" than the landmark trees themselves. Other photographs by Cuvelier show the humble subjects popular with his painter friends—the corner of a rustic farmyard, the streets of Barbizon, grapevines in a garden courtyard, and after-the-hunt still-lifes—as well as the château and gardens of nearby Fleury. In the mid-1860s, he also made photographic excursions in and around Arras (including Courances, Achicourt, Fampoux, and Rivière), where the heavily pruned trees, lakes, open fields, and other aspects of the landscape afforded possibilities different from those to be found in Fontainebleau Forest.

Cuvelier, Eugène. Fontainebleau Forest. *The Metropolitan Museum of Art, Purchase, The Howard Gilman Foundation and Joyce and Robert Menschel Gifts, 1998 (1988.1031) Image © The Metropolitan Museum of Art.*

In later life, Eugène and Louise Cuvelier retired to Thomery, a small town on the Seine just east of Fontainebleau, across the forest from Barbizon. Eugène died in 1900, at the age of sixty-three, and Louise four years later. Hélène, their only child, who was born in 1860, married late in life and died without children in 1905. Most of the family papers and possessions are said to have been destroyed in World War I.

Adalbert and Eugène Cuvelier were known to art historians for their connection with the cliché-verre, but few of their works were identified until recently. Only in 1962 was a landscape photograph first recognized as having been made by Adalbert (Scharf, Aaron, "Camille Corot and Landscape Photography," in *Gazette des Beaux-Arts*, ser. 6, 59 [February 1962], 99–102.) Eugène's photographs were slightly better known: a handful of beautiful salted paper prints were donated to the Bibliothèque nationale by Paul Blondel in 1924, and by mid-century a few others were collected by specialists in nineteenth-century French photography. Only in the late 1980s and 1990s, however, did the majority of the Cuveliers' best prints surface. More than one hundred photographs by both father and son were found by the descendants of Louise Ganne's sister, Victoire; many of these, including Adalbert's most impressive works, were bought by the Bibliothèque nationale, with the rest finding their way to various collectors and institutions in Europe and America. A second large cache of photographs by Eugène Cuvelier was discovered in 1989 in a packing crate—along with seascapes by Gustave Le Gray and landscapes of the American West by Carleton Watkins—and was sold at a country auction in New England, leading to the speculation that the photographs were collected and brought home by one of the many American painters who traveled to Barbizon in the early 1860s. We now know more than 250 images by Eugène—over half of his oeuvre, to judge by the numbers inscribed on his negatives.

Adalbert and Eugène Cuvelier were the subject of an exhibition at The Metropolitan Museum of Art in 1996. A related exhibition of photographs by Eugène was organized by the Staatsgalerie Stuttgart and exhibited there and at the Musée d'Orsay, Paris, in 1997.

MALCOLM DANIEL

Biography

Adalbert-Auguste Cuvelier was born in Arras, March 2, 1812 and died in Boisleux-au-Mont, February 15, 1871. Adalbert's son, Eugène-Adalbert Cuvelier, was born in Arras, April 6, 1837. He learned photography from his father, and studied painting as a teenager. On March 7, 1859, he married Marie-Louise Ganne, daughter of the innkeeper at Barbizon. He made the majority of his photographs in Barbizon and the nearby Fontainebleau Forest in the half dozen years following his marriage. Cuvelier died in Thomery, near Fontainebleau, on October 31, 1900.

CYANOTYPE

During the brilliant summer of 1842, Sir John Herschel was experimenting with highly-coloured, light-sensitive chemicals, when in June, following a suggestion by Dr Alfred Smee, he chanced upon a novel process for printing photographs in Prussian blue—a pigment already familiar to painters for over a century. Herschel called his process Cyanotype, which was negative-working in its simplest form. He also devised a positive-working version, but this presented difficulties that were partially solved in 1877 by Henri Pellet. Herschel published his processes in 1842, without restraint by patent, like all his photographic inventions. Cyanotype did not begin to enjoy wide use, however, until 1872, the year following Herschel's death, when it was taken up commercially by Marion and Company of Paris, who bestowed upon it the proprietary name of "Ferro-prussiate," and marketed a paper chiefly for copying plans in drawing offices. Thus the word "blueprint" entered our language, to describe the first reprographic process, with its advantages of low material cost compared with silver photography, and a simplicity of processing that required nothing but water. The manufacture of blueprint paper grew rapidly into a profitable industry, becoming the dominant process of reprography for the next 80 years.

Cyanotype is just one of several iron-based processes for positive printing invented by Herschel in 1842. The key to them all is the light-sensitive substance, ammonium ferric citrate, which was then being promoted by pharmacists as an iron tonic. This salt is mixed, in ca.20 per cent aqueous solution, with ca.16 per cent potassium ferricyanide, to make the sensitizer for coating plain paper. On exposure to sunlight, the ferric salt is reduced to the ferrous state, which then combines with the ferricyanide to yield Prussian blue (also known as Turnbull's blue)—which is not ferrous ferricyanide, as was long-believed, but ferric ferrocyanide. Ammonium ferric citrate is an ill-defined substance, with no precise formula, and Prussian blue also varies in composition, so the following chemical equations representing these two reactions are necessarily approximate:

Illustration

UV light + $2Fe^{3+}$ + $C_6H_6O_7^{2-}$ → $2Fe^{2+}$ + $C_5H_6O_5$ + CO_2

UV light + ferric + citrate → ferrous + acetone + carbon dioxide

ions ions ions dicarboxylic acid

Fe^{2+} + $K_3[Fe(CN)_6]$ → $KFe[Fe(CN)_6]$ + $2K^+$

ferrous + potassium → ferric ferrocyanide + potassium

ions ferricyanide (Prussian blue) ions

As the exposure proceeds, the image prints out in Prussian blue, but dense regions of the tonal scale reverse to pale grey (overexposure causing the formation of Prussian white, ferrous ferrocyanide, $K_2Fe[Fe(CN)_6]$), which gives the provisional image a solarized appearance. However, re-oxidation by air restores the shadow densities fully within a few hours. Because the unexposed sensitizer and reaction products are very soluble, the cyanotype needs nothing more than a wash in water to complete its processing—a fixing procedure that Herschel regarded as ideal. Cyanotypes have a perfectly matte surface, with no binder layer; the monochrome blue may vary in hue, and there are numerous methods of toning the image to violet, green, brown, red, or even black, as discovered by John Mercer in the 1850s. Like all iron-based processes, cyanotype has a very low sensitivity to light and can only be used for making contact prints and photograms.

Herschel used his invention to copy steel engravings and scientific notes, but it was taken up chiefly by botanical illustrators for making photograms of plant specimens; the first and most celebrated practitioner of "autobotanography" was Anna Atkins, a friend of the Herschel family, one of the first women photographers, and the author of the world's first book illustrated with photographs, *British Algae: Cyanotype Impressions*. Over the period 1843–61, Anna Atkins, in collaboration with her close friend Anne Dixon, hand-printed several elegant cyanotype albums of botanical and textile specimens, which have now become treasures of the early photographic canon.

As John Mercer discovered in the 1850s, the cyanotype process is also particularly well-suited for printing photographs onto cotton textiles: the sensitizer is cheap and non-toxic, processing is easy, and the absence of any binding agent ensures that the fabric remains unstiffened, and can drape in a natural fashion. In the 1890s a company existed in North America to print clients' photographs as cyanotypes onto pillow covers, quilts, and other soft furnishings.

Regarding the pictorial use of cyanotype, many connoisseurs experienced aesthetic difficulty with its ineluctably blue images. In Britain, Peter Henry Emerson set the tone with his acerbic dictum: "No one but a vandal would print a landscape in red, or in cyanotype." The English photographic establishment deemed cyanotypes to be inferior, and unworthy of acquisition or exhibition. The process was largely confined to proofing the domestic negatives of hobbyist photographers. As a consequence, 19th-century pictorial cyanotypes

are almost totally absent from all the major UK collections. In contrast, some curators and practitioners in France and the USA embraced the process. The still-life photographs of Henri Le Secq printed in cyanotype are well-represented in Paris, and have survived better than his silver prints. There is also a set of fine ethnographic studies of native North Americans by Edward Curtis at the George Eastman House.

Cyanotype was used for some 19th-century documentary photographs; their subjects were large-scale engineering projects, such as the construction of the Forth Bridge (1883–90), the cutting of the Panama Canal (1888–93), and various aspects of railway and locomotive engineering. This print medium was a natural choice, in view of the availability of blueprint paper in quantity on such projects. Preparatory to their publication in a 'proper' medium, the human and animal locomotion studies by Eadweard Muybridge were proofed in cyanotype, revealing interesting details that were suppressed in the final published images. Edwin Linley Sambourne made extensive use of cyanotypes to assemble an archive of reference images for his *Punch* cartoons.

Prussian blue reacts readily with alkalies: cyanotypes are destroyed irreversibly in a few minutes by a solution of only pH 9 (corresponding to a saturated solution of chalk). To protect them, a slightly acidic environment (i.e. a pH less than 7) is paramount—a requirement which runs counter to the currently approved practices of paper conservation, where alkaline buffering against acid embrittlement is the norm. Cyanotypes also tend to fade in strong light, but this is reversed in the dark; their densities recover completely within a few days in air, provided the light exposure has not been excessive. Despite these vulnerabilities, cyanotypes are archivally stable: fine specimens have endured well from the earliest days of photography, and the process continues to attract artists today.

D

DAGUERRE, LOUIS JACQUES MANDÉ (1787–1851)

French painter, decorator, printmaker, entrepreneur, inventor, and photographer

Daguerre was born on November 18, 1787, in Cormeilles-en-Parisis to Louis Jacques Daguerre and Anne Hauterre. He later attended the public school of drawing, and perhaps apprenticed to an architect, in Orléans, where his father was a process-server in the bailiff's court. Daguerre arrived around 1803 in Paris, where his godparents, the wine merchants Louis and Marie-Louise Fromont, most likely received him.

Daguerre spent the majority of his career seeking popular support and official recognition as an artist during one of the most politically and socially complex periods in French history, living through the French Revolution, Empire, Bourbon Restoration, and July Monarchy. If his contributions to photography eventually overshadowed his work as a painter, the French government's ultimate support for the daguerreotype in 1839 nevertheless demonstrates Daguerre's ambition and entrepreneurial prowess, as well as his determination, resiliency, and political savvy. Perhaps his most significant legacy to modern art and photography was this ability to negotiate artistic and political viability with popular forms of visual art.

Although Daguerre's early years remain somewhat obscure, he began his career in Paris around 1804, when he was one of the first students to enter the painting studio of the Paris Opéra, then under the direction of Ignazio-Eugenio-Maria Degotti. He may also have been a student of Jacques-Louis David, and early biographies of Pierre Prévost (who was hired by James Thayer to paint the panoramas for his two rotundas in the Boulevard Montmartre) state that Daguerre was one of Prévost's assistants, even though extant documentation does not exist to support the claim.

Daguerre first appears in the records of the Opéra as a day laborer in December 1808 for the opera *Alexandre chez Apelle* and again in November 1809 for *Fernand Cortez*. In 1810 Daguerre served as painter of ornaments for *La Mort d'Abel*, and the same year, he and Pierre-Luc Ciceri completed the decorations for the second act of *Les Bayadères*. In 1812, Jean Baptiste Isabey, who had assumed leadership of the Opera studio in 1810, recommended Daguerre as one of the studio's four first painters. Daguerre held various posts in the painting studio through 1816, when he was named the chief decorator of the Ambigu-Comique theater. He returned briefly to the Opera studio as co-chief painter with Ciceri from 1820–22. Daguerre's most prominent work with Ciceri were the decorations for *Aladin, ou la lampe merveilleuse*, which inaugurated gas lighting at the Opéra on the rue Peletier in February 1822.

Daguerre's early paintings share much in common with the "troubadour" style exemplified by Pierre Révoil and Fleury-François Richard, the gothic interiors popularized by François-Marius Granet, and the work of various artists in the weekly salons of Ciceri, including Carle and Horace Vernet, Jean-Baptiste and Eugène Isabey, Charles-Marie Bouton, and Jean-Pierre Alaux. Despite the fact that Daguerre began his own career under the Empire, and associated with several artists in Ciceri's salon known for their "bonapartist" tendencies, he nevertheless was favored by the newly restored Bourbon monarchy. Daguerre's family was closely tied to the Bourbons through an aunt, Marguerite Dully de Chérix, who had raised his father. Upon her death in 1790, she left her fortune to Louis XVI, and Daguerre's father was placed under house arrest and was almost incarcerated during the Reign of Terror because of this will. Louis XIII purchased Daguerre's first entry into the official Parisian Salon, *Intérieur d'une chapelle de l'église des Feuillants* (1814). Daguerre remained skilled

throughout his career for employing both his art and social connections to gauge changing public taste and to curry the favor of the current regime in power.

In 1810, Daguerre married Louise Georgi(en)ne Schmit(te) (called Arrowsmith or Smith), daughter of William Schmit (called Smith), who had immigrated to France from London in 1783, and eventually served as porter for the Orléans family. During the early days of the July Monarchy, and the return of the Orléans to power, Daguerre converted to the new spirit of republicanism. He was one of the first artists to become a member of the Société libre des beaux-arts, which professed a program of conservative liberalism. Opposing both the outdated traditions of the Academy and the abandon of romanticism, this group of artists, founded by Charles Farcy of the *Journal des artistes*, supported Victor Cousin's doctrine of beauty and utility in the arts. Cousin had energized the fashionable, liberal society of the Restoration with his philosophy classes at the Sorbonne, which were discontinued in 1822, and recommenced in 1828. Seen as threatening to the politics of Charles X, Cousin's philosophy went hand-in-hand with the program of industrial progress of the July Monarchy. This program, along with the conservation of French national heritage responsible for François Guizot's creation of the Commission des monuments historiques in 1830, later played an essential role in state support of the daguerreotype. During the Restoration, Daguerre catered to a slightly liberal public that came into power and prestige under the July Monarchy. In this way, he survived not only the change of political power, but personal bankruptcy as well.

Daguerre was also among the first French artists to experiment with lithography, registering two lithographs, printed by Charles Motte, on 20 June 1818: *Souterrain exécuté pour l'Ambigu Comique 1817* and *Citerne en ruine à Montmartre*. In 1819, his lithograph *L'Entrée de l'église du St. Sépulcre* for Count Auguste de Forbin's *Voyage dans le Levant*, was shown at the Salon. In 1820, Daguerre contributed to the first volume of Charles Nodier and Baron Isidore Taylor's *Voyages romantiques et pittoresques dans l'ancienne France*. His lithograph *Ruines de l'abbaye de Jumièges* (Ancienne Normandie, t. I, pl. 12) was shown by the printer Godefroy Engelmann in the Salon of 1822. Between 1820-33, Daguerre contributed (preparatory drawings or lithographs) to a total of 11 plates for successive volumes of this publication, including Ancienne Normandie, t. II, 1825; Franche-Comté, 1825; and Auvergne, t. I, 1829 and t. II, 1833. His theater decorations for Victor Ducange's *Elodie*, presented at the Ambigu-Comique in 1822, were popularized by the lithographer Jean-Philippe Schmit and shown in the Salon of 1824.

Daguerre was best known as the entrepreneur and creator of the Diorama, which he organized as a limited stock company in 1821 with his partner Bouton. The society was registered under the name "Bouton, Daguerre et Cie" on January 3, 1822, with shareholders including Jean-Baptiste Isabey and the Count Charles de Clarac, the curator of antiquities at the Louvre. In 1823, Daguerre formed a second society with the printer James Smith to exploit the Diorama in London under the supervision of John Arrowsmith. Daguerre and Bouton jointly directed the Paris Diorama until September 1830, when Bouton left the society for declared health problems. Despite his declaration of bankruptcy in 1832, Daguerre continued as sole director of the Paris Diorama until it burned down on 8 March 1839.

The Diorama was a building designed by Daguerre that housed two large, semi-transparent paintings illuminated by natural light. Inspired by the success of the panoramas, as well as the transparent paintings of Louis Carmontelle and Franz-Niklaus Kœnig, Daguerre and Bouton employed blinds and colored screens to represent natural effects of time, light, and movement in contrasting interior and exterior views. The public, seated in a central auditorium, was transported from one scene to the next by means of a rotating viewing platform. On rare occasions, Daguerre used the Diorama as a venue to capitalize on current political events in order to win political favor, as with the *Vue de Porte Sainte-Marie* (1824), which depicted the Duke d'Angoulême (son of the future Charles X) meeting Ferdinand VII in Spain during the French effort to restore the absolutist Spanish monarch to the throne. Shortly after the Duke d'Orléans assumed the throne as King Louis-Philippe, Daguerre depicted the taking of the Hôtel de Ville during the spontaneous insurrection of French citizens and the National Guard against the army on 28 July 1830. In 1834, Daguerre and his student Hippolyte Sébron developed the double-effect diorama. Like the earlier diorama pictures, the double-effect paintings featured temporal and climatic changes, but were also episodic; the paintings represented events or scenes that often included the appearance of figures, painted on the back of the canvas, which were only visible when lit from behind. In *The Inauguration of the Temple of Solomon* (1836), for instance, a nighttime scene of a deserted architectural setting was gradually transformed into a magnificent, candelabra-lit golden temple in which viewers eventually saw thousands of people celebrating the dedication of the temple.

Although Daguerre envisioned the Diorama as a permanent public display of his work, he exhibited at three other Paris Salons as part of his program to gain official, as well as public, recognition for his art. In 1824, he showed *Chapelle d'Holyrood* and an oil sketch, *La*

Chapelle de Roslin. The same year he was awarded the cross of the Legion of Honor and Forbin, then director of the Louvre, described him as one of the most remarkable painters of the time. His 1827 Salon entry, *Village d'Unterseen en Suisse* (lost in 1848) was purchased by the Duke d'Orléans. All three of these works were also subjects of Daguerre's Diorama. The repetition of diorama subjects was not merely a commercial endeavor, but also represented Daguerre's concern with establishing his reputation as a painter outside the realm of the ephemeral and popular pictures for the Diorama. His final Salon entry, in 1834, was an original landscape, *Paysage*, and is unique in Daguerre's oeuvre for its heavily worked foreground, in which the impasto of the paint is apparent. The rugged terrain and foliage of the foreground reveal the influence of the new school of landscape represented by Théodore Rousseau and indicate the direction Daguerre's Salon painting might have taken had he continued to exhibit.

By 1834, however, Daguerre was completely occupied with experiments related to the Diorama and photography. For his diorama paintings, he had already studied different materials according to their reaction and sensitivity to light, in particular working with phosphorescent materials in a camera obscura in an attempt to produce incandescent colors. Daguerre's talent for lighting effects and illusionism, along with his solid understanding of printmaking techniques, led to the invention of the daguerreotype, the first publicly announced and commercially successful photographic process. After five years of joint experimentation with Joseph Nicéphore Niépce, Daguerre produced his first daguerreotypes as early as 1834 and announced the invention in the *Journal des artistes* on 27 September 1835. The daguerreotype is a photographic image with a mirror-like surface on a silver or silver-coated copper plate. A unique photograph, the daguerreotype is not produced from a negative, and the final image appears either positive or negative depending on the angle of reflected light.

Daguerre first contacted Niépce in January 1826, after hearing about his heliographic experimentation from the optician Vincent Chevalier. Niépce eventually visited Daguerre at the Diorama in August 1827, and the two men formed a company on 14 December 1829 in order to exploit both Niépce's invention, based on the photosensitvity of bitumen of Judea, and Daguerre's improvements to the camera obscura. After Niépce's death (5 July 1833), Daguerre signed a new contract in 1835 with Niépce's son, Isidore. The new contract changed the name of the partnership from "Niépce-Daguerre" to "Daguerre and Isidore Niépce," in light of Daguerre's recognition of the chemical bases of the daguerreotype, iodine and mercury. A final contract was signed in 1837, naming Daguerre as the sole inventor of the new process, which was announced by the politician and scientist, François Arago, on 7 January 1839. Arago formally divulged the process to a joint meeting of the Académie des Sciences and Académie des beaux-arts on 19 August 1839, after King Louis-Philippe signed the law granting lifetime pensions to Daguerre and Isidore Niépce on 7 August 1839.

According to the terms of the law, Daguerre was required to publish details of the daguerreotype process and techniques for painting diorama pictures. In addition to Arago's public explanation of the technical production of daguerreotypes, Daguerre produced an illustrated manual outlining the various steps of the process. Daguerre added his correspondence with Niépce, in which he suggests experimenting with the photosensitivity of silver and iodine, in order to demonstrate that the daguerreotype was indeed his own invention. The cited letters—which document the fact that Daguerre's systematic experiments with silver nitrate, and eventually mercury, led him to the discovery of his own photographic process—only revealed part of the picture. In fact, Niépce already had used iodine, but only as a kind of "developing agent," to darken the shaded parts of his proofs. Daguerre's claims in the manual angered Niépce's son, Isidore, who responded with his own pamphlet, in which he asserted that his father invented the daguerreotype.

Following Arago's announcement, Daguerre sent daguerreotypes to Ludwig I of Bavaria, Ferdinand I of Austria, Nikolaus I of Russia, Friedrich Wilhelm III of Prussia, the Austrian chancellor Klemens Metternich, and Austrian ambassador to France, A.G. Aponyi. Daguerre also offered daguerreotypes to Arago and Alphonse de Cailleux. These dedication plates, like many of the images the first generation of photographic artists produced, comprised views of Paris and still-life arrangements of plaster casts, architectural fragments, bas-reliefs, and copies of sculpture. Daguerre's earliest extant daguerreotype is generally considered to be the still life presented to Cailleux, which includes a bas-relief after Jean Goujon. Georges Potonniée, who first exhibited the plate in 1920, dated it to 1837 based on an inscription that is no longer visible. The image itself is now almost completely faded, as is the case with many of Daguerre's earliest daguerreotypes. The state of many of these early plates, along with lack of documentation, accurate provenance, and conservation studies, renders precise dating, as well as firm attribution, difficult at best. For these reasons, the date and identification of Daguerre's earliest portrait daguerreotype remains a debated topic.

After Arago's disclosure of the daguerreotype process, Daguerre gave a series of public demonstrations in

September of 1839, in addition to weekly consultations to daguerreotypists at the Conservatoire des Arts et Métiers. He also supervised daguerreotype production at the shop of Alphonse Gustave Giroux, the son of his art dealer and the first manufacturer of daguerreotype equipment. In 1840, Daguerre retired to the village of Bry-sur-Marne. While he continued to work on the daguerreotype, periodically sending news of improvements to Arago, photography was no longer his affair. He painted his last diorama for the church of St. Gervais-St. Protais at Bry in 1842. In 1848, he constructed a natural grotto in the park at Bry, returning to the source of his original inspiration, the landscape. He died on 10 July 1851, the same year he was planning another religious diorama painting, a cavalry, for the church at Perreux, in the neighboring town of Nogent-sur-Marne.

STEPHEN C. PINSON

Biography

Louis Daguerre was born 18 November 1787 in Cormeilles-en-Parisis, France and attended public school in Orléans before moving to Paris around 1803. In 1808, he appears in the official records of the painting studio of the Opéra, where he held various posts through 1816, when he was named the chief decorator of the Ambigu-Comique theater. He returned briefly to the Opera studio as co-chief painter with Pierre-Luc Ciceri from 1820–22. Daguerre also exhibited five paintings in the official Parisian Salon, was among the first French artists to experiment with lithography, and was the entrepreneur of the popular spectacle known as the Diorama, which opened in Paris in 1822. On 14 December 1829, Daguerre formed a company with Nicéphore Niépce in order to exploit Niépce's invention of heliography, and Daguerre's improvements to the camera obscura. After Niépce's death (5 July 1833), Daguerre signed a new contract on 9 May 1835 with Niépce's son, Isidore. The new contract changed the name of the partnership from "Niépce-Daguerre" to "Daguerre and Isidore Niépce," in light of Daguerre's recognition of the chemical bases of the daguerreotype, iodine and mercury. A final contract was signed on 13 June 1837, naming Daguerre as the sole inventor of the new process, which was announced by the politician and scientist, François Arago, on 7 January 1839. Arago formally divulged the process to a joint meeting of the Académie des Sciences and Académie des beaux-arts on 19 August 1839, after the purchase of the process by the French government. In 1840, Daguerre retired to Bry-sur-Marne, where he painted his last diorama for the church of St. Gervais-St. Protais in 1842 and died on 10 July 1851.

DAGUERREIAN JOURNAL (1850)

When the first issue of *The Daguerrean Journal* appeared on November 1st 1850, American photographers experienced their first specialist journal devoted to the new art, and the world welcomed the first commercially produced photographic magazine. It was not, strictly speaking, the first journal to promote the daguerreotype—that goes to John Plumbe's short-lived publication *The Plumbean* in the late 1840s, but in terms of a widely published and distributed periodical, *The Daguerrean Journal* was an undoubted first.

The editor and publisher was Samuel Dwight Humphrey, born in Hartland Connecticut, himself a daguerreotypist in New York with several years experience, and already by that time, co-author with M. Finley of the 1849 manual on the process, *A System of Photography Containing an Explicit Detail of the Whole Process of Daguerreotype*.

The publication's full title—*The Daguerreian Journal: Devoted to the Daguerreian and Photographic Art. Also embraces the Sciences, Arts and Literature*—made Humphrey's intention explicit.

The first issue had, as its frontispiece, a portrait of Daguerre, and while a year's subscription of the twice-monthly publication was set at 'three dollars in advance' single issues could be purchased for twenty-five cents.

Initial reaction to the journal was highly positive and, at the end of its first year of publication, Jeremiah Gurney, in a letter to the editor published in May 1851, noted that "a journal, therefore, devoted as yours has been to affording so many valuable hints in the operative department of the new artist, is a most invaluable aid… …We have at once in our power the means of union and advancement. We have a medium through which, no matter how distant we may be placed, we may inter-

communicate and establish that good fellowship which should exist between all exercising a common calling… …The only hope in raising our calling is in publication and communication; the opportunity is within our grasp; and I trust when the current volume terminates its career, and that we have all been weighed in the balance, we shall not be found wanting."

Before the end of the first volume of publication, Levi Hill had made the first announcement of his achievement at producing daguerreotypes in what he stated were natural colours. So impressed was Humphrey by Hill's claims that he invited him to become co-editor of the *Daguerreian Journal*, an offer which he quickly regretted. Hill's reluctance to detail his process brought widespread opprobrium from within the photographic community, despite his assertions that he was withholding publication until he had the process in a more perfect state. The daguerreian community, and Samuel Humphrey, quickly lost faith in Hill's claims. He was accused of trying to swindle the purchasers of his manuals, and his co-editorship of *The Daguerreian Journal* was terminated before the completion of volume two.

The journal attracted readers and contributors from Europe as well as America, including such luminaries as the leading British writer on photography, Robert Hunt, whose writings on 'Researches on Light,' 'Helichrome' and 'On the Application of Science to the Fine and Useful Arts' were all included in 1851, as was a review of his book 'Photography—a Treatise.'

After two years of successful publication, and three volumes, the *The Daguerrean Journal* name was changed to *Humphrey's Journal of the Daguerreotype and Photographic Arts*—usually thereafter referred to as *Humphrey's Journal*—a title it retained until the end of volume 13. With the exception of a brief cessation between January and march 1852, publication under this name continued until late 1863.

For volume 14 only, a further name change was introduced—to *Humphrey's Journal of Photography and the Heliographic Arts and Sciences*.

Renamed again in 1864 as *Humphrey's Journal of Photography and the Allied Arts & Sciences*, the magazine continued to enjoy success until 1870 (the end of volume 21) under the editorship of John Towler.

DAGUERREOTYPE

The daguerreotype process—the first practical means of capturing a lasting image by a photochemical reaction—was developed in France in the 1820s and '30s by Joseph-Nicéphore Niépce and by Louis Jacques Mandé Daguerre, after whom it is named. In this process, a copper plate that has been coated with silver, polished, and sensitized is exposed to light and then chemically treated to produce and fix a single positive photographic image. The finely detailed picture that results from the process alternately appears to its viewer as a positive or a negative, depending on the angle of light in which the cased mirror-like plate is held. The first daguerreian cameras reversed the image from right to left from the original perspective; by 1840, the introduction of mirrors in place of, or in addition to, lenses allowed for right-reading images. Initially, the long exposure time required to produce a daguerreotype inhibited its use for portraiture, but by the early 1840s, important chemical additions to the process and improvements in camera- and lens-making allowed daguerreotypy to be used for imaging human subjects. Its accuracy, relative rapidity, and affordability made daguerreotypy the dominant form of photography until the 1850s, when it was supplanted by negative-to-positive processes that produced and reproduced images more easily and inexpensively.

Daguerre's Process

Daguerre's original process involved several complicated steps that exceeded the capacities of most curious amateurs. First, a sheet of copper was carefully coated with a thin layer of silver, then cleaned and polished. The characteristic reflectivity of the daguerreian plate's mirror-like surface was achieved using an abrasive mixture of pumice and oil that was washed from the plate with nitric acid and water.

In a darkened room, the polished plate next was sensitized through exposure to iodine flakes in a specially designed box until a chemical reaction introduced a thin layer of silver iodide on the silvered surface, turning it a bright golden color. Once placed in a plate holder and covered with an opaque protective slide, the plate was ready for exposure in a camera. These early cameras were relatively simple: they consisted of a lightproof wooden box within another box that had been fitted with a ground glass, a mirror, and a brass tube containing a

lens. Daguerre's original camera used a meniscus, or simple convex-concave, lens.

In preparation for taking the picture, the camera's lens was focused and capped and the plate holder inserted into the camera. In place of a shutter, the protective opaque slide was pulled away from the plate and out of the camera and the lens cap removed to begin the exposure. The first daguerreotypes could require twenty minutes or longer of exposure, depending on light conditions. Once the estimated exposure time was reached, the lens cap and protective slide were replaced and the plate holder removed from the camera and returned to a darkroom for development.

In the darkroom, the plate was suspended face-down in a box containing a small amount of mercury that had been heated to 120 to 180 degrees Fahrenheit by means of a spirit lamp to distribute it evenly across the bottom of the box. Mercury vapors chemically reacted with areas of the silvered plate that were exposed to light. The daguerreotypist examined the plate at intervals to check the progress of the developing latent image.

Once the picture was visible and the contrast in its light and dark tones deemed satisfactory, it was bathed in a heated solution of salt or "fixed" in a bath of sodium thiosulfate, or "hypo," for approximately thirty seconds to remove the sensitized chemicals that remained on the plate. The hyposulfite was then rinsed off with water and the plate carefully dried to avoid spotting. The finished plate was then enclosed behind glass in a protective frame.

Development of the Daguerreotype Process

In the early nineteenth century, a number of artists, scientists, and amateurs simultaneously were experimenting with various chemicals, surfaces, cameras, and lenses to fix a permanent image that was generated by light instead of by an artist's hand. In England, Thomas Wedgwood, Sir Humphry Davy, and William Henry Fox Talbot were working to print such images on paper, and in France, Nicéphore Niépce and Daguerre each were searching for a means of capturing pictures on metal plates. Daguerre had turned to photographic experimentation after the popular and profitable exhibition of his diorama paintings in Paris. These large-scale, semi-translucent canvases featured *trompe l'œil* paintings illuminated with various lighting effects to give the illusion of passing time. Having used a camera obscura to create his paintings, Daguerre became interested in devising a method to capture the camera's projections. In 1826, he learned from the Parisian opticians Charles and Vincent Chevalier that another of their clients, Niépce, had been using bitumen of Judea to print images on pewter. Daguerre wrote to Niépce to inquire about his process, which Niépce had named *heliography*. The two began a tentative correspondence, with each reluctant to divulge the extent of his progress to a rival. In late 1829, after concluding that their independent work could advance more quickly in collaboration, Niépce and Daguerre became partners. When Niépce died three and a half years later, his son Isidore succeeded him in the partnership; Daguerre continued experimenting.

By 1837, Daguerre's progress in stabilizing the photographic process was such that he revised the original terms of the partnership that had designated Niépce as the inventor of the process and Daguerre as its improver to give himself the primary role. He had happened upon a combination of common salt, silver, iodine, and mercury that finally succeeded in developing a latent photographic image and permanently fixing its subtle shades on a copper plate. Seeing the potential profit in the improved process, Isidore Niépce acquiesced to Daguerre's terms. In attempting to sell his findings to subscribers in France and abroad, Daguerre approached François Jean Dominique Arago, director of the Paris Observatory, permanent secretary of the French Academy of Science, and a member of the French Parliament's Chamber of Deputies. Having experimented himself with light-sensitive materials and with means of measuring the effects of light's intensity, Arago immediately recognized the commercial, scientific, and artistic potential of Daguerre's process. At the 7 January 1839 meeting of the Academy, Arago proposed that "the Government should compensate M. Daguerre direct, and that France should then nobly give to the whole world this discovery which could contribute so much to the progress of art and science" (qtd. in Gernsheim, 1968, 84). In July 1839, the French government passed bills awarding Daguerre and Niépce an annual pension of six thousand and four thousand francs, respectively, in exchange for a detailed history and description of the promising daguerreotype process. For the additional two thousand francs, Daguerre also was asked to reveal the secrets behind the realistic effects of his diorama paintings.

The Public Introduction and Adoption of Daguerreotype

In keeping with Arago's hopes and with Daguerre's and Niépce's agreement with the French Government, the daguerreotype process was introduced to the public at a joint open meeting of the Academies of Science and of the Fine Arts on 19 August 1839. In front of a rapt crowd that filled the Academy's halls and courtyard, Arago detailed, but did not demonstrate, the necessary equipment and procedures on Daguerre's behalf. The

response to the announcement was overwhelming. According to one account, only an hour after Arago's lecture, all the opticians' shops were besieged, but could not rake together enough instruments to satisfy the onrushing army of would-be daguerreotypists; a few days later you could see in all the squares of Paris three-legged dark-boxes planted in front of churches and palaces. All the physicists, chemists, and learned men of the capital were polishing silvered plates, and even the better-class grocers found it impossible to deny themselves the pleasure of sacrificing some of their means on the altar of progress, evaporating it in iodine and consuming it in mercury vapor" (qtd. in Gernsheim, 1968, 101).

Théodore Maurisset's "La Daguerreotypomanie," published in December 1839, offers a humorous depiction of the French public's tremendous enthusiasm for the new discovery. In the lithograph, a smiling sun shines down on a carnivalesque scene of endless multitudes seeking, posing for, purchasing, taking, and manufacturing equipment for making daguerreotypes.

Soon after Arago's lecture, Daguerre wrote a pamphlet entitled *Historique et description des procédés du Daguerréotype et du Diorama, par Daguerre* [*A History and Description of the Process of the Daguerreotype and of the Diorama, by Daguerre*], published by Alphonse Giroux in Paris, to meet the intense public demand for more information about the process. Daguerre also commissioned lenses from Charles Chevalier to be used in cameras manufactured to his specifications and to be sold by Giroux. As word of the daguerreotype spread beyond France, Daguerre's instructions were quickly translated and republished throughout the world. Yet early attempts to replicate Daguerre's success by following his procedure often resulted in disappointment, as novices found the process difficult to master. In response to these frustrations, Daguerre agreed to offer demonstrations of his process and his advice to the public.

At the first demonstration, held on 7 September 1839, an audience of nearly one hundred and twenty people observed each step of the procedure and applauded Daguerre's results after an hour and a half.

When the process was successfully carried out, the results were incomparable. As Samuel Finley Breese Morse, the American painter and inventor, marveled after viewing several of Daguerre's examples before their public release,

> [n]o painting or engraving ever approached it. For example: In a view up the street, a distant sign would be perceived, and the eye could just discern that there were lines of letters upon it, but so minute as not to be read with the naked eye. By the assistance of a powerful lens…every letter was clearly and distinctly legible, and so also were the minutest breaks and lines in the walls of the buildings, and the pavements of the streets. (qtd. in Taft, 1964, 12)

Yet as Morse noted, these first daguerreotypes were incapable of capturing any moving objects. Due to the lengthy time of exposure, the pedestrians and carriages traveling on the streets in Daguerre's 1838 picture of the Boulevard du Temple in Paris were rendered invisible, with the exception of a man having his boots polished by a bootblack. Because both men remained stationary for the duration of the exposure, they are the only traces of any human presence in the otherwise desolate scene.

This initial shortcoming and the difficulty of the process, however, did not hinder the documentary potential of the daguerreotype. In the same year that the process was revealed to the public, Noël Marie Paymal Lerebours, an optician and publisher, solicited and commissioned over a thousand scenic daguerreotypes of important historical sites around the world. His *Excursions Daguerriennes*, published between 1840 and 1844, featured one hundred and fourteen copperplate engravings taken from daguerreotypes of locations ranging from Paris to Moscow and Algeria to Niagara Falls.

In detailing the range of potential uses for the daguerreotype, Arago also predicted that it would "procure for [the artist] an increase in work" conducted "less in the open air, and more in his studio" and would "provide physicists and astronomers with very valuable methods of investigation," thus benefiting art and science alike (qtd. in Gernsheim, 1968, 83). By mid-century, the accuracy and detail of the daguerreotype led to the word's broadened popular use as a metaphor for a precise and vivid description, whether of objects, people, or memories.

As knowledge and the practice of daguerreotypy spread throughout the world, an important potential rival to the process emerged in England. Upon hearing of Daguerre's research in early 1839, Talbot presented examples of his efforts to capture photographic images on paper to the Royal Society in London in an effort to protect the integrity of his own discoveries. Significantly, Talbot's initial "photogenic" process and its successor, the calotype, or talbotype, produced a negative image from which multiple positives could be printed—a distinct advantage over the necessarily singular daguerreotype, and a first glimpse of a photographic process that would come to dominate from the mid-nineteenth through the late-twentieth century. But because Talbot was printing on paper rather than on metal plates, his process yielded less precise images that did not differ as drastically as did Daguerre's from lithography and other manual forms of printing. As Sir John Herschel complained of Talbot's process to Arago, "compared to the masterful daguerreotype, Talbot produces nothing but mistiness" (qtd. in Newhall, 1964, 33). What is more, Talbot's efforts to enforce a patent on his process significantly restricted its initial use. For these reasons, the finely detailed surface of the daguerreotype and the publicly available details of its manufacture became more significant than its comparative limitations, leading to its wider adoption and dominance until the rise of the wet collodion process in the 1850s.

Innovations in the Daguerreotype Process

The desire to put the daguerreotype to use for making portraits led to international experiments with, and significant improvements in, Daguerre's original process and equipment. Cameras featuring double lenses with a larger aperture and a shorter focal length, designed by Josef Petzval and built by Peter Voightländer in Vienna, offered reduced exposure times better suited to portrait photography. In America, Alexander S. Wolcott and John Johnson introduced a camera in 1840 that used mirrors instead of lenses to focus light on a small daguerreian plate, also shortening exposure times, with the added benefit of avoiding the reversed image of early lens cameras. By the mid-1840s, various manufacturers in Europe and America were selling cameras that were more compact and more portable than Daguerre's original camera.

While daguerreotype plates initially were coated with silver and sized by individual daguerreotypists, newly formed supply companies in France and America began offering pre-prepared plates and other materials specific to the emerging trade. A full sheet, or a "whole plate"—the largest size that fit in a standardized daguerreotype camera—measures approximately six and a half by eight and a half inches. Whole plates were divided into smaller sizes and offered to customers at lower prices, resulting in the typical half-, quarter-, sixth-, ninth- and sixteenth-plate options. In the mid-1840s, American daguerreotypists began adding to the layer of silver on their purchased plates with electroplating, or "galvanizing,"

in which the daguerreotype plate and a block of silver were attached to two separate wires and suspended in a container of potassium cyanide. When the wires were then connected to a wet battery, molecules of silver were transferred to the plate through electrolysis. This procedure became known as the "American process" and was adopted by French plate manufacturers in the 1850s as the new standard for the preparation of daguerreotype plates.

Newly developed tools and methods for polishing the silver-coated plates were introduced into the revised process as well. Abrasive powders such as iron oxide and decomposed limestone, fine pumice stones, buckskin- and silk-covered buffing blocks and wheels, and jeweler's rouge were used to bring plates to a mirror-like shine. Careful polishing with such materials was essential to ensuring that the silver coating was entirely smooth and that the appearance of lines any other visible imperfections was minimized.

Further experiments with the chemical sensitization of the polished plate resulted in the introduction of additional steps into Daguerre's original process. In late 1839 in Philadelphia, Robert Cornelius, the son of a plated goods manufacturer, and Dr. Paul Beck Goddard, a chemist, first used bromine as an accelerator in the sensitization process. Other innovators, like John Frederick Goddard (an Englishman of no relation to the American Goddard) and Franz Kratochwila (a Polish civil servant), experimented with bromine as well. Antoine Claudet (a Frenchman working in London) developed a technique for using bromine and chlorine as accelerated sensitizing agents. This multi-phase sensitization of the daguerreotype plate, in combination with the larger aperture lenses used in cameras, reduced exposure times from minutes to as little as three seconds, depending on light conditions. These significantly reduced exposure times made daguerreotypy a practical medium for portraiture.

Word of these innovations spread quickly, and daguerreotypists began exposing their iodine-sensitized plates to bromine in the second of what was now three steps in the sensitization process. Suspended face-down in a box containing a mixture of bromine and quicklime, the iodine-treated, gold-colored surface of the plate turned a silvery blue. Subsequently, the plate was briefly re-exposed to iodine and its sensitization completed. During each step, the progress of the plate's sensitization could be examined by viewing its tones through glass windows in the different coating boxes.

Additional experiments in the chemistry of daguerreotypy also improved the durability of the image on the daguerreian plate's surface. In 1840, the French physicist Louis Armand Hippolyte Fizeau discovered that washing the fixed plate with a weak solution of gold chloride that had been heated and spread over the image would enhance its tones as well as stabilize and preserve it against further chemical reactions. Daguerreotypists employed this gilding technique from its introduction to the end of the daguerreian era.

Even when gilded, daguerreotypes remained fragile and needed to be enclosed in a protective case behind glass. Mass-produced cases made of leather and, later, of an early type of plastic made from gum shellac were sold to daguerreotypists. Brass mats of different shapes and case linings of silk or velvet were added to the case to enhance the appearance of the finished daguerreotype. Customers could choose among the options in each to embellish their portraits, while daguerreotypists used stamped cases and mats to advertise their work.

A general desire for images that were both realistic and aesthetically appealing drove much of the continuing experimentation with the daguerreian process. In 1851, a daguerreotypist named Levi L. Hill in upstate New York announced that he had discovered a process for capturing vivid reds, greens, blues, and browns on the silver daguerreian plate, resulting in images that appeared even more lifelike and beautiful than the daguerreotype. There was good deal of popular excitement about the advance, and Hill advertised manuals describing his process for three dollars. Yet when Hill delayed displaying examples of his achievement in an effort to perfect and patent his process, suspicions of a hoax were raised. Upon applying for a patent, Hill testified about his process and finally displayed examples of his "hillotypes," as he termed them, to a Senate committee that concluded that he could not patent a "strictly chemical" process (qtd. in Barger and White, 41). Late-twentieth century examinations of Hill's process, as he detailed it in his 1856 *Treatise on Heliochromy* and as it can be studied through sixty-two hillotypes held by the Museum of American History of the Smithsonian Institution, have concluded that it differs significantly enough from daguerreotypy, despite Hill's use of daguerreian plates, to be considered a separate photographic process.

The Popularity and Demise of the Daguerreotype

By the mid-1840s, daguerreotype studios had been established in most of the world's major cities. The profitability of making portraits for an eager public led many people from all walks of life to take up the practice of daguerreotypy. Itinerant daguerreotypists went so far as to improvise horse-drawn and shipboard studios and in doing so, extended the practice of daguerreotypy to the far reaches of the world. In 1840 in Rio de Janeiro, the fourteen- year-old Brazilian emperor Don Pedro II was so taken with a visiting priest's demonstration of the daguerreian process that he purchased a camera and became Brazil's first photographer. In Australia, the first

daguerreian studio was opened in late 1842 on the roof of the Royal Hotel in Sydney. The first professional daguerreotypists also arrived in Mexico in the early 1840s, capturing the likenesses of wealthy families in Mexico City, of landowners in the provinces, and of traders on the coasts, despite the limited availability of the necessary chemicals and the challenging climate. By 1845, Russian daguerreotypists had succeeded in adapting the process to capture images on brass and copper instead of more expensive silver. The Canadian daguerreotypists Eli J. Palmer and Thomas Coffin Doane submitted samples of their high-quality work to the Paris Exhibition of 1855, where they were awarded honorable mention against the tough competition of the best daguerreian artists working in France and the United States.

As the ranks of daguerreotypists throughout the world swelled, some sought a commercial advantage by outfitting their studios with luxurious interiors and flattering portraits of prominent clients. Although the daguerreotype initially had been promoted as an art form made without an artist's intervention, as competition among daguerreotypists increased and prices for a portrait dropped, those who charged more for their images increasingly separated themselves from less-skilled daguerreian "operators" by designating themselves as daguerreian "artists."

In America, the studios of such noted artists as Albert Sands Southworth and Josiah Johnson Hawes in Boston and Mathew B. Brady in New York and Washington, D.C., became destinations for the nation's most eminent citizens to be daguerreotyped. At the tonier studios, a full-plate portrait could cost more than five dollars and a "mammoth" plate, measuring as much as fifteen by seventeen inches, sold for the extravagant sum of fifty dollars; however, most daguerreotypists charged a dollar or less for a sixth-plate or smaller cased picture. By the 1850s, prices had dropped to as little as twelve-and-a-half cents for two portraits taken by an ordinary daguerreotypist. The largest American studios, capable of taking as many as a thousand pictures a day, typically divided the labor of the process among several people, including a plate preparer, a camera operator, and painter who could add color tinting to the image for an additional charge. By 1849, the daguerreotypist had become such a familiar figure in American society that an article in the popular magazine *Godey's Lady's Book* declared, "In our great cities, a daguerreotypist is to be found in almost every square; and there is scarcely a county in any state that has not one or more of these industrious individuals busy at work in catching 'the shadow' ere the 'substance fade'" (qtd. in Rudisill, 1971, 199).

Even as daguerreian portraiture became a commonplace of mid-nineteenth century life, first-time visitors to a daguerreotypist's studio often were disappointed with both the experience and the result of being photographed. Comical stories of the frustrating experience of seeing oneself in a daguerreotype abound in European and American periodicals from the 1840s and '50s. Discomfited by the use of restraining head braces, by the obligation of sitting still for the time of exposure, and by the limitations on colors and patterns that one could wear while being daguerreotyped, sitters frequently complained that they appeared uncomfortable and unnatural in their portraits. Others were displeased with the detail with which the less-flattering aspects of their appearance were too-faithfully imaged. To discuss strategies for dealing with unsatisfied customers, and to publicize the latest advances in daguerreian technology, trade journals such as *La Lumière*, *The Daguerreian Journal,* and *The Photographic Art Journal* were established. Articles recommending techniques for redirecting light and for posing sitters in positions that highlighted their best features, and diminished their worst, appeared regularly in such publications alongside discussions of new equipment and processing techniques.

In England, however, daguerreotypy was less widely practiced, due to Daguerre and Niépce having patented the process there. They also authorized their patent agent to sue anyone who made, displayed, or sold daguerreotypes without permission. In 1846, only four daguerreian studios were operating in all of London. Such restrictions, along with Talbot's continuing work on negative-to-positive photography, contributed to the English development of the wet collodion process. Once photographers learned this method of producing high-quality photographic images much more quickly, easily, cheaply than the most refined daguerreian process would permit, the daguerreotype effectively was outmoded. Although it continued to be practiced with some obstinacy in the United States into the 1860s, the rest of the world largely had abandoned the daguerreian process by the mid-1850s.

DAINTREE, RICHARD (1832–1878)

Englishman Richard Daintree was born in 1832 and came to Australia for health reasons and to prospect for gold. He joined the Geological Survey of Victoria as an assistant and undertook further training at the Royal School of Mines Laboratory in England in 1856 and around this time he took up photography. Back in Melbourne in 1857 however, Daintree set up as a photographer in partnership with the flamboyant French journalist Antoine Fauchery. The pair produced, in parts, one of the first albums in Australia showing views of Victoria including images of Aboriginal people in 1858. Employed by the Geological Survey Victoria from 1859–1864 Daintree used of photography in geological reporting also having them hand coloured for effect. From the start Daintree's use of a range of processes and strategies and his understanding of the promotional value of photography was inspired. He also supplied images for publication as stereographs and made transparencies.

In 1864, Daintree took up pastoral leases in North Queensland but was appointed northern Queensland Government Geologist in 1867. He was commissioned to prepare photographs and mineral samples for the London International Exhibition of 1870. and he had his photographs enlarged and coloured as more effective displays. He produced a Queensland album in autotype in 1872 as well as folios of views of bush life. In 1872, Daintree became the Queensland Government Agent-General in London where he promoted immigration using his Australian photographs.

Daintree exhibited at the Imperial Exhibition (1872), the Vienna Exhibition (1873), and the Philadelphia Centennial Exhibition (1876). Ill health forced his resignation in 1876 and he died in England in 1878.

GAEL NEWTON

D'ALESSANDRI, FRATELLI (1818–1893)

Studio, Italy

Consisting of Antonio D'Alessandri & Paolo Francesco D'Alessandri (1827–1889) Fratelli D'Alessandri became one of the foremost studios in Europe, known for their elegant approach to portraiture. Father Antonio Alessandri was granted financial and social success overnight when he became the first official photographer, *fotografico pontifico*, to the Pope and the Vatican court with world-wide distribution of Papal imagery. In 1858 he was awarded a 'grand medal of gold of His Holiness Pius IX.' These were troubled times, not least that Rome, led by the Pope, was to continue its decline as the cultural capital of Europe, to be eclipsed by Paris. Pope Pius IX (1792–1878) became pope in 1846 but if he did appear to have liberal leanings, these were all destroyed in the short lived revolution of 1848 when he fled Rome and sought the help of French troops. By July 1849 the rebellion was over. While the rest of the Kingdoms of Italy joined in the idea of the Unification, but not without difficulty, Pius resolutely refused to acknowledge the possibility. Thus Rome filled up with the French, along with many destitute priests who had fled from the other provinces as they were no longer required to be the civil service. It is strange for us today to conceive of a Pope running a country, complete with an army, (largely made up of Catholics from outside Italy together with a foreign army), and a Pontifical

D'Alessandri, Paolo Francesco. Inner view of an Intalian Renaissance Palace.

state police. In effect it was a priest state, (priests were the only industry) with many public executions by guillotine. D'Alessandri was used therefore to project the image of a *different* society, one of affluence, stability: propagating the establishment's culture, by demonstrating through photography these perceived virtues. When the Bourbons fled from Naples in 1862 their court added itself to Rome's glamorous society, along with Roman aristocracy and the rich and famous who were still on the Grand Tour, *all* became the clients of the photographer-priest, such as: 'Alessandro Torlonia and his daughter,' 1872, (Torlonia was the richest man in Rome in the 19th Century) or that of 'HRH Prince of Wales. the future King of England,' 1859. The Pope continued to demonstrate his control by public displays using his photographer: 'Pope Pius IX blessing the Column of the Immaculate Conception,' 1857, which commemorated his 1854 dogma. In 1864, he set his face against science with his 'Syllabus of Errors' that ruled that scientific theory must always be subservient to church teaching. Just as the photographic topographers, for technical reasons, displayed the cityscape as an empty, barely populated, peaceful sanctuary of aesthetic splendour, of ruin and palace, these organised political photographs, along with the portraiture of Rome's 'nobility,' hid the real world that was taking place in the street. D'Alessandri does not portray the field labourers who lived out their lives, just beyond the boundary of Rome, in grass huts, or demonstrate a Rome of street beggars, rampant malaria, unsanitary conditions, poverty, where the education system, also ran by the church, produced a country with 78% illiteracy. The mask slips, albeit unintentionally, only a few times: D'Alessandri took perhaps the first examples of Italian photojournalism: the Papal troops at Anzio, 1862, and the battlefields of Mentana and Monterotondo in 1867 which were reproduced in the *L'Illustration, Journal Universal* (Paris), no doubt to much French enthusiasm. At Mentana, north east of Rome, Garibaldi's ragged 4,700 red shirts' march on Rome were wiped out by 12,000 French and Papal troops. D'Allesandri depicts the empty battlefield littered with corpses, not with intended sadness but presumably as a warning to the citizens. Just as the photograph of 'Pius IX blessing the troops at *Campi di Annibale*,' 1868, is meant to signify virtue. But in 1870, with the French once more changing sides, the breach in the city walls of the 20th September, marked the end of the Pope's temporal power after 14 centuries of rule. His introduction of the 'Dogma of Infallibility' in the same year, and his declaration that he was now a prisoner in the Vatican, did nothing to stop the Unification. It also marked the end of D'Alessandri's Pontifical contract: '*Padri del Concilio Ecumenico,*' 1870, being one of the last of such photography commissions. But the great and the good continued to be his clients and, presumably in defiance of the Pope, D'Alessandri went on to photograph the new rulers.

It is most unusual for a priest to become interested in photography and very rare, if not unique, for one to run a successful business, even in the Papal States where all businesses had to obtain a Vatican licence. To date, there is no understanding of how his interest came about. As he had no artistic training, this might explain his gravitation to portraiture, as distinct from landscape and architecture, but it does not explain his concentration on producing expensive photographs

for a rich clientele. In that he obtained the *fotografico pontifico* then he would have had full approval for *all* his endeavours by the Vatican who no doubt could see the importance of photography, not least as a means of communicating propaganda to its citizens: what better than to have a trained priest to run it? Since he remained unmarried, one could assume he did not forgo his calling. It is the much more likely therefore that the politics of the Vatican had a role to play in D'Allesandri's business from the very beginning and much control throughout, for it was always strong on censorship of all the arts, including what its citizens were reading and viewing. One incident brought his name momentarily into scandal when a fake (montage) nude photograph of Mario Sofia, the former Queen of Naples, who fled to Rome in 1862, was circulated and 'a priest' was accused. During the investigation, another priest, Filippo Bottoni, was sent to jail when he was found to have a hoard of pornographic photographs which he had been supplying for sale.

Father Antonio D'Alessandri, born L'Aquila, took up an interest in photography while at l'Università Romana in 1852 when he also appears to have made frequent visits to the nearby photographic studio of the Luswergh family (Angelo 1793–1858, father and sons Giacomo 1819–1891 and Thommaso 1823–1907), the first Italian studio to produce a catalogue in 1855 (of 131 entries of views and portraits). With the coming of the prospects of much money to be made on the arrival of the albumen and glass plate negative, post 1851, D'Alessandri joined the many and opened a studio in Rome in 1856 in Via del Babuino 65 (until 1865), then at Via del Corso 10–12, and, after his death, the family business moved to 61–63, with his nephew Tito in charge and where they could boast a terrace where group portraits of up to 200 people could be taken. Antonio worked with his brother, Paolo Francesco, who was an excellent photographer in his own right (and is often overlooked). Eventually Paolo's children, Alessandro (1862–1941), Tito (1864–1942), Cesere (1871–1933), and Mario (1874–1943) also worked in the company with Tito becoming an especially able photographer and main director. Such was the success of the enterprise that Fratelli D'Alessandri, in collaboration with Giacomo Arena, opened in Naples at Via della Pace 7, and had distribution facilities in Paris and Vienna. Antonio became an honoured member of the *Société Française de Photographie* in 1859 and a friend of Nadar. Between 1860–1880, when they were at their most successful, the company employed over 20, including all family members, male and female. Fratelli D'Alessandri exhibited in the major international exhibitions of industry and photography mostly portraits of the great and the good but also with some *Vedute di Roma*: Florence 1861, Rome 1870 (gold medal) with 40 photographs depicting living bishops along with a portrait of the Pope, Paris 1878 (gold medal) with views of Rome, Milan 1881 (bronze medal) with a series of hand coloured portraits for which they had become well known, Turin 1884 exhibited interior shots of the Palazzo del Quirinale, and Rome 1890 (gold medal). Paolo's children all died in 1942/1943 but the firm managed to last until 1950.

DALLEMAGNE, ADOLPHE JEAN FRANÇOIS MARIN (B. 1811)

Adolphe Jean François Marin Dallemagne was first a painter and then a photographer. Born in 1811, near Paris, he learned how to paint from Ingres (1780–1867), Léon Cogniet (1794–1880) and Raimond Quinsac Monvoisin (1794–1870), all in the neoclassical style. According to Nadar, in his autobiography, "Quand j'étais photographe," he began his practice under the influence of his friend, another painter, Hippolyte Lazerges (1817–1887). Dallemagne's studio was located at 9 avenue de Ségur and in this studio, Dallemagne created his main piece which was the Galerie des artistes contemporains. This consisted of photographs of better known artists of the day like the writer Henri Monnier, the painter Frédéric O'Connel, and of Edouard Manet too.

Dallemagne worked with models as well which were photographed with items making obvious Dallemagne's allusions to certain occupations. These images appeared in different painting frames from the time periods and styles of Louis XIV, Louis XV or Louis XVI's, complete with a theatrical velvet curtain.

During this time, photography copied paintings and often looked for acknowledgment in it. Dallemagne also displayed his photographs during several exhibitions of the Société française de Photographie in the years 1863, 1864, 1865, and 1870. Later, the images appearing in these shows were distributed by Nadar's studio.

The painter kept his photographic studio until 1872, after which little is known including the year in which he passed.

MARION PERCEVAL

DALLMEYER, JOHN HENRY (1830–1883) & THOMAS ROSS (1859–1906)

J. H. Dallmeyer Limited was founded in 1859 at 19 Bloomsbury Street, London.

About 1888 the company moved to 25 Newman Street, London, and from about 1907 kept a sales office at 31 Mortimer Street, London, and a works in Willesden, in north west London.

A naturalised British subject, John Henry Dallmeyer (1830–1883) was born in Loxten, in Westphalia and, having shown a talent for science and mathematics, was apprenticed to an optician. He came to England in 1851 and joined the optical firm of Andrew Ross, subsequently marrying a daughter of his employer. Ross, on his death in 1859, left Dallmeyer a third of his private fortune and a substantial part of the company's machinery and equipment, thus allowing Dallmeyer to set up his own company, supplying initially the astronomical telescopes for which Ross had gained a high reputation and which had been made by Dallmeyer during the six years prior to Ross's death.

As a company, J. H. Dallmeyer produced lenses and other optical and photographic equipment, including lenses for microscopes. Dallmeyer was a skilled and inventive lens designer, fully aware of the latest scientific developments and maintaining close contact with prominent scientists of the day, notably Sir John Herschel. In 1861 he was elected a fellow of the Royal Astronomical Society. From the early 1860s he began to design and manufacture camera lenses, to the same high quality as his telescopes. He gradually relinquished to his employees, whom he had trained, the manufacture of many of the company's products, and devoted his time to improvements in photographic optics and associated equipment. Notable early designs included the Triple Achromatic lens and the Patent Portrait, the latter being a modification of the well-known Petzval formula, and with a further modification that allowed a variable diffusion of focus. This lens was extensively used by portrait photographers during the second half of the nineteenth century.

Dallmeyer also designed lenses at this time that worked at very large relative apertures, including a portrait lens of the Petzval type with a maximum aperture of f/2.2—much used for photographing children, due to the shorter exposures that it allowed—and, for a small camera called the Pistolgraph, a Petzval-type lens of approximately f/1. During the 1860s he also produced lenses designed for astronomical photography. In 1866 the Wide Angle Rectilinear and Rapid Rectilinear were produced. The latter, for which Dallmeyer made use of a special type of glass made by Chance Brothers of Birmingham, was a long-lived design that lasted well into the following century.

A high profile was maintained by advertising and also by exhibiting the company's products. Dallmeyer lenses gained the highest awards in London in 1862, Dublin & Berlin in 1865, Paris in 1867 and 1878, and Philadelphia in 1876. J.H. Dallmeyer also wrote an informative pamphlet 'Photographic Lenses: On Their Choice and Use,' that ran to six editions and was a valuable addition to the company's advertising. It was re-issued in 1892, with much additional material, by T.R. Dallmeyer. The company had a substantial export trade, supported by a reputation for high quality and consistency. Exports to the USA were especially important, the New York company E.& H.T. Anthony acting as Dallmeyer's sole agents. Dallmeyer lenses also found their way to most parts of the British Empire, not least as part of that process of documentation of the empire undertaken by British photographers. In 1878 John Henry Dallmeyer was awarded the Legion of Honour by the French Government. He also received the Russian Order of St. Stanislaus.

From about 1880, as J.H. Dallmeyer's health deteriorated, his son Thomas Ross Dallmeyer (1859–1906) progressively took over management of the business, which he retained until 1892 when the firm became a limited company. T.R. Dallmeyer was, like his father, a prolific and talented lens designer, gaining his B.Sc. at King's College, London. In the 1880s, at a time when other makers were attempting to take advantage of the company's reputation by producing copies of Dallmeyer lenses, he maintained the commercial advantage by continuing to produce new lenses, notably the Rapid Long Focus Landscape Lens in 1884, and the Rectilinear Landscape Lens in 1888.

With the arrival of the new anastigmat lenses from Zeiss of Germany, using the latest types of glass developed at Jena, and with a performance superior to the Rapid Rectilinears, it was imperative that Dallmeyer should produce a comparable lens. The new design was called the Stigmatic, designed by H.L. Aldis and announced by Dallmeyer in 1896. These lenses, with periodic modifications, continued in production into the 1920s.

Dallmeyer was also prominent in the development of the telephoto lens, being, in 1891, the first company to produce a practical lens of this type. T.R.Dallmeyer remained an active lens designer despite delegating much of the work to others. In 1890, at the request of his friend the photographer P.H. Emerson, he designed a lens that was intended to replicate the characteristics of the eye. In 1893 he designed, at the request of J.H. Bergheim, a soft-focus portrait lens, the Dallmeyer-Bergheim, that went into production in 1896.

The company's Lens Books show that Dallmeyer lenses were purchased by many of the most prominent photographers of the mid- and late nineteenth century.

Their publicity also claims Julia Margaret Cameron as among the users of their lenses.

Under J.H. Dallmeyer, the company also began to supply cameras, concerned that their lenses should be fitted to well-made and accurately-registered instruments. A range of studio and field cameras was made available, mainly manufactured by George Hare. Subsequently, folding hand cameras were also supplied.

After 1900 the company continued to design and produce lenses for still and cine use, including projection and enlarging lenses. During both World Wars production was given over to gun-sights and other military equipment. The company was formally dissolved in 1993.

DALLY, FREDERICK (1838–1914)
English architectural photographer

Frederick Dally professional portrait and landscape photographer (born Southwark, England 29 July 1838; died Wolverhampton, England 28 July 1914). Educated at Christ's Hospital, London, Dally arrived in Victoria, Vancouver Island, in 1862 at the height of the Cariboo gold rush and began business as a general merchant. In June of 1866, he opened a photography gallery on Fort Street, where he produced carte-de-visites of prominent citizens, and sold albums and views of public buildings, local scenes, and special events. He documented the buildings of the colonial government in Victoria and New Westminster and of the Royal Navy at Esquimalt. As a keen observer and amateur anthropologist, he produced an extensive record of the native peoples of British Columbia and also collected native artifacts.

Best known are his 1867–68 photographs of the Cariboo Wagon Road and the goldfields. Many of these views were later used to produce engravings for publication.

In response to 1869 circulars Dally supplied photographs of prominent buildings and scenery and of native peoples to the Colonial Office. In September 1870, he sold up and left Victoria to study at the Philadelphia Dental College, returning to England in 1872 where he set up practice as a dental surgeon, briefly in London and subsequently in Wolverhampton. He maintained an interest in British Columbia, and eventually sent his photographs and papers to the Provincial Archives in Victoria just before his death.

DAMMANN, CARL VICTOR (1819–1874) AND FRIEDRICH WILHELM (1834–1894)

Carl Victor Dammann was born at Muess, Schwerin, northern Germany; Friedrich Wilhelm Dammann, born at Ludwigslust, is described as his brother although they were half-brothers or possibly cousins. Carl trained initially as an architect. It is not known when he took up photography or who taught him. However by January 1869 he is listed as having a photographic business at Grosse Johannisstrasse 4, Hamburg. He is remembered solely for one work, *Anthropologisch-Ethnologiches Album in Photographien*, a massive project undertaken in the 1870s with the Berliner Gesellschaft für Anthropologie, Ethnologie und Urgeschichte (BGAEU), and with which Friedrich also became involved.

How Dammann came to work in ethnological photography is not known. He appears to have been a portrait photographer, so the production of ethnological 'types' might be seen as a broadly related practice and aesthetic. As a major port, Hamburg offered ample opportunities. In 1870–1 Dammann made a series of photographs of African and Arab seamen from Zanzibar. Taken against a plain background, in full face and profile aspects, they were in the accepted scientific aesthetic. These photographs were followed by a similar series of a group of Japanese acrobats. They received unanimous approval from members of the German anthropological establishment, the BGAEU—Adolf Bastian, Robert Hartmann and Rudolph Virchow. Recommended in *Zeitschrift für Ethnologie,* they formed the basis of the collaboration between Dammann and the BGAEU from which the *Album* emerged.

Anthropologisch-Ethnologiches Album in Photographien was published through 1873 and 1874 in ten sections of five folios each, containing 642 photographs in all. Edited by Dammann and published by Wiegandt, Hemel und Parey (Berlin), conceptually it is not dissimilar from Etienne Serres' call in 1845 for a photographic 'museum' of the races of mankind for scientific purposes. Between 6 and 18 tipped-in albumen prints are grouped geographically and culturally, and arranged in a grid within a printed boarder on the folios measuring 48 x 64 cm. Ethnic group is given in a letterpress caption beneath each photograph and each folio carries a short ethnological caption and, in most cases, an acknowledgement of the donor of Berlin's photographs. It was an expensive production, aimed at learned and scientific societies and

universities. The first folios were awarded a silver medal at the 1873 Vienna World Exhibition.

The project gathered photographs from all over the world. The BGAEU appealed to the German expatriate community with anthropological interests to collect and submit photographs. These were sent to Berlin, and forwarded to Dammann by the BGAEU. Sources varied widely. Some donors were scientists, such as Gustav Fritsch whose photographs of south African groups comprise some nine folios of the *Album.* Some appear to have been submitted by the photographers themselves. Others were from the existing collections in Berlin or from the Museum Godeffroy in Hamburg. The majority were sent in by German traders and colonial officers, including many images from commercial photographers, the stock-in-trade of the 'ethnic' carte de visite market available locally. This resulted in a wide range of photographic styles, from the anthropometric to the naturalistic and 'domestic,' being absorbed into precisely scientific meanings. While the *Album* presents a racial classification and reflects German anthropological thinking of the period, it lacks taxonomic precision —a serendipitous element being determined by its simultaneous collection and publication.

Although some of the photographs were made from original negatives, many were from copy negatives made of prints submitted for the project. There is a clear qualitative difference. The method can be seen in surviving whole plate negatives made by Friedrich in 1874–6. Prints were laid out on newspaper and copy negatives made. These were printed and then trimmed, mostly to standard carte de visite or cabinet sizes. While donor- photographers or scientists presumably gave their permission, overall the *Album* demonstrated the level of unauthorised copying and lack of global copyright protection for photographers at this period, which, in part, made it possible. Some copy prints survive on Dammann's studio card; printed, in red, in typical style of the period.

Friedrich Dammann, who lived in England, only appears to have got involved with the project after the death of Carl in April 1874 He liaised with the BGAEU and undertook some of the production. However as the last folios appeared by September 1874, it is not clear how much input he had to the *Alum* itself. Like Carl, it is not known how and where he learned photography but he appears to have been a competent operator.

While the heart of the project were the great German folios, there were other very different editions. An English popular edition, *The Races of Man: Ethnological Photographic Gallery of the Various Races,* was published in London 1875 by Trübner. It comprised 24 plates, measuring 24 × 32 cm, and contained 167 photographs. There is a clearer evolutionary narrative starting with 'Civilised' Europeans and ending with Australians, Melanesians and Micronesians. Although Carl's name appears on the title page, it was produced by Friedrich and includes material not in the *Album,* added to the project after 1874. Friedrich was also responsible for a 'schools' edition' *Anthropologisches Schul-Album in Photographien* (n.d. 1875/6?). Although the same format as *The Races of Man*, the 179 photographs used and its intellectual shape had more in common with the *Album*. It also includes material not published in the *Album*. Friedrich must also have been responsible for the realization of the 1876 *Ethnologischer Atlas sämmtlicher Menschen-Racen in photographien* although it was published under Carl's name by Meissner of Hamburg.

Overall the dissemination outside Germany was not extensive. Several copies of the *Album* and the other editions survive. While some of the material was returned to Berlin in the 1880s, and is in the collections of the BGAEU and the Museum für Völkerkunde, the residue of carte de visite prints and copy negatives made in the latter stages of the project by Friedrich, were bought from his executors in 1901 by Pitt Rivers Museum, University of Oxford. The project remains the most remarkable collaborative anthropological and photographic endeavour of the nineteenth century.

DANCER, JOHN BENJAMIN (1812–1887)

English innovator and inventor of microphotography

Like many of his contemporaries in the early Victorian period John Benjamin Dancer used his enquiring mind over a broad spectrum of scientific endeavours to make inventions and develop innovations that have since become fundamental to our lives. While the invention of photography was clearly the province of Nicephore Niepce, Louis Jacques Mande Daguerre and William Henry Fox Talbot, Dancer falls into the second wave of innovators who developed the process on further, frequently with the minimum of information.

Dancer made known the results of his work through papers to the Manchester Literary and Philosophical Society and the various Manchester and Liverpool photographic societies. The professional and personal relationships he subsequently expanded on provides the key to the rapid development and understanding of the photographic processes in the Manchester area. Dancer's observations were regularly recorded in both the *Memoirs and Proceedings of the Manchester Literary and Philosophical Society* and in the *Liverpool and Manchester Photographic Journal* (later to become the *British Journal of Photography*). There is also a direct connection with the Edinburgh circle through constant correspondence and argument between Dancer and Sir David Brewster on the subject of stereoscopy. Similarly, Dancer was in correspondence with Frederick Scott Archer, who had himself spent his early life in Manchester.

In the year prior to his death he attempted to define his contribution to photography in a letter under the title "Early Photography in Liverpool and Manchester" published in the *British Journal of Photography* on 11 June 1886.

> "Having many reasons for believing that I was one of the first to practice the Daguerreotype process in this country, and also to introduce camera photography into Liverpool and Manchester.... Unfortunately for my purpose, the early descriptions of Daguerre's method of proceeding were crude and obscure. In consequence of this I had six weeks of hard work, numerous failures, and accidentally was nearly suffocated by the vapour of iodine, before I obtained satisfactory results. Being a practical optician, the camera used was one of my own construction, such as I had frequently supplied to artists for tracing the outline of views in the camera. An achromatic object-glass from a telescope gave fair definition. My photographs were objects of great curiosity to scientific friends and acquaintances.... At the request of friends I publicly exhibited the Daguerreotype process to an audience of 1500 people. The object then photographed was a flea, magnified as large as a 7 x 5 (inch) silvered plate would permit, the instrument being a gas microscope of my own construction. Many other microscope objects were enlarged, and some were reduced. One, a printed placard, was reduced to an eighth of an inch square, being perfectly legible under the microscope."

The daguerreotype was not Dancer's first excursion in photography. He observed that the "accounts given of the beautiful pictures (daguerreotypes).... induced me to abandon the photographic paper process." We can assume from this that from 1839, or even earlier, Dancer had experimented with Talbot's process. As with other individuals of this period Dancer would have been more impressed by the definition of the daguerreotype rather than the opportunity to make multiple prints offered by Talbot's photogenic drawings. The links between Talbot and Dancer's father are strong, with their mutual interest in Arabic, Hebrew and cuneiform scripts. At the time of Dancer's father's death in 1835, a connection between Talbot and Dancer would have been established.

When in 1841 Dancer came to live in Manchester he realised that the daguerreotype process had not been practised in the city. He then sold daguerreotype apparatus and taught the process to John Dale, a chemist, and Joseph Sidebotham, a calico printer and dyer. From that time many Mancunians became amateur photographers and "it soon became a popular amusement." In November the same year, Richard Beard opened a Daguerreotype Portrait Gallery in rooms over the Manchester Exchange.

Dancer's greatest claim to fame is his invention of microphotography. Dancer referred to his productions as microscopic photographs; the term microphotography was introduced following a public disagreement in the pages of the *Liverpool and Manchester Photographic Journal* over Dancer's priority of the microphotograph between Joseph Sidebotham supporting Dancer and the Editor of the *Journal*, George Shadbolt. In 1839, only a few months after the introduction of the process, Dancer produced greatly reduced images on a Daguerreotype plate but these could only be usefully viewed at 20 diameters magnification. The image structure was too coarse and the reflectivity of the image may also have been too low for convenient examination at higher magnifications. Dancer's earliest successful results date from February 1852, although there may be an argument for an earlier date, and were based on Scott Archer's wet collodion process. This adequately fulfilled Dancer's requirements and he soon produced minute images containing groups of portraits in a circle of 1/16 inch diameter. Dancer produced microphotographs commercially and sold the images mounted on a 3 inch × 1 inch microscope slide. Sir David Brewster exhibited Dancer's microphotographs to the Academie des Sciences, Paris in 1857 and later in Paris and Rome. In Rome, Dancer's microphotographs were shown to the Pope. Dancer also succeeded in producing graticule images by photographic means.

In 1852 Dancer invented a binocular stereoscopic camera. The idea had also been brought forward by Brewster in 1847. An instrument was actually made in 1849, the only known model of Dancer's camera, but was destroyed in 1940. An improved version, an instantaneous camera patented on 5 September 1856 (Patent No 2064), is better known. Its features included magazine loading, a spirit level and a double rotating shutter.

Dancer's inventions and innovations were not limited to photography. He was a passionate and talented inventor in many fields. He discovered the basis of electrotyping by depositing copper electrolytically on an engraved copper plate. In 1838 he introduced the porous pot for the Daniel cell, and these pots were later used

in Leclanche cells. He crimped the plate of the Daniel cell to double its own area, and he produced ozone in 1838 but failed to recognise its significance. Also that year he invented the subdivision of secondary windings of an induction coil to produce choice output voltages, and he devised the magnetic circuit breaker. Among his other inventions is a shellac-coated card that could be used in place of glass in electrophorous and leyden jars. He invented a six-way tap to control the supply of gasses to dissolving lanterns, and introduced achromatic projection lenses to magic lanterns. He supplied James Robertson with lanterns and gas equipment, and the Manchester Mechanics Institute with a dissolving limelight lantern.

He was the first person to supply achromatic microscopes for Boston, Optician of Liverpool, and he also made one for John Dalton. He introduced the Davies Shutter and constructed a binocular microscope for the Field Naturalist Society. Dancer is also known to have designed special lenses for his microscopes, and may have done so for camera lenses as well. He made improvements to telescope mountings, rain gauges, speed indicators, surveyor's levels and air pumps. He invented an apparatus for Sir Joseph Whitworth for checking the accuracy of rifle barrels. He developed an accurate thermometer for James Joule in 1843, and made apparatus for Joule's determination of the mechanical equivalent by heat. He invented a fairy fountain; a multi-jet fountain illuminated from below with coloured lights and controlled by an electric keyboard.

Dancer's most active years in terms of invention and innovation appear in the twenty years from 1837 to 1857. After this period his activities were devoted mostly to manufacture and refinement of earlier work. While he was well known and respected by his peers it is since his death in 1887 that he has disappeared into relative obscurity. In 1960 his great granddaughter received from the National Microfilm Association of America a posthumous Medal of Meritorious Service to the microfilm industry. Not only was John Benjamin Dancer the inventor of microphotography, in a very real sense he was the father of photography in the Greater Manchester area.

MICHAEL HALLETT

Biography

John Benjamin Dancer was born on 8 October 1812 in London, and died on 24 November 1887 in Manchester. He is buried in Brooklands Cemetery, Sale. His father Josiah Dancer was born in 1779, and had in turn worked under his father, Michael, who was a joiner. Josiah Dancer became an optician from 1817 and then moved to Liverpool where he died in 1835. Dancer joined the Manchester Literary and Philosophical Society in 1842, being sponsored by John Dalton and was made an Honorary Member in 1884. He was elected a Fellow of the Royal Astronomical Society in 1855 and appointed optician in Manchester to HRH the Prince of Wales in 1869. While, on occasions, he took photographs, Dancer never operated as a professional photographer. By trade he was a scientific and optical instrument maker taking over his father's business in Liverpool in 1835 and moving to Manchester in 1841 to set up a similar business under the name of Abraham and Dancer. For the majority of his life in Manchester Dancer was in business on his own account at 43 Cross Street. In 1870 John Benjamin Dancer contracted diabetes, and his sight began to fail. After three operations for glaucoma, he gave up his business in 1878. The business transferred from Cross Street to Ardwick under his daughters, Eleanor Elizabeth and Catherine, and became E.E. Dancer & Company. On the 11th August 1896 it was sold to Richard Suter for £50.

DANDOY, ARMAND (1834–1898)
Belgian photographer and painter

Armand Dandoy, christened Ernest, was born in the small town of Gougnies, in Hainaut province, Belgium, on 11 November 1834, second son of Joseph Dandoy (1801–1850), manager of a smelting plant, and his wife Jeanne née Janne (1801–1871). In 1838, the Dandoy family moved back to their native town of Namur, where

Joseph became director of the municipal gasworks. Presumably educated locally at Jesuit college, Armand Dandoy showed early artistic inclinations, and he attended the *Atelier Saint-Luc*, an academy which spearheaded the Realist movement in Brussels. Here he joined his childhood friend, Félicien Rops (1833–1898), whose precocious talents were already marking him out as a artist and engraver of promise. Their friendship would be lifelong, attested by an extensive correspondence and underpinned by a shared passion for rowing, especially on the river Meuse which flows through Namur province.

Armand Dandoy opened his first photography studio in partnership with his elder brother Héliodore (1831–1909) at Rue de Gravière 14, Namur, on 1 July 1856 under the denomination *Dandoy frères* [Dandoy brothers]. Armand alone exhibited portraiture and "instantaneous" studies of horses at the Brussels photography exhibition of 1856, and again at the Société française de Photographie in 1857. The studio transferred to Rue de Fer 82 in about 1858, from which address the Dandoy brothers issued a set of stereo views *Bords de la Meuse* [Banks of the Meuse]. Héliodore opened a branch studio in Spa, Place Royale 454, in May 1861, which traded as *Dandoy frères* until its closure in April 1866, and for which Rops produced an advertising poster in lithography. From 1862, Armand continued running the Namur studio under his own name.

Jeanne Dandoy acquired a plot of land in 1865 on the site of recently dismantled fortifications, on which she had a customised portrait studio constructed. Title of the premises at Rue de la Station 6, renamed Rue Mathieu, was transferred to her son Armand, who opened the studio on 10 September 1866. He operated it continuously until his death thirty-two years later, secure in his reputation as portrait photographer of choice to the regional bourgeoisie.

Armand Dandoy married Charlotte De Coster (1831–1912), known as Caroline, on 24 October 1867. She was the sister of Charles De Coster (1827–1879), prominent man of letters and member of the same loose-knit group of Namur artists as Dandoy and Rops. Dandoy immortalised the "colony" in a group portrait, taken on a river excursion at Anseremme, in the Meuse valley, in 1875, in one variant of which the photographer himself appears to one side.

Affable and clubbable, Armand Dandoy served on the municipal fine-arts committee and the *commission des fêtes* [festival committee]. A long-standing member of the *Cercle artistique et littéraire*, he exhibited landscapes at the club's triennial salons from 1868 to the year of his death. A painting companion of Rops,' Dandoy's artistic reputation was high enough for him to be a serious though ultimately unsuccessful candidate for the post of professor of painting at the local Academy on two occasions in the 1880s.

What raises Armand Dandoy above all this provincial worthiness and places him in the forefront of early Belgian photographers is the inventory of the historic landscapes, monuments and cultural artefacts in the Namur province which he realised over a ten year period. In the tradition of the "missions" undertaken by Guillaume Claine and Edmond Fierlants in previous decades to record Belgium's architectural and artistic heritage, the idea ironically was the brain-child of another prominent photographer. Joseph Maes addressed a letter to the governor of Namur province on 1 May 1868, setting out his proposal for such a photographic campaign, citing the advantages for promoting tourism in the region and underlining the need for a visual inventory of monuments, many of which were under threat from redevelopment or the ravages of time. Dandoy made a counter-offer in a letter transmitted and overtly supported by the interior minister. After much debate by the provincial council, and sustained lobbying by Dandoy, which included undercutting Maes' estimate by a half, the authorities decided in Dandoy's favour. The *Comité provincial des Monuments* drew up an initial list of seventy-one views in October 1868, and the following July Dandoy agreed to take 100 full-plate negatives and deliver three prints of each, in fascicles of ten prints, at a price of 200 francs per fascicle.

The first part of *La Province de Namur Monumentale & Pittoresque* [The Province of Namur Monumental and Picturesque] was completed in October 1869 but the project would extend through the next decade, due as much to the photographer's lackadaisical character, as to his perfectionist approach in matters of view-taking and print-making. View-taking required many field campaigns with a photographic wagon (visible in some of the images) into idyllic but inaccessible countryside, while the resulting richly toned albumen prints were mounted on heavy litho-tinted bristol board, individually captioned and carrying the statement "Publié par l'Auteur sous le Patronage de la Province et de l'Etat" [Published by the Author with the Patronage of the Province and the State]. Dandoy did not adhere strictly to the list of monuments which the provincial committee had proposed, but in the end produced 140 plates. Of these 110 are recorded as having been issued, in eleven fascicles of ten plates, supplied to the authorities and commercialised in parallel by the photographer in partnership with the Brussels lithographers Simonau and Toovey. The first ten were issued between 1872 and 1875, and a final part appeared in 1879. Selections were exhibited widely and to critical acclaim in Belgium and internationally, firstly at the international exhibition in London in 1871 and most notably at the universal exhibition in Paris in 1878, where Dandoy was awarded a bronze medal.

Dandoy's most accomplished achievement technically

was his documentation of the subterranean caverns at Han-sur-Lesse, a two week campaign in November 1876, resulting in thirty views obtained with a system of twenty-two portable magnesium lamps. His final innovation was the publication of postcards in collotype in 1895 for *Namur-Attractions*, a tourist promotion agency.

Armand Dandoy died on 14 July 1898. The portrait studio continued operating under his widow's name until 1902, thereafter under the authority of Edmond Rosbach (born 18 April 1865), Dandoy's operator since about 1892. Dandoy's widow bequeathed him the contents of the studio, with the exception of negatives from the series *La Province de Namur Monumentale & Pittoresque*, which she left to the *Société archéologique de Namur*.

There are substantial holdings of Dandoy's work at the Archives du Palais du Roi, Brussels, Bibliothèque royale Albert Ier—Cabinet des estampes, the Bibliothèque universitaire Moretus Plantin, Namur and the Société archéologique, Namur. The glass plate negatives in the latter institution were copy printed in 1995, and transferred to disquettes accessible to the public at the Division du Patrimoine, Ministère de la Région wallonne, Namur.

STEVEN F. JOSEPH

Biography

Armand Dandoy, christened Ernest, was born in Gougnies, Hainaut province, Belgium, on 11 November 1834, second son of Joseph Dandoy (1801–1850), manager of a smelting plant, and his wife Jeanne née Janne (1801–1871). He opened his first photography studio in partnership with his elder brother Héliodore (1831–1909) at Rue de Gravière 14, Namur, on 1 July 1856. A customised portrait studio was constructed at Rue de la Station 6, renamed Rue Mathieu, and opened on 10 September 1866. Dandoy operated it continuously until his death. He married Charlotte De Coster (1831–1912), known as Caroline, on 24 October 1867. He was secure in his reputation as portrait photographer of choice to the regional bourgeoisie,

Armand Dandoy's major achievement is the landscape series *La Province de Namur Monumentale & Pittoresque*, comprising 110 prints issued between 1869 and 1879. Armand Dandoy died on 14 July 1898.

DARKROOM AND DEVELOPING CHAMBER

In the course of the second half of the nineteenth century, the darkroom evolved from being a simple 'darkened room' for the preparation and development of photographic materials, to become the photographic developing and printing room with which analogue photographers today would be familiar.

In the 1840s, the period in which the daguerreotype and calotype were in ascendancy, their low sensitivity to light permitted much of the preparation work to be carried out in candlelight. By the end of the century, conditions required for the processing of the high speed panchromatic materials of the day required the exclusion of all light.

At the height of the daguerreian era, Henry Morley, Editor of Charles Dickens' popular periodical *Household Words* painted an eloquent picture of the work rooms behind John Jabez Edwin Mayall's London studio in an essay for the magazine in March 1853:

> The den of the photographer, in which he goes through those mysterious operations which are not submitted to the observation of the sitter, is a small room lighted by a window, and communicating into a dark closet, veiled with heavy curtains.... There, having carefully excluded daylight, the operator lifted up the lid of a small bin, rapidly fixed the plate, silver side downwards, in a place made underneath for its reception....

The term 'dark chamber' or 'dark-room' originated in the earliest years of the daguerreotype, when it was assumed that all the stages of sensitisation had to be performed in the dark. That idea was dismissed by Antoine Claudet in his 1841 British Patent No. 9193 of 1841, in which he patented the idea of

> 'performing all the operations upon the plates which were formerly carried on in the dark now in a room lighted through the media of various colours, such as red, orange, green and yellow, but red I prefer, which, having very little effect upon the plates covered with the sensitive coating, allows the operator to see how to perform the work without being obliged as before to remain in a dark room.

In his 1841 patent for the calotype, British Patent No. 8842 'Photographic Pictures,' however, William Henry Fox Talbot made no mention of a dark room or dark chamber. For the first stage in the making of a calotype, he refers only to the fact that 'all this process is best done in the evening by candlelight' and suggests drying the paper, once brushed with silver nitrate, 'cautiously at a distant fire.'

Talbot, like many other travelling photographers who came after him throughout the 1840s, 1850s and 1860s, thought nothing of converting hotel bedrooms into makeshift darkrooms for the preparation and later development of their materials. Indeed, innkeepers in the 1850s were known to keep towels and bed-linen, already stained with silver nitrate, for when photographers came to stay.

Studio-based photographers had their darkrooms adjacent to the studio itself—essential in the days of wet collodion as the plate had to be coated and exposed while still damp. Travelling photographers in the wet plate era had to take their darkrooms with them on location, and as the sensitivity of materials improved, the requirements for an effective darkroom—either fixed or transportable—became more stringent.

Writing in *The Silver Sunbeam* in 1864, at the height of the wet collodion era, Professor John Towler MD offered his readers advice on the construction of their darkroom and developing chambers

> The Dark-Chamber and the ordinary work-room may be constructed on the northern side of the glass-house, the window of one being glazed with an orange-yellow glass, in order to absorb the actinic rays, and the other with common crown-glass. On the outside of the side windows, small platforms are formed for the reception of the printing frames

(The making of prints, at the time, was in contact with the negatives and exposed to daylight.)

> The chamber intended for all operations of sensitizing, commonly called the Dark-Room, ought to lie contiguous to and open into the common operating or work-room of the photographer; and both these rooms ought to open directly into the glass-house…a single pane of orange-yellow colored glass is all that is needed.…This mode of admitting light permits the progress of the development to be distinctly watched much more effectively than by reflected light.

Four years later, William Lake Price, in his *Manual of Photographic Manipulation* introduced the idea that a well designed and well-maintained darkroom made for greater productivity as well as ensuring the health of the operator.

> Small and inconvenient dens may be made to do duty on occasions, but if it be possible to obtain a certain space, say sixteen feet by twelve, for this purpose, it will be well bestowed, both in the increased convenience for the production of the negatives, and for the health of the operator, by the superior ventilation it affords…
>
> … Let the darkroom contain only those things which legitimately belong to it; let the shelves &c. be washed frequently and kept free from dust, the sinks in the cleanest condition, and the floor covered with oil-cloth, as being the material with the most unbroken surface and most easily purified from dirt.

As early as 1864, the suggestion that darkrooms be fitted with safe-lighting had been postulated—gas lighting held within yellow glass tubes suspended above the developing sink.

For his 1854 journey through Yorkshire, and his pioneering expedition the following year to the Crimean War, Roger Fenton converted a Canterbury wine-merchant's van for use as a mobile darkroom, fitting yellow glass panels in the side, while others used tents of yellow canvas for the same purpose. Portable dark-tents which could be carried as back packs were popular throughout the 1850s, 1860s and 1870s, vying for popularity against designs built around wheelbarrows and other small wheeled vehicles.

With the advent of the dry plate, and the commercial availability of mass-produced materials, the darkroom lost one of its functions, but gained another—becoming the printing chamber as well as the processing room. Enlargers, powered by variety of light sources brought printing indoors and relegated the large plate and the daylight-exposed contact printing frame to the history books for all but a few photographers.

DARLOT, ALPHONSE (1828–1895)

French inventor and merchant

Born on 3 September 1828 in Seignelay, France, Darlot served his apprenticeship at the Paris optician's of Noël Lerebours and Secrétan where he obtained his Mastership aged 21 years.

Darlot joined the firm of Jean Theodor Jamin which had been established in 1822 in 1855. On Jamin's retirement in 1860 he took over control of the business. From 1860–1861 the firm's lenses carried both names. Darlot lenses were widely imported into the United States and sold by Benjamin French & Co. M. Carey Lea, the American photographic writer wrote: 'Jamin's (now Darlot's) view lenses are very good, and of extraordinary cheapness. The amateur of small means who wishes to take views cannot do better than begin with one or two of them.'

Darlot's most distinctive lens design was the Cône Centraliser lens made by Jamin and Darlot from 1855. It had a flared back section designed to prevent internal reflections. Darlot's other distinctive design were lenses with three swing-out stops. The firm made an extensive range of lenses with most of the Petzval type, landscape lenses and Rectilinears sold under the Hemisphérique or Hemispherical names and they were widely fitted to cameras in Britain and the United States.

Darlot was also active selling cameras and other optical equipment. The firm was awarded a silver medal at the 1867 Paris International Exhibition.

On his death on 5 October 1895 the factory was acquired by L. Turillon who continued manufacturing lenses under the Darlot name.

DARWIN, CHARLES ROBERT (1809–1882)

Charles Darwin was not a photographer himself, but his publications had a lasting effect on how photographs are used in scientific research. Darwin used photographs in preparing at least four of his books: *The Variation of Animals and Plants under Domestication* (1868), *The Descent of Man and Selection in Relation to Sex* (1871), *The Expression of the Emotions in Man and Animals* (1872), and *The Formation of Vegetable Mould through the Action of Worms* (1883). In *Variation,* Darwin published a wood engraving made from an anonymous photograph of a domesticated Yorkshire pig; in the second edition of *Descent,* he published another wood engraving after a photograph of an orang-utan foetus supplied by the German zoologist Hinrich Nitsche (1845–1902). Darwin's last book, *Vegetable Mould,* contained several engravings after photographs of earthworm castings, probably provided by George King (1840–1909), Superintendent of the Calcutta Botanical Gardens. However, it was with *Expression* that Darwin made his most significant contribution to photographic illustration. In addition to wood engravings copied from photographs, *Expression* was illustrated with seven heliotype plates, each containing numerous separate figures. The inclusion of 'real' photographs in a popular scientific book was unprecedented.

Expression is the third in a trilogy of works that lay out Darwin's theories of evolution. The first was the legendary *On the Origin of Species (1859),* followed some twelve years later by *Descent* and the following year by *Expression.* The subject of *Expression* is the evolutionary origins of human emotional expressions. Darwin argued that human expressions can be traced to animal ancestors; for example, that sneering expresses displeasure because it is a vestige of biting to attack in our evolutionary progenitors. This was considered radical, as it is was a purely mechanical interpretation of human behaviour, affording no role to the soul or other spiritual factors. *Expression* influenced generations of physiologists, some of whom used photography themselves, notably including Jean Martin Charcot (1825–93) and Sigmund Freud (1856–1939).

Because many expressions occur faster than the naked eye can comprehend, Darwin struggled to understand which muscle groups are involved in certain expressions. He supposed photography could help by freezing and recording transient expressions for analysis. Technologically, this idea was ahead of its time as instantaneous photography had not advanced to the point at which rapid action could be depicted. Nevertheless, Darwin tried to obtain photographs depicting common human expressions. Beginning around 1869, he began to shop for appropriate photographs in London print sellers and photographic studios. At least forty-one such pictures are held in the Darwin Archive at the University of Cambridge Library. They include examples by The London Stereoscopic Company, Giacomo Brogi, and James Landy among others. He also obtained photographs from friends and acquaintances, principally in Europe. Among these was a group depicting crying infants by the German painter and photographer Adolph Diedrich Kindermann (1823–92), two of which were published in *Expression.*

During this time Darwin encountered Guillaume-Benjamin Duchenne de Boulogne's influential atlas *Mécanisme de la Physiologie Humaine.* Darwin owned two copies of the book, illustrated with photographs by Adrien Tournachon. Darwin corresponded with Duchenne and, with his permission, reproduced eight of his photographs in *Expression.* Darwin also corresponded with the psychologist James Crichton Browne (1840–1938), who had begun using photography to study patients in his care at the West Riding Lunatic Asylum.

Working under the influence of Hugh Welch Diamond, Browne believed photographic imagery could help diagnose and document various psychological disorders. He shared many of his photographs with Darwin.

Ultimately disappointed with existing imagery, Darwin commissioned custom-made photographs depicting certain expressions. He seems to have begun by approaching George Charles Wallich (1815–99), an oceanographer who opened a photographic studio in South Kensington in the late 1860s, but only one of Wallich's photographs was good enough to include in the book.

In 1871 Darwin met Swedish émigré Oscar Rejlander, who became the main photographer on the project. Rejlander is best known for his artistically experimental photographs made by composite printing two or more negatives in a single print, and his propensity for altering and manipulating photographic imagery is well documented. However, he was also an adept portraitist, and at the time of his commission had developed a niche industry making expressive portraits for painters to use as studies. It was this latter ability that commended him to Darwin, although Rejlander did include composites in the imagery he supplied. Rejlander began by looking for suitable images in his studio inventory. Several of these made their way into *Expression.* However, the vast majority of pictures he provided were made from 1871 to 1872 to illustrate specific behaviours requested by Darwin.
