Among these was a photograph of a crying child, published as Plate 1, Fig. 1 of the book. It was a huge popular success, prompting Rejlander to sell independent carte-de-visite and cabinet card versions. It became known as *Ginx's Baby* after the title of a popular novel about an orphaned boy by Edward Jenkins. Six of the photographs in *Expression* feature Rejlander himself, posing in a distinctive velvet smoking jacket and enacting the expressions of surprise, indignation, and shrugging the shoulders. Rejlander's wife Mary probably assisted in their production, and she also appears as the subject of a photograph depicting sneering. In total Rejlander supplied at least nineteen of the thirty photographs published in *Expression.* Rejlander also supplied dozens of photographs which Darwin chose not to use; many of these are preserved in the Darwin Archive at Cambridge.

Darwin is the subject of numerous photographic portraits, including several by Rejlander. Portraits by Ernest Edwards (1837–1903) and Julia Margaret Cameron (1815–79) are also well known. Darwin lodged at Cameron's guesthouse on the Isle of Wight in 1868. After *Expression* was published, Lewis Carroll (1832–98) wrote to Darwin offering his photographic services, but Darwin declined.

DAUTHENDEY, KARL (1819–1896)

German professional photographer

Dauthendey was a German national, born in a family of lawyers. In 1839, he studied at Tauberg Optical Institute in Lindenau, Germany. In 1840 he acquired daguerreotype equipment and opened a studio. Dauthendey's first show of daguerreotype portraits was in May 1842 in Leipzig. However his attempt to become established in any of the German cities failed. In 1843 he created successful portraits of the duke and duchess of Dassau and received from the duke a letter of recommendation to the Russian Imperial Court. In 1843 Dauthendey arrived from Magdeburg to St. Petersburg where he opened a studio in 1844. His studio specialized in taking portraits and reproducing photography. Dauthendey made attempts to show natural colours on daguerreotypes by using different methods to paint them. Knowing neither Russian language, nor local traditions, and having no friends in Russia Dauthendey very soon felt the lack of funds. In 1844 to distinguish himself among the professional photographers of St. Petersburg he made the first experiments using Talbot's method. He went to Leipzig in February 1847 to improve this method. When he arrived back in St. Petersburg he began to create portraits on paper by using Talbot's method which helped him improve his finances and even become one

of the well-known professional photographers of St. Petersburg. In 1862 he left Russia. In 1864 he opened a photographic studio in Wurzburg which remained until his death in 1896.

ALEXEI LOGINOV

DAVANNE, LOUIS-ALPHONSE (1824–1912)

French chemist, photographer, and innovator

Davanne was born in Paris, France on 12 April 1824. Davanne was a chemist and an important innovator in photographic processes. From 1852 onward, he spent much of the following 50 years experimenting with methods that led to more permanent photographic printing. In collaboration with Barreswill, Lerebours and Lemercier, he worked to make a photolithographic process perform better using bitumen of Judea. He also invented several new types of cameras and photographic equipment. In 1856 he was a founding member of the Société française de photographie (S.F.P.). Davanne served on its board and as vice-president, chairman, and honorary president. He took photographs of Versailles and presented to the Institute a portfolio of lithographs from negatives by Le Secq, based on photographs of Versailles.

The calotype was a difficult artistic process, often affected by chance whose effects could be unintentionally and easily modified during printing, and was not a big commercial success. The technique spread however thanks to personal contacts and exchanges between practitioners, and this process's advancement was facilitated in the 1850s by photographic exhibitions. The creation in Paris in 1851 of the Société héliographique, the first gathering of amateur photographers (mostly calotypist), was a particular response to this need of sharing information about this uncertain technique. This meeting allowed a space for sharing methods and tips, and a forum through which photographer could discuss recent improvements. A little group was also formed in the neighborhood of Chalon-sur-Saône, in Burgundy, where Nicéphore Niépce had been located, consisting of Petiot-Grofier, the mayor of the town (who accompanied his master Baldus at the Auvergne in 1854), and Eduard Loydreau, archeologist and mayor of Chagny. Another group was formed at the Sèvres works around Victor Regnault, consisting of a physician who had become director of the company in 1852, and included among others Louis Robert, head of the painting workshop, E. Béranger, and J. Diéterle. An additional third group developed at the 'Caffé Greco' in Rome, appearing around 1850, which included G. Caneva, Count Flachéron, Eugène Constant, and Alfred Normand, to whom one might also add Alphonse Davanne and Thomas Sutton, who participated briefly.

The technical industrialization of photography during the 1860s meant that around 1875 albumen prints had become the standard to be superseded in turn in the 1890s by gelatin-bromide prints. As from 1855, many people like Baldus, Fenton, Le Secq and Davanne tried to overcome the problem of the non-permanence of photographic prints by using the photogravure process.

From 1854 to 1863 he worked with Aimé Girard (1830–1898) on a study of the means of formation and constitution of positive photographic images. In 1857 he had an exhibition together with Aimé Girard.

He received the gold medal within the framework of the Prix du Duc de Luynes in 1859 for this collaborative work. Together they researched the permanence of photographic positives and later published their results in 1864. In 1855 however, Davanne created a rotating bellows camera, which was later constructed by Relandin. Additionally Davanne invented a portable field camera, 18 × 23 cm format, which was constructed by Koch in Paris.

In the 1860s, photographers recorded the localities, their infrastructure, and the indigenous people living there. Alphonse Davanne did this as well and published a series of photographs of Tréport, Dieppe, Trouville, and Le Havre in addition to the large number of individual stereoscopic views in circulation.

In 1861 his images of the Pyrenees and of Menton were shown in an exhibition and in 1862 he illustrated "'l'Hiver à Menton" by Alphonse de Longperier-Grimoard.

From 1863 onward however, his photography became more concerned with the theory of physical development, the Taupenot process, the cause of changes in positive prints, alcline developing and experiments with Chardon emulsion.

In 1863–1864, in yet another exhibition, Davanne showed his view of Normandy. In 1864 he received the Prix de Duc de Luynes. In 1865–1870 he wrote parts of the Photographic Yearbook to be published by Gauthier-Villars. From 1866 until 1876 he was vice-president of Société française de photographie. In 1867 he invented a focimeter, which was constructed by Secretan and by this time, he had become a member of the Duc de Luynes award committee.

The kings of France took an early interest in the building and unkeep of roads and public works, mainly with the aim of benefiting commerce. In 1747, a school, the Ecole des Ponts et Chaussées, was created, providing special training, linked at first to the Administration des Mines (1817) then later to the Ministère des Travaux Publics (1839). Engineers examined the various aspects of their work in France, focusing on the design, construction and the use of highways, waterways, and railways. Ecole des Ponts et Chaussées was a particularly intense center for learning and education, and through

its efforts to teach its student, the school inadvertently produced an important reference collection of structural photography. The School took trouble to integrate lessons derived from practical experience into its empirical approach. Photography turned out to be an ideal teaching aid for capturing the work of the engineers. In 1857, following a suggestion by one of the Bissons brothers, the School began teaching photography to its students, which continued until 1911. Davanne was the teacher from 1872 to 1886 , and the School published his 'Lectures on Photography' in 1883.

In 1876–1901 Davanne became chairman of Société française de photographie board.

In 1877 he wrote *Impressions Photographiques aux encres grasses analogues à la lithographie*. In 1879 he started teaching at the Sorbonne, Paris. In 1891 he gave lectures at Conservatoire des Arts et Métiers and in 1901 he became the honorary president of the Société française de photographie. In 1904 he wrote "Protection due aux oeuvres photographiques et leur assimilation aux oeuvres artistiques" (Protection due to photographic works and their assimilation in works of art). He used Daguerreotype, calotype, salted paper, waxed, with wet collodion, albumenized. He lived at 82 Rue Neuve-des-Petits-Champs, Paris. Davanne produced photographs in a number of media. His work, including views of France, Germany, Italy, Spain, and North Africa, was frequently shown throughout Europe. Davanne also wrote extensively, including an essay on the protection of photographic works and their assimilation as works of art.

Davanne died on September 19, 1912 at St-Cloud.

DAVIDSON, THOMAS (1798–1878)

English camera manufacturer and photographer

Thomas Davidson was born in Deehunt, Northumberland in 1798, where his father was a road labourer. He had minimal schooling and was apprenticed as a weaver. Aged twenty, in 1818, he married, but by this time had discovered his natural skills as a mechanic. In 1836, he moved, with his family, to Edinburgh, and working initially for an optician named John Davis, and subsequently for the rather more prominent horologist, Robert Bryson, Davidson set up in business in 1839, just in time to benefit from the new mania for photography.

At least one of his daguerreotype cameras survives, which, although unsigned, is as described by Davidson in a paper which he read before the Society of Arts for Scotland in 1841, and for which he was awarded the Society's Silver Medal. Davidson himself took daguerreotypes (some examples of which survive) out of the high window of his premises in Edinburgh's High Street, which apparently sold so well that he had to take on extra staff, while he continued to make improvements to apparatus. Among his Scottish clients were James Howie, the University of St. Andrews, James Good Tunny (and his more than 200 amateur students), and Sir David Brewster's son, Captain Henry Brewster. South of the Border, Henry Collen, Antoine Claudet and Calvert Richard Jones all extolled the virtues of his lens-making. The Davidson lens of the Edinburgh calotypists, D.O. Hill and Robert Adamson, survives in the collection at Bradford, and has been described as an 'unsymmetrical doublet lens of about 17" focal length and maximum aperture of about *f*10.'

With the eager participation of amateurs, especially in the Scottish capital, demand for Davidson's lenses remained high into the wet collodion period, and he should have been a prosperous man. But it was not to be; Davidson had poor commercial sense, and his photographic business failed after about fifteen years. He retired to his native Northumberland, where he died in June 1878.

A.D. MORRISON-LOW

DAVISON, GEORGE (1854–1930)

George Davison was one of the most important figures in the development of Pictorial photography at the end of the nineteenth century. A founder member of The Linked Ring, he was a highly influential figure, exhibiting widely and writing extensively. His position as Managing Director of Kodak Ltd brought him affluence as well as influence.

George Davison was born in Lowestoft, Suffolk, in September 1854. From a comparatively modest family background—his father was a shipyard carpenter—he alone of his siblings received a secondary education. In his late teens he passed the entry examination for the Civil Service and in 1874 he became a clerk in the Exchequer and Audit Office in Somerset House, London. Davison first took up photography in about 1885 and

joined the Camera Club when it opened in November that year, becoming honorary secretary the following year. He first exhibited his work in 1886, showing six pictures in the Photographic Society of Great Britain Exhibition. He became a member of the society in November 1886.

An advocate of Naturalistic photography and selective focusing, Davison initially espoused the ideas of P H. Emerson. However, their relationship soon deteriorated into a series of bitter exchanges published in the photographic press.

Davison experimented widely with different techniques and processes in his efforts to achieve the impressionistic effect which he desired in his work. He was one of the first to use a pin-hole camera for pictorial photography. In 1890, one of his pin-hole photographs, *An Old Farmstead* (later retitled *The Onion Field*) was awarded a medal at the Photographic Society of Great Britain's annual exhibition. A prime example of the 'fuzzy' school of photography, this picture provoked considerable comment and discussion.

The following year, Davison found himself at the centre of a controversy which blew up surrounding his late submission of entries for that year's Photographic Society exhibition. Through a combination of misunderstandings, personal rivalries, petty bureaucracy and inflexibility, this minor incident escalated into a situation where Davison, together with a number of other prominent members of the society, including the vice-president H. P. Robinson, resigned their membership. In 1892 this secessionist group formed an association called *The Linked Ring* and established an annual Photographic Salon, the first of which was held in October 1893. Each 'Link' was given a name—Davison being known as 'Deputy High Executioner' because of his shared responsibility with Robinson for 'hanging' exhibitions. Within a couple of years, the Photographic Salon had established itself as one of the most important events in the photographic calendar and presented a serious challenge to the primacy of the Photographic Society exhibition.

In 1889, George Eastman had invited Davison to become a director of the newly-established London branch of the Eastman Photographic Materials Company. Davison bought twenty-five shares at £10 each, using money borrowed from a friend—an investment which was to prove extremely profitable. This was the beginning of Davison's long association with George Eastman and Kodak. In 1897, he left his, now senior, position at the Audit Office to become assistant manger of the Eastman Photographic Materials Company. One of his first tasks was to organise a major competition and exhibition of amateur photography. The exhibition, presented at the New Gallery, Regent Street, London, was a spectacular success and was visited by more than 25,000 people during its three-week run. Davison gave free Kodak cameras and film to his photographer friends in return for permission to use their pictures for advertising purposes. These included, Paul Martin, Eustace Calland, James Craig Annan and, most prolifically, Frank Meadow Sutcliffe. In 1898, Davison became deputy managing director of Kodak Limited, as it had then become. With an annual salary of £1,000 and owning thousands of shares in the company, he was now an extremely wealthy man. The sudden death of the managing director, George Dickman, resulted in Davison taking over the post in March 1900.

Despite his growing corporate responsibilities, Davison continued to photograph and to exhibit his work. In 1898 he showed gum-bichromate prints for the first time and the following year he started what was to become an annual custom of sending photogravure reproductions of his photographs to his friends as New Year's gifts. Inevitably, however, his output declined. In 1908, for the first time, the Photographic Salon contained none of his work. By this time, The Linked Ring had lost its original impetus and sense of unity. In 1910, it was agreed that no exhibition would be held, effectively marking the end of The Linked Ring. A group led by Davison formed the London Secession which held a single exhibition in May 1911. Davison exhibited a single print, of Harlech Castle. It was to be his last contribution to a photographic exhibition. By this time, Davison was preoccupied with other matters.

Undoubtedly stemming from his humble origins, Davison had a life-long interest in social reform. Although more of a committed Christian Socialist than an anarchist in the Marxist sense, he had been associated with anarchist organisations for several years. In 1908, George Eastman, considering him to be unsuited to the cut and thrust of commerce, asked Davison to resign as managing director of Kodak Ltd. Davison remained on the board of the company for a few years but his political activities had made his position untenable in Eastman's eyes. In 1912 he was forced to resign his directorship, ending twenty-four years of association with the company.

Davison moved to Harlech, North Wales, where his splendid house became a focus for artistic and political gatherings. As his health declined in the 1920s, he spent more time at his home near Antibes in the south of France, where he died in December, 1930.

DAVY, SIR HUMPHREY (1778–1829)
English chemist and inventor

Davy's name is forever linked with his famous miner's lamp introduced in 1815. His name is also linked that of Thomas Wedgewood and the experiments conducted by the two men, together and separately, towards the establishment of a photographic process.

He was born in Penzance in 1778, moving to Bristol where he was apprenticed to a surgeon, and in 1797 he embarked on a course of study in the sciences.

The Wedgewood/Davy experiments with silver nitrate in the early 1800s, place Davy's work at the dawn of photography. The two men reportedly produced visible imagery on both leather and paper, which continued to blacken as they could not ultimately stop the action of light and 'fix' the image. Much of the work was Wedgewood's, with Davy adding important notation before presenting the paper 'An Account of a Method of Copying Paintings upon Glass, and Making Profiles by the Agency of Light upon the Nitrate of Silver' to the Royal Institution, London, in 1802. These experiments, however, are not his sole contribution to the evolution of the medium.

In 1802 he was appointed Professor of Chemistry at the Royal Institution, and during the period 1800-1815, his chemical exploration and experimentation identified and isolated the elements sodium and potassium, so central to photographic chemistry, and by 1815 he had discovered iodine, another key component of the photographic process.

JOHN HANNAVY

DAY, FRED HOLLAND (1864–1933)
American photographer and philanthropist

Day was born in South Dedham (later incorporated into Norwood), Massachusetts on 23 July 1864, the only child of wealthy and supportive parents. His father Lewis, a successful leather merchant and entrepreneur, was based in Boston where the Day family also had an apartment. Day's mother, Anna Smith Day, was philanthropic and individualistic, involved in the cultural, social, and charitable life of Boston. Day inherited this trait of helping and supporting and had the time and wealth to pursue the altruism which was to become the most important aspect of his life after 1900.

Day's lifelong passions were literature, art, photography, and aesthetics. By his early twenties, he had amassed large collections of works relating to the English Romantic poet John Keats and the French writer Honoré de Balzac. He had also become interested in photography, writing to a friend, Ada Langley, in the summer of 1887 "[I] have become a full-fledged amateur in the art of photography, and a most delicious time I've had of it, too...."

This same year, he struck up a relationship with the forthright Boston Irish Catholic poet, Louise Imogen Guiney. The question of romance was soon removed from the equation but the two remained friends for over 30 years. Day never married and, while it is widely assumed that he was homosexual, his sexual orientation was, like much else about him, a very private matter which remains unclear.

Until 1888, Day fitted his photography around work as a depository secretary witha bookseller. After he left this employment he regularly travelled to Europe, especially London, for several months at a time, pursuing Keatsiana (eventually unveiling a bust of John Keats at Hampstead Parish Church in July 1894, paid for by public subscription organized and collected by Day and Guiney in Boston) and meeting luminaries like William Morris, William Butler Yeats, Arthur Symons and Oscar Wilde (whose autograph Day had secured as a schoolboy in 1882 during Wilde's U.S. lecture tour) thus establishing connections that would bear fruit in both his publishing and photographic careers.

During 1889 or 1890, Day also met the British bookseller turned photographer, Frederick H. Evans. Evans not only involved Day in the British photography scene but also got him interested in the powerful and stylized drawings of Aubrey Beardsley, then still a teenager. Day and Evans had much in common—books, art, photography and a fascination with visionaries, and they remained close friends, exchanging photographs and ideas, for the rest of their lives. Day's increasing links with the British photographic scene, through Evans and George Davison and the growing confidence and excellence of his own photography meant that he was elected to the British photographic society, the Brotherhood of The Linked Ring, on 26 November 1895. By this time, Day had begun to use the name F. Holland Day for his photography, finding it more appropriate to his status as an artist than the colloquial "Fred."

From 1893 to 1899, Day set up and self-financed a publishing house with the writer and editor Herbert Copeland. The publishing company of Copeland and Day, based in Boston, was initially much influenced by the ethos and style of William Morris's Kelmscott Press (set up in 1891) and the resurgent Arts and Crafts movement in Europe and the United States. Copeland and Day never made a profit during its six years of operation but produced almost a hundred courageously and beautifully designed and printed books, gaining notoriety (and much needed sales) by publishing the American edition

of Wilde's *Salome*, illustrated with Beardsley drawings (1894), and a journal, *The Yellow Book* (1894–1896), again illustrated by Beardsley until 1895.

By the time the publishing house closed in 1899, Day had already taken on a new role as one of the undisputed leaders, along with the New-York based Alfred Stieglitz, of the American art photography movement. Both men realized that in order to establish photography as an art form in an era before the widespread proliferation of galleries devoted solely to photography, images had to be supported by lectures, articles, interviews, and exhibitions, and by encouraging mutually supportive groups of like-minded individuals. An eventual stand-off between Day, who disliked New York and avoided visiting the city at all costs, and Stieglitz, who felt much the same about Boston, was inevitable.

Day's photography blossomed astonishingly rapidly in the 1890s. He photographed his friends and colleagues, initially concentrating on portraits of women, often using a sepia-toned printing-out paper. He also began to photograph a variety of exotic female, and then male, models, dressing them in flowing draperies and with props of Middle Eastern, African, or Greek inspiration. The years 1896–1897, when he had established himself in a new rented studio at 9 Pinckney Street in Boston, were seminal in his development as a photographer. He began to photograph male nudes or partially draped figures, often using black models of supreme grace and beauty (the most notable being J. Alexandre Skeete, a professional model and an aspiring artist himself). He did so with a control of light and shadow on skin tones, and a placement of his subjects in an artistic and allegorical metier, that rendered them on the aesthetically acceptable side of the erotic. The models featured in such photographs as "Ebony and Ivory," "An Ethiopian," "Menelek," "Nubia," and "Smoker," was variously accessorized with an ivory (actually plaster) statuette, body jewellery, robes, pigeon-wing head-dress, leopard skin, bows and spear—all the accoutrements of an imagined exoticism.

These photographs were much exhibited, much reviewed, and much discussed. Day trod a very fine line between homoeroticism and the depiction of the male body as a "Greek" ideal. While the photographs in this series have an undoubted erotic and sensual charge, they were not taken, unlike the photographs of Day's contemporary Baron von Gloeden, solely with the male viewer in mind . Day defended his ideals with consummate skill in public lectures and in articles in both the national and photographic press. For instance, in an article of July 1898 ("Art and the Camera," published in Stieglitz's journal *Camera Notes*), Day outlined his three rules for producing art with the camera, observing that "Boticelli's circle was not made with a compass, neither is art produced by the lens and bellows" but by the artist using the lens and bellows in the eye, the heart, and the brain respectively.

From July to September 1898 Day, although seemingly holding no strong beliefs in any organized religion himself, began to work in earnest on a series of 250 negatives of sacred subjects depicting the events around the Crucifixion in an attempt to use the camera to produce religious art (much as Julia Margaret Cameron had done with her *Madonna* series of 1864–1865). His first foray into this controversial territory in 1896, "The Entombment," had shown Day himself as Christ, prostrate with painted wounds and a cardboard halo at a rakish angle. As his first recorded self-portrait, it was an astonishingly bold choice. It became obvious to the photographic world that Day was not only a man who took calculated risks but was able to carry them off with undeniable photographic expertise and aesthetic judgement. These ideas were to culminate in the final photographs in the Crucifixion series, "The Seven Words," a set of self-portraits as the dying Christ. The visual style of the Crucifixion work was also strongly influenced by the passion plays of Oberammergau (which Day had seen on a trip to Bavaria in 1890), as well as by his knowledge of Renaissance art, his reading of Walter Pater, Oscar Wilde, Algernon Charles Swinburne and the rites of the Rosicrucian sect, which performed ritualistic crucifixion ceremonies.

The outdoor Crucifixion scenes were photographed near Day's home in Norwood—Roman soldiers, weeping women, onlookers—were friends and hired actors. The meticulous attention to authentic detail, such as a crown of thorns and cedar wood imported from Lebanon for the cross, has been well documented elsewhere in publications by Jussim, Crump, and Curtis (see Further Reading). The close-up portraits, "The Seven Words," taken at Day's Norwood family home, used a mirror attached to the camera and a long shutter release cable to achieve the correct facial expressions.

In an identification fashionable at the time, Day doubtless saw the crucified Jesus as a symbol for the suffering and misunderstood artist—and especially aesthetes such as Keats, Wilde, Beardsley, and Day himself. The photographs aroused initial controversy, tempered by eventual praise. A private showing to members of various religious groupings in Day's studio received a remarkably open reception.

> To this exhibition there came people of all shades of religious belief—Quakers, Jews, Anglicans, and Roman Catholics, Nonconformists, Swedenborgian, priest and clergymen. Among them many were known to hold adverse opinions before seeing the prints, but with the exception of a single individual, those prejudices entirely disappeared. (Day, "Sacred Art and the Camera," *Photogram*, 6 (1899): 97–99)

Day's profile in Boston, and in American art photography circles, was high. In 1899, he worked with the wealthy Boston painter and photographer Sarah Choate Sears to secure a permanent gallery space for photography at the city's Museum of Fine Arts. This was intended to act as a photographic salon for exhibitions of the pictorial photography of a much discussed but eventually unrealized grouping of Boston artist photographers, to be named the American Association of Artistic photography , based along the lines of the Linked Ring. Despite the failure of this idea in Boston Day decided to press ahead and arrange an exhibition in London.

In April 1900 he sailed to London with several hundred photographs by over forty American pictorial photographers, among them Edward Steichen, Alvin Langdon Coburn, a distant cousin of Day's, Gertrude Kasebier, and Clarence White. In October 1900, the exhibition of *The New School of American Photography* opened at the London headquarters of the Royal Photographic Society, after his request to show it at the annual Linked Ring Salon was refused thanks to a last-minute intervention by Stieglitz.

The exhibition was a *succes de scandal*. Day showed 113 of his own photographs and his subject matter—naked black men and religious scenes—and his elaborate methods of presenting his photographs on multi-layered coloured paper supports in ornate gold and wooden frames, were unlike anything seen in a photographic exhibition in London before. Reviews in the photographic press veered between vitriolic sarcasm and heady praise. The photographs, most especially the contributions of the 21-year-old Edward Steichen, shocked London to the core.

Day's diplomatic skills, determined conviction and personal charisma won him a wide circle of admirers, while his personal appearance—brocade waistcoats, swirling capes, auxiliary wardrobe of Oriental and Middle Eastern attire, and stylishly coiffed hair—declared him to be an exotic aesthete in the tradition of the now disgraced Oscar Wilde. Like Wilde, Day believed that publicity, be it good or bad, was better than apathy and silence. In December 1900, just a few days after Wilde died in Paris, Day and his controversial exhibition arrived there. The French reception of *The New School of American Photography*, which showed at the Photo-Club de Paris from February to March 1901 and was championed by the influential Robert Demachy, was this time wholly favourable.

Back in Boston later in 1901, Day threw himself into re-establishing his ties to his roots. He also began to spend more time and money mentoring and educating young immigrant boys, funding them through school, art and literature classes and teaching them photography. An earlier protégé and photographic model of 1896, a 13-year-old Lebanese immigrant called Kahlil Gibran, was blossoming into a poet, author, and artist thanks to Day's guidance (Gibran's book *The Prophet*, published in 1923, now enjoys cult status).

In 1901, Alfred Stieglitz finally established his own coterie of American pictorial photographers, the Photo-Secession, firmly rooted in his native New York. Two years later he launched *Camera Work,* probably the most beautiful, lavish, radical and opinionated photography journal ever published. Day had lost the chance to be the front-runner in American photography but, eventually, seems not to have cared unduly, perhaps glad to hand over the baton to a more energetic and single-minded participant.

In 1904 Day's new studio in the Harcourt Building in Irvington Street burnt down. He lost much of his previous life in photography; 2,000 negatives taken over the previous 18 years, an unknown number of prints, his collection of photographs by friends, and his cameras. The fire also destroyed some of his art collection, antiques, and books.

In many ways, the fire and destruction seem to have acted as a cleansing and liberating process; from 1905 onwards Day's photography was quite different. Shot through with openness, freshness, liberation and freedom, frankness and honesty, humour and joy, it became astonishingly modern. For the rest of his active photographic career until 1912, he concentrated on marrying a celebration of nature with a celebration of the naked male body and also began to explore portraiture of close friends from a new and vivid angle (see the entry in Fitzroy Dearborn's *Encyclopedia of 20th-Century Photography*).

In his forties, Day simplified his life, spending eight months of each year at his property in Maine where he built a house to enable the establishment of a Utopian community where he could entertain friends and organize summer schools for immigrant boys raised in the Boston slums. From 1916 until his death in 1933, Day retired back to his family mansion in Norwood, physically bedbound but still mentally active.

DE AZEVEDO, MILITÃO AUGUSTO (1837–1905)

Brazilian photographer and actor Militão Augusto de Azevedo was born in Rio de Janeiro on June 18, 1837, to Antonio Inácio de Azevedo and Lauriana Augusto de Azevedo. He studied photography in Europe in 1878, and may have worked with Alphonse J. Liébert. Known professionally as Militão, he worked for the Carneiro & Smith photographic studio in Rio in the 1850s, and by 1862, he ran the Carneiro & Gaspar studio in São Paulo. He produced an *Album of Views of the São Paulo Railway* in 1865 and several urban landscapes in about 1870. In 1875, he bought the studio and renamed it Photographia Americana. The business failed in 1885 and he went to Europe, returning with the idea for his *Comparative Album of Views of the City of São Paulo, 1862/1887.* He considered this collection of 60 original albumen photographs his masterwork and swansong. Militão also produced *carte-de-visites* and portraits of people from all walks of life, including black poet and abolitionist Luís Gama. He died in São Paulo on May 24, 1905. Collections: Museu Paulista, São Paulo; Shomburg Center for Research in Black Culture, New York; Moreira Salles Institute, São Paulo/Rio de Janeiro; Emanoel Araújo Collection, São Paulo.

SABRINA GLEDHILL

DE BANVILLE, VICOMTE AYMARD ATHANASE (1837–1917)

French photographer

As a member of the 1863 expedition led by the prominent French Egyptologist Vicomte Emmanuel de Rougé, de Banville spent several months photographing the sites and monuments of Egypt. It is unclear whether he worked directly under the supervision of de Rougé or selected his own subjects. Prior to his work in Egypt, he had been an amateur painter and sculptor and had made some attempts at photography as early as 1860. While in Egypt he produced a concentrated body of work, more than 200 photographs in less than six months. That work formed the basis for a lavish publication, *Monuments Egyptiens* (1865), which included 165 of his photographs. He exhibited a number of the prints in the Société Française de Photographie exhibition that year. It seems clear that de Banville's position in society and his association with de Rougé, the successor to Champollion, gave his work a higher profile than that of other photographers working in Egypt at that time. He was awarded the Legion of Honor for his work.

KATHLEEN HOWE

DE BEAUCORPS, GUSTAVE (1825–1906)

French photographer

Born into an aristocratic family in France, the count Gustave de Beaucorps began to photograph in the mid 1850s. A talented amateur, he is best known for his architectural photographs of monuments and landscapes taken on travels through western Europe. Algeria, Egypt, Morocco, Palestine, and Turkey. His photographs, primarily studies of architecture, landscape and figures made upon his travels, were generally bound in albums. De Beaucorps also collected Spanish and Arab decorative arts, some of which he photographed. Although de Beaucorps primarily employed the waxed paper negative process to make both salted paper and albumen prints, a few albumen prints from wet collodion glass negatives have been identified. A member of the Société Française de Photographie, Beaucorps exhibited with the S.F.P in 1859, 1861, and 1869. His work is included at the Canadian Center for Architecture, Montréal, the Bibliothèque Nationale, Paris, and the Société Française de Photographie, Paris.

SARAH KENNEL

DE BRÉBISSON, ALPHONSE (1798–1872)

Alphonse de Brébisson was born in Falaise, Normandy, where he lived all his life and where he acquired a reputation as an eminent botanist. He was interested in photography since 1839, and began researching methods to simplify and improve the processes of the daguerreotype. The results of this work led to the publication of *De quelques modifications apportées aux procédés du daguerréotype* (1841). He experimented with negative paper photography and in 1848, one year after the introduction of the calotype in France, he published notes on the subject. He later used albumen on glass, collodion

on glass, and subsequently Taupenot's dry albumenized collodion process. He was one of the first to use wet collodion photography in France. De Brebisson published several papers on the subject, including a treatise on 'instantaneous dry collodion' in 1863. Through these publications he was instrumental in the popularization of collodion photography. He was the first to make a complete method of photography with collodion (1852) in France. Alphonse published several papers on the subject (of which consisted a treaty of instantaneous dry collodion in 1863).

Brébisson practiced the stereoscopy, microphotography (applied to botany), and the carbon process as well, which he developed himself. He also invented a printing frame. Alphonse printed his tests as paper versions according to the method developed by Blanquart-Evrard in 1847. He collaborated in *l'Album photographique de l'artiste et de l'amateur* published by Blanquart-Evrard in 1851. As a founding member of the Société française de photographie in 1854, he remained faithful the society until his death. He participated in three of their exhibitions, in 1857 with the studies of landscapes on albumenized collodion; in 1859 with the landscapes on albumenized collodion printed with uranium and gold according to the method of Niépce-of-Saint-Victor; and in 1861 with albumenized dry collodions of the monuments of Falaise and the surroundings area. He also took part in two exhibitions of Alençon (1858, 1865), in l'exposition de Marseille in 1861 and the International Exhibition of 1862 in London. In 1859, Alphonse provided within one frame, three samples of the same image of the Rocks of Noron, which were obtained successively by uranium oxide nitrate, cerargyrite, and coal. A critic evoked these tests: "under skilful and exerted hands all the processes are good; there is such a similarity between these three tests, which one would be embarrassed of saying which is the best "(Re-examined photographic). With such tests, the process of this experimentation became well known outside of the laboratory of the scientists, allowing the public too to participate.

Almost all of the daguerreotypes and negative paper of Brébisson's disappeared, but an important a number of albumen and collodion plates were preserved with the Photographic archives and the BNF. His oeuvre consists of very diverse scenes: portraits, landscapes, monuments, nature, and reproductions of other works. In 1865, on his way to Alençon, he photographed his famously artistic Falaise exposure of 1864 (process with tannin) and a reproduction of an engraving. All the portraits taken by the end of 1840 were on negative paper, consisted of self-portraits in which he only posed with his friend Humbert de Molard, and images of his family. He experimented with all genres and his talent undoubtedly was displayed best with landscape photography. He took many shots of Falaise and the surrounding area in various formats (30 × 40 cm or 21 × 27 cm), in accordance to negative paper or glass with albumen. Alphonse had a predilection for edges of rivers, the reflective quality of water, and the underwoods. In these landscapes, he illustrated a great sensitivity to the atmosphere and the luminous effects.

In 1861, Felix Deriège was filled with wonder inspired by Brébisson's landscapes, in particular by the image of la Saint-Trinité de Falaise. His only reservation related to the tone of the deer, due to the use of uranium oxide. Apart from his oeuvres, Brébisson left an album to the Paris, Musée of Orsay, which contained signed test images of the great names of the photography of the time like Hippolyte Bayard; Louis de Clercq; Andre Giroux; Gustave le Gray; Henri le Secq; Charles Nègre; and Joseph Vigier. To these names of course, it is necessary to add that of Domenica Gaumé, professor of drawing in Mans, with whom Brébisson began photography, and Edmond Bacot and Charles Ancelle.

Alphonse de Brébisson typifies the inquisitive amateur. He represented the perpetually, inventive spirit having followed all the stages of the new medium, and running tests himself with all the techniques and all subjects. He was greeted by the critics as an "intrepid researcher" (photographic Review, 1859), and as a" man of taste and…[an] experienced expert" (Ernest Lacan, 1861). With his qualities as a man of science, one could combine those of an aesthetic sensitivity to the beauty of nature and ability to compose an image.

DE CLERQ, LOUIS (1836–1902)

French archaeologist and photographer

Born Louis-Constantin-Henri-François-Xavier De Clerq to a wealthy family in Northern France, De Clercq, was from an early age a passionate amateur archaeologist

de Clerq, Louis. Denderah, Porte d' Entrée.
The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 [2005.100.500.4 (35)] Image © The Metropolitan Museum of Art.

and photographer. In August 1859 he joined an expedition organized by Emmanuel-Guillaume Rey, under the aegis of the Ministry of Public Education, to study Crusader architecture in Syria and Asia Minor. After spending six months with Rey, De Clercq continued to travel through Syria, Palestine, Egypt and Spain photographing architectural ruins, landscapes, cities, and rural scenes using the waxed paper negative process, possibly because it was less cumbersome than using collodion glass negatives. He returned to France in 1860 and published the result of his travels in a six-volume work entitled *Voyage en Orient, 1859–1860*. Consisting of 222 prints (primarily albumen) made from negatives measuring about 21.5 × 28 cm and several panoramas made from negatives joined together, *Voyage en Orient* reveals de Clercq's affinities for sweeping panoramas, dramatic chiaroscuro lighting, and stark compositions dominated by architectural masses. In 1861, de Clercq exhibited the entire *Voyage en Orient* at the *Société Française de Photographie's* fourth exhibition. In 1862, he exhibited three photographs at the Universal Exhibition in London, where he received an honorable mention. Institutions with complete sets of *Voyage en Orient* include the Gilman Paper Company collection at Metropolitan Museum of Art, New York; The Canadian Center for Architecture, Montréal; The Louvre, Paris; and the Musée d'Orsay, Paris.

DE LA RUE, WARREN (1815–1889)

This English astronomer, chemist and physicist is best known for his pioneering work on astronomical photography, which opened up a tremendous series of opportunities for astronomers. However, he had a varied career in more than one scientific field, and was himself a craftsman, as well as an industrial inventor.

Warren was the son of Thomas de la Rue. His father, Thomas de la Rue, who had been a newspaper publisher in Guernsey, later founded a large firm of printers and stationers in London in 1821. On completion of his education at the Collège Saint-Barbe in Paris, Warren began working at his father's printing business, but in his spare time he began conducted research into chemistry and electricity in his spare time. In 1829 he had made the first known attempt to produce an incandescent light bulb. Although an effective design, his use of platinum for the filament made it commercially unviable. Between 1836 and 1848 he published several papers into his findings on both chemistry and electricity. Warren's interest in astronomy was sparked while watching his friend, the Scottish engineer, James Nasmyth (1808–1890) at work on the casting of a speculum for use in a telescope for observing the sky at night and this caused de la Rue's own thoughts to turn to astronomy. De la Rue later commissioned Nasmyth to make him a 13-inch speculum which Warren ground and polished himself and used in the construction of a reflecting telescope in 1850, which Warren then used to observe and make drawings of celestial objects.

In 1851 Warren saw a daguerreotype of the moon by G. P. Bond exhibited at the Great Exhibition in London. When de la Rue saw the daguerreotype of the moon he was inspired to attempt to use the wet collodion process to take photographs of the surface of the moon. The wet collodion photographic process had been only recently

devised. It was less expensive to produce than the daguerreotype, and had the added benefit of providing a single glass negative from which multiple positive photographic prints could be generated. By 1854 de la Rue had succeeded in producing well-defined photographic images of the surface of the moon which would not be bettered until the 1960s. The cameras he used to capture these images, which would have been attached to his 13-inch reflecting telescope, are held by the Museum of the History of Science at the University of Oxford. Stereoscopic views de la Rue's lunar photographs were later made commercially available to the general public.

In 1854 de la Rue was approached by Kew Observatory, who had in turn been contacted by John Herschel, who had convinced Kew of the need for daily photographs of the surface of the sun. For this purpose de la Rue invented a telescopic device known as a *photoheliograph* for the purpose of taking photographs of the surface of the sun. The device was built by the noted camera maker, Andrew Ross, to de la Rue's specifications. An eyepiece was used to project an enlarged image onto a wet collodion plate. In this way, on sunny days, over 2700 photographs were taken of the surface of the sun at the observatory at Kew between (March) 1858 and 1872, and then, using the same device, from the Royal Observatory at Greenwich from 1873 until 1882. The images produced were approximately ten centimetres in diameter and clearly showed sunspots and faculae. The original *photoheliograph* is now held by the Science Museum in London.

From 1856 to 1862, de la Ruepublished papers on chemistry in collaboration with Dr Hugo Muller twice President of the Chemical Society.

In 1860 de la Rue took his *photoheliograph* to Rivabellosa, in Spain, to record a total eclipse on the 18 July. Luckily, the sky was clear for the event and of the thirty-five good plates that de la Rue secured, one was a particularly stunning image of 'totality.' This image, when considered in conjunction with another photograph of the eclipse taken by Secchi 400km to the south east of where de la Rue was based, provided conclusive evidence that the corona that becomes visible during a total eclipse belongs to the sun, rather than to the moon. In 1862 de la Rue received the Gold Medal from Royal Astronomical Society and was its President from 1864 to 1866. In 1864 he was awarded the Royal medal from the Royal Society. From 1868 to 1883 he investigated the discharge of electricity through gases by means of a battery of over fourteen thousand silver chloride cells, which he invented for the process.

By 1873 de la Rue's eyesight was failing. He sold his observatory and gifted most of his equipment to the University of Oxford. By then he had discovered over five hundred nebulae. He died in London on the 19 April 1889. A crater on the north-east portion of the near side of the moon measuring 134 metres in diameter has since been named after him.

Brian Liddy

DE MEYER, BARON ADOLPH (1868–1946)

Photographer and writer

Baron Adolph de Meyer, as a photographer, was noted for his magnificent backlighting and elegant soft focus techniques, as a well as for his modernist experiments in his layouts and graphic design in his years at *Harper's Bazar.* (In 1929 the magazine became *Harper's Bazaar.*) The biographical details of de Meyer's life are not totally verified, since de Meyer is said to have fabricated certain details about his existence, often depending on the circumstances, depending upon what social circles he might find himself in. Gregarious and charming, de Meyer was socially adept in various settings.

The chronology listed here is primarily taken from two sources: *"The Collection of Alfred Stieglitz: Fifty Pioneers of Modern Photography"* by Weston Naef and *"De Meyer: A Singular Elegance"* by Anne Ehrenkranz.

In the 1880s, as de Meyer was coming of age, the new artistic currents of Symbolism and Impressionism were to have significant influence on the young de Meyer, just beginning to experiment with a camera. De Meyer's correspondence and friendship with Alfred Stieglitz, editor, photographer, and gallery owner, who was to fight tirelessly for the cause of photography as a Fine Art, was to serve as catalyst and support for de Meyer. The Secessionist exhibits in the United States and Europe were illustrative of amateur photographers' attempts in a variety of countries, to elevate photography from a solely documentary, technical medium to an aesthetic, artistic medium.

De Meyer's purchase, in 1903, of a special Pinkerton-Smith lens, ground sharply in the center, producing a soft focus effect, allowed him to produce dramatic, shadowy effects that evoked mystery and nuance. His photographs such as *"The Shadows in the Wall—Chrysanthemums,"* c. 1906 (Metropolitan Museum of New York, Alfred Stieglitz Collection), or *"Glass and Shadows,"* c.1909 (Baltimore Museum of Art), are works that carry the viewer into a transcendent realm that is ethereal and suggestive.

Stieglitz's decision to include de Meyer in two "Camera Work" issues, as well as to include him in Photo-Secessionist exhibits at his 291 Fifth Avenue, New York City gallery, was important for de Meyer. De Meyer's solo show at the Photo-Secession galleries, opening in February 1909, included four still lifes and three portraits. Issue number 40 of "Camera

Work" was devoted to de Meyer's work with fourteen de Meyer photogravures. Among the images in that issue was an example of one of his haunting and exotic portraits—"*Marchesa Luisa Casati,"* 1912 (Baltimore Art Museum). De Meyer had met Casati in Venice, where she frequently appeared in exotic dress designed by Leon Bakst, and floated down the Grand Canal in a gondola accompanied by exotic creatures and an entourage of servants. In the portrait the viewer meets the Marchesa head on, her chin resting on her bejeweled hands, her large dark eyes, searching, and piercing the viewer's eyes.

The signature that de Meyer used on many of his mats was influenced by the style of the Vienna Secessionists for their graphics. As Stieglitz, de Meyer was also drawn to the autochrome process in 1907, and experimented with color imagery and the subtle nuances the autochrome process allowed.

De Meyer was drawn to the work of the German and Austrian Symbolists, particularly Gustav Klimt, as he attempted in portraits such as the portrait of Marchesa Luisa Casati, his wife Olga, Gertrude Vanderbilt Whitney, Josephine Baker, or Vaslav Nijinsky, to go 'beneath the surface' of an elegant exterior, probing and suggesting a complicated, and sometimes troubled interior.

De Meyer photographed his wife Olga, frequently. A 1900 untitled portrait of her (International Museum of Photography at George Eastman House, Rochester, NY) shows her in profile, with a lacy shawl, set against the soft focus background of a grape arbor. Her hair is swept upward, visually integrated with the grape vine tendrils, linking the young woman with the fruits of nature. Her regal features made Olga a natural model.

In his numerous images of Nijinsky, de Meyer captures not only the likeness and adeptness of Nijinsky's dance techniques, but also transports the viewer into Nijinsky's world of fantasy and grace. (Nijinsky's career ended in 1919 due to insanity, three years after de Meyer's portrait of him as the "*Favorite Slave in Schéhérazade"* appeared in "*Vogue,"* May 15, 1916.)

De Meyer's magazine work included not only his photographs, but also his writing editorials, beginning in 1915 at *"Vogue."* His writings were primarily observations of social life and the fashion world. De Meyer's magazine photographs were noted for their luminosity that highlighted jewelry, exotic fabrics and the sheen of his models' hair. One of his most noted series in "*Vogue"* was a 1918 series entitled the *"Bride's Yearbook."*

De Meyer's move to "*Harper's Bazar"* in 1922, inaugurated his experimentation with a more "modernist look" as his layouts began to employ sharp geometric shapes, sometimes fractured, and layered, suggesting the influence of Cubist or Bauhaus forms.

De Meyer's wife, Olga, died during the end of his time at "*Harper's Bazar*." Her death left de Meyer somewhat adrift circulating around Europe, often accompanied by younger men with whom he was reported to have had a number of affairs. Indeed, when he fled Europe in 1938 to escape the oncoming war, he brought one of these young men, Ernest, to the United States with him to live in Los Angeles. Ernest served first as de Meyer's chauffeur and then was later adopted by de Meyer to validate his presence in the United States.

De Meyer, in his last years in Los Angeles, did a few society portraits, wrote a screenplay, an autobiography, and some romantic novels, none of which were published. In 1940 Mrs. Edward G. Robinson organized an exhibition of his work. But since he had destroyed much of his photographic work, he had to contact Stieglitz to find out what Stieglitz had.

De Meyer died in 1946 of coronary thrombosis, at age seventy-eight. His obituary in the *Los Angeles Times* did not mention his photographic work. His remaining estate was left primarily to his lover, and adopted son, Ernest; in 1980 much of that material was auctioned at Sotheby's in New York.

De Meyer's photographic work did indeed help lift photography to the realm of fine art. From his soft focus pictorial images to his Modernist magazine layouts, de Meyer's beautifully lit portraits, of all levels of society from the few peasants of the European and North African countryside to the affluent upper-class, to his magazine layouts, to his elegant but simple still lifes-these works provide a lasting legacy, illustrating the power of the photographic medium beginning early in the twentieth century, in black and white, and in color.

KATHERINE HOFFMAN

Biography

1868—Born Adolph Meyer to Adele Watson and Adolphus Meyer (later adopted name Meyer-Watson; Baron not used until after 1898).

1870s–1880s—Childhood in Paris and Germany.

1894–1895—Exhibits photographs in London, Paris, Brussels, New York; Listing, Dresden, 8 Park Strasse, as addresss

1896—Moves to London, joins London Camera Club, exhibits work at London Camera Club, Royal Photographic Society; becomes part of London upper class social circles related to the Prince of Wales.

1897—Meets and marries Olga Alberta, reportedly the illegitimate daughter of the Prince of Wales (later Edward VII) and Blanche, Duchess of Caraciolla; Photograph of Olga published in "*The Photographic Times*".

1898–1899—Joins Royal Photographic Society and elected to The Linked Ring

1900—Photographs shown in exhibit organized by F. Holland Day: "New School of American Photogra-

phy"; Travels around the world, visiting Japan, China, India, and Ceylon.

1903—Buys English Pinkerton-Smith lens that produces soft focus effect; Begins correspondence with Alfred Stieglitz while subscribing to "Camera Work"; Visits United States and stays with Gertrude Käsebier in Newport, Rhode Island, where she photographed him.

1907—Exhibited at Stieglitz's Photo-Secession galleries January 25-February 12, New York with work of George Seeley; Learns the autochrome process.

1908—Issue number 24 of *"Camera Work"* by Alfred Stieglitz was devoted entirely to de Meyer's work, including seven photogravures; Joint exhibit with Alum Langdon Coburn at Photo-Club of Paris; Resigns from The Linked Ring.

1909—Becomes fellow of Photo-Secession group in New York; Work exhibited again at Photo-Secession galleries: "The Exhibition of Photographs in Monochrome and Color by Baron Adolf de Meyer of London and Dresden," February 4-22; Meets Alfred Stieglitz in person in Germany.

1910—Included in Albright Art Gallery exhibit, organized by Stieglitz, 25 photographs shown.

1911—Exhibits autochrome at Newark Museum, "Modern Photography" exhibit organized by Max Weber and Clarence White, April.

1912—Photographs Vaslav Nijinsky in "Ballets Russes, *Prélude à l'Après-midi d'un Faune";* Shows photographs in Photo-Secession galleries ; Travels to the United States ; October issue of "*Camera Work*" devoted again to de Meyer—14 photogravures.

1914—Publishes book of photographs of Nijinsky and other members of the Ballet Russe; Flies to New York with wife after they were accused of being German spies; Hired by Condé Nast as "*Vogue's*" first full time photographer—signs contract to work only for "Vogue" and "Vanity Fair" for $100/week.

1916—Photographs Nijinsky as Favorite Slave in *Schéhérazade* in New York; an astrologer suggests he and his wife change names to Gayne (Adolph) and Mhahra (Olga).

1917—Begins designing clothes and doing interior design, new couture line called Gayne House.

1921—Leaves "*Vogue"* to work for Willliam Randolph Hearst's "Harper's Bazar"; By the early 1920s spends more time in Paris.

1922—Signs ten year contract with Hearst Corporation, seen as fashion connoisseur.

c. 1931—Olga de Meyer dies.

1938–1940s—Destroyed much of his own photographic work; returns to the United States; Settles in Hollywood.

1946—Dies January 6th of coronary thrombosis in Los Angeles.

DE PRANGEY, JOSEPH-PHILIBERT GIRAULT (1804–1892)

French historian of architecture and daguerreotypist

Joseph-Philibert was born in Langres, October 21, 1804, to a medium-sized family. His father was a wealthy landowner. After studying at the college of Langres, he graduated in 1826, and continued his studies for a time while attending drawing classes of the School of Langres. I twas here that he met the future painter, Ziegler, who also had an interest in photography. During this time, he expressed an interest in architecture, practical painting and in watercolour. In 1836, he organized the historical and archaeological company of Langres, within which he served many functions.

After voyages to Germany, Italy, and Spain at the beginning of the 1830s, he turned to the study of Moorish art and architecture, in 1834. In 1836, *Monuments arabes et moresques de Cordoue, Séville et Grenade* appeared, and later, two other works were published in 1837 and 1839. The work is remembered for its scholarship as well as for the quality and the precision of the plates, which were based on the drawings of the author.

That same year, Joseph-Philibert exhibited at the Salon a painting "Promenade et tours d'enceinte de l'Alhambra", before publishing in 1841 a new work, *Essai sur l'architecture des Arabes et des Mores en Espagne, en Sicile et en Barbarie*. Girault de Prangey had worked with the daguerreotype since 1841. His first images were of the views from his villa of Courcelles, Langres, and its surroundings Chaumont, Troyes, including Paris, and in particular Notre-Dame and the of Tileries.

In 1842, Girault de Prangey went on a new lengthy trip to study in the Middle East. He left Marseilles, and travelled to Genoa, Rome, and Tivoli, Italy. His two year tour led him to Athens, Greece, Constantinople,

Turkey, Lebanon, Syria, Alep, Baalbek, Damas, Beirut, and Jerusalem near Palestine, and Cairo, Alexandria, Memphis, Thèbes, Louxor, Karnak, Philae, and Assouan in Egypt. Girault de Prangey took daguerreotypes of these places, primarily of monuments and landscapes but also some portraits as well.

In 1844 or 1845, he returned to France with more than one thousand plates and an abundance of written documents. The exceptional quality of these images was due both to his mastery of the chemistry and his compositional skills. Girault de Prangey used lengthened vertical or horizontal formats (panoramic), which were obtained by dividing the full plates (19 × 24 cm). These were used, resulting in strange images and unusual sizes (often 9.5 × 24 cm). Some of them were used for Arab illustrations *Monuments arabes d'Egypte, de Syrie, d'Asie Mineure dessinés de 1842 à 1845*, and *Monuments et paysages de l'Orient*, which were taken respectively in 1846 and 1851.

Girault de Prangey was elected as an Honorary member and Royal corresponding member of the Institute of British Architects in 1846. The beginning of the 1850s seems to have been devoted primarily to his field and his passion of botany, even though he continued to practise photography, and not just the daguerreotype but also stereoscopy during the 1860s. He died on December 7, 1892, in his villa of Tuaires with Courcelles-Valley-in Esnoms (Haute-Marne). In 2001, the Bibliotheque nationale acquired a major collection of nearly one hundred and fifty of his daguerreotypes, illustrating the great breadth of his photographic work. Together with their existing holdings (acquired form a descendent, the Comte de Simony, in 1950), this acquisition made it possible to assess the importance of his work with the daguerreotype, both quantitatively and qualitatively. In addition, in the summer of 2002, sixty-one daguerreotypes of views of Switzerland (Bern, Oberland, and the mountains) were discovered in the Musée Gruérien, in Bulle, Switzerland, which revealed new perspectivies on his work. In addition to significant holdings in private collections, a number of de Pragney's daguerreotypes are also housed in the Gernsheim Collection, University of Texas at Austin. Some of his later stereoscopic views are preserved at the Musée Nicéphore Niépce in Châlon-sur-Saône.

DEANE, JAMES (1801–1858)

In the 1850s Dr James Deane MD of Greenfield, Massachusetts developed a procedure for photographing delicate trace fossils he had first observed in 1835 in sandstone slabs quarried in the Connecticut valley. Deane proposed that these "curious impressions" were the prints of extinct birds (later proved to be dinosaurs footprints). He sold casts and promoted his ideas to natural historians including Reverend Edward Hitchcock (1793–1864) the Professor at Amherst College Massachuisetts. Hitchcock went on to become a major authority in the field known as ichnology; a branch of paleontology concerned with animal and plant fossil traces. Deane later complained Hitchcock had taken his priority. From 1843 he published many articles in scientific journals but no books prior to his premature death in 1858. A an account of his 20 years of research titled *Ichnographs from the sandstone of Connecticut River* including 22 salt prints of his photographs, was published in Boston in 1861.

Deane was not the first to publish photographically illustrated scientific treatises, fossils photographs had been published in Europe and in America; Dr John C. Warren (1778–1856) founder of Harvard Medical school, used a salt print of a fossil slab taken by professional George Silisbee, as a frontispiece in his 1854 book *Remarks on Some Fossil Impressions in the Sandstone Rocks of Connecticut River.* Deane's work was also overshadowed by the massive tome published in 1858 by Hitchcock on the fossil prints. It was illustrated with seven albumen prints by a professional photographer, J. Lovell of Amherst. Supplements of Hitchcock's volume were published in 1863 and 1865, with dramatic irregular shaped photographs.

DEGAS, EDGAR (1834–1917)

French painter, draftsman, pastellist, sculptor, and photographer

In the mid-1890s, after making the majority of his paintings and experimenting with pastel and monotype, Degas briefly focused on photography, producing a small body of fascinating pictures that were never exhibited during his lifetime. Unrecognized as part of his creative output and therefore excluded from the internationally renowned atelier sales of 1918 and 1919, much of Degas's photographic oeuvre may have been dispersed, discarded, or destroyed after his death. The majority of his surviving photographs are figure studies, self-portraits, and portraits of his intimate circle of friends—the poets Stéphane Mallarmé and Emile Verhaeren, the painter Auguste Renoir, Degas's brother René, and the Halévy family—in settings suggestive of realms more psychological than physical.

While its influence on his painting is a much debated topic, Degas was certainly aware of photography from the beginning of his career. He posed for carte-de-visite portraits, studied the stop-action photographs of Eadweard Muybridge in the late 1870s, bought photographic reproductions of other painters' work, and had photographs made of his own canvases. In 1885, a decade before he himself took up the camera, Degas set up an amusing tableau-vivant parody of Ingres's *Apotheosis of Homer* before the camera of a local photographer, Walter Barnes, in the seaside resort of Dieppe.

Not until the summer and fall of 1895, however, did Degas take up photography as part of his own artistic practice, embracing it with passion and enthusiasm. By then, the motifs in his paintings and pastels—dancers, women at their toilette, horses, and rare forays into landscape—were established, as were his untraditional viewpoints, lighting effects, and compositions. One might imagine that Degas would have adopted as his own the accidental cropping, instantaneity, casual compositions, and texture of modern life that were fast becoming common characteristics of amateur photography a half-dozen years after the introduction of the hand-held Kodak camera. In fact, however, the opposite was true. He worked in a far more deliberate fashion, using a larger tripod-mounted camera and 9 × 12 cm gelatin dry-plate negatives, and he carefully posed and lit his subjects for exposures that lasted two to three minutes. Just as he rejected the snapshooter's casual approach to the medium, he also eschewed the accepted standards of professional photographic practice, the decreed fashions of the portrait studio, and the aesthetics of the "Photo-Club" artist. Instead, as had been the case with paint, pastel, and sculpture, his unorthodox technique was driven exclusively by the effect he wished to achieve.

Letters written by Degas in August 1895 from the spa town of Mont-Dore to his photographic supplier and printer in Paris, Guillaume Tasset, reveal the intensity of his engagement with the mechanics and chemistry of the medium. On occasion, he developed and contact-printed his own negatives, and even when relying on Tasset and Tasset's daughter Delphine for photo-finishing and enlarging, Degas specified the cropping, tonality, and contrast of his prints. Despite the technical failures he encountered, Degas tried to make photography conform to his vision, for example asking Tasset for tips that would help him photograph close to nightfall. "Daylight gives me no problem," he declared. "What I want is difficult—the atmosphere of lamps and moonlight." With his eyesight gradually failing and the precious daylight hours reserved for working on pastels and sculptures, Degas preferred to photograph in the evening, when he could impose greater control over the lighting. Throughout the autumn and winter of 1895, Degas dined frequently at the home of his close friends Ludovic and Louise Halévy and their sons Elie and Daniel. Many such evenings concluded with long photographic sessions, vividly described in Daniel Halévy's journal: "Degas raised his voice, became dictatorial, gave orders that a lamp be brought into the little parlor and that anyone who wasn't going to pose should leave….These days, all his friends speak of him with terror. If you invite him for the evening you know what to expect: two hours of military obedience." The photographs made on those remarkable evenings and preserved by the Halévy family and their descendants now constitute the bulk of Degas's known work in the medium.

Degas found a powerful spiritual content in photographs, independent of artistic intention or appreciation, and his activity in the medium seems closely related

to his profound melancholy. In a desperate attempt to bring back before his eyes his dying sister Marguerite, who had moved hastily to Buenos Aires a half-dozen years earlier, he shipped a camera and supplies to her in August 1895 and beseeched her to send photographs of herself, her family, and their home. Her death in October, just two years after that of their brother Achille, deeply affected Degas. Photography provided him with an activity that bound him to a surrogate family—the Halévys—in a situation he could control, especially during the evening hours when his mind would otherwise have dwelled on the death and dispersal of his own family. Degas's most psychologically expressive portraits, in which figures emerge from lugubrious surroundings, are the product of this mournful period.

Among the most intriguing aspects of Degas's work are those few instances in which his strikingly idiosyncratic photographs informed his paintings and pastels of the 1890s. The Getty Museum's *Nude Drying Herself*, an extraordinary image of a nude model leaning on the back of a chaise longue and twisting her body, served as the basis for one of Degas's major late canvases, the Philadelphia Museum's *After the Bath* (1896), and for several smaller studies in pastel and charcoal. Equally without parallel are three glass negatives that show a dancer in various poses; these, too, served as direct models for dozens of drawings and pastels in the late 1890s, and for one of Degas's small statuettes. Their extraordinary appeal lies in their unusual appearance—shades of orange and red, with some portions reading as negative and others as positive—and in their treatment of a central theme of his art with a formal structure, grace, and intimacy that are uniquely his.

Only a single photograph, a portrait of eight- or nine-year-old Claudie Léouzon le Duc, is documented as having been made after Degas's burst of activity in 1895. That this portrait was made in 1901 suggests that he continued to use his camera from time to time, even as his eyesight and enthusiasm waned. Degas's photographic equipment remained in his studio at the time of his death in 1917.

Four photographs by Degas—two landscapes and two negative-print copies of his paintings—were included in the 1936 retrospective exhibition at the Pennsylvania (now Phhiladelphia) Museum of Art, but his work in the medium was otherwise relegated to illustrational purposes until the 1980s, when it was included in two major monographic surveys: "Degas: Form and Space" at the Centre Culturel du Marais, Paris, in 1984, and "Degas" at the Galeries Nationales du Grand Palais, Paris, the National Gallery of Canada, Ottawa, and The Metropolitan Museum of Art, New York, in 1988. Degas's photographs were the subject of a focused exhibition, "Edgar Degas, Photographer," at The Metropolitan Museum of Art, New York, in 1998 and the Bibliothèque nationale de France, Paris, in 1999, accompanied by a catalogue raisonné of the same title.

Major holdings of Degas photographs are found at the Musée d'Orsay, Paris, including many negatives and prints from the Halévy family; and at the Bibliothèque nationale de France, Paris, where Degas's brother René deposited archival material from the painter's studio in 1920. Other public institutions possessing photographs by Degas are: The J. Paul Getty Museum, Los Angeles; The Metropolitan Museum of Art, New York; The Museum of Modern Art, New York; The Fogg Art Museum, Cambridge, Mass.; the Musée départemental Stéphane Mallarmé, Vulaines-sur-Seine; the Bibliothèque littéraire Jacques Doucet, Paris; The Sterling and Francine Clark Art Institute, Williamstown, Mass.; The Achenbach Foundation for Graphic Arts, San Francisco; and George Eastman House, Rochester.

MALCOLM DANIEL

Biography

Hilaire Germain Edgar De Gas was born July 19, 1834, the eldest son of banker Auguste De Gas and his wife Celestine née Musson. He entered the studio of Louis Lamothe, a pupil of Ingres, in 1854; attended the Ecole des Beaux-Arts in 1855–56; and traveled to Italy 1856–59 to draw, paint, and copy the Old Masters. He was a founding member of the Impressionist group in 1874, and exhibited in seven of the eight Impressionist exhibitions during the next dozen years, although his subjects, style, and technique were at odds with the *plein air* painters who constituted the majority of the group. Degas briefly experimented with photography late in his career, principally in the summer and fall of 1895. He died in Paris, September 27, 1917.

DELABORDE, HENRI (1811–1899)

French photographer

Delaborde was born in a wealthy family, which gave him the title of count. He studied human sciences at the university. His parents hoped their son would work as lawyer, but he ended up in the artistic sector.

He met Paul Delaroche in 1829, and spent a lot of time in his studio to study classicism. During the years 1834, 1839n and from 1842 until 1845, he travelled to Italy. He made these trips to enrich his knowledge. Yet, he didn't participate in the Prix de Rome. During these years he studied the paintings of the Renaissance and made drawings and aquarelles. It was his intention to print and to publish all his work. Some unhappy events occurred in his life, so only the first publication from the series was realized.

In 1836, when he was 25 years old, he had his first show in Le Salon with a painting *Agar dans le desert*. In the painting one can see the influence of his master Delaroche but also his admiration and adoration for Ingres and for the Italian Masters of the Renaissance and especially for Raphaël. Delaborde offered this painting to the Musée de Dijon after an exhibition there in 1840.

Delaborde had several distinctions and the French State gave him many commitments. Quite often, he participated at shows in Le Salon. In 1850 he became ill and the physicians forbid him to remain in a standing position.

So he had to quit painting and his friends encouraged him to start a career as an art critic. This was something new in the art world. The work of an art critic was connected with writers. It was a progressive statement as a former artist to work as a writer in the field of art. He did this until the end of his life. His critics still consider his writings as important because of his audacity, firmness and acuteness. He published mostly in *Revue des deux mondes* in which Delacroix also contributed.

Delabordes' passion went out to gravures and that was the basis of a 30 yearlong job as Chief Conservator of the Cabinet des Estampes in the Bibliothèque Nationale in Paris. He was responsible for the purchase of lots of photographic art reproductions as reference material. This position and involvement in the archives gave him also the challenge to work as art historian. Topics he studied were Italian Art and especially from Giotto to Perugino. He became the reference as a historian in the world of gravures and lithography. Even today his work on Marc-Antoine Raimondi is remarkable. He defined art criticism as a judgment that presupposes interpretation, and interpretation presupposes description. The critic needed an understanding—hopefully a defensible and convincing understanding—of what an art work is about before judging it. He explained that criticism was too frequently confused with negative value judgments because of its everyday connotations. The term criticism in the language of aesthetics encompasses much more. He wrote that the purpose of the aesthetics of art history and art in general is to teach how to judge and to appreciate art works and to provide a context for expressing this judgment verbally on the basis of a sound argumentation. So he did. In 1866 his most important writings were published in *Mélanges sur l'art contemporain*. In 1868 he became secretary of the Academy of Science and Art in Paris and kept this position for 24 years. His writings are an enormous source for academic research of the history of art in the 19th century.

In 1898 he ended his activities; he died when he was 88 years old in 1899.

DELACROIX, FERDINAND VICTOR EUGÈNE (1798–1863)

French painter

Ferdinand Victor Eugène Delacroix, the most important French romantic painter, was born in 26 April 1798 at Charenton Saint-Maurice in the Val-de-Marne. His father was minister of Foreign Affairs, under Le Directoire. His early education was at the Lycée Louis Le Grand. In 1815 he began his training with Pierre-Narcisse Guérin in the neoclassical style of Jacques-Louis David, but he was strongly influenced by the more colorful and rich style of the Flemish painter P.P. Rubens and fellow French artist Théodore Géricault. He showed his particular talent already in 1822, with its colored "Dante and virgil crossing the lake which surrounds the infernal city of Dité" which caused a scandal.

In 1824, he was obviously inspired by paintings of John Constable, which were exhibited in Paris. He stayed several months in the United Kingdom, where he came influenced of the poet Lord Byron and once again of the lively and clear colors in the landscapes of Constable. Meanwhile an inheritance of ten thousand pounds gave him the freedom to concentrate on his art. He put impressive historical shows on canvas and in 1831, he exposed on the fair are famous "Freedom runs into the people." In 1832 he traveled to Spain and North Africa, a trip that would influence the subject matter of a great many of his future paintings. Between 1833 and 1847 he had assignments in the Salon du Roi en de libraries of Palais Bourbon and the Palais de Luxembourg.

In the last ten years of his life he realized important decorative ensembles: the central ceiling of Apollon-galery in the Louvre, the Salon de la Paix in City Hall in Paris and the Saint-Agnes Chapelle of the Saint-Sulpice-Church.

From 1851 Delacroix was a member of the group of artists and writers who went on to form the Société héliographique. He used photography to make artists' studies for use in future paintings. He worked with Eugène Durieu who made graphic prints as well as photographs. Delacroix took photographs during his holidays in Dieppe. On 10 January 1857 he was incorporated in the Institut of the Academicians, taking the place of Delaroche. Delacroix triumphed in 1855 at the Exposition Universelle in Paris with showing 42 paintings. In the period 1856–1863 he is accepted as member of the Société française de photographie in which he became very active. He endeavoured to give photography proof of his esteem in attaching himself, among other things, in 1859, to a group of seven artists, members of a committee wanting to include photography in the Paris Salon. They succeed. Delacroix was one of the painters who, with Francis Wey and Le Gray, help the photographers to find their own terminology. Beside his work as painter, Delacroix worked also as an illustrator of books of William Shakespeare, the Scottish writer Sir Walter Scott and the German writer Goethe.

Delacroix has had much influence on others, especially by his expressive use of color. He died on 13 August 1863 in Paris.

DELAGRANGE, BARON ALEXIS (1825–1917)

French photographer and landowner

Alexis Delagrange was born into an ancient and noble family in Douai on 4 April 1825. His father, Baron Prosper-Amauri-Louis, was a colonel in the army and an officer of the Legion of Honor. Alexis attended the Ecole Polytechnique in Paris and upon graduation served in the naval artillery from 1844 to 1847.

In 1849, equipped with a camera, he departed for a two-year trip to India accompanied by his older cousin, the statesman Felix Lambrecht (1819–1871). Theirs was an unusual itinerary since, unlike Egypt or Palestine, India was not part of the "Grand Tour" undertaken by wealthy young Frenchmen of the time. In addition, they traveled primarily in the northern interior part of the country, stopping at only one of the few, small French colonies still in existence along the coast. Their trip is also unusual in that travel photography was in its infancy and Delagrange was among its first European practitioners in India, anticipating the British government-funded photographic surveys beginning the mid-1850s along with the inauguration of the field of Indian architectural history.

Despite the pioneering nature of his work Delagrange

envisioned his trip as being solely for his own amusement. In this he differed radically from his ambitious contemporary Maxime Du Camp whose travels in Egypt and the Near East during the same period resulted in the publication of the first major travel album of its kind. Delagrange and Lambrecht did indeed amuse themselves. According to the latter's *Souvenirs* (1873), the two young men socialized with the British residents, hiked in the Himalayas for several months, and took great pleasure in hunting tigers and elephants in other regions particularly renowned for such sport. No photographs by Delagrange exist to document these aspects of their trip. Perhaps due to unfavorable weather conditions and technical limitations, there is not a single landscape of the Himalayas such as those by Samuel Bourne taken in the 1860s. Less explicable is the absence of any pictures of hunters posed around their dead prey, a theme that became a staple for British 19th-century tourists.

Returning to France in 1851 Delagrange assembled two leather-bound photographic albums of Indian architecture both titled "Photographies de l'Inde Anglais" [Photographs of British India]. One, dedicated to the statesman Adolphe Thiers, contains 61 albumen prints, each circa 17 by 21 cm, accompanied by Delagrange's extensive handwritten notations. The other is captioned but without a dedication or annotations. It contains 48 albumen prints, all but two identical to those in the Thiers album. Five of these prints, two co-signed by Lambrecht, appeared in an album assembled by Victor Regnault in 1851. Another five were included in Blanquart-Evrard's first publication, *L'Album photographique de l'artist et de l'amateur* [The Photographic Album of the Artist and the Amateur] (1851).

From the existing prints that are known to be by Delagrange it would appear that he took only 63 photographs during his two-year trip, although it is likely that he exposed a few negatives during his short stay in Egypt before arriving in India, even if only as a demonstration for Du Camp to whom he taught the wet waxed paper negative process by Blanquart-Evrard that they both used throughout their travels. Also missing are any photographs that Delagrange may have taken during his first four months in India and the last seven months of his trip in Cylon, Java, Malaysia, and Singapore.

There is no indication that Delagrange assembled other albums, or exhibited his pictures, or took up the camera again after 1851. For the remainder of his life he turned most of his attention to the administration of his considerable fortune. In 1870, however, dismayed by the uprisings of the common people during the Commune, he entered into politics, eventually becoming a right-wing member of the senate. He left public service in 1881, retiring to his chateau at Sebourg where he died 11 February 1917.

All of Delagrange's known photographs depict architectural monuments and urban views, the one exception being a portrait of an Indian servant that opens the Thiers album. Within this circumscribed range Delagrange's choices were eclectic. Not surprisingly, he took pictures of some of the most famous monuments (three of the Grand Mosque at Delhi and six of the Taj Mahal) but he also photographed lesser known tombs and temples, including a general view of a Muslim cemetery. Along with pictures of famous palaces are those of private residences, such as the home of an Indian banker and a British neo-classical bungalow.

Delagrange's admiration for Indian architecture is clearly expressed in words, shining through the dry technical data that characterizes his running commentary on the photographs. He frequently noted the decaying conditions of the monuments he depicted and his criticisms of their materials and faulty construction indicate his schooling as an engineer, yet he avoided a display of these elements of disintegration in the actual photographs. This selectivity, along with his straightforward, centered compositions produces an overall impression of grandeur and stability. In this regard Delagrange differs from Linnaeus Tripe, for example, whose focus in the mid-1850s was primarily on princely palaces, seeing them, in both image and text, as the ruins of a former political order. In general, Delagrange's photographic choices are indicative of those of a tourist without a specific agenda, imperial or otherwise.

Delagrange's photographic oeuvre was rarely noted publicly by his contemporaries, and then only summarily, receiving little attention until the turn of the 21st century when the unusual nature of his accomplishment began to be recognized. One album entered into the public domain in the collection of the Canadian Center for Architecture in Montreal. This acquisition and its subsequent exhibition stimulated an interest in Delagrange prompting a closer look at his annotated album in the Bibliothèque Thiers in Paris and at the 36 salted paper prints at the Musée d'Orsay, also in Paris. In addition to these institutional holdings there are a scattering of Delagrange prints in private collections.

JULIA BALLERINI

Biography

Alexis Delagrange was born into a noble family in Douai on 4 April 1825. In 1849, equipped with a camera, he departed for a two-year trip to India, Cylon, Java, Malaysia, and Singapore accompanied by his older cousin, the statesman Felix Lambrecht (1819-1871). Returning to France in 1851 he assembled two photographic albums of Indian architecture, one whose intended recipient is unknown and the other dedicated to the statesman Adolphe Thiers. Although he was one of the first Europeans to photograph Indian monuments,

there is no indication that he produced other albums, exhibited his pictures, or took up the camera again after 1851. A few of his prints appear in an album assembled by Victor Regnault and in another published by Blanquart-Evrard. Apart from a brief political career in the 1870s, Delagrange devoted most of his life to managing his considerable fortune. He died in his chateau at Sebourg 11 February 1917.

DELAMOTTE, PHILIP HENRY (1820–1889)

British photographer, author, and teacher

One photographic commission dominates the career of Philip Henry Delamotte—the photography of the dismantling of the Crystal Palace in Hyde Park after the Great Exhibition of 1851, and its rebuilding on a new site at Sydenham, Kent, England.

The decision to engage a photographer to record the progress of the project initiated one of the first major industrial photography commissions in Britain. The resulting body of work is tangible evidence of the heightening of photography's profile immediately following the Great Exhibition itself, and certainly since the original construction of Joseph Paxton's masterpiece in Hyde Park. While there was little enthusiasm for photography during the original construction, the rebuilding, opening, and contents of the Sydenham Crystal Palace were all covered by a number of photographers, and commercially exploited by Negretti and Zambra and others.

By the time of the Crystal Palace commission, Delamotte was already an accomplished photographer, having been introduced to the calotype process in the late 1840s. By the early 1850s he was advertising his services both as a photographic printer and as a portrait photographer, claiming in 1853 to have made arrangements with William Henry Fox Talbot—described as "the Patentee"—to practise Scott Archer's newly discovered wet collodion process. Many photographers at that time agreed to acknowledge Talbot's claimed patent interests in all negative/positive processes rather than risk litigation, until a later court case clarified the matter.

Through both his early contact with the calotype process and his associations with the art world, he became acquainted with Roger Fenton, Francis Bedford and photographer/publisher Joseph Cundall, and through a shared interest in antiquity, he became a friend of Dr Hugh Welch Diamond. Many of these early associations and friendships would result in collaborations later in his career.

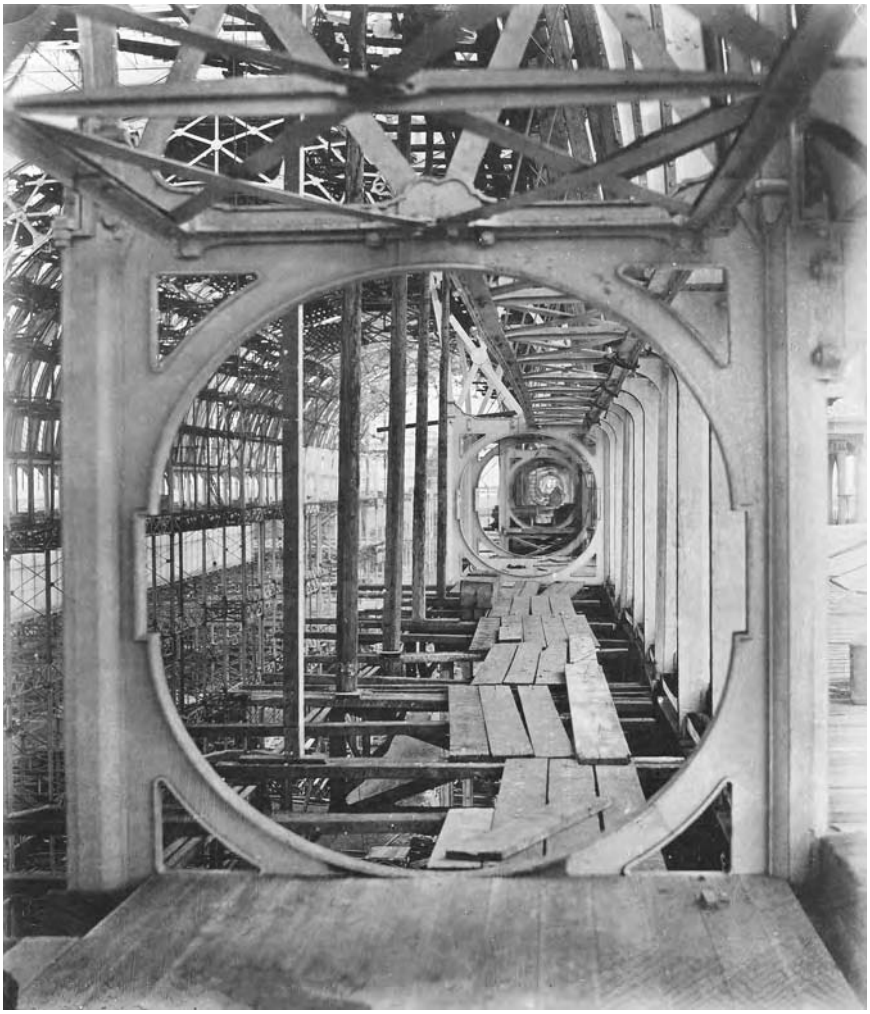
Delamotte was the son of the landscape painter and lithographer William De La Motte, and during his career adopted two alternative styles for his name. As an artist and an engraver, in his first two publications *On the Various Applications of Anastatic Printing and Papyrography* (1849) and *Choice Examples of Art Workmanship Selected from the Exhibition of Ancient and Mediaeval Art at the Society of Arts* (1853) he styled himself Philip DelaMotte. However, for the first edition of his book *The Practice of Photography; a Manual for Students and Amateurs*, also published in 1853, he used the style Delamotte, under which name all his subsequent work seems to have been published. That volume drew on his friendships with fellow photographers, including details of processes used by Talbot, le Gray, Cundall, Diamond and others.

The earliest recorded account of the publication of any of his photographs comes in an 1852 review in *The Atheneum* of two of his images in parts I and II of *The Photographic Album*.

That he was already an accomplished photographer and recognised authority on photographic processes is evidenced by the 1853 publication of *The Practice of Photography*—which would subsequently run to three editions. Curiously, that volume proclaims that it contains "a calotype portrait taken by the collodion process"!

When the British Museum was seeking in 1853 to establish a "photographic room"—which would later lead to the appointment of Roger Fenton as Museum Photographer—it was to Delamotte that the trustees initially turned for advice on the construction and equipping of the facility.

The publication of *Photographic Views of the Progress of the Crystal Palace, Sydenham* in London in 1855 was Delamotte's third publication on the subject, but his first to be illustrated with original photographs rather than his drawings, or engravings derived from his photographs. In all 160 images were published in the



Delamotte, Philip Henry. The Upper Gallery.

two volumes, and as was typical of such publications at the time, there were alternative versions of several of the images. This led to differences between one published set and another, depending on which collodion negatives had been used to make the prints. The importance of the albums in raising architectural photography well above straightforward representation has subsequently been recognised, and the legacy of Delamotte's achievement can be traced through the work of many other photographers. His images, celebrating the interaction of light with the dynamic geometry of the Palace's construction, stand as an eloquent tribute both to Paxton's original concept, and to Victorian engineering.

Delamotte was one of a number of photographers who became increasing concerned about the possibility of impermanence in their photography. Along with Roger Fenton and others, he was a member of a committee formed in 1855 to investigate the problem. After some deliberations, the "First Report of the Committee Appointed to take into Consideration the Question of the Fading of Positive Photographic Pictures Upon Paper" appeared in the *Journal of the Photographic Society* and was reprinted in the *Photographic Fine Art Journal* in January 1856. Given the proven durability of the work of both Fenton and Delamotte in the 150 years which have followed, their concerns were perhaps overstated. Delamotte's 1856 booklet *The Oxymel Process in Photography* included a chapter of advice on the preservation of photographic prints, drawn directly from this work.

In 1857 he became the founder editor of *The Sunbeam*, a photographic magazine published by Chapman and Hall, each issue containing four original photographic prints. The first part contained images by Delamotte himself, John Dillwyn Llewellyn, Sir Jocelyn Coghill, and Francis Bedford, and was well reviewed in *The Atheneum* in February 1857. Six issues were published, followed by a bound volume in 1859, entitled *The Sunbeam: A Book of Photographs from Nature,* containing work by Bedford, Cundall, Delamotte, F.R. Pickersgill and others.

In 1855, and alongside his growing workload as a photographer, Delamotte accepted the post of Professor of Drawing at King's College London, a post he held

for over 30 years. In addition, he offered his services as an occasional instructor at the Photographic Institution in New Bond Street.

He continued to publish extensively, working sometimes alone, and sometimes with Cundall. Together they illustrated *A Photographic Tour Among the Abbeys of Yorkshire* published by Bell and Dalby in London in 1856.

The majority of his publications after 1855, however, were concerned with drawing, glass painting, engraving and with illustrating art history.

Many of his early photographically illustrated books are held in the British Library.

JOHN HANNAVY

Biography

Philip Henry Delamotte was born in London in 1820, the son of the painter and William de la Motte, then the drawing master at the military academy at Sandhurst. He also studied art and was an accomplished and published lithographer by the age of 30. Taking up photography in the late 1840s, he experimented first with the calotype and waxed paper processes before turning to wet collodion for his photography of the Crystal Palace. His manual *The Practice of Photography* was published in 1853, and a pamphlet *The Oxymel Process in Photography* followed three years later. He was Professor of Drawing and Perspective at King's College, and King's College School, London, a post he held from 1855 until 1887. His book *The Art of Sketching from Nature* was published by Bell and Dalby in 1871. Although he continued to exhibit photographs, after 1859 his publications were all concerned with drawing except the two-volume *Holland House* by Princess Marie Lichtenstein in 1874, for the special edition of which he produced 37 Woodburytypes. Delamotte died in 1889.

DELAROCHE, HIPPOLYTE (PAUL) (1797–1856)

French painter

Delaroche was born in Paris on 17 July 1797, the second son of parents who were well connected in artistic circles. His father Grégoire-Hippolyte was a picture-dealer and collector who held an official position at the Mont de Piété, the state pawnbroking institution. Through his mother, Marie-Cathérine Bégat, he was related to Adrien-Jacques Joly, the curator of the Print department of the Bibliothèque Nationale. Both he and his elder brother, Jules-Hippolyte (1795–1849) were directed to an artistic career by their father. However the privilege of training in the more prestigious genre of history painting went to Jules, who entered the studio of Antoine-Jean Gros in 1816. Paul (so called from his childhood onwards) was placed in the studio of Louis Watelet to train as a landscape painter, and classed fifth in the first Prix de Rome for historical landscape in 1818. It soon appeared that he was more talented than his brother, but not in the domain of landscape. He transferred to Gros's studio, and rapidly made his mark among a group of peers which included the English painter Richard Parkes Bonington and the pioneering lithographer, Nicolas-Toussaint Charlet.

Delaroche's first showing at the Paris Salon was in 1822, where he gained the approval of the dying Théodore Géricault for his *Joas sauvé*. He achieved wide-spread recognition for his *Joan of Arc* at the 1824 Salon, with Stendhal predicting that he would soon make his reputation. A visit to England in 1827 helped him to improve his knowledge of the visual sources for British history, which was in vogue in Paris at the time, as a result of the popularity of Walter Scott's novels. A direct outcome was his *Death of Elizabeth* (1828), showing the dying English Queen attended by her courtiers. After the elder branch of the Bourbons had been expelled in the July Revolution of 1830, Delaroche distinguished himself with two major examples of historical genre for the 1831 Salon. His *Princes in the Tower* drew on English illustrations to Shakespeare's *Richard III*, and his *Cromwell and Charles I* used Chateaubriand's account of the English Civil war to present a pictorial meditation on the morality of revolutions. The critic Horace de Viel-Castel wrote of visitors pausing 'for whole hours' before the spectacle of the decapitated king.

Delaroche's prominence among the Romantic generation of French artists received official recognition when he was elected to the Académie des Beaux-Arts in 1832, at the ununusually early age of 35. In 1833, he accepted the post of Professor at the Ecole des Beaux-Arts, and began to direct one of the most successful studios in Paris. Together with Horace Vernet, who

became his father-in-law, he represented the liberal vanguard within the Academy, pressing unsuccessfully for a reform of the jury system which was preventing talented younger artists from showing at the Salon. His most substantial work of the decade, completed in 1841, was the huge semi-circular *Hémicycle des Beaux-Arts*, erected in the official amphitheatre of the school, which offered a colourful pageant of 'artists of all ages' from the Ancient Greeks to Nicolas Poussin. The format of this work, which spread his reputation throughout Europe, compares with the spectacular panoramas then popular in Paris.

Delaroche's name has entered the mythology, if not the history, of early photography as a result of an apocryphal remark, supposedly made on seeing his first daguerreotype: 'From this day painting is dead!' ('La peinture est morte, à dater de ce jour!) No earlier source for this anecdote can be found than the tendentious *Les Merveilles de la photographie*, first published by Gaston Tissandier in 1873. It is, however, certain that Delaroche was asked by François Arago to provide a brief report on the artistic potentiality of Daguerre's invention for the decisive meeting of the Academies of Sciences and Fine Arts on 19 August 1839. Arago quoted from this report at the meeting, and Delaroche's manuscript, which contains significant additional material, is preserved in the Cromer Collection (George Eastman House). The notion that Delaroche chose this occasion to make the attributed remark (repeated by Helmut Gernsheim and others) is inherently improbable. What cannot be challenged is Delaroche's affirmation, quoted by Arago, that the daguerreotype would aid the education of painters by providing unequalled studies of the 'distribution of light.'

In effect Delaroche was familiar with Daguerre's work long before August 1839. In a speech to the Academy of Sciences on 7 January 1839, the astronomer Jean-Baptiste Biot spoke of visiting Daguerre's 'new gallery of light drawings (*dessins de lumière*)' in company with Delaroche.In a subsequent letter to Willaim Henry Fox Talbot, Biot revealed that Horace Vernet and Louis Hersent, then Vice-President of the Academy of Fine Arts, were also present. A painting by Prosper Lafaye (*Conférence dans le salon de M. Irisson,* Musée Carnavalet) portrays both Delaroche and Vernet giving a 'lecture on the discovery of photography' in a private house in Paris. This suggests that, quite early in 1839, Delaroche and his father-in-law were playing a role in facilitating the understanding of the new medium.

Unlike Horace Vernet, Delaroche seems not to have practised photography, nor indeed to have been photographed. Yet it is no accident that several major French photographers of the next generation, such as Gustave Le Gray and Henri Le Secq, were originally his students. Delaroche was identified more than any other painter with the public announcement of the invention of the daguerreotype, and the attempt to justify its utility for artists. It can also be held that he came to understand some of the wider historical and cultural implications of photography. Several paintings produced shortly before his death in 1856 indicate close study of light effects produced from a small aperture in a darkened chamber, and one shows Saint Veronica prostrate before the imprint of Christ's face, which radiates light.

Delaroche's privileged connection with photography did not end with his death. As a result of the initiative of his print editor, Adolphe Goupil, the English-born photographer Robert Jefferson Bingham was entrusted with the task of recording his life's work, much of which was on view at a posthumous exhibition in 1857. The *Oeuvre de Paul Delaroche*, published in 1858, was the first *catalogue raisonnné* to be fully illustrated by photographs.

STEPHEN BANN

Biography

Paul Delaroche was born on 17 July 1797 in Paris. Brought up by parents who were closely engaged in the world of the visual arts, he nurtured an early ambition to be a painter, and studied first of all with the landscape painter Louis Watelet and secondly with the history painter, Antoine Gros. His exhibition of paintings at the Paris Salon, between 1822 to 1834, did much to popularise the new category of 'historical genre,' in which the subject matter was taken from medieval and early modern history. He was elected to the Académie des Beaux-Arts in 1832, and became Professor at the Ecole des Beaux-Arts in 1833. Among the pupils in his studio, which was open until 1843, were several major French photographers of the next generation. In 1839, he provided a favourable report on the relevance of the daguerreotype to artists, which was utilised by Louis Arago. After the death of his wife in 1845, he retired from public life, and spent much of his time in his studio in Nice, working on paintings with religious themes. He died in Paris on 4 November 1856.

DELESSERT, BENJAMIN FRANÇOIS MARIE (1817–1868) AND ALEXANDRE HENRI EDOUARD (1828–1898)

French photographers, writers, and businessmen

Two cousins, members of an influential family of bankers, politicians, civil servants, and philanthropists, Benjamin and Edouard Delessert studied photography with Gustave Le Gray. Both exhibited at the *Exposition universelle* in 1855.

In 1853–1854, Goupil and Colnaghi co-published Benjamin's *Notice sur la vie de Marc Antoine Raimondi* (67 salt paper prints from paper negatives, mounted on 59 plates). This was among the first significant uses of photography for art history. Delessert selected the best Raimondi prints he could find in public and private collections, photographed them, and contributed an essay. His scientific ambition manifested itself in the size of the photographs, which replicated the size of the originals. Goupil reprinted copies of the photographs in 1864. Benjamin was a founding member of the *Société française de photographie* (SFP).

A nephew of Léon de Laborde and a friend of Olympe Aguado (with whom he made several portraits), Edouard Delessert traveled to Sardinia in 1854 and there photographed architectures and landscapes. Goupil published 40 of these pictures. Involved in the beginnings of the SFP, Edouard left quickly in disagreement but re-enlisted in 1859. In 1861 and 1863, he exhibited at the *Société* the dramatic enlargements he obtained with a device of his own called a *porte-lumière*.

Pierre-Lin Renié

DEMACHY, (LEON) ROBERT (1859–1936)

French photographer

(Leon) Robert Demachy was active from the late 1870s until 1914; he was one of the best known and most influential photographers of those times. He was one of the most important European pictorialist photographers known by the use of new techniques and for his artistic skills.

Robert Demachy was born in Saint-German en Laye the 7th. July 1859, he was the youngest child of a wealthy bankers family, and, like many amateur photographer of its time, was able to lead his life and art without any major financial problems. His childhood was marked by his family's stay in Brussels, during the Franco-Prussian war. This fact allowed Demachy to concentrate on his art, as he never showed ability to the family's banking activity.

His friends were to be found among the artists, the bohemian Paris cafes were his favourite spot.

In 1893 he married Julia Adelia Delano, an American he had met at the 1889 Universal Exhibition; it was not a happy marriage, as both were too independent. Robert Demachy hated the high society life that Julia Adelia valued. The couple divorced in 1909.

He died the December 29th, 1936, and was buried in the Père Lachaise cemetery, like many of the most illustrious Frenchman.

Maybe he got the passion for photography by influence of his painter friends, all we know is that he started photographing, using the wet collodiom process, during the 1870s. However, it was in the early 1880s that his work started being known and recognized.

In 1882 he was elected to the *Societè francaise de photographie*, he was also a member of Royal Photographic Society, Linked Ring and Photo Secession. Soon he became the undisputed leader of French, and even of European, pictorialist photography.

At the time there was a strong opposition between pictorialist and naturalist photography and he attacked naturalist photography's main ideologist, Peter Henry Emerson, accusing him of artistic contradictions and falsities.

His English language skills helped him to a series of contribution to the British and American photographic press including the *British Journal of Photography* and *Camera Work*, in addition to many writings he published in French magazines. In an article published in 1898 in the *Paris Photo-Club* magazine he asks whether photography can be considered as an art. A rhetorical question, of course, as he had the answer, and in words, as well as in pictures he tried to prove photography was, indeed an art form. In a *Camera Notes* 1899 article he would question the difference between a good photograph and an artistic photograph. As for other pictorialist photographers the print was the key to artistic photography.

His exhibited work had great success, since the Exposition Universelle, Paris 1889, where he won a bronze medal. He was to participate in several exhibitions, not only in France, but also in Belgium, Germany, Great Britain, Italy, Switzerland and United States, where he was a participant in the Photo Secession exhibition in Philadelphia, and at the New York Little Galleries Exhibition in 1906. He was one of the few photographers of his time to have their own personal exhibitions, some were held in his personal studio, but others crossed the channel and were held in the Royal Photographic Society (1901, 1904, 1907).

His technique, the use of new processes and his themes, along with his artist mastery were the keys to his success. The search for new processes was one of the pictorialists' main reasons of being, they tried to produce photographs closer to other art forms, and the "conventional" photographic processes were unfit to this role. Pictorialists were searching for the individual-

ity not possible with mass produced materials entering photography since the 1880s. They were part of late 19th Century individualist reaction to industrial society. Demachy one of the first to use gum printing, he was also a pioneer of bromoil printing. He was not only a user of these processes, but one of their most prominent advocates, writing about their practice. Gum printing allowed the photographer to have a hand in manipulation and in the choice of textures, colours, and papers closer to what was possible to painters or etchers. These printing processes were no more than a means to his idea of an interpretative photography, the only one where the photographer could put his creativity to work, thus creating an art piece, not only a mere reproduction of a scene, they were in the heart of pictorialist photography theory and practice. The use of these processes led to the critics and public acclaim of Demachy's work, however there were also negative reactions. Naturalist photographer P. H. Emerson was a critical voice, considering Demachy's work theatrical and ill composed. Others had a less critical point of view, but regretted the overstatement.

He was an adept user of the telephoto lens, and also wrote about it. This lens would allow him to get a smaller depth of field, desirable to his interpretative photograph.

The female nude and the landscape, especially when including water, account for some of his best known photographs. Many photographers, up to the late 20th century, tried to imitate him, even in his fondness for photographing very young girls. Some of the work inspired by Demachy had, even during his time, considerable success, however in most instances the imitation often lacked Demachy´s artistic quality. Using children and prepubescent girls in his nude photographs was not an attempt to make them erotic, but was instead an attempt to lower his erotic intensity, and the use of unconventional forms of printing like gum and bromoil, increased this effect. He made other photographs with oriental themes, urban scenes, especially when showing the kind of picturesque quality found in northern France, or the atmospheric effects prized by pictorialists. He was also an adept of speed as theme for photography, one of the most important fads of early 1900's photos. Speed was a major concern for all society, and for photographer was a means of showing great skills. Less known are his folk costume pictures.

Fog in the river, the raging sea, little dressed girls in a pseudo oriental scene are among the most popular 1900 pictures, they were made over and over again, but their popularity owes mostly to Robert Demachy who made them first, and in an such an outstanding way, that inspired admirers and imitators for over half a century.

With his fellow Frenchman Constant Puyo and American Alfred Steiglitz he is considered one of the great masters of pictorialist photography, however, unlike Stieglitz he did not create an organized movement.

In 1914 the First World War was beginning; the artistic movements, born in the late 19th century, were coming to an end. Photography was to go through major changes: the Linked Ring was dissolved in 1910; the Photo-Secession would survive a few years more, but Camera-Work would be the first magazine to show new, opposed to pictorialism, approaches to photography.

Robert Demachy stopped photographing in 1914; it is not possible to say whether he was aware of the changes going on photography. He reportedly never touched a camera again. In 1931 his friend Puyo organized a retrospective exhibition of his work. He gave part of his collection, which included work by himself and other photographers, to the Royal Photographic Society, another part to the Paris Photo-Club.

DEMENŸ, GEORGES EMILE JOSEPH (1850–1917)

French born inventor, chronophotographer, film maker, and physical education instructor

Born at Douai, France, 11 June 1850, Georges Demenÿ's mother's name was Adéle (née de Vignron); his father Philippe Joseph Demenÿ was a musician. Georges studied at Douai and Lille, then in Paris with physiologist Etienne-Jules Marey. From 1882 Demenÿ worked as Marey's assistant at the Station Physiologique, photographing sequences of animal and human movement, from 1888 on strips of paper and later on celluloid. In 1892 Demeny patented the Phonoscope, for direct viewing or projection of a short sequence of such photographs mounted around a disc.

Demenÿ broke away from Marey, in order to commercialise his invention. He designed the important 'beater movement' camera, and produced charming

Phonoscope scenes, including Danseuse de French-Cancan, Premiere pas de bébé, and Passage du train.

Following a contract with Leon Gaumont, the Phonoscope disc viewer / projector (renamed Bioscope) was offered for sale late 1895, and early 1896 the Biographe camera using 60mm unperforated film. The disc machine gave only very brief projections, and failed commercially, being immediately superseded by film projectors. However, Gaumont successfully exploited the 'beater' mechanism in later machines, and Demenÿ returned to his first interest, gymnastics instruction. He died in Paris on 26 December 1917.

STEPHEN HERBERT

DENIER, HENRY (ANDREJ IVANOVITCH) (1820–1892)

Professional photographer

A. Denier was born in Mahilyow in 1820 in the family of Swiss settlers. In 1849 he graduated from the St. Petersburg Academy of Arts.

In 1851 Denier opened the "Daguerreotype studio of the artist Denier" in which some of the future well-known artists such as I. Kramskoj worked as retouchers. Denier was a famous master of the photographic portrait. In 1859 Denier's works were shown in a session at the Paris Academy of Science. Denier was a member of the Société française de photographie. After the exhibition of the St. Petersburg Academy of Arts in 1860 Denier was given a title of the "Photographer of the Imperial Academy of Arts."

In 1865 the "Album of the photographic portraits of the famous personalities of Russia" was published. As a result 13 publications were made, with each album containing 12 mounted cartes-de-visite. Apart from the photographs of celebrities each album contained one cartes-de-visite illustrating a peasant. Denier participated and won prizes in many Russian and foreign exhibitions—for example in ones which took place in Berlin (1865), London (1862, 1871, 1872), Moscow (1872) and others.

Denier died in St. Petersburg in 1892.

ALEXEI LOGINOV

DENMARK

A few days before the release of Daguerre's process in Paris, the Danish consul general in Paris, the archaeologist Christian Tuxen Falbe, went to see the inventor and get a personal introduction to his work. His quest was not on his own behalf. The consul general came as a representative for the Danish crown prince Christian Frederik, the later King Christian VIII, and in a sense for the people of Denmark. In a letter to the crown prince, Falbe described the visit and the works Daguerre presented to him in the few hours he spent in his studio: "They look like those copperplates that used to be known as 'the black art.' One must use a magnifying glass to see—with the highest degree of admiration—the detail in every paving stone, read every letter in the inscriptions of the street signs, and contemplate even the finest irregularities that are revealed in the joints of plaster figures." The process would, he gathered, become of great interest to both scientists and artists in Denmark.

Over the following couple of decades, Tuxen Falbes premonition proved true. The photographic medium spread to more or less all circles of society with a speed that mirrored the rest of Europe and America. Naturally, the spread of the different processes, photographic formats and trends in some instances came to the Scandinavian countries with a slight delay. The vitrotype and the pannotype came to Denmark around 1855, and negative based paper prints, used from the beginning of the 1850s, were made on salt paper until around 1857, when salt was replaced by albumen. Collodion emulsion chloride paper came to be used alongside albumen paper from 1865, both lasting into the 1890s, and from 1880 gelatin emulsion paper and similar types competed with the two. Cartes-de-visite were introduced in Denmark in 1860 by the photographer Rudolph Striegler, and the cardomania throve until 1865. In 1866, the somewhat larger cabinet cards replaced the cartes-de-visite, and in the 1880s these saw a revival in the family photo albums with photographs of stars from the theatre. Stereoscope photographs became very popular around 1850, and their popularity lasted into the 20th century. The postcard format was introduced in the last part of the 1880s, and unlike the other card formats, the postcard came to stay.

By the 1860s, people of all classes could afford having their portraits taken by one of the growing number of studio photographers all over Denmark. Having one's portrait taken was a fashionable type of leisure, and a signal to the community that one's priorities were in the right order. Placing oneself and one's family on the photographic map signified an interest in family chronology, social and industrial progress, and society in general. The standardized portraits were placed in albums, hung on walls and distributed amongst friends and family. The Danish Royal family, with King Christian IX in the front and some very photographic daughters behind him, helped promote the image of visually reproducible nuclear family happiness. In pictures of the royal family, the public saw a relaxed atmosphere with family people they could relate to. Cartes-de-visite, cabinet cards and postcards with the royal family were cherished memorabilia in the Danish homes, and comparable to the mass produced celebrity posters that are popular today, they projected an image of obtainable idealism that inspired

the growing middle class to follow in their footsteps. The distinguished fairy tale writer Hans Christian Andersen, albeit not a family man, was also among the most enthusiastic clients in the photographers' studios right from the beginning. With his more than 250 portraits he was the most photographed writer at his time.

It was, of course, not just idyllic pictures of happy families that were produced in the photographers' studios during the 19th century. Deathbed portraiture, although not as widespread in Denmark as in America, England or France, was part of the visual memento mori culture, especially during the last decade of the 19th century and a couple of decades into the 20th. The custom was not standardized, and yet the photographs that remain reveal visual aspirations that evoke the classical tradition from deathbed painting. Social and documentary photography, on the other hand, did not break through until the beginning of the 20th century. The most celebrated photographer in this domain was the reporter Jacob A. Riis, who had immigrated to America and photographed the poor people of New York, reproduced in *How the Other Half Lives* in 1890. But in Denmark, the closest thing that came to social documentary photography were the photographs taken of the slum quarters in Copenhagen before the redevelopment at the turn of the century by people like Frits Bentzen, and the photographs Peter Elfelt, photographer to the king, took of social outcasts in the Copenhagen street life. These, however, were mass produced and sold as commercial postcards, and many of the unfortunates were brought into the studio and photographed away from their surroundings.

The question of whether or not photography should be acknowledged as a creative genre with affiliations to art was not asked with the same energy and enthusiasm as in for example England. The discussion of its status came up on a regular basis throughout the nineteenth century, but the arguments were less heated and the authorities that rejected its creative potential rarely contradicted. It was not until the latter part of the 20th century that photography was appreciated as an art form. As an example of the moral double standards of artists towards the closing of the 19th century, painters such as the Skagen group, counting Michael Ancher, Anna Ancher and P.S. Krøyer, frequently used photography as a means to create quick sketches from which to paint their impressionistically inspired views of the town of Skagen, its people and the sea. But the photographs, although highly aesthetic and well composed works in themselves, were never recognized as independent accomplishments. Technical painterly skills defined the artist, and photography was merely a useful tool in the creative process.

DEVELOPING

Processes (general)

Broadly considered, developing refers to making a latent image visible by means of a chemical agent, following the exposure of a light-sensitive surface to light. Given this definition, the use of a solvent—such as lavender oil in the original heliographic process, or water in the cyanotype process—would qualify as developing. Similarly, the use of mercury vapors to bring out the image in the daguerreotype process would also qualify as developing.

To prevent such examples from multiplying in a bewildering manner, it is necessary to redefine developing in a narrower sense: a controlled chemical reaction in which ions associated with an exposed, light-sensitive silver compound (silver chloride, iodide, bromide, or nitrate) respond to the introduction of a solution containing a deoxidizing reagent by causing metallic silver to precipitate in the form of a visible image.

From this narrower definition, two kinds of developing may be distinguished: chemical development and physical development. Chemical development refers to the direct reduction of exposed silver halide forming the latent image to silver by a reagent in the developing solution. Physical development—as applied to nineteenth century photography—refers to an indirect reduction

of silver nitrate to silver by a reagent in the developing solution; the silver is then deposited on the latent image serving as a framework for image formation.

Physical development was the predominant manner of developing in the early days of photography—a period spanning 1839–1862. During this time, it was mostly used for negative-making purposes, although a few photographers in the 1850s, like Louis-Désiré Blanc-quart-Évrard and Thomas Sutton, also used it to make positive prints from negatives. Significant photographic processes that utilized physical development during the period included the calotype process (beginning 1839–1840), the albumen process (beginning 1848), the wet-collodion process (beginning 1850–1851), and the waxed-paper negative process (beginning 1851). Significant reagents used in physical development during the period included gallic acid (beginning 1839–1840), ferrous sulfate (beginning 1844), and pyrogallic acid (beginning 1850–1851).

For a photographic image to be formed by physical development at the time, there needed to be an excess of silver nitrate in proportion to the halide used to make the light-sensitive surface; otherwise, the operation would not have succeeded due to a lack of oxidizing material.

Mid-nineteenth century photographers obtained an excess of silver nitrate in one of two ways: either they could leave excess silver nitrate in the sensitive surface being formed (which necessitated an immediate exposure and development while the negative was still damp due to the oxidizing tendency of the silver nitrate) or they could rinse the sensitized negative in water (thus removing excess silver nitrate), dry it for exposure at a later date, and then reintroduce excess silver nitrate to the developing solution just prior to development. The former "wet" method predominated with calotype and early wet-collodion photography (1839–1862); it continued to be used with wet-collodion until the 1880s, due to its familiarity and the relative brevity of exposure times that were obtained with it. The latter "dry" method was confined to the dry, waxed-paper negative and dry-collodion processes (1851–1862). While convenient for the voyager, the dry processes suffered from one major drawback when coupled with physical development: exposures were much longer than with the wet processes.

With physical development, the developing solution needed to be acidic or neutral, rather than alkaline, in order to prevent a spontaneous reduction of the excess silver nitrate to silver, which would have blackened the image entirely. This being the norm, there were a few noteworthy exceptions. In 1851, two French photographers, the abbé Léon-Emmanuel-Simon-Joseph Laborde and Baron Louis-Adolphe Humbert de Molard, succeeded in reducing exposure and development times by adding trace amounts of acetates to developing solutions, making them mildly alkaline. In 1856, an English photographer, W.D. Parr, added sodium acetate to a preliminary iodizing solution, causing it to function as a built-in accelerator. The success of these experimental methods was limited, and their unreliability (given the excess silver nitrate in solution) prevented them from being fully adopted.

Chemical development may be said to have begun around 1860, with the anonymous American practice of fuming an exposed, dry-collodion plate with ammonia, prior to developing it with a neutral solution containing pyrogallic acid. More certifiably, it may be said to have begun in 1862–1863, with the publication of Major Russell's bromided pyro-ammonia formula. By the end of the nineteenth century, it was the prevailing method of developing.

At first, chemical development was exclusively used to make negatives, but by the 1880s, it also had come into regular use for developing positive prints. During this period, chemical development was used in the following photographic processes: the dry-collodion process (beginning ca. 1860), the gelatin dry-plate process (beginning 1871), and the various bromide, chloride, and chlorobromide positive printing processes (beginning ca. 1874). Significant reagents used during this period were pyrogallic acid (beginning ca. 1860), hydroquinone and pyrocatechin (beginning 1880), amidol, glycin, metol, and para-aminophenol (beginning 1891).

In order to form a photographic image by chemical development, the excess silver nitrate used in forming the light-sensitive silver halide needed to be removed. At first, this was achieved by rinsing the sensitized sheet of glass or paper in water; but following the introduction of gelatin dry-plates in 1871–1873, the silver bromide emulsion was rinsed prior to being coated on the glass. Following the rinsing stage, only the silver halide remained, so a reagent could then be employed in an alkaline solution in which the alkali acted as an accelerator, reducing both exposure and development times by absorbing the released halogen at the same time as the reagent reduced silver.

In spite of the great improvement made in removing the excess silver prior to development in an alkaline solution, chemical development still had an undesirable tendency to reduce all of the silver halide in the negative to silver, rather than just the exposed areas. This problem—known as chemical fog—was only partially held in check by the use of a restrainer (i.e., ammonium bromide) in the earliest pyro-ammonia developing solutions, because the reagent exhausted rapidly in the absence of an oxygen-absorbing preservative. In this regard, the introduction of sodium sulfite in 1882 marked a significant advance. Similarly, the silver bromide grains suspended across the gelatin dry-plate emulsions required more selective developing agents, resulting in the introduction of numerous patented reagents from 1880 onwards. With the introduction of the first metol-hydroquinone combination in 1893, the stage was set for most of the black-and-white developing formulations that would predominate in the twentieth century.

DEVERIA, ACHILLES (1800–1857) AND THÉODULE (1831–1871)

Father and son Achilles and Théodule Devéria practiced photography on paper from the early 1850s. Achilles Jacques Jean Marie Devéria, born on February 6, 1800 in Paris, also raised painters Laffite and Girodet, and was primarily known for his work as a draughtsman, engraver, and especially lithographer. In this technique, which he intensively practiced beginning in the 1830s, he left an enormous and eclectic body of work, in particular, reproductions of pictures of his brother, the painter Eugene Devéria (1808–1865).

When he entered the Estampes de la Bibliothèque Nationale in 1848, he was interested in photography on paper like many painters and engravers of his generation. Among his friendships of the period was one with Louis Robert, a photo hobbyist and director of the painting workshops of the Porcelain factory of Sevres - for whom Devéria worked episodically from 1839 to 1848. Nevertheless, it remains difficult to determine with certainty the degree of involvement Devéria had in the new medium. It appears in 1853 in Paris at the beginning of the publication of the first French scientific work illustrated by photography, *Photographie zoologique ou représentation des animaux rares des collections du musée d'histoire naturelle*, which contained photogravures by Abel Niépce de Saint Victor based on photographs made by Louis Rousseau, assistant at the Museum and,

it would seem, the father Devéria. Another indication of the interest he brought to the technique is the existence of a photographic album of his family (Getty collections) containing various portraits made between 1853 and 1857 and some of which, when touched-up, could be used as models for his lithographs. However, it remains difficult to determine with certainty their author: Devéria father or son? No print to date that was modified has been attributed to him with certainty. His involvement was of short duration because he died on December 23, 1857, only a few months after being named curator of the cabinet of the Prints of the national Library.

Better identified is the photographic work of his son Théodule, born in Paris on July 1, 1831. His work was held high regard in the artistic medium of Bohemian romantic upon which his father focused. But according to his son and first biographer, Gabriel Devéria, the decisive meeting for his vocation was with the Egyptologist Emile Prisse d'Avennes in 1843. A visit to the museum of Leyde in 1846 confirmed this and he expressed a new taste for epigraphy. He studied Eastern coptic languages with the architect Charles Lenormand, and Arabic with the Eastern languages while following the teaching of Quatremère at the College of France.

In 1851, he entered the Cabinet of the Prints where his father was then the preserving assistant. It was perhaps his father or of one of his friends such as Louis Robert that, in those years, introduced him to photography. In 1854, with his first darkroom, he photographed the Scribe of the Louvre museum. Another amateur photographer evolving during this period was the amateur archaeologist John B Greene: in 1855 Théodule created lithographs based on negatives brought back from Egypt for a publication of the printer Firmin-Didot, *Fouilles exécutées à Thèbes dans l'année 1855*.

This same year, on recommendation of the Egyptologist the Viscount of Rougé, Devéria entered the Department of Egyptian antiquities of the Louvre, with the mission of helping to catalogue the thousands of excavated objects sent from Egypt by Auguste Mariette, director of the department who worked on antiquities in Egypt and discovered in 1850 Sérapéum de Memphis. Devéria's talents as lithographer and his meticulousness were then important contributions. In 1856, he illustrated Mariette's work *Choix de monuments et de dessins découverts ou exécutés pendant le déblaiement du Sérapéum de Memphis*.

In December 1858, Mariette called him to Egypt to assist in reading inscriptions. It was the first of four voyages during which Devéria, combining drawings, stampings and photographs, endeavored to document various archeological sights as precisely as possible. This first trip led him to Cairo and its surroundings (Saqqarah, Gizeh, Memphis, Louxor, Karnak, Medinet-Abou). The same concern with precision is found in almost the whole of the photographic works then carried out, by having only used the technique of the calotype: inscriptions, objects of excavation, general sights of archeological sites, and, more rarely, landscapes and portraits. His approach to the subject was usually direct, and his images (never more than 20cm × 30cm) have a marked documentary style. The group of images, however, betray his limited technical ability (spots on the negatives, images sometimes fuzzy, prints faded and prematurely yellowed due to inadequate washing.

After becoming preserving assistant of the department of Egyptology of the Louvre in 1860, he returned to Egypt in 1861–62, on this occasion traveling up the Nile as far as the First Cataract (Philae) then into Nubie as far as Ibsamboul. With his return he assisted Mariette in the development of the publication of the first series of descriptions of excavations in Egypt, 1850–54.

At the beginning of 1865, he completed a third voyage in Egypt, in the company of Henri Péreire, Surel, and of the orientalist Arthur Rhoné, during which he also took photographs. This voyage was preserved in an album of 77 plates. In contrast with the photographs taken at the time of the first two voyages, the work is more alive and convivial, being interested more in the protagonists and landscapes than with the sites themselves. In the autumn of 1865 until 1866, he undertook a fourth and last voyage in Egypt with Mariette.

Knighted of the Legion of Honour in 1868, he died in Paris on January 31, 1871, without having seen published the great work of Mariette Bey, to which he had collaborated so much. With his death, a large portion of his papers, handwritten notes, and photographs were sold by his widow to the Louvre. In 1986, the photographs (more than 300 prints and negatives) were assigned to the Musee d'Orsay. Photographs taken at the time of his first voyage (prints and negatives) are also found in the collections of the National Library. It should be noted that although the majority of known images were taken in Egypt, there are also images of Normandy taken around 1859 (negatives at the Musée d'Orsay).

DEVILLE, ÉDOUARD (1838–1924)
French survey photographer

Édouard Deville surveyor, civil servant (born La Charité-sur-Loire, France, 21 February 1838; died Ottawa, Canada, 21 September 1924). Deville studied at the naval school in Brest, and on his retirement as a hydrographer from the French navy, immigrated to Quebec, Canada, in 1874. He immediately went to work for the provincial government as a surveyor and astronomer and by 1877 he was appointed Inspector of Surveys. In 1880 he joined the federal government in Ottawa to work on western homestead surveys, at which he excelled. In 1881 he was appointed Inspector of federal surveys, the following year he made Chief Inspector, and in 1885 Surveyor-General.

In an effort to extend federal surveys into the western mountainous regions, Deville turned to photography. Using a sturdy but light field camera of his own design, and building on Aime Laussedat's metrophotographie of Paris, Deville developed the mathematical formulae that converted oblique views taken from mountain peaks into topographic maps. By the 1920s his photo-topography had enabled Canada to a map 52,000 square miles of the western Cordillera at a fraction of the cost of more traditional survey techniques. Although Deville also experimented with copy cameras to reproduce maps for field use, he is best known for having been the first Canadian to use photography as a tool of measurement (photogrammetry). Deville's photo-topography was used in the western mountains up to the early 1950s, long after the introduction of aerial photography, which it complemented.

JEFFREY S. MURRAY

DIAMOND, HUGH WELCH (1809–1886)
British photographer

Hugh Welch Diamond's father was a surgeon for the East India Company who later settled in Kent, where Diamond was born. Diamond followed in his father's footsteps by studying medicine first at the Royal College of Surgeons beginning in 1824 and continuing his work in 1828 at St. Bartholomew's Hospital. He set up private practice in Soho Square shortly after this and became a Fellow of the Royal College of Surgeons in 1834. During this early portion of Diamond's career, photography was not yet a feasible form of artistic expression or scientific analysis. However, in the 1840s when photography became more accessible Diamond both shifted his medical interest from surgery to psychiatry and began to practice and write about photography in conjunction with his profession, becoming known as the "father of clinical psychiatric photography." Diamond's photographs can be found, without accompanying case studies, in the collections of the Royal Society of Medicine, the Norfolk Record Office and the Royal Photographic Society.

Diamond studied psychiatry at Bethlem Hospital under the tutelage of Sir George Tuthill in the early 1840s and became resident superintendent of the Female Department of the Surrey County Lunatic Asylum in 1848, a post which he inhabited until 1858. This decade marks Diamond's most significant achievements as both a clinical psychiatric photographer and writer of technical and medical treatises about photography. Diamond's work during this period relied not just on advances in photographic practice such as the calotype and glass plate collodion photography, but the widespread belief that photography was intrinsically linked to empirical truth, making it useful for such scientific fields as psychiatry, which because of Diamond's work was the first to use photography in a systematic way to "diagnose" and "treat" patients.

Between 1852 and 1854 Diamond published more than twelve articles about photography in the journal *Notes and Queries*, including "On French collodion" (1852); "On photography applied to the microscope" (1852); "On the simplicity of the calotype process" (1853) and "The application of photography to the copying of ancient documents, prints, pictures, coins, etc." (1856). The range of these pieces demonstrates the author's varied interests in photographic technique, the scientific uses of photography, the popularization of photography (particularly the calotype process developed by William Henry Fox Talbot which allowed for use of paper negative and therefore multiple prints), and archaeology, one of the doctor's many hobbies. Diamond read "On the simplicity of the calotype process" to the Photographic Society in November 1853 and the successful article was later reprinted.

In addition to his writing, Diamond was consistently taking photographs of his economically deprived resident patients at the Surrey County Lunatic Asylum and using them to physiognomically identify types of insanity much as Alexander Morison and J.E.D. Esquirol had done before him using line drawings rather than photographs to illustrate their work. Diamond presented a photographically illustrated lecture series on this topic in London in 1852, the photographs from which later formed the basis for psychiatrist John Conolly's 1858 case studies on "The Physiognomy of Insanity" published with lithographic translations of the photographs in *The Medical Times and Gazette*.

Conolly's case studies coupled with Diamond's photographs provide a useful barometer of mid-nineteenth-century attitudes toward the economically disadvantaged mentally ill as well as an indication of how Diamond's

Diamond, Hugh Welch. Patient, Surrey County Lunatic Asylum.
The Metropolitan Museum of Art, Gilman Collection, Purchase, Ann Tenenbaum and Thomas H. Lee Gift, 2005 (2005.100.19) Image © The Metropolitan Museum of Art.

supposedly objective photographs were influenced by such modes of artistic photography as were practiced by Diamond's friend Henry Peach Robinson, who took one of the only known photographic portraits of Diamond, and formal studio portraits. One of Conolly's case studies of religious melancholy, for example, was inspired by Diamond's c. 1852 photograph of a modestly dressed, pensive young woman wearing a large cross around her neck. The woman sits in front of a black curtained backdrop as if she is in a portrait studio and rests her left elbow on a plain wooden table while her hand rests against her cheek in an iconographic gesture suggestive of melancholy when used in painting and sculpture. The subject has clearly been posed and manipulated to produce the necessary effect leading to her "diagnosis." Conolly's text responds to both the subject's pose and her facial features, stating that

> "we discern the outward marks of a mind which, seemingly, after long wandering in the mazes of religious doubt, and struggling with spiritual niceties too perplexing for human solution, is now overshadowed by despair. The high and wide forehead, generally indicative of intelligence and imagination; the slightly bent head, leaning disconsolately on the hand; the absence from that collapsed cheek of every trace of gaiety. . . all seem painfully to indicate the present mood and general temperament of the patient." (Conolly, 1858)

In other photographs Diamond added suggestive props such as flower wreaths and farm animals to intimate information about the patient's malady.

Diamond offered his opinions about the use of psychiatric photography in an address entitled "On the Application of Photography to the Physiognomic and Mental Phenomena of Insanity" presented to the Royal Society of Medicine in May 1856. In this treatise he outlined the three primary functions of psychiatric photography, which were to record the appearance of the patient for physiognomic study; to identify the patient in the case of readmittance; and to show the patient his or her aberrant appearance in the hope that self-recognition would result in self-help.

Diamond left his post at the Surrey County Lunatic Asylum in 1858 to open a private asylum in Twickenham House, Middlesex, which he operated until his death in 1886. It appears that he stopped taking psychiatric photographs at this time, but his work continued to have a great influence on the psychiatric communities on both sides of the Channel for Dr. G.B. Duchenne, Jean-Martin Charcot and Sir Francis Galton all used photography for medical purposes. Diamond did remain active in the photographic community, however, serving as editor of the Photographic Society's journal from 1859 until 1869 and serving as secretary and a vice president of that organization as well. In 1867 he was awarded the medal of excellence from the Photographic Society.

KIMBERLY RHODES

Biography

Hugh Welch Diamond was born in Kent in 1809, the son of a surgeon who had worked for the East India Company. He studied medicine at the Royal College of Surgeons beginning in 1824 and continued his work at St. Bartholomew's Hospital in 1828. He set up a private practice in Soho Square soon after this and became a Fellow of the Royal College of Surgeons in 1834. Diamond became interested in psychiatry in the 1840s and studied with Sir George Tuthill at Bethlem Hospital. In 1848 he became resident superintendent of the Female Department of the Surrey County Lunatic Asylum and remained in this post until 1858. During this period he became actively involved with the practice of clinical psychiatric photography and wrote articles about the technical and scientific aspects of photography for such journals as *Notes and Queries*. In 1852 he presented a photographically illustrated lecture on the physiognomy of insanity in London. These photographs were used by John Conolly in his 1858 publication "The Physiognomy

of Insanity." In 1856 he presented "On the Application of Photography to the Physiognomic and Mental Phenomena of Insanity" to the Royal Society of Medicine. He opened a private asylum in Twickenham House, Middlesex in 1858, which he operated until his death in 1886, and discontinued his psychiatric photography. From 1859 until 1869 he edited the Photographic Society's journal and served as a secretary and vice-president. In 1867 he was awarded the medal of excellence from the Photographic Society.

DICKSON, WILLIAM KENNEDY-LAURIE (1860–1935)

French-born photographer

Born in France in August 1860, to an English father and Scottish mother. Dickson emigrated to the USA 1879 and joined Edison around 1883, working as his 'official' photographer. He married Lucy Agnes Archer 1886. Dickson became involved in motion picture work from 1888; first micro-motion pictures on cylinders, then perforated 35mm film. The electrically-driven kinetograph camera supplied motion pictures for the kinetoscope peepshow viewing boxes, the first commercial motion picture film machines, which were set up in arcades. In 1894 Dickson and his sister Antonia wrote a biography of Edison. Meanwhile he was secretly working with a rival motion picture group, the Lathams. Edison found out, leading to Dickson's departure. Disenchanted by the Lathams he joined Elias Koopman, Harry Marvin, and Herman Casler; the beginnings of the American Mutoscope and Biograph Company, responsible for large-format Biograph films and the Mutoscope coin-operated arcade viewer. Dickson shot many subjects for the company. Settling in England in 1897, he became European cameraman for the British Mutoscope and Biograph Co., and the parent company. In 1898 he filmed Pope Leo XIII in Rome. From late 1899, he filmed the Boer War in South Africa. Subsequently, he worked on experimental industrial projects. Dickson remarried when first wife died, and adopted a son. He died September 28, 1935 at Twickenham, England.

Stephen Herbert

DILLWYN, MARY (1816–1906)

English photographer

Mary Dillwyn was born in Wales in 1816 to Mary Llewelyn Dillwyn and the wealthy industrialist Lewis Weston Dillwyn. Before taking up photography, she was a student of the artist Peter de Wint and made drawings of family members. Her family, which includes William Henry Fox Talbot and John Dillwyn Llewelyn, is well known for their pioneering contributions to photography. Mary Dillwyn is considered one of the first women to experiment with photography. "The Mary Dillwyn Album," in the collection of the National Library of Wales, is a small photograph album (110 × 90 mm) that contains 43 photographs dated to c. 1853, seventeen of which are initialled by Mary Dillwyn. Her photographs consist of flower studies, fowl studies and portraits of family and friends, mainly in outdoor settings. Her portraits are known for their informality and spontaneity, which she achieved by using a smaller camera that allowed for shorter exposure times. Most often noted are her portraits that include family pets and the two images that record the building of a snowman. She married the Reverend Montague Earle Welby in 1857, after which time her photographic activity declined. She died in Wales in December of 1906.

Andrea Korda

DISDÉRI, ANDRÉ-ADOLPHE-EUGÈNE (1819–1889)

André-Adolphe-Eugène Disdéri's (1819–1889) tenacious entrepreneurial spirit led him to open his first photographic studio in 1848 or 1849 in Brest where he had moved from Paris with his wife and infant daughter. Their choice of Brest as a location was precipitated by the fact that his wife's brother, who helped finance this new endeavor, lived there. Disdéri appears to have been self-taught daguerreotypist and became fairly skilled in obtaining natural poses and lighting despite the limitations and challenges of the technique. From the beginning, his wife assisted him in the studio. Around this time, Disdéri also entered into business with Joseph Diosse and opened a diorama to the public in Brest in mid-July 1852. After the diorama failed financially and closed within six months, Disdéri left Brest and his

family and headed for Nîmes, leaving his wife and her family to maintain the Brest photography studio.

He spent his time in Nîmes researching the new collodion-on-glass negative process and experimented with Gustave Le Gray's waxed paper negative technique. Collaborating with Joseph Jean Pierre Laurent, he was able to cut the exposure time for collodion negatives down to two seconds. They also researched ways to reinforce paper negatives. His first of several books *Manuel opératoire de photographie sur collodion instantané* (1853) summarized his Nîmes research.

Disdéri returned to Paris in 1853 and established Disdéri et cie. at 8, boulevard des Italiens, described by Ernest Lacan in *La Lumière* as "the largest [studio] in Paris." It was spread across two floors. The first floor consisted of a sales area, a framing studio, a reception room. Above, there were two large terraces with skylights, an elegant salon for the ladies and separate laboratories for the preparation of plates, collodion, and printing. An astute marketer, Disdéri had initiated a correspondence with *La Lumière* before his arrival in Paris which created a buzz in Parisian circles and set the stage for what was to become a prosperous enterprise.

It was at this studio that Disdéri first introduced a large Parisian public to a new photographic portrait format—the *carte-de-visite*. Though he did not invent it, Disdéri is the photographer most closely associated with the *carte-de-visite* because he patented it in November 1854. His studio quickly became one of the most popular places to have one's portrait taken. Disdéri developed standard settings and poses for his *carte-de-visites*. Typically, he would show his subjects in a full-length pose in an interior setting with a column, potted plant, and/or curtain in the background. At times he also seated his

subjects and portrayed them absorbed in some activity such as reading or writing, rather than looking directly at the camera.

Along with an ever-growing desire to have one's portrait made, the Second Empire French public also acquired a taste for collecting *carte-de-visite* portraits of contemporary celebrities such as political leaders; actors and actresses in various roles; and literary and artistic figures. Disdéri, as well as other photographers, nurtured and exploited this market through the 1850s and 1860s. Between 1860 and 1862 Disdéri published fortnightly one-franc installments of a *carte-de-visite* portrait accompanied by a biography on the sitter. This series called *Galerie des contemporains* [Gallery of Contemporaries] could be purchased in volumes of twenty-five or could be selected by subscribers according to their own taste.

Disdéri's *carte-de-visite* portrait business enjoyed a great success through the 1850s and 1860s. This was, in part, due to the prime location of his studio as well as his carefully cultivated reputation and his numerous assistants. Records show that in 1855 he employed as many as seventy-seven individuals. During this period Disdéri also took steps to expand his business. In conjunction with the 1855 Paris Exposition Universelle Disdéri formed the Société du Palais de l'Industrie and obtained the rights to photograph all the products and works of art exhibited at the Exposition. In 1861 he opened a studio specializing in equestrian portraits in St. Cloud. His sister and her husband oversaw the production and sale of photographic paper at several locations in Paris between 1863 and 1864. In March 1865 Disdéri opened a studio on Brooke Street in London which was run by a Mister Léon. He also opened an equestrian portrait studio in West London in early 1868.

In the 1850s and 1860s Disdéri patented several other photographic inventions as well. His patents included one for the preparation of a positive paper which did not require the addition of gold salts to a toning bath in March 1858, and in March and April 1867 he patented in Paris and London "a procès de photomoulure pour impression et gravure" which was very similar to the Woodburytype process. Disdéri also published several more books and brochures, *Renseignements photographiques* in 1855; *Application de la photographie à la reproduction des oeuvres d'art*, a brochure in 1861; and in 1862 his best known book, *L'Art de la photographie* which was later translated into English as *Universal Textbook of Photography* in 1864.

Disdéri consistently exhibited his work during this period as well. In 1854 he had a one man show at the Studio Disdéri. In 1855 he exhibited at the Société Internationale Industrie in Amsterdam and at the Paris Exposition Universelle. He won a medal for his enlarged photography at the 1862 London International Exhibition and also exhibited at the 1867 Paris Exposition Universelle. His work was also shown at the Société française de photographie biennial exhibitions in 1857 and 1859.

Despite the fact that many of Disdéri's photographic endeavors thrived through the 1850s and 1860s, he, nonetheless, experienced some great financial blows, declaring bankruptcy several times and was forced to sell aspects of his businesses. Disdéri was, however, resilient and able to regroup, find new backers, and open up shop again and again. As the *carte-de-viste* trend slowed down in the late 1860s Disdéri followed suit by switching to the larger cabinet format portrait. His work in this format was not very well-received.

All of Paris was greatly affected by the political events of the Franco Prussian War (1870-71) and the Commune of 1871. When the Prussians began to bombard Paris, Disdéri, like many Parisian photographers, began to document the current events going on around them. With the limitations of photography at the time, their work consisted of recording damaged buildings, posing soldiers, and sometimes creating photomontages to reconstruct important events. During the Commune of 1871 Disdéri recorded the areas of Paris that suffered damage by the Communards.

Disdéri eventually moved to Nice and set up a new photographic business around 1879. He returned to Paris in 1888 or 1889 and died on October 4, 1889 in the Hôpital Ste.-Anne, an institution for indigents, alcoholics and the mentally ill. A large body of Disdéri's work can be found at the Biblothèque Nationale because of the *dépôt légal* which was instituted in 1851 requiring that copies of all photographic images which were to be sold commercially be deposited in a public archive. Due to the high volume of his production, cartes-de-visite and uncut cartes-de-visite sheets by Disdéri can be found in numerous collections in Europe and the United States.

CAROLYN PETER

Biography

André-Adolphe-Eugène Disdéri was born on March 28, 1819 in Paris to Jean André Disdéri a cloth merchant and his wife Louise Eugénie. He was the eldest of six children. As a young man he briefly studied painting, and between 1837 and 1840 acted in the Théâtre de Grenelle which presented melodramas, vaudevilles, and comedies. The death of his father in 1840 obligated Disdéri as the eldest son to take on the responsibility of working in his father's unstable fabric and accessories business to support his mother and siblings. In 1843 he married Geneviève Elisabeth Francart. They had several children, but only one, Jules (c.1851–1880) survived to adulthood. After the failure of several clothing and accessories businesses Disdéri went into photography.

He is best known for his carte-de-visite business which flourished through the 1850s and 1860s. He worked persistently to promote and expand his enterprise. Toward this end, he filed numerous patents for photographic inventions, including the *carte-de-visite*, and wrote books and brochures outlining his research, technical and aesthetic processes, and philosophies about photography. He died on October 14, 1889 in the Hôpital Ste.-Anne, an institution for indigents, alcoholics and the mentally ill.

DISDÉRI, GENEVIÈVE-ELISABETH (1817–1878)

French photographer and studio owner

Geneviève-Elisabeth Disdéri was born Geneviève-Elisabeth Francart in France in 1817. She married André-Adolphe-Eugène Disdéri in 1843 and gave birth to six children over the following decade, but only one son survived childhood. In 1848, the family moved from Paris to the French town of Brest, where her brother was a prominent member of the community and helped them open a daguerreotype studio. Portraits from their studio are labelled "M. et Mme. Disdéri." Mme. Disdéri is known to have added gold highlights to some daguerreotypes by hand. M. Disdéri left Brest in 1852 due to political and financial troubles, and later opened a successful photographic studio in Paris. Mme. Disdéri remained in Brest and continued to run the studio until the late 1860s, adopting the new collodion technique and producing the *carte de visite* photographs popularized by her husband. In addition to portraits, she produced a series of views of "Brest et ses environs" from 1856-1858. One photograph from the series, "Cimétière de Plougastel, groupe de paysans" (c.1856) portrays both architectural elements and local people. In 1872, she moved to Paris and set up her own photographic studio. She died on December 18, 1878 in a Paris public hospital.

ANDREA KORDA

DIVALD, KÁROLY (1830–1897)

The Divald Family is one of the most famous and widely known photographer-dynasties in Hungary. Károly Divald, born in Selmecbánya, now in Slovakia November 1830—died in Budapest, November 1897, was one of the pioneers of the 1860s due to his Hungarian alpine photography. In the 19th century he was the best-known landscape photographer of the country, and the best known owner of several photographic studie and photoreprographic printing offices. His photos taken of the High Tatra, the Carpathians and the neighbouring small towns became highly popular in contrast to the graphic prints of that time. The photographic studios and printing offices established by him in Eperjes, Bártfafürdö and Budapest, under the name of Károly Divald and Sons (Divald Károly és Fiai) worked efficiently and successfully up until the 1940s. Three of his sons—Adolf, Lajos and Károly Jr.—followed in their father's footsteps, and at the turn of the century the studios had become big enterprises and expanded to the cities of Budapest and Bártfa, Eperjes in the then Upper Hungary, today Slovakia. The Divald's shops were the biggest picture postcard manufacturers of that time. Károly Divald's fourth son, Kornél became a famous short-story writer and art historian, his work consisting of collecting topographical of the ten public monuments of Upper Hungary. He was the first art historian and advocate of monuments who regarded taking photographs of the spotted public monuments, art treasures as an organic part of his work.

Károly Divald was the first in the 19th century to photographed townships and historic monuments in Upper Hungary, a territory which was a part of the Austro-Hungarian Monarchy until 1921. Upper Northern Hungary was the first place where, in the 1860s and '70s, mass tourism and bathing resorts developed, which fostered local tourism. This novelty and modernity, brought about not only considerable changes to the area's way of life but also the introduction of new trades, including photography. The social and professional rise of Károly Divald was in part due to these changes. In the course of this part of his career a new and special genre was formed in Europe, tourist photography, which supplied travelers with souvenir-like products of a particular town or place. Divald's series of books, *Photographs of High Tatra.* Published in *Eperjes* in 1873 is a good

example of this. Photographs were for sale in different sizes and mounted on pasteboard or doubleweight paper in postcard format or in leather cover binding with gilt. Besides the landscapes he took photographs of thermal baths, hotels, mountain climbers' refuge, restaurants and holiday resorts as these had become part and parcel of the steadily growing new middle class, and also fit well into the dynamic development of Upper Hungary in the 19th century. A publication of photographic series in those days, which focused on the natural and historical values of Hungary was not only considered a very modern innovation and a good business adventure, but also a national obligation. After having produced a number of rewarding publications, in 1882 Károly Divald wanted to start publishing a series of books on the artistic heritage of Upper Hungary. Unfortunately, due to the indifference of scientific circles and the lack of a sufficient number of subscribers he could not carry out this plan.

Károly Divald on his father's side was born in a middle class family. His father, János Ferdinánd Divald (1787–1845) was a well-known botanist and forester of Hont and Zólyom counties. Two of his sons, Adolf Divald and József Divald, were also very successsful in forestry and mining. Károly Divald, however, did not follow the footsteps of his brothers: he made good use of his knowledge in the new field: photography. He pursued his studies at the Lyceum in Eger, and after finishing high school he went to Vienna where he received his diploma in pharmacology and chemistry, on 17 July 1855. Subsequently he worked as an assistant in Eperjes. Here he married Borbála the daughter of a wealthy patrician, Lajos Steinhübel. Three of his sons, Lajos (1861–1931), Károly junior (1858–?) and Adolf (?–1931) became professional photographers, and worked together with their father under the aegis of family enterprise. The fourth son of Divald senior, Kornél (Eperjes 1872–Budapest 1931), became a widely known researcher of Medieval art and also an excellent photographer.

Károly Divald started photography in 1860 in a shed in the backyard of his house in Bártfa. Soon his pharmacy was known not for medicine however but for photographs. In 1862, Divald, as a result of severe financial difficulties, sold his pharmacy and chose photography as the means of living for the rest of his life. After many years of hardships, in 1871 his financial situation was consolidated and due to his wife's dowry he moved into a house in Eperjes. This, under the name of Divald Institute, became the center of his business ventures. The building served as a portrait studio, reproduction press, publication center, landscape-shop, and family home. Apart from portrait photography, which provided him with steady income, he continued his photographic experiments with great enthusiasm in High Tatra. According to the rules of contemporary outdoor photography he used large sensitized sheets of glass processed with a colloidal solution in order to achieve high resolution. Developing the negatives in those days was not easy, and it had to be done rather quickly after the photograph was taken. Often, the photographer had to carry the photo-lab on his back throughout his tour. It is for this reason that Károly Divald recruited a small group of 10–20 people from neighbouring villages for a few days to help him. It stands to reason that under these circumstancies the expeditions of Károly Divald often enden up in failure due to the capricious alpine climate.

Divald's work was closely connected to the Carpathian Society of Hungary, founded in 1873, which created favourable conditions for tourism by using the results of scientific exploration of High Tatra through the publication of guide-books, and also by building tourist routes and mountain climber's refuges. All these things proved to be very fruitful for Divald since he received more orders and made more acquaintances. He took part in the work of the Society, of which he also was a founding member, first as a photographer and later as a publisher with the benefit of cheaper printing costs. He doggedly followed the explorers and was among the first photographers to take pictures of the famous, and also World Heritage listed, stalactite cave of Aggtelek in 1890. It was also Divald who took photos of the stalactite cave of Szepesbéla in 1881.

It was due to his great interest in landscapes and townscapes that led Divald to engage in typographical reproduction. For this reason, with his son Károly junior, he went to Münnich in 1877 to study collotype there. This was followed by another journey to Dresden in 1879, where they could see high-speed printing at work. Returning home in tha same year, they opened the first high-speed printing collotype press in Hungary. They were able to print almost everything from architectural drawings to typographical reproductions. After 1879 the Divald Institute took on the name of Károly Divald and Sons Co. Their firm won the monopoly in portrait photogaphy. In addition to the studio they had Eperjes, there were also studios in Bártfa, Igló, Bártfafürdö and Tátrafüred, where they worked mostly during summer months.

Károly Divald in 1890 at the age of 61, handed his extensive business network over to his sons. Lajos Divald inherited the Divald Institute at Eperjes, and Adolf Divald the studio and postcard-shop at Bártfafürdö. Károly Divald junior took over the studios at Igló, Késmárk and Tátrafüred, but soon his interests and strengths were focused on the capital city. After moving to Budapest he opened reproduction presses and a publishing house, and in 1909 he founded a company of shareholders. Apart from Eperjes, Budapest stood more and more in the focus of the activities of Divald photographers not so accidentally. In the first year of WWI, Budapest as the capital city of the Austro-Hungarian Monarchy,

rose to the level of Vienna, Prague and Paris. It was only natural that new industrial and artistic ideas were realized in this thriving environment.

The sons of Divald senior, Lajos in Eperjes, Károly junior in Budapest, in the course of a few years became the most known enterpreneurs of the Hungarian postcard industry. Their annual output consisted of 3–4 million postcards, which well qualified their activity. Károly Divald established a new enterprise with György Monostory in 1912. The employees of the Divald and Monostory Co, which functioned until the beginning of 1940s had taken photographs of virtually all the towns and cities of Hungary, which were published in a series of excellent quality. Lajos Divald's Institute in Eperjes started to decline after WWI, partly because the local industrial area lost its significance, to the extent that the buildings were demolish in the 1970s.

The youngest member of the dynasty, Kornél Divald, was more an art-historian than a businessman. The photo-historical researher of past years brought to surface, Kornél Divald's great impact on documentary photography. The topics of his photogaphs were church monuments and artifacts in Upper Hungary, whose territory then covered one quarter of Royal Hungary. These monuments and often fragments thereof were discovered in artics, behind altars, in granaries and lumber-rooms. These discovered relics of the past such as tryptichs, devotional articles, textiles, paintings were arranged and photographed outdoors by Divald. His goal was simply not just to document, but to research the monuments and artifacts in detail. His composition was comprised of not only taking photographs of the objects, but, since knowing everything about these monuments, knew what to take pictures of. According to Divald, photography was a very important tool similar to writing or taking notes. His original glass negatives and their copies, which are rare, were discovered together with his diary in which he took notes of the specifics of his photography like exposure, technique, topic, and route. Kornél Divald illustrated his books and studies written on the history of architecture whith his own excellent photogaphic collection.

DIXON, HENRY (1820–1893) AND THOMAS JAMES (D. 1942)

English printers, photographers, and studio owners

Henry Dixon was born on 14th April 1820, the son of Thomas Dixon, a printer, and by 1836 was himself apprenticed as a printer.

He took up professional photography before 1860, at which date he operated a studio in London's Sussex Terrace, Bayswater, moving to Albany Street before 1864. His studio operated at two addresses in that street under his own name until 1886 when his son Thomas James joined him as a partner. Thereafter the studio was known as Henry Dixon & Son, and continued under that name until shortly before Thomas's death.

From the late 1860s, he photographed many of the vanishing buildings of the city for the *Society for Photographing Relics of Old London*, along with other photographers including Alfred and John Bool. Their negatives survive in the National Monument Record, and the Guildhall Library.

Throughout the 1870s, Dixon's printing works produced many of the society's carbon prints, from negatives by the Bools and others as well as his own.

Dixon & Son also photographed the animals at London Zoo, as well as portraiture and undertook a wide range of photographic commissions from pianos to copying works of art.

Captain Henry Dixon (1824–1883), who photographed in India and exhibited widely in Britain in the 1860s, was a separate individual.

JOHN HANNAVY

DMITRIEV, MAXIM PETROVICH (1858–1948)

Russian professional photographer

Maxim Petrovich Dmitriev was born in 1858 into a

Dmitriev, Maxim Petrovich. Peasant woman Sinitsina and her five-day old child—typhoid carriers. *From the album The Year of Poor Crops of 1891-1892 in the Nijnij Novgorod Province. Private Collection: Alexei Loginov.*

family of house servants. Although abolished in 1861, this was the time of serfdom in Russia, and Dmitriev's family worked for the local landlord. Even so, he was fostered by a peasant from the Ryasan region and there he received his primary education at a parochial school. Because of hard economic times in his village, he decide to go to Moscow to earn a living. Like many boys of his age and social background, his first job was as a laborer at a dime-house. From his childhood experiences, he knew quite well what the life of the poor was like. It was this knowledge that influenced his range of interest regarding the choice of subject matters in his photographs.

In 1873 he became a bound apprentice to a well-known Moscow photographer M. Nastjukov. At the same time, he attended drawing classes at Stroganov Art College, one of the best of art colleges in Russia. Not only did Dmitriev learn a technical mastery from Nastjukov, he also learned how to view his surroundings with an artistic eye. Thus the large format photos of Volga with its neighborhood and monuments of architecture made by Nastjukov in 1860s, inspired Dmitriev to create his "Volga Collections."

While developing his photographic skills, Dmitriev started to work in studios throughout the various towns of Russia. Then in 1877 he became a retoucher in Leibovsky's studio in Nizhny Novgorod. This was the time when Nizhny Novgorod—the city on Volga, the country's thoroughfare—was becoming known as one of the largest industrial and transportation centers of Russia. Here Dmitriev dove into the midst of the turbulent life of the country. He had the opportunity to watch all classes of society, from paupers and hobos to recently established tycoons. Since 1880 he worked for several years under the guidance of an outstanding Russian photographer, A. Karelin, and learned the mastery of pictorial photography and methods of creating scenes in studio photography, but Karelin's creative ideas contradicted Dmitriev's artistic principles.

In the 1870s the ideas of the peredvizhniks dominated Russian painting and literature, which influenced problems within the society. The commonplace citizen became the main and the favorite character of art. The works illustrated the hardships of the peasants, who at that time, was the majority of the country's society. These subjects became the focus of Dmitriev's creative photography. In 1886 Dmitriev established a photo-studio in which he worked for more than forty years. Dmitriev made studio photo-portraits and his works of high artistic value often won prizes at various exhibitions. He also took photos of Nizhny Novgorod and its neighborhood, often converting them to large-format prints with dimensions up to 50×60 cm and frequently sold the photos to tourists.

The influence of the best landscape painters started to appear within the trends of the peredvizhniks, like I. Shishkin's influence upon Dmitriev's early works. This representation was recreated in Dmitriev's "Volga collection," and as a result became a sensation at Moscow and St. Petersburg exhibitions of 1889. This series consisted of large-format photographs with beautiful Volga landscapes, monasteries and fairs, typical characters of the place as well as scenes of city life. In Russia it was virtually the first significant photographic series devoted to ordinary folk life. In his works he was able to show the new potential of photography. He, like P. Emerson (1856–1936), stuck to the purity of photo-images and the reality of scenes. He won a silver medal at the 1889

Expositions Universelle, Paris due in part to his style and technique.

From 1891 to 1892, Dmitriev created one of the best of his works. He was ordered by the Food Commission for People's Health to travel to Nizhny Novgorod region, which suffered from a severe drought that caused an epidemic of typhoid fever and cholera. At the hazard of putting his own health at risk, he recorded the terrifying woes and illnesses of the peasants. These photographs still make the same impression upon us today that they did back then. Among them, the "Peasant woman Sinitsina and her five-day old child—typhoid carriers," "The peasants receive the charity bread" and others. His photographs not only recorded the events but evoked sympathy as well. Dmitriev was the first photographer in Russia to make an attempt to influence public opinion by means of photography, and as a result, eventually made the government more active in helping the aggrieved. This was the first Russian photo-report and ancestor to the activities of R.E. Stryker and American photographers of 1930s.

By the 1890s Dmitriev opened a photo-type studio in which his album "The Year of Poor Crops of 1891–1892 in the Nijnij Novgorod Province" was published in 1893. The photo-type technology made it possible to increase the number of the album's copies printed. This circumstance alone allowed more people access to the published prints and henceforth, enlarged the influence on public opinion. This album inspired other Russian photographers to depict folk life. The works of such theme started to appear on the pages of magazines and newspapers, ultimately creating the basic principles of the Russian photo-report.

The photos combined the picturesque of highly artistic photography and the documentary veracity of reality. The leading Russian critics and public figures thought very highly of his works. In their opinion, the works would undoubtedly be earmarked as socially significant and be considered a new step in the development of photography. In 1892 Dmitriev's works were awarded a golden medal at the first international exhibition of photography in Paris, clearly placing his as the best among the pictorial professional photographers. He also won a golden medal at an exhibition in Moscow, and in 1895, Dmitriev won the highest award, the diploma at the Holland World photography exhibition. The French photographer F. Nadar highly appreciated Dmitriev's work.

In 1894 Dmitriev took a trip, sponsored by the Communication Lines office, from Rybinsk to Astrakhan via the Volga River on a steamboat named "Olga." In the course of the trip, he was to photograph the views, architectural monuments, and to make ethnographic photosgraphs of the inhabitants of the region. He worked for ten years, making photographs of the region from the mouth of the Volga all the way to Astrakhan, gathering over 4000 negatives in the process. He used these photos as the basis for photo-cards, of which there were over 700 scenes for them. Dmitriev's captured unique photos of the lifestyle of Old Believers, a group of people who lived isolated from the outside world. He photographed their monasteries and their homemade crafts. While he had an interest in the unusual, Dmitriev also had a great interest in taking photographs of the famous Nizhny Novgorod fairs. This compilation of diverse environments created a most interesting panoramic series of sketches reflecting the life of the Volga region and its people.

Dmitriev's aspiration to capture realism in photography in the absence of studio arrangements should be considered as an important step forward in the development of Russian photography.

In 1896 Dmitriev's works were displayed in the photography department of the All-Russia Exhibition in Nizhny Novgorod. His contemporaries said of him: "The most outstanding exhibit here is undoubtedly the work by a local photographer Dmitriev. He exposed in his beautiful showcase, one of the best showcases in the exhibition, more than 100 views of Volga," "This picturesque description of the great Russian river is definitely the central work of the exhibition."

In this year Dmitriev made friends with the great Russian Writer M.Gorky. This friendship led to the creation of a varied series of portraits of the writer. Dmitriev also created a gallery of outstanding figures in Russian culture. On Gorky's request, Dmitriev made photo-sketches of a couple of inhabitants of Nizhny Novgorod, which the writer used as prototypes to create some of the characters of his plays, and the protagonists of his short stories.

In the 1900s, Dmitiriev was still making photographs of the city life, exposing the social contrasts, demonstrating and recording the life of workers, paupers, and the living conditions in night shelters. Dmitriev's disapproving opinion of pictorialism could be found in his exact and realistic photography.

After the revolution of 1917, Dmitriev found himself under the pressure of Soviet authorities since he was a proprietor of a studio that used wage labor. Dmitriev developed problems with his health, a large majority of his negatives were taken from him, and had been directed to make a few photo-reports of the new life in Nizhny Novgorod. In 1928 Dmitriev took part in a large exhibition "10 years of Soviet photography" but even so, little by little his works slipped into oblivion. Dmitriev's death in 1948 in Nizhny Novgorod, then called Gorky, went unnoticed.

ALEXEY LOGINOV

Biography

Maxim Petrovich Dmitriev was born on the 9th of August, 1858 in the village of Povalishino, in the Tambov region. In 1873 he became a bound apprentice to a well-known Moscow photographer, M. Nastjukov. At the same time he attended drawing classes at Stroganov Art College. In 1877 he moved to Nizhny Novgorod and took the position of retoucher in Leibovsky's studio. From 1880 he worked in the studio of a famous photographer from Nizhny Novgorod A. Karelin. Then in 1886, Dmitriev managed to establish a photo-studio, in which he worked for more than forty years. He demonstrated his works at home and abroad, winning prizes. From 1891 to 1992, Dmitriev created a series devoted to the woes of inhabitants of the Volga region, who suffered an epidemic of typhoid and cholera caused by severe drought. For ten years following 1894, Dmitriev made photos of Volga and its neighborhood from the mouth of the Volga to Astrakhan. He took photographs of architectural monuments and made ethnographic photos of inhabitants of the region. In 1894 he became a member of the Russian Photographic Society in Moscow. After the revolution of 1917 Dmitriev found himself under the pressure of Soviet authorities since he was a proprietor of a studio, and the majorority of his negatives were taken from him. Dmitriev died in Nizhny Novgorod in 1948.

DOCUMENTARY PHOTOGRAPHY

Using the camera as a documentary tool was its favored purpose at the inception. Well before it was embraced as a fine art medium, it was understood to be a unique graphic witness to moment and place. Both in its level of perceived veracity and its ability to be reproduced and disseminated, was the ideal method for communicating the image of the Industrial Revolution.

In the early years, spontaneity and productivity were hampered by technological limitations, as well as the cost of transporting the equipment. The first decades of the medium, however witnessed numerous indomitable adventurers who overcame all logistical obstacles [and their attendant expense] and traveled to the remotest and most challenging terrain.

Images of remote places; the landscapes of the American West; scientific records of archaeological digs and anthropological studies, architectural records; police photography; images of war, as well as the urban and rural poor were among the documents that we associate with the century. Often, the making of these pictures served dual purposes: official and commercial, for example, those made in the Western United States, which were commissioned by an official survey team and also resulted in literally hundreds of thousands of stereo cards and other published manifestations.

Capturing exotic locales by camera was a continuation of an established tradition of publishing prints and illustrated books on the lives, locations and customs of the "exotic," and the "primitive" cultures. As soon as it was technologically feasible, photographers carried on with that business, for which there was a proven audience, with satisfyingly popular results, given that the look of the photographs was such a pronounced departure from the romanticized lithographic interpretations.

Frances Frith, who traveled from London to Egypt in the late 1850s, worked very much in that 18th century style, creating luxurious albums of his views. Désiré Charnay, a French archeologist, photographed ruins in Mexico and the Yucatan in 1857 and Madagascar in 1863 in a similar fashion. Samuel Bourne climbed the Himalayas in 1863, with sherpas dragging his cumbersome photographic lab up the mountains, and subsequently authored a narrative account of his travels. He compared the terrain's beauty unfavorably with the Swiss Alps, which had been photographed by Louis Auguste and Auguste Rosalie Bisson, French brothers, who accompanied Napoleon III and Empress Eugenie there in 1860.

Francis Bedford accompanied the Prince of Wales on his tour of the Middle East in 1862, as a documentarian for Queen Victoria, who would naturally require a reproducible album of commemoration for so important an official journey.

John Thompson, a Fellow of the Royal Geographic Society, devoted his early career to the Far East, but less its structural marvels than its local customs and people. His *Illustrations of China and Its People* in 1873–74, featured 200 Albertype photographic images, concentrating more on people and picturesque locales than distinctive monuments.

Ethnographic views of foreign cultures were made by photographers such as Felice Beato, Samuel Bourne and John Burke, all of whom traveled to the South Asian

regions then under British rule, and Felice Beato in Japan by 1863, very soon after it was open to the West. He published his *Photographic Views of Japan with Historical and Descriptive Notes* five years later.

Under the direction or commission from an official body, or independently, photographers made images of groups of vernacular structures, such as churches, and both very new and very old architectural marvels, starting with Hippolyte Bayard, one of the founding fathers of the medium. Among these, Charles Marville, documented the transformation of streets and alleys of Paris, during and after Baron Hausmann's modernizations. This he did for the Prefecture of the Seine, City of Paris, starting in about 1857. It appears that France, the United States and Great Britain all commissioned photographers to preserve visual records for their archives, but it was not widespread elsewhere.

Baron James de Rothschild commissioned Edouard Denis Baldus in 1855 to record the construction of the rail line from Boulogne to Paris, Lyons and the Mediterranean, which he did through 1859. These were gathered into presentation albums and exhibited at industrial exhibitions, to great acclaim. Baldus, who had photographed the effects of Rhone floods earlier and the building of the new Louvre museum, was the quintessential documentarian of the era, in that he succeeded in applying an artist's mastery of formal pictorial conventions with a prolific provision of detailed information.

Decades later, as the pictorial images of immense engineering marvels became the norm in publications and in the thriving stereo card market, images of the surreal difference in scale between the workers and their product were popular. These are exemplified by the Albert Fernique photographs of the Statue of Liberty's creation in France and installation in the United States.

Nadar (Felix Tournachon) brought a breadth of experience with him to found his Paris photographic establishment in 1853, having been a medical student, journalist, spy, critic, caricaturist, novelist and balloonist. All of this contributed to his catholic interests in subject matter, photographing both above Paris and below. In 1858, he devised a floating darkroom and camera mount for a balloon, creating aerial photographs of the city and later, when electric lights were able to adequately illuminate it, he photographed the catacombs and sewers below, using early arc lamps attached through manhole covers to their batteries.

Documenting wars was the most "modern" manifestation of photography during the century, since they were used as conduits for relaying information about events of wide import. Hippolyte Bayard made calotype images of the barricades in the 1848 revolution in Paris, but it was really with the introduction of collodion glass plates that war became more feasible to document. Roger Fenton was commissioned to photograph the Crimean War in 1855, in part to allay public fears about the manner in which the war was being conducted by the British authorities. He arrived at Balaclava Harbor in March of 1855 with 2 assistants, 5 cameras and 700 glass plates, all to be fit into a horse-drawn darkroom van. Despite all of the obstacles, he managed to make 360 images. Later, James Robertson, Superintendent of the Mint at Constantinople, began photographing and their images were collected for use in albums, exhibited in London and Paris.

After that, the best-known conflicts captured photographically were the Second Opium War, which Felice Beato photographed, presumably at some peril to himself, and, of course, the American Civil War.

Matthew Brady, and 22 photographers working for him, made a tirelessly prolific record, the most comprehensive of the century. From the first Battle of Bull Run of 1861 to the surrender at Appomattox in 1865, thousands of images were made and transmitted to the press for publication. Using 16 × 20, 8 × 10 and stereograph cameras, his men photographed literally everything except the actual battles, due to the still lengthy exposure times. The first publication to come of it was *Incidents of War*, which only recorded Brady's own name, although he was primarily working as an impresario.

The period after the war was one of increasingly rich documentary possibilities for photographic artists, who set out on official missions, creating a body of images uniquely evocative of the American idea of Manifest Destiny, and very much prized by the public worldwide.

Timothy O'Sullivan, one of Brady's war photographers, joined the geological exploration of the 40th Parallel Survey in 1873, photographing Canyon De Chelly National Monument in Arizona. William Henry Jackson went on the Geographic Survey of the Territories in 1870 and in 1875 was shooting 20 × 24 in. plates of the Rocky Mountains to adequately express their grandeur (naturally, all prints were at that time were contact prints). Both Carleton Watkins and Edweard Muybridge were photographing Yosemite with large plates in that decade.

Edward S. Curtis, an established Seattle photographer, made a monumental work of photographing the Native tribes of North America, which he recognized were already endangered, and with financial support of the banker J.P. Morgan, produced a 20 volume survey. These are heroic, formal and romantic, rather more pictorial than objective record, but, nevertheless, these minutely detailed renderings were long used as reference points for identifying tribes.

Photography's evolution was towards ease and rapidity of operation and, hence the capability to capture more ordinary life. Thomas Annan's images were of the closes, wynds and buildings in which the poor lived and

were commissioned by the Glasgow Improvement Trust in the 1860s were stark in their dissimilarity to other graphic representations of poverty, due to the exacting detail and the matter of fact gazes of the subjects, who are, after all, like the natives of other places that photographers were traveling to in that decade.

After he returned from the Far East, John Thompson expanded his interest in people and customs to his native London, publishing *Street Life in London* in 1877. To a modern eye, Thompson's images look the most like candid snapshots of the twentieth century, despite the fact that he would have been a conspicuous figure in the streets with his cumbersome equipment.

Jacob Riis, a Danish born news reporter without photographic training, took up the camera to reinforce his advocacy of the slum dwellers of New York's Lower East Side. Because of the speed and preparation and execution, pictures of this urban milieu seem compositionally spare and drawing upon minute details that are discovered through assertive examination. Riis' aim was to mobilize the public to take up the plight of the poor through his books like *How the Other Half Lives* (1890).

Riis' work was the counter opposite of Oscar Rejlander, who endeavored to capture the Victorian sentimentality of street urchins for the marketplace. There were no qualms on his part of stage managing these tableaus and portraits in his studio and was unapologetic about their theatricality.

Paul Martin, a former engraver, made truly candid photographs in the 1890s by concealing his portable camera in a parcel. In that way, the impression is that of a cinematic "slice of life," something that prefigures the work of the great documentarians of the twentieth century.

Even in the age of the daguerreotype, photography was immediately partnered with medical science as an essential recording device. The first micrographs were taken by John Benjamin Dancer, and although an atlas of engravings based upon micrographs by Jean Bernard Foucault was issued in Paris in 1845, it was later improvements in lenses and shutters that catalyzed this union. Photographs were used to illustrate medical conditions as a matter of course by the late 1850s, and visual symptoms of diseases were recorded for reference, and already an established aspect of the practice by 1870.

Photographs of the appearance of mental patients were made by Hugh Welch Diamond starting in 1852, and lantern slides were even employed therapeutically for the entertainment of mental patients in the Philadelphia Hospital for the Insane.

The medical photographic experiments of Duchenne de Boulogne, a Paris neurologist who published a seminal text on physiognomy, were well known to Charles Darwin, who was acquainted with photographers Julia Margaret Cameron and Rejlander, from whom he commissioned photographs as evidence of his own inquiries into human physiology. It is Darwin that most historians consider the first scientist to have used photographs as the basis for a published theory.

Darwin's cousin, Francis Galton, a leading biological scientist, endeavored to gather statistical data from quantities of photographs, but there was not yet a uni-

form method for making photographic records, and so, gradually, the need for consistent administration of photographs led to guidelines that would result in measurable comparisons. This is the method that was employed in criminology starting in the 1870s.

The "mug-shot" became a protocol in the arrest of criminals from the 1840s, and crime-scene photography was a mechanical aid, much in the way that medical photography was employed, for evidentiary purposes, with confidence in photograph's virtuosity in capturing more than the naked eye. It was Alphonse Bertillon, hired by the Paris Police Service in 1879, who implemented strict guidelines for how accused were photographed upon arrest. "Bertillonage" consisted of an exact proportion, the profile, and mounting the image on a card with the supporting data.

It is not a coincidence that the rapid advances in the technology of photography were catalyzed by the great confidence that the public placed upon it from the start. It was, after all, an imperative part of the period of the World Expositions, celebrating how universal applications of science and technology were bringing the whole world closer, and photography was acting as a conduit for that information as well as exemplar of those ideals.

DODGSON, CHARLES LUTWIDGE [LEWIS CARROLL] (1832–1898)

British author, mathematician, Oxford don, and amateur photographer

Charles Lutwidge Dodgson, better known to the world by his pseudonym as the children's author, Lewis Carroll, was born on 27 January 1832 the eldest son and third child of Charles and Frances Dodgson. His father was a gifted man taking a double first in classics and mathematics at Christ Church, Oxford where he received a studentship that gave him tenure to remain within this academic environment for as long as he chose. But when he married Frances Lutwidge, the college authorities required he give up the post. At first he became the perpetual curate of Daresbury, Cheshire, where Charles was born, before moving to Croft in Yorkshire, which offered a more comfortable standard of living for his rapidly expanding family that finally numbered eleven children in all.

As the eldest son it was perhaps inevitable that Dodgson would follow the example of his father and from an early age his education and upbringing was directed towards that goal. After a brief and formative period at Richmond School, Dodgson became a pupil at the distinguished public school in Rugby where gentlemanly conduct, morality and Christian worship were valued more than academic attainment. For Dodgson, always the intellectual, his time at Rugby was deeply unhappy and it must have been with some sense of relief that he was accepted (matriculated) into his father's old college of Christ Church in 1850 where, in common with most graduates, it was fully expected, he would train for the priesthood, take holy orders and join the growing ranks of the clergymen who devoted their lives to the welfare (spiritual and otherwise) of others. But religious doubts and personal anxieties held him back from full ordination. However, he was ordained as Deacon in 1861, and this allowed him to conduct church services and become a Reverend gentleman, a designation that fitted his personality and outlook at Christ Church which, for the next thirty-seven years lay at the very heart of Dodgson's existence. It was his home and place of work

Carroll, Lewis. Alice Liddell as "The Beggar Maid."
The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 (2005.100.20) Image © The Metropolitan Museum of Art.

and the centre of his intellectual, spiritual and emotional life. In every sense he was an "Oxford man."

When Dodgson entered Christ Church, photography was just emerging from its early and formative period of the 1840s, to become during the 1850s, widely accepted as a social accomplishment for those with sufficient disposable income and adequate leisure time to invest in its success. It was Dodgson's appointment as a lecturer in mathematics in November 1855 that gave him the financial independence to consider photography and with the encouragement and example of his colleague Reginald Southey, an accomplished photographer himself, Dodgson began photographing in May 1856. It became his major preoccupation during the next twenty-five years, during which time it has been estimated he took about three thousand negatives, the majority of which were portraits and all made using the collodion process. A survey of his photographs reveals that, contrary to widespread belief, only fifty percent of these were of children, the remainder being of adults and families (30%), Dodgson family photographs (6%) and topography (4%), the remainder being miscellaneous studies of still lives and paintings. Few amateur photographers of the time can match this output as most gave up after the space of just a few years when their enthusiasm waned and fashionable pastimes changed.

In his first flush of enthusiasm Dodgson took his camera with him during the "long Vacation" away from Christ Church taking the opportunity to photograph patient relatives and friends both in London and Croft. Even at this early stage it is clear that Dodgson had mastered the difficult techniques of the collodion process, which were far from straightforward, and understood how to calculate exposure times by looking at the light and estimating its power. Both were considerable technical achievements and not readily achieved, but it is entirely in keeping with Dodgson's personality that he persevered until he achieved perfection. Apart from Southey, to whom he turned initially for practical advice, he also studied the work of other photographers at the annual exhibitions of the Photographic Society of London, where he especially admired the works of William Lake Price and Oscar Rejlander. In later years he also appreciated and collected the work of Lady Clementina Hawarden and Julia Margaret Cameron. In his quest to become an artist he also visited fine art exhibitions at every opportunity where he carefully studied the works of art in great detail, making notes about the composition and the arrangement of hands for use in his photography. He was painstakingly meticulous in everything he did and nothing would deter him once committed to a particular course of action. The apparently contradictory aspects of his personality, artistic and imaginative on the one hand, and pedantically careful on the other, became the mainspring of his creative output, both as Charles Dodgson, the photographer, and as Lewis Carroll, children's author.

The twenty-five years of his photography falls into three quite distinct phases, the latter two characterised by his use of a photographic studio. The first phase, which ran from 1856 until 1862 saw Dodgson at his most productive, fired up with the all the enthusiasm of a beginner in love with his medium. During this period he added the better part of seven hundred negatives to his inventory, some of his most memorable photographs among them. This is also the period that saw Dodgson working extemporaneously without a permanent studio. Instead he would rig a temporary backdrop of dark cloth outdoors to create a suitable environment. Above his sitters he draped a diffuser of muslin to soften the light. Even though it would have dramatically shortened his exposure times he rarely used direct sunlight, preferring smooth expressive lighting.

From the very start Dodgson concentrated on taking portraits, an aspect of photography that also sets him apart from most of his contemporaries who much

preferred the idyllic charms of the countryside and picturesque ruin. Unlike trees and distant landscape portraiture presented very real challenges to every photographer who sought to reach beyond the exterior surface and express something of the personality of his sitters. Popular myth portrays Dodgson as a shy, retiring individual, ill at ease in company and hesitant in conversation. Based on the evidence of his portraits the very reverse seems to have been the case as Dodgson clearly enjoys a wide social circle of relatives, friends and acquaintances who invariably appear comfortable before his camera. He posed his family groups with great care and characteristic attention to detail, creating a vital composition dependent upon the willing co-operation of all concerned. With children he often set his camera below their eye line, looking upwards slightly to dignify their features, and one can well imagine him kneeling beside the tripod engaging the child's attention before lifting the lens cap to make the exposure. How different to commercial studios where formulaic poses and wooden expressions were commonplace.

The photograph which best exemplifies this early period is his portrait of Alice Liddell as *The Beggar Maid,* made during the summer of 1858. Dodgson's relationship with the Liddell family and the story of how he took the children rowing to Godstow one summer's afternoon and invented the story that was to become *Alice's Adventures in Wonderland* (1865) is part of the myth and legend that surrounds the man. Much has also been made of his supposed association with Alice, which has him falling in love, proposing marriage, and being rejected by Mrs Liddell. This speculative narrative has no basis in fact as Dodgson's diary, the usual source of day-to-day knowledge, is missing for this crucial period. Further speculation surrounds his study of *The Beggar Maid,* which is frequently offered in evidence of his alleged unhealthy fixation with the six year old Alice whose exposed nipple is seen as a corroborative truth. But this study photograph is most frequently seen out of context and separate the paired study made at the same time showing Alice dressed as a young lady in her best outfit. Following Rejlander's example, it is easy to believe that Dodgson originally intended both photographs to be seen as a diptych contrasting wealth and poverty. The aesthetic and technical quality of *The Beggar Maid* ensured its primacy, relegating the other study to little more than a Liddell family photograph.

The second phase of Dodgson's photography covers the period from 1863 to 1871 and is characterised by his rented use of a photographic studio in Badcock's Yard, close to Christ Church, Oxford. Here, for the first time, Dodgson had a place he could dedicate exclusively to photography, with a darkroom to prepare and develop his collodion plates. However, he rarely printed his own photographs, preferring to hand the task to professional photographic printers in London, and later in Oxford, where consistent results were ensured. Working within a studio setting imposes its own limitations upon a photographer, not least the amount and quality of available light, which in the case of Badcock's Yard seems to have been less than ideal as many of the portraits Dodgson made there lack the spontaneity of his outdoor portraits. It was however a base, a proper photographic studio where he could invite distinguished individuals and colleagues to sit before his camera. Even so, his work in Badcock's Yard was only one part of his photography with increasing numbers of photographic forays into London and elsewhere dominating the pattern of his vacations. The nine years of this middle period are those of his greatest creativity and maturity as he not only added the better part of twelve hundred negatives to his inventory but also published *Wonderland* (1865), *Phantasmagoria* (1869), and *Looking Glass* (1871) under his pseudonym of Lewis Carroll.

In October 1868 Dodgson had the good fortune to move into new accommodation at Christ Church. With ten rooms on two floors they were far larger than anything he had previously occupied and it was here, on the roof which was readily accessible, that he came to build his own photographic studio. It took almost four years for Dodgson to obtain the necessary permissions and build the studio but clearly he thought the effort and expense worthwhile as it allowed him to bring together all his photographic activities under one roof and in March 1872 he made his first portrait there. This final phase of his photographic career is perhaps characterised as the period when he might have flourished given the ideal circumstances of his studio, but which saw him less actively involved than ever before, taking on average between sixty and eighty photographs a year. In some years he barely photographed at all and seldom took his camera with him when he travelled. Teaching, writing, and family commitments all made demands upon his time and little by little he began to turn away from photography as other interests took precedence. His most frequent and favourite sitter was Alexandra Kitchin, better known by her pet name of "Xie." Over the years he photographed her more often and in a wider variety of costumes and settings than any other person and so she, above all others, has come to epitomise the period of the Christ Church studio.

Whenever Dodgson's photographs are reviewed or mentioned the one issue which dominates the discussion is his relationship with children and young, prepubescent girls in particular. There is a widespread notion that Dodgson was a pedophile, someone who preyed upon children, using photography as his primary means of approach and gratification, a claim that is given credence by the photographs he took of children in the nude. But there is not a shred of evidence or a single photograph

to support these unfortunate claims. More dependable are his diary entries, which reveal that he made nude photographs on eight occassions over the course of thirteen years and these involved the willing participation of both children and parents of just six families. This is not the record of a habitual voyeur, pornographer, or pedophile, but the response of an overtly sentimental bachelor with artistic inclinations to the innocent beauty and grace of childhood. To Dodgson children were magical, a gift from God that gave meaning and purpose to his life as a reverend gentleman, children's author and photographer. Throughout his life their company reaffirmed his sense of humanity and fuelled the vital spark of creativity that informed both his writing and photography. He was a polymath of remarkable talent whose legacy still enriches our lives today.

DOMESTIC AND FAMILY PHOTOGRAPHY

Domestic photography during the nineteenth century was defined by two distinct, though inter-related practices. The first and by far the most important of these was a demand for imagery on the part of middle class households, a demand that began with a multi-faceted use of portraiture and, after mid-century, came to include an unprecedented acquisition of mass produced images. Compared to this acquisition of images, the actual taking of family photographs was, until the 1880s, more important as an ideal than as a practice. Yet when a practical technology for home photography finally became available, it yielded not only a second wave of photography's industrial development but also the beginnings of a redefinition of the role of domestic iconography.

Gisèle Freund, in her early writing on the sociology of photography, argued that a desire for cheap portraiture on the part of the rising middle classes provided a major impetus for the medium's invention. Freund's assertion is given credence by the rapid appearance of portrait studios in major cities of Europe, the United States and, to a lesser extent, Asia and Latin America, between 1840 and 1845. Portraits became yet more common in the decades that followed with the opening of studios in smaller communities as well as the work of itinerant photographers.

From the early years of the medium, the social status of the photographic portrait was assured by the willingness of the rich and powerful to have their photographs taken and circulated. This meant that for the middle and working classes, the photograph represented not simply an inexpensive portrait but rather a democratization of the once exclusive realm of portraiture itself. Moreover, in the mid-nineteenth century home, portraits became essential components of the family's rites of passage. Wedding pictures of the bride, groom and the clergyman who married them were often incorporated in marriage certificates. Graduation photographs of both individuals and classes date from at least 1853. Post-mortem portraiture was commonplace, especially for children, the newly deceased being posed by photographers who specialized in the practice. In some instances, already interned bodies were exhumed because no post-mortem photograph had been taken. By the 1850s, specially coated portraits of the deceased in life or death begin appearing on tombstones.

In other areas as well, the placement of photographs was an essential element in their domestic use. The necessity of shielding daguerreotypes and ambrotypes as well as the small size in which these portraits were usually produced, led to their being kept as keepsakes in ever more elaborate cases and lockets. "Stanhopes," extremely small albumen or collodion transparencies, were embedded in jewelry and viewed through magnifying lenses. Other processes allowed photographs to be transferred onto cloth or ceramics, integrating images of family members into the household's daily life.

From 1854, with André Adolphe-Eugène Disdéri's invention of the *carte-de-visite*, the domestic placement of the photograph lent itself to a more complex social narrative. The cartes, originally images of illustrious figures, were not simply bought and displayed but collected in the albums that, beginning in 1858, Disdéri created for the purpose. When the middle class began sitting for its own *cartes-de-visite* (or tintypes) it was up to the keeper of the album, usually the woman of the house, to integrate family portraits with the images of the figures and institutions to which the family felt an affiliation. Placing royalty, presidents, clergy and the places or monuments associated with them at the front of family albums continued after the mid-1860s with the cabinet cards and the albums designed to hold them. Through the remainder of the nineteenth century, the increasingly ornate designs of family albums made them, in Elizabeth McCauley's description, "the new, positivist Bible...in which all that was admired or held sacred by the family could be preserved and exhibited to friends and visitors."

As was the case with portraiture, the esteem accruing

to the family photographic albums flowed from the highest levels of society. The British Royal family retained the services a group of photographers, known as the photographers to the Queen, to create *carte-de-visites* and cabinet cards to which they added the images of their possessions as well as the cartes and cabinet cards given them by distinguished visitors—an undertaking that would eventually yield 110 albums containing more than 100,000 images. John Mayall's publication of fourteen photographs of the Royal Family in a *carte-de-visite* album in 18602 clearly influenced the Victorian public's demand for family photographic albums of their own.

Queen Victoria and Prince Albert were also responsible for the popularity of the stereoscope, an instrument that, thanks to their endorsement at the Great Exhibition of 1851, quickly became a household item throughout Europe and North America. Between 1854 and 1856, the London Stereoscopic Company sold two million stereoscope viewers—this before Oliver Wendell Holmes designed and placed in the public domain the archetypal nineteenth century stereoscope device. By the early 1860s, the most successful of the British, American and French stereoscope companies were each selling nearly one million stereographs (stereo cards) per year. Before the interest in stereography faded in the early twentieth century, some two to five million different stereograph images would be produced in the United States alone.

Stereographs, like the *carte-de-visites*, tintypes, ambrotypes, cabinet cards and, after the mid-1870s, a new generation of gas and oil powered magic lanterns, brought an ever accelerating profusion of imagery into the nineteenth century home. They also spawned a global industry, as tens of thousands of photographers worked to fill the catalogues of hundreds of suppliers. In 1861, Paris alone supported some 33,000 photographers and other workers in the photography industry.

Among the intellectual leaders of the time, the response to this rapid influx of visual imagery was shaped by the era's deeply held belief in technological progress. Holmes, for instance, in his June 1859 *Atlantic Monthly* article, "The Stereoscope and the Stereograph," called for the creation of stereograph museums as a means of documenting the nineteenth century world. Others advocated the large-scale photography of works of classical art as a means of not only preserving the art but also spreading appreciation of the objects to those who would otherwise never see them. To this end, the Alsatian photographer Adolph Braun, compiled from 1866 on, a catalogue of half a million art works available as *carte-de-visites* and stereographs.

Stereography and magic lanterns also contributed to the creation of the mode of industrialized culture we now know as "entertainment." Increasingly elaborate stereograph and lantern slide sets introduced viewers to the basic strategies of visual storytelling they would see after 1895 in early cinema and well after that in home movies and television.

The net effect of this influx of photography into the nineteenth century home was a coupling of the public and private spheres, as families repeated, through their assembly of images, the acquisitive agenda of the industrial, imperial world. In their albums, boxes and drawers and on their walls, families collected the images of industrial wonders, national landmarks and conquering heroes. They also collected the stereotyped images of non-western peoples and "exotic" locales. Women too were commodified as the first wave of mass produced erotic imagery was brought into the home and locked away for discreet viewing by the patriarch and his confidants—and indeed, as Malek Alloula has demonstrated, Orientalism and erotic photography often complemented one another. Even the photography of classical art proceeded according to the reverence for ancient and Renaissance artistic practices and, conversely, with a deep distrust of contemporary work.

In contrast to the overwhelming influx of commercial imagery into the nineteenth home, the production of domestic photography by family members themselves was a small and slowly evolving practice. William Henry Fox Talbot's conception of photography as a tool for recording one's immediate surroundings was practiced only in a relatively few upper middle class households. However, despite its inaccessibility—and the dangers of working with early photo chemicals—early photography did become an acceptable domestic craft for women, some of whom chose to transcend the pursuit of purely domestic subjects and apply their skills to scientific and artistic goals. Victorian mores also allowed for women to work alongside their husbands in portrait studios and, to a lesser extent, to maintain studios of their own.

Domestic photography advanced slowly with Frederick Scott Archer's invention of collodion, the publication of countless photography manuals and, after 1853, the growth of photographic societies. There also remained the ideal of a more accessible photographic technology, as exemplified by the several failed attempts to simplify the medium, e.g. Adolphe Bertsch's 1860 *chambre noire automatique*, J.B. Spenser and A.J. Melhuish roll paper film in 1854, and the slightly more practical design by Leon Warnecke in 1875. But perhaps the most optimistic gesture in the direction of amateur photography was John Herschel's coining of the term "snapshot" in 1860.

The reality was that for most middle-class families, prior to 1880, amateur photography remained an unaffordable and daunting process. Photographers were required to mix their own chemicals for both taking and developing images, a process that was not only difficult but which also made for inconsistent results. What were

regarded as inexpensive cameras were inexpensive only if one expected to recoup their cost by working as a professional photographer.

Technological solutions to these problems began in earnest with Bolton and Sace's development of dry collodion in 1864, followed three years later by Johanna Baptist Obernetter's commercial manufacture of silver chromide paper. In 1878, Charles Bennet described a means of mass producing the gelatin dry plates developed by Richard Maddox eight years before. The result was that, by the early 1880s, it became increasingly possible to take photographs with the assurance of premixed, standardized chemistry.

The demand for mass-produced gelatin dry plates provided a strong incentive for the further development of non-professional photography. Throughout the 1880s, George Eastman and his collaborators (most notably, William H. Walker, F.M. Cossett and Frank Brownell) made what was arguably the most determined effort to develop the mass production of multiple exposure film stock and simplified cameras. From the beginning, Eastman targeted his protect at a potential mass market of amateur photographers (with the deliberately stated inclusion of women and children). His 1888 Kodak camera defined not only consumer photography but also the consumer photographer. In one of the more profound statements of the second industrial revolution, "you take the picture, we do the rest" Eastman separated the photographer from the means of production and from any necessity to understand the process that yielded what was, nevertheless, a personalized object.

It was not until Kodak's 1895 Pocket Model camera or even the appearance of the first Brownie in 1900 that the potential of universally accessible photography was fully realized. But even as these final improvements were made— the introduction of the film cartridge, a better shutter and a much-reduced price— the rise of mass photography was becoming manifest. In 1893, Ernst W. Juhl, founder of the Society for the Advancement of Amateur Photography, organized the first exhibition of amateur photographs at the Hamburg Kunsthalle, an event that showed some six thousand images. Kodak's mushrooming sales as well as those of its many imitators increased to the point where, at the 1900 Exposition

Universelle, Paris, it is estimated that some 17% of visitors arrived with their own "pocket" cameras.

By the turn of the twentieth century, the impact of mass photography was also becoming apparent in the way photographs were stored and presented. The family photographic album was filled with images generated by the family, images that were personal in a way unattainable in the portrait studio and images that would incorporate the family within the same frame in which public sites were depicted. Ornate albums gave way to plainer covers and pages, spaces in which prefabricated imagery was less important than the personalized arrangement of homemade photographs. Thus, while nineteenth century photography began by bringing the visual world into the home, the amateur photographer who appeared at century's end would reverse the process, segregating the public image and creating the iconography of an entirely private domesticity.

DONISTHORPE, WORDSWORTH (1847–1914)

Born in the northern industrial city of Leeds, England, in 1847. His father was an inventor. Educated at Cambridge, Wordsworth Donisthorpe became a barrister but didn't practise, becoming instead a political activist.

On 9 November 1876 Donisthorpe applied for a patent for an apparatus "to facilitate the taking of a succession of photographs at equal intervals of time, in order to record the changes taking place in or the movements of the object being photographed, and also by means of a succession of pictures so taken ... to give to the eye a representation of the object in continuous movement...." It is possible that Donisthorpe became interested in the idea of motion pictures while still at University, as his examiner in 1869 was physicist James Clerk Maxwell, whose own improved zoetrope moving image device was revealed that same year.

Donisthorpe's kinesigraph camera was evidently inspired by the "square motion" wool-combing machine designed by his father, with the "falling combs" replaced with falling photographic plates. The camera was built, but how well it worked is not recorded; there appears to have been no demonstration of results. On 24 January 1878, a letter from Donisthorpe, "Talking Photographs," appeared in the British science journal Nature, in which he suggested that his kinesigraph, used in conjunction with Edison's recent invention the phonograph, could produce a talking picture of Prime Minister Gladstone: "the life size photograph itself shall move and gesticulate precisely as he did when making the speech, the words and gestures corresponding as in real life." Each individual photograph was to be illuminated by an electric spark and projected in sequence onto a magic lantern screen. The materials available for photography at that time did not lend themselves to motion picture work, and nothing else is heard from Donisthorpe on this subject until 1889, when he patented a film camera and projector. Another motion picture experimenter, Louis Aimé Augustin Le Prince, was living in Donisthorpe's home town of Leeds at that time, and it may be that word of Le Prince's 1888 experiments revived Donisthorpe's interest in the problem.

The Patent for Donisthorpe's new camera, also called the Kinesigraph, was taken out jointly with his cousin William Carr Crofts. Crofts had a family connection with Charles Darwin—his sister married Charles' son Francis—and Donisthorpe had been at University with Francis. As keen Darwinists it may be that the two in-

ventors saw the machinery of the industrial revolution, specifically the wool-combing machines jointly devised by their fathers, as a legacy that could evolve into a mechanism of the communications revolution—the motion picture camera—ensuring their financial security, and perhaps even useful in promoting their extreme libertarian views.

It was a unique camera mechanism, which again had more in common with textile machinery than with other photographic devices. A shuttle carrying the film moved upwards as the film itself was pulled down, resulting in the film being stationary relative to the lens during each exposure. Development was entrusted to Crofts, a member of the Camera Club which met in central London, and it was perhaps at a Club lecture that he became aware of Eastman celluloid roll film. The new medium was ideal for their camera. Some time between late 1889 and early 1891, Donisthorpe and Crofts set up their kinesigraph in a building overlooking London's Trafalgar Square, and shot at least one short film. It is an evocative, multi-layered view. Foaming water from one of the famous fountains is framed against a sooty background of the domed National Gallery building. Its colonnaded frontage is background to the bustling traffic of pedestrians and horse-drawn omnibuses, the latter bearing bold advertisements for cocoa. Closer, two carriages clip on their way, beneath the triple glass globes of an elaborate gas street lamp. A sequence of nine frames survives in the collection of the National Museum of Photogaphy, Film & Television at Bradford, and a single frame from the same sequence is in the Cinémathèque Française collection.

Donisthorpe and Crofts were among the first experimenters to take photographic sequence pictures with a single-lens camera using a flexible photographic medium. Others included physiological analyst Etienne-Jules Marey, cinema visionary Le Prince, and portrait photographer William Friese-Greene. In America, William Kennedy-Laurie Dickson was working on experiments that would culminate in the Edison kinetoscope. Attempts to solve problems with the Donisthorpe and Crofts projector mechanism continued for months at least, but were unresolvable. Public presentation of their films eluded them. In the meantime, the perforated films of the Edison team had proved a success in a peep-show viewing machine. An arcade featuring Edison kinetoscopes, the first device to commercially exploit motion picture films, opened in London's Regent Street on 17 October 1894. In November W.C. Crofts died, and any hope that might have remained for the eventual success of the kinesigraph project died with him.

Donisthorpe continued his involvement in fringe politics, and wrote books on weights and measures and the poll tax. In his 1898 travel yarn Down the Stream of Civilization—an account of a yachting trip with his chess friend George Newnes (whose company published the book) and two other cronies—an increasingly melancholy Donisthorpe wrote: "Being unable to retrace our steps in Time, we decided to move forward in Space. Shall we never be able to glide back up the stream of Time, and peep into the old home, and gaze on the old faces? Perhaps when the phonograph and the kinesigraph are perfected, and some future worker has solved the problem of colour photography, our descendants will be able to deceive themselves with something very like it: but it will be but a barren husk: a soulless phantasm and nothing more. 'Oh for the touch of a vanished hand, and the sound of a voice that is still!'"

Donisthorpe later assisted his sons in experiments with color and sound motion pictures. His final book Uropa, A New Language was published in 1913.

STEPHEN HERBERT

Biography

Born in Leeds, 24 March 1847. Father George Edmund Donisthorpe, mother Elizabeth Wordsworth. Attended Leeds school, and in 1865 was admitted to Trinity College, Cambridge, where he was a Maths Wrangler and successful at billiards. Visited battlefields of the Franco-Prussian War in 1870. Married Annie Maria Anderson, 1873. In 1876 his first book, Principles of Plutology was published. 1882 founded, with his cousin William Carr Crofts and others, the Liberty and Property Defence League, to promote their Individualist ideas. In 1885 he helped found the British Chess Association, and the British Chess Club. From 1870s experiments with a camera featuring fast-changing glass plates, the invention of photographic moving images was a recurring ambition. With Crofts, in 1889 he patented and had built a film camera. A sequence of Trafalgar Square indicates some success, but they failed to make their projector work. Donisthorpe died at Hindhead, Surrey, on 30 January 1914.

DONNÉ, ALFRED (1801–1878)

French photographer and physician

In Théodore Maurisset's caricature of early daguerreotypes, the French physician, Aldred Donné, is believed

to be one of the characters caricatured. Donné was an early portrait photographer as well as a doctor, and the first person to make etchings from daguerreotypes, in 1839—an achievement also featured in Marisset's cartoon.

But it is not only as a photographer that Donné is remembered. He was published widely on a range of medical topics. He identified the component of blood which we now know as 'platelets' in 1842 and was an early advocate of natural breast-feeding. Criticising the widespread practice amongst the Parisian upper class of using 'wet nurses,' and promoting the improved bond between mother and child which natural breastfeeding ensured, he published a pamphlet on the subject in the same year, 1840.

Donné is widely reputed to have taken the earliest datable portrait in Europe—a fact reported in *Spenersche Zeitung* on October 22nd 1839—although the portrait was of poor quality, he was one of the first to publish an account of Daguerre's invention.

A keen microscopist—a subject on which he taught, wrote and published widely—in 1840, working with Léon Foucault, he produced some of the earliest photomicrographs using the daguerreotype process. The images were later published, having been used as the basis for engravings.

DOWNEY, WILLIAM ERNEST (1829–1915), DANIEL (DIED JULY 1881), & WILLIAM EDWARD (DIED 1909)

William Ernest Downey was the head of W & D Downey of Ebury Street, London, and according to the *British Journal Photographic Almanac* (1916, p. 417) was 'the doyen of British professional photographers.' William Edward Downey was the son of William and Daniel Downey was a partner in the business. The business was dominated by W. E. Downey until his death.

William Ernest Downey was a native of South Shields and started in business on the Tyne. He had, by the time of his death, been a photographer of Royalty for more than forty years and had photographed Queen Victoria in the early 1860s and every subsequent monarch. Downey first attended the Queen at Balmoral and he and his assistants accommodated themselves and their equipment in a labourers cottage on the estate where they were visited by the Prince of Wales with provisions and wine. He had recognised the difficulties they would have being some distance from the Castle. According to obituaries Downey was the possessor of sound business instincts and had been one of the first to recognise the business opportunity presented by the picture postcard over the cabinet card and at the height of the postcard craze was reported to have sold 2½ million cards of a theatrical beauty.

W & D Downey's London studio was first recorded in the London Post Office Directory in 1872 at 61 Ebury Street, it expanded to number 57 from 1879 until 1890). The firm remained at 61 until 1941 when it was last recorded in the directories.

The firm held two Royal warrants. The first was granted as Photographers in Ordinary to Her Majesty on 24 March 1879 and the second, as Photographers to Her Majesty on 7 June 1890. Downey was apparently popular and regularly photographed members of the Royal family, notably at Balmoral and Frogmore for the Prince of Wales throughout the late 1860s. Their carte-de-visite portrait of the Princess of Wales with Princess Louise being carried on her back was one of the most popular ever issued with sales of over 300,000. In the 1897 the firm produced the Queen's official Diamond Jubilee portrait.

W. Downey's son, a partner in the assoiciated firm of J. J. & F. Downey of South Shields received a command to go to Balmoral in 1897 and took along a newly completed cinematographic camera designed by a 'valued assistant' in the firm Mr T. J. Harrison. The film of Queen and other members of the Royal family was projected at Windsor Castle on 23 November with father and son Downey in attendance. The film was subsequently exhibited by J & F Downey in South Shields and elsewhere. It was the first film ever taken of the Royal family The company gained a favoured position to taking moving pictures of the 1897 Queen's Diamond Jubilee procession in London.

Even by 1910 the firm was still being called upon to produce formal portraits and it photographed nine European sovereigns at Windsor for the funeral of King Edward VII. According to Downey interviewed in *The Lady's Pictorial Supplement* of 5 December 1896 Queen Victoria was the greatest patroness photography had ever had. The possibility of photographs fading had made her insist upon portrait photographs being printed in carbon and platinotype, while special photographs had to be enamelled. Downey also reported that she was an excellent sitter aiding the photographer as much as possible to achieve the required effect.

Royal patronage undoubtedly assisted the firm which grew to be one of the premier society photographers of the late nineteenth century. Their location in London was important in attracting aristocracy, politicians, military men, learned men and women and later on celebrities of the day. Between 1890 and 1894 the publishers Cassell & Co produced The Cabinet Portrait Gallery in five volumes illustrated from original photographs by W & D Downey and their photographs were widely used in commemorative books such as *The Royal Visit to Wolverhampton* (1867) and as frontispieces in, for

Downey, W. and D. Sarah Bernhardt the as Empress Theodora in Sardou's "Theodora."
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

example, *Jottings… from the diary of Amelia, Countess and Heiress of Derwentwater* (1869) which featured a portait of the author.

The *Illustrated London News* from at least 1865 made engravings from photographs credited to the Downey studio as did other periodicals up to and beyond 1900. According to Downey they never published a portrait without the full consent of the sitter. Between April 1883 and April 1890 the firm registered over 230 portraits of Royalty and celebrities at Stationer's Hall.

H. Baden Pritchard in his series of reports of commercial photographic premises published in the *Photographic News* during the 1870s and 1880s and collected together in *The Photographic Studios of Europe* (1882) reported on Downey's London studio and their general business methods. The report allayed some of the exclusivity attached to the firm: "Some people may suppose that the Messrs Downey reserve to themselves the right of photographing titled personages; this is a mistake. A circular published by them certainly conveys the idea that 'anybody, as calls himself anybody,' must perforce be portrayed by the famous Newcastle firm which has now established itself in the neighbourhood of Buckingham Palace." The firm charged one guinea for one pose with additional fees for additional positions, which brought the charges into line with contemporary firms. Cartes were one guinea per dozen.

The firm occupied 'two modest little houses in Ebury Street' with showrooms on the ground floor and studios and dressing rooms up a short flight of steps. Number 61 Ebury Street had two studios and number 57 one glass room 42 × 14 feet which by 1882 had just been completed. Most of the Downey's printing was done in Newcastle where a new studio and premises had been opened in 1864. This was also where all the pictures for publication were mounted and finished. The firm had additional premises at 10 Nevern Square, Earls Court, London which may have been used for printing and finishing prints.

A collection of Downey's court and social work from the early 1860s to 1920s is held by the Hulton Archive (www.getty-images.com) and National Portrait Gallery in London have holdings of the Downey studio work.

DRAPER, JOHN WILLIAM (1811–1882)
English-born chemist and photographer

John William Draper was born in England in 1811, and died in 1882 in New York. After emigrating to America he earned a M.D. at the University of Pennsylvania and in 1839 was hired at New York University to teach chemistry. Draper's early work in photochemistry makes him the most important American precursor of photography. Draper realized, ahead of most, that the photographically active spectrum (blue-violet) did not match the visual spectrum, and therefore that the photographic focus would differ from the optical one. He also deduced a fixing solution from an early paper of John Herschel's on hyposulphites. When the daguerreotype process was made public in New York, in September 1839, he started experimenting, and by the end of the

year obtained satisfactory portraits. His 1840 portrait of his sister is considered one of the oldest in existence. In early 1840 Draper teamed up with painter-inventor Samuel Morse, creating a portrait studio on the roof of New York University. He was also the first American, in 1840, to photograph the moon. In later years, Draper left practical photography for theoretical studies on light, photochemistry, and spectrum analysis, a field in which he was seconded and eventually succeeded by his son Henry; he also wrote on intellectual history and American history.

François Brunet

DRY PLATE NEGATIVES: GELATINE

The 1871 paper by Richard Leach Maddox "An Experiment with Gelatino-Bromide" (Maddox, 1871, 422) is generally seen as the event that led to the introduction of fast gelatine dry plates. However, it made little immediate impact on contemporary photographers. In the search for what seemed like the Holy Grail of photography—dry plates that matched the qualities of wet collodion plates—the announcement of promising dry processes that ultimately disappointed had become a regular feature of the photographic press. Gelatine as a substitute for collodion was well known to photographers and at least two workers, W.H. Harrison and Thomas Sutton, had recognised the potential of gelatine bromide emulsions. And as Maddox himself recalled, his paper was "hurriedly written and fragmentary" and "compared with collodion, the gelatine was slower" (W.J. Harrison, 1888, 131–132). Almost two years passed before it emerged that Maddox's paper had not gone completely unnoticed.

In July 1873 John Burgess, a London Photographer, advertised a bottled emulsion which enabled a photographer to "prepare dry plates equal in sensitiveness and superior in many respects to the best wet plates" (W.J. Harrison, 1888, 63). Burgess did not disclose the nature of his emulsion but it was soon revealed to be gelatine bromide. Although it received an early welcome from the photographic press, it was found to decompose readily and exposure times did not match those of wet collodion. It was not a commercial success. Undaunted, Burgess soon offered pre-coated dry plates for sale. They too were imperfect and a market failure but did impress some photographers. In a glimpse of the future, John Beattie reported in *Photographic News* how he thought they could be useful to "a professional artist who may be called from home to photograph some special domestic occurrence, such as the first family wedding;" (Beattie, 1873, 526).

Some of the problems with Burgess's emulsion was caused by a build-up of soluble salts, which could by remedied by a washing-out process independently advocated in November 1873 by Joshua King and J. Johnston. Richard Kennett claimed an earlier interest in gelatine emulsions was revived when Burgess announced his products. (Kennett, 1874, 290–292). On 20th November 1873 Kennett patented a dried gelatine silver bromide emulsion, which he called a pellicle. When marketed, the user was directed to dissolve the pellicle in water and warm before pouring onto a glass plate. Kennett's pellicle received a mixed reception from photographers. There were enthusiastic advocates who claimed the process to be superior to other dry processes and wet collodion but also many sceptics. Ultimately, neither the pellicle nor the prepared plates Kennett later introduced were a commercial success. Of the pellicle, John Werge claimed "It gave excellent results, but preparing the plates was a messy and sticky operation, which I feared would be prejudicial to its usefulness and success." (Werge 1890, 96). It also seems that most photographers could not come to terms with the sensitivity of Kennett's emulsion and regularly over-exposed.

Despite the market failure of the products outlined above, refinements, such as W.B. Bolton's incremental method of adding gelatine, J. Johnston's use of ammonia and Charles Bennett's hot ripening technique, led to improved plates of more consistent quality. Most importantly, exposure times measured in fractions of seconds were now possible. Further commercial exploitation became inevitable. The first business to produce dry plates in large quantities was the Liverpool Dry Plate Company established in the1860s to market Tannin plates and later, collodio-bromide plates. In 1876 it introduced Kennett's gelatine plates and in 1878, Bennett's more sensitive plates. The business was not outstandingly successful but it showed the way. In 1879, when Alfred Harmen set up his Britannia Works Company to manufacture dry plates there were over twenty brands of pre-prepared dry plates on the market. Alfred Harmen's business began with staff coating plates by hand with emulsion from a teapot. Within a few years dry plate companies had introduced machines coating 12,000 plates a day. By 1891 Alfred Harmen's company was claiming to be the largest manufacturer of dry plates in the world. Ten years later it adopted the name that was to become one of the most famous in photography, Ilford, Limited.

The development of gelatine dry plates was primarily a British concern. Most early users were amateurs; professional photographers were complacent and conservative. Werge described how in 1878 he visited Messrs. Elliot and Fry to promote rapid gelatine dry plates but was mockingly accused by an incredulous Fry of being "an enthusiast." (Werge, 1890, 96–7). It was only in the 1880s that professional photographers began using gelatine dry plates in large numbers. Even then, one writer visiting Messrs. Window and Grove found them using gelatine during the dark winter months but was

told by Grove " I shall get back to wet collodion when I can" (Pritchard, 1883, 93).

If gelatine dry plates simplified photography in many ways, they also presented new problems. H. P. Robinson echoed widespread complaints when writing about the variation and lack of standardisation of mass-produced plates. "One maker's '30 times' is quicker than another's '40 times'" (Robinson 1888. 6). Plate speeds expressed in arbitrary wet collodion equivalents favoured by some was clearly unsatisfactory. Scientific intervention was the answer. The first practicable device for measuring film speed was Leon Warnerke's sensitometer of 1880 but more important was the work undertaken by Ferdinand Hurter and Vero Driffield. By establishing the basics of sensitometry during the 1880s and 1890s, they were able to determine numerical values to represent the speed of an emulsion. Although manufacturers were slow to make use of scientific development the first steps towards standardisation had been made. Exposure tables and calculators began to become available and by the 1890s exposure meters were being widely sold.

The introduction of reliable fast dry emulsions had an enormous impact and marks the beginnings of modern photography. Its consequences included the introduction of hand cameras, roll film and moving pictures. Vast numbers of newcomers were brought into photography and new styles of picture making emerged. Emulsion manufacturers added processing and printing to their interests and a giant new industry was created. By 1900, photography had undergone an industrial revolution.

DRY PLATE NEGATIVES: NON-GELATINE

In his colourful account of 19th century photography, John Werge claimed that wet collodion photography "was barely a workable process when it became the anxiety of every amateur to have a *dry* collodion process…. Hence the number of Dry Plate processes published about this period and the controversies carried on by the many enthusiastic champions of the various methods. Beer was pitted against tea and coffee, honey against albumen, gin against rum, but none of them were equal to wet collodion"(Werge 1890, 77). The great advantage of the wet collodion process was that a competent practitioner could be relied on to produce consistent results with exposures of a few seconds. The major disadvantage was that wet plates had to be prepared, exposed and processed immediately, thus photography in the field usually required a cart or van to transport the bulky equipment, chemicals and water. For the amateur, short exposures and consistent results were not always a necessity but pre-prepared plates, convenience and mobility were. As one writer noted, "The inconveniences inherent in the in the employment of wet-collodion in out-of-door operations are so numerous, as to render its use almost impossible" (Collard 1858, 75).

Although all the pioneers experimented with methods of depositing silver salts in a dry medium onto glass plates, the first widely practised dry plate process was that announced in France in 1847 by Niepce de Saint-Victor. Albumen was used as the binding agent to hold the sensitised silver salts to a glass plate. Albumen plates produced high quality negatives and were widely used by landscape photographers throughout Europe. However, exposure times were long and, according to Thomas Sutton, the manipulations were "too difficult for the amateur" (Sutton 1862, 75).

During the 1850s and 1860s several dry collodion processes were proposed. Marc Gaudin's methods of 1854 proved to be unsatisfactory and the collodion-honey processes of George Shadboldt and Maxwell

Lyte barely practicable. More useful was the collodio-albumen process published in 1855 by the French scientist, J.M.Taupenot. The process involved washing wet collodion plates in a silver nitrate bath. After coating with a protective layer of albumen, the dried plates could be stored. Another silver bath a few hours before they were needed sensitised the plates and after drying they were ready for use. Taupenot's process formed the basis of several similar processes. Particularly popular in England were those by Thomas Fothergill and Joseph Sidebotham. In 1856 Richard Hill Norris patented a process where a collodion plate was coated with gelatine or gum arabic to preserve its sensitivity. Norris dry plates were introduced commercially and sold widely. Another popular dry collodion technique was the tannin process introduced by Major C. Russell in 1861. The sensitised collodion plate was washed before applying a tannin solution and drying. It was much favoured by English amateurs because it was simple and reliable. In 1864 W.E. Bolton and E.J. Sayce announced an important development, a process which involved mixing silver bromide into collodion forming an emulsion. This was the first practicable photographic emulsion.

With the processes described above, dry sensitised plates could be produced which were relatively stable and in the case of collodio-bromide emulsions had a degree of consistency and reliability. It is also clear that negatives could be made that matched the best made from wet collodion. But what publications of the period do show is that for most photographers, dry collodion plates could not match the speed of wet plates. Using collodio-albumen, one popular handbook suggested exposures "about double the time required for wet collodion negatives" (Cox 1857, 26). A *Photographic News* contributor similarly reported "experience has shown me that dry collodion is two or three times less sensitive than the wet collodion;" (Collard 1858, 75). Comparative tests by the Manchester Photographic Society in 1858 confirmed these views. The Taupenot process was considered "the best dry process yet discovered…" but it pronounced that "The exposure required is moderate; pictures may be taken with an exposure of 15 seconds and upwards." Fothergill's variation was considered inferior and the Hill Norris gelatine process was said to require exposures "at least double that of the collodio-albumen (*Photographic News,* 1858, 117). Russell's Tannin Process, if anything, normally required longer exposures. Sutton claimed "about four minutes for a sun-lighted view…" (Sutton, 1862, 88), while H.C. Jennings suggested three minutes (Jennings, 1863, 577). Contemporary commentators also agreed that while the Bolton and Sayce emulsion plates kept particularly well, they were slower than wet collodion. Jerome Harrison suggested 15 seconds as the average exposure (Harrison 1888, 127).

A few photographers however, claimed results with dry plates that matched the so-called `instantaneous photographs,' made by the likes of George Washington Wilson and Valentine Blanchard using wet collodion. In 1862 Sutton published details of a `rapid dry process' based on the tannin process, which he claimed "had been known to Dr. Hill Norris for upwards of two years" (Sutton 1862, 106). There seems little doubt that `instantaneous' pictures were obtained using dry collodion processes but short exposures with dry collodion probably required considerable skill and a great deal of luck. A *Photographic News* review of a Sutton pamphlet confirms seeing "excellent pictures with very rapid exposures" but also writes of "utter and disgusting failures." It bemoaned the fact that the majority of photographers failed and groped towards explanations (1864, 266). Part of the answer was that too many dry processes incorporated the impure kitchen consumables alluded to by Werge. They were added as preservatives or sensitisers but their chemical composition was wildly variable and their action imperfectly understood.

The American, Carey Lea, rightly observed "it is not random experimenting that does good—not publishing that a few plates have been obtained by this or that preservative. Useful experimenting must be systematic and comparative" (Carey Lea, 1868, 504). At the end of the 1860s, most dry plate practitioners were amateurs while their professional colleagues relied almost entirely on wet collodion. More than a decade was to pass before all photographers began using the same sensitive materials.

DU CAMP, MAXIME (1822–1894)
French photographer and writer

Du Camp was born in Paris on 2 February 1822, the only child of wealthy aristocrats. His father, Théodore-Joseph, a surgeon, died a year after Du Camp's birth and his mother, Alexandrine, when Du Camp was fifteen. He departed on his one and only photographic excursion to Egypt and the Near East not long after the Revolution of 1848 in which he was wounded and awarded the Medal of the Legion of Honor. Just before he set sail in 1849, his last remaining relative, a grandmother, died. Du Camp wrote of the deaths in his family as determining the course of his life, especially that of his mother. She mother became "that gentle ghost … [who] followed me on my travels, became a part of my intimate existence, my work, even my pleasures." (*Souvenirs littéraires*, (Recollections of a Literary Life), Paris: Aubier, 1994, 139) Indeed, Du Camp remained a lifelong bachelor despite several amorous liasons.

Du Camp's obsession with death was also nurtured by having come of age at the end of the Romantic movement. "Never had death been more loved," wrote Du Camp. "The generation of artists and writers that preceded me, to which I belonged, suffered … an abstract sorrow, inherent to their being or to their epoch." (*Souvenirs littéraires*, 156–157). In his teens Du Camp gorged himself on Romantic literature, especially the poems and novels of his idol, Victor Hugo.

Like many youths of his generation, Du Camp was swept up by a wave of Orientalism focused on Egypt in particular as the site of an extinct culture often described as "the cradle of Western civilization." It was upon the realization of his dream of going to Egypt that Du Camp took up photography, but not as a means of personal expression. For him the camera was "an instrument of precision … which would allow me exact reconstructions." Along with Du Camp's youthful romantic leanings was an obsession, perhaps also influenced by familial losses, with detailed and exact

documentation of places, persons, and events. It was this aspect of his personality, together with a driving ambition to make a name for himself, which led him to the take on the new medium. As the practical opportunist that facts and contemporary accounts reveal him to have been, he prepared extensively for this trip in other ways as well. He read widely among ancient and contemporary works, copying long extracts in his even, cramped script. He procured an official mission from the Ministry of Public Education as well as membership in the scholarly Société orientale [Oriental Society], all with the promise that he would bring back abundant documentation. He studied photography with Gustave Le Grey but had little success with his method and switched to the wet waxed paper negative process of Blanquart-Evrard that he learned from Alexis Delagrange en route. Once launched Du Camp photographed with a vengeance throughout the entire length of Egypt from Alexandria to the second cataract. His good friend and traveling companion Gustave Flaubert commented, "I don't know how Maxime hasn't killed himself with this raging mania for photography" (Letter to his mother, 15 April 1850). Du Camp also kept copious notes and

made papier maché impressions of wall carvings and hieroglyphs. After leaving Egypt for Palestine and Syria his production tapered off considerably.

Du Camp's photographs, all of monuments, reflect his working purpose and follow the pattern of earlier documentary etchings and lithographs, especially those in the 24 volumes of the Napoleonic *Description de l'Egypt* [Description of Egypt] (1809–1828). Du Camp moves from a distant overall view to a closer one, at times honing in on a detail or two, always positioning his subject in the center of the frame. The overall effect is straightforward and banal. The poor quality of the photographs printed by Du Camp himself also indicate a lack of concern for aesthetics. The one original aspect of his work is his use of a Nubian man, ostensibly as a measure of scale, but who is often almost invisible, posed in odd nooks and crannies of the ancient tombs and temples.

Upon his return in 1851 Du Camp showed his photographs to the newly founded Société Heliographique and that September Francis Wey published an extensive celebratory review in *La Lumière* [The Light]. Du Camp's efforts resulted in the first travel album of its kind, *Egypte, Nubie, Palestine et Syrie*. Published in May 1852 by Blanquart-Evrard in an edition of approximately 200 large leather-bound copies, it contains 125 photographs and a lengthy introduction. Elegant and costly, the album was partially funded by individual and government subscriptions. Photographs were also sold separately and occasionally exhibited, as in 1855 at the Exposition Universelle in Paris where they garnered a Second Class medal.

Despite his success Du Camp subsequently abandoned photography completely to devote himself to what became a prodigious literary production. He had already published *Souvenirs et paysages d'Orient* [Oriental Recollections and Landscapes] (1848), an account of an 1844 trip to Greece, Constantinople, and Algeria. Two subsequent books are directly related to his photographic trip, an autobiographical fiction, *Memoires d'un suicidé* [Memoirs of a Suicide] (1853) and a travel account, *Le Nil* [The Nile] (1854), as well as a short story, "L'Ennuque Noir" [The Black Eunuch]. In addition, during the 1850s and 1860s, Du Camp published poems, reviews of art exhibitions, and was a founder of the literary journal *Revue de Paris* (1851-1858). Later he turned his attention to the documentation of his native city and its political upheavals. He devoted nine years (1866–1875) to his most ambitious documentary enterprise, a six-volume account of the functioning of Paris, its food supplies, transportation systems, prisons, and so forth. He was admitted to the prestigious Academie Française in 1880, fourteen years before his death in Baden-Baden on 8 February 1894.

Du Camp's voluminous archives, including correspondence, manuscripts, negatives and unpublished photographs are in the Bibliothèque de l'Institut de France in Paris. Copies of his album can be found in several major institutions such as the Bibliothèque National in Paris and the Metropolitan Museum in New York. Individual prints are in numerous public and private collections. His work is highly regarded, primarily for its pioneering status, having had little direct stylistic influence on subsequent photographers.

JULIA BALLERINI

Biography

Maxime Du Camp was born of aristocratic parents in Paris on 2 February 1822. He learned photography in preparation for a trip with Gustave Flaubert to the Near East in 1849–1851 and produced the first major travel album of its kind, *Egypte, Nubie, Palestine et Syrie* (1852). Subsequently Du Camp abandoned photography to devote himself to his activities as a writer. Two books published in the 1850s, an autobiography and a travel narrative, are related to his photographic trip. Du Camp also published poems, reviews of art exhibitions, and was a founder of the literary journal *Revue de Paris* (1851–1858). Later in life he turned his attention to the documentation of his native city and its political upheavals, his most ambitious enterprise being a six-volume account of the workings of Paris, from sewers to summits. He was admitted to the Academie Française in 1880. Forever a bachelor, he died in Baden-Baden on 8 February 1894.

DUBOIS DE NEHAUT, CHEVALIER LOUIS-PIERRE-THEOPHILE (1799–1872)

Franco-Belgian proto-reportage photographer

Louis Pierre Théophile Dubois de Nehaut was born in Douai, in northern France, on 10 August 1799. His family seat and main residence was the château at Auby, six kilometres from Douai. Dubois was a magistrate by profession, judge at the tribunal of first instance in Lille until revolution broke out in France in 1848. For bravery in upholding law and order in the face of personal danger, when his actions contributed to preventing the uprising spilling over the border into Belgium, Dubois was appointed a knight of the Order of Leopold.

On 2 December 1851, the very day that the future emperor Napoleon III carried out his coup d'état, Dubois registered his residence in Brussels. It is probable that Dubois preferred to pursue his business interests in Belgium rather than attempt to exercise his profession in a France grown politically uncongenial. In any event, Dubois arrived alone: his wife Louise Victoire Costeau de Semarcourt, remained in Paris. Dubois rented an apartment at 7 Place de Cologne, intending to stay a fortnight. He would live there for nearly twenty years, only moving next door to number 9 on 11 March 1871.

He was a committed collodion photographer by May 1854, when he made full-plate views in Constantinople. On another journey to Spain, many of his plates broke in transit, although a series of portraits of Basques dressed in native costume did survive the trip. On a return visit to France, he made studies of a country house and its grounds, presumably his family seat at Auby. While comfortable with traditional portraiture and landscape work, Dubois' preferred subject matter lay elsewhere: it was as a pioneer of photographic reportage that Dubois would gain his reputation, posthumously consolidated, as the most talented and inventive practitioner active in Belgium in the 1850s.

By 1854, Dubois felt confident enough of the results he was achieving to put together a personal album *Promenade aux environs de la place de Cologne à Bruxelles* [Stroll around and about the Place de Cologne in Brussels], the prints in which are accompanied by captions which show Dubois as an amusing but conscientious commentator on his own work. Two views of "La place pendant les fêtes de septembre" [The square during the September festivities] are early attempts to capture a public event 'on the wing,' as Dubois pushes the generally sluggish collodion process to its technical limits; he manages to keep the blurring of people and traffic to a minimum by the use of a high vantage point, a technique he would exploit in his later work. Taking the camera futher afield, an image of Mechelen railway station, capturing motion under extreme lighting conditions, is captioned "Epreuve instantanée au passage d'un train au soleil couchant. Ciel d'orage 1854" [Snapshot of a passing train at sunset. Stormy sky 1854]. Another print of Dubois with the stationmaster pays

de Nehaut, Louis-Pierre-Théophile Dubois. Another Impossible Task. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 (2005.100.372.32) Image © The Metropolitan Museum of Art.*

tribute to his manservant Jean Maertens (born 1832) for acting as operator and for transporting the cumbersome equipment.

Some of Dubois' finest earlier images feature in a series documenting the Brussels zoo, opened in 1851. The animal studies confirm his primary preoccupation with capturing movement and comprise a number of repeated exercises in achieved immediacy. The most appealing is a portrait of the Indian elephant Miss Betzy performing a trick with her keeper. Captioned "Encore un impossible à faire. 12ème glace" [Another impossible feat. 12th plate], it records Dubois' tenacity in the teeth of improbable odds.

Dubois' unquestionable masterpiece is his photoreportage of the silver jubilee celebrations held in Brussels for Leopold I, king of the Belgians. Over a period of three days in July 1856, Dubois recorded the highspots of this outpouring of patriotic fervour, including processions, an open air thanksgiving ceremony, and the inauguration of commemorative fountains. Assisted by fellow member of the Société française de Photographie Baron Humbert de Molard (Dubois had been a member since October 1855), Dubois and his team took about sixty negatives, of which two-thirds gave successful prints. Dubois' "Les Fêtes de Juillet" [July Festivities] were a tour-de-force of planning as well as execution. Dubois used his influence with the authorities to gain direct access to the royal party, setting up a battery of cameras along the route of the various manifestations. The presence of Dubois' team attracted its fair share of popular and journalistic attention, with Dubois himself cutting a Pickwickian figure in a broad-brimmed hat which he would employ as a camera shutter. The photoreportage earned Dubois a medal at the 1856 Brussels photographic exhibition, but otherwise contemporary reaction was surprisingly muted. Dubois' vision was perhaps simply too radical, thereby failing to chime with the prevailing aesthetic. That the unposed images were indeed considered insufficiently "artistic" to contemporary taste, is something Humbert de Molard himself admitted in a report on the Brussels exhibition (*Bulletin de la Société française de Photographie*, 2, 1856: 280). Dubois, as an amateur, felt no pressing need publish the series, which received only limited dissemination in the form of a handful of presentation albums.

Dubois' next major photoreportage was a review of the Imperial Guard in the newly redesigned Bois de Boulogne in June 1857. It shared characteristics with the Jubilee series, both royal occasions offering set-piece opportunities to capture organised masses in the open air. Dubois sub-titled the series of thirty prints "Etudes de photographie rapide dans toutes les conditions de lumière" [Studies of rapid photography in all light conditions]. Dubois' final major series was a departure from his usual subject matter. "Les Trésors de l'art ancien dans les Flandres" [Treasures of ancient art in Flanders] covers territory more readily associated with Edmond Fierlants. In fact, the two of them photographed the Memlings at St John's Hospice in Bruges simultaneously. Dubois' genial nature was expressed in his offer to donate some of his profits to the hospice, and in his self-portrait with the hospice nuns. This series of art reproductions, totalling 70 plates, was published in early 1859. Sold as individual prints, it is the only series which Dubois is known to have commercialised.

Although Dubois continued to photograph into the 1860s, using smaller format and stereo cameras, including a notable series of Antwerp street scenes, like many of his contemporaries in the Société française de Photographie, his enthusiasm seems to have waned as these leisured pioneers gave way to a new generation of workaday professionals and entrepreneurs. Chevalier Dubois de Nehaut died on 21 September 1872 in Brussels.

The Bibliothèque royale Albert Ier—Cabinet des estampes, Brussels, holds copyright copies of "Les Fêtes de Juillet" and "Les Trésors de l'art ancien dans les Flandres," and the Bibliothèque nationale de France —Département des estampes et de la photographie a copy of "Revue de la Garde du Bois de Boulogne." The Gilman Paper Company Collection owns the series *Promenade aux environs de la place de Cologne à Bruxelles,* including the reportage on the Brussels zoo.

STEVEN F. JOSEPH

Biography

Louis Pierre Théophile Dubois de Nehaut was born in Douai, in northern France, on 10 August 1799. His family seat and main residence was the château at Auby, near Douai. Dubois was a magistrate by profession, judge at the tribunal of first instance in Lille. On 2 December 1851, Dubois moved to Brussels, his wife Louise Victoire Costeau de Semarcourt remaining in Paris. Dubois rented an apartment at 7 Place de Cologne (renamed Place des Nations, the present-day Place Rogier), intending to stay a fortnight. He would live there for nearly twenty years, moving next door to number 9 on 11 March 1871. Dubois was a pioneer of photographic reportage, and undoubtedly the most talented and inventive practitioner active in Belgium in the 1850s. His masterpiece is a series of about forty images recording the silver jubilee celebrations held in Brussels for King Leopold I in July 1856. Chevalier Dubois de Nehaut died on 21 September 1872 in Brussels, survived by his separated wife.

DUBOSCQ, LOUIS JULES (1817–1886)

French optical and photographic equipment manufacturer. Born at Villennes, northern France in 1817, Jules Duboscq was apprenticed in May 1834 to the Parisian optician Jean-Baptiste François Soleil, who had inherited the business from his father François. In 1839 Duboscq married one of J.B.F. Soleil's daughters. Soleil's workshops were at 30 rue Monsieur-le-Prince. The public store was at 35 (later 21) rue de l'Odeon, and stock included lantern slides, anorthoscopes (instruments for displaying image distortion effects), as well as oxy-hydrogen limelight, and electrical illuminants. When J.B.F. Soleil retired in 1849, Duboscq took over the instrument workshop; the workshop for lenses was run by Soleil's son Henri.

From 1849 Duboscq produced optical effects—sunrise, a rainbow—at the Paris Opera, by means of an electrical arc lamp. At a time when screen projection was taking on considerable significance in scientific and lecturing circles, with the introduction of photographic slides and projection of scientific experiments, Duboscq was producing important projection apparatus. The 'Lanterne Photogénique' of 1850 featured a carbon arc with electrical regulator, designed by Léon Foucault and improved by Duboscq. This was a very early use of electricity as an optical lantern illuminant, which was chiefly used for microscopic projection, demonstrations of polarisation and of the spectrum.

Duboscq made and offered for sale a number of different models of projecting phenakistiscopes, with short cyclic motion sequences featuring images based on designs used with the familiar viewing device for opaque cardboard discs. With Duboscq's novel mechanism placed in front of an optical lantern the color sequences, painted in translucent colors on glass, could now be seen in motion on the screen.

Following Charles Wheatstone's invention of the stereoscope David Brewster devised a box-form version, but was unable to interest any of the British instrument makers in manufacturing stereoscopes to his design. In 1850 while visiting Paris, Brewster was introduced to Duboscq by the Abbé Moigno, an advocate for educational uses of new optical methods. Brewster showed the instrument to Duboscq, and the firm began manufacturing the stereoscope, developing several models incorporating improvements.

Duboscq also provided daguerreotype views for these stereoscopes, initially taking two exposures sequentially with a single camera moved horizontally between exposures. The stereoscope became immensely popular following the Great Exhibition of 1851 at the Crystal Palace in London, where Queen Victoria reportedly enjoyed the device and, according to some sources, was presented with a Duboscq stereoscope. He was soon able to offer stereoviews on daguerreotype plates, glass, and paper. Lists included busts of notable public figures, statues, and natural history. A small number of outdoor views by Claude Marie Ferrier comprise the earliest stereoscopic images of Paris. Duboscq patented the device in February 1852, French patent no. 13,069; with no mention of Wheatstone or Brewster. (But with an 1857 lawsuit, Duboscq lost his monopoly for the stereosope). Historian Paolo Brenni considers that Duboscq is today "considered a real master of early photographic still life."

In an addition to the stereoscope patent, Duboscq mentioned the Stereo-Fantascope or Bioscope, a viewer for showing animated stereoscopic photographs. Twelve or more pairs of photographic images were placed around a cardboard disc, the images of each pair arranged one above the other. The pictures could be viewed through two small angled mirrors. Duboscq advertised several models of his 'Bioscope' device, but the fact that no example is known to exist indicates very limited sales. The only known example of a surviving Bioscope disc came to light in the 1990s, and is in the Museum of the History of Science, University of Ghent, Belgium. It features sequential albumen photographs of a steam engine. The prominent French physicist Jules Antoine Lissajous stated: 'This apparatus which is particularly remarkable because it represents the solution to a difficult problem has, unfortunately, no chance of being sold in quantity, since the number of the pictures needed is very considerable: not less than 32 pictures [actually 24] are required.' Ironically, the eventual success of sequential motion pictures would, of course,

require many hundreds of photographs to achieve even a monoscopic result.

Duboscq's 1853 book *Règles pratiques pour la photographie* [Practical Rules for Photography[includes details of his various types of apparatus. In July 1854 he gave a lantern demonstration at the famous Royal Polytechnic Institution in London, well-known as a venue for public demonstrations of new developments in the image projection field. Duboscq devised an early version of the vertical projector—known today as the overhead projector—for the projection of objects which could only be placed in a horizontal position. Duboscq's prismatic model was demonstrated in the 1860s, and took the form of a separate attachment to be used with any lantern.

Other photographic advances included improvements to collodion plates, and an 1861 idea, the polychronograph camera attachment for producing a large number of small pictures on a single plate. Duboscq also made René Dagron's equipment for producing and projecting microphotographs, including early 'microfilm' (gelatine-based microphotographs) used during the 1870 Seige of Paris.

In July 1879 Duboscq, with his nephew and son-in-law Albert Alexis Duboscq, formed the business into a short-lived company. In July 1885 he formed another company with engineer Philibért-François Pellin. Duboscq died in 1886. Pellin and his son Félix Marie continued the tradition of high quality optical work well into the 20th century.

STEPHEN HERBERT

Biography

Louis Jules Duboscq was born at Villennes (Seine-et-Oise), northern France, March 5, 1817. His father was a cobbler. After marrying (in 1839) Rosalie Jeanne Josephine Soleil, one of the daughters of his employer J.B.F. Soleil, Louis Jules Duboscq became an integral part of the firm, and eventually took over a major part of the business. Certainly one of the most talented and respected optical instrument makers of the 19th century, Duboscq's instruments were to be found in laboratories and cabinets throughout Europe. His brother Theodore was for many years the firm's technical director. An Officer of the Legion of Honour, Duboscq died September 24, 1886. A photographic portrait, and a useful Soleil-Duboscq family tree, appear in the comprehensive article *19th Century French Scientific Instrument Makers. XIII: Soleil, Duboscq, and Their Successors.*

DUCHENNE, GUILLAUME-BENJAMIN-AMANT (1806–1875)

French electrophysiologist

The great achievement of Guillaume-Benjamin-Armand Duchenne was to bring together three of the most important developments of the nineteenth century: electricity, physiology, and photography. Duchenne's photography also embraced medicine and neurology, evolution, physiognomic typology, and the education of artists.

Descended from generations of seafarers, Duchenne took up medical studies in Paris in 1836, practiced in his natal town Boulogne-sur-Mer from 1831, and returned to Paris in 1842. An outstanding neurologist and diagnostician who specialized in the application of electricity to the body as a method of neurological investigation and therapy, Duchenne had no official hospital position. Yet he was welcome at the important Paris hospitals, his experiments eagerly followed by the most important practitioners of the time including J.-M. Charcot, founder in 1878 of the first photographic laboratory at the Salpêtrière hospital where Duchenne did much of his work.

Duchenne was the inventor and master of localized faradization: the use of an induction current applied to the body with an electrode so skillfully that he could stimulate a single muscle at a time without piercing the skin. His results were significant: they included the location of the origin of certain muscular diseases; the identification of one of these afflictions, "Duchenne's myopathy," a form of muscular dystrophy; the individuation of the facial muscles and the contribution each made to facial expression. By expanding the use of electricity from a painful instrument of medical remedy

to an objective tool of physiological inquiry, Duchenne created a kind of living anatomy.

Duchenne's interest in photography stemmed from his desire to have permanent records of his facial faradizations. In 1856, after availing himself of the assistance of Nadar's younger brother Adrien Tournachon—there is disagreement about his contribution, but the photographs showing four electrodes and those in which Duchenne and his assistant figure together are generally identified as the ones Tournachon had a hand in—Duchenne set out on his own, learning the wet collodion process so that he could be in control of his results and the viewer's attention. He chose seven models for the variety of their ages, shapes and sex: two young girls, a youthful and an older woman, a handsome anatomist who could mimic the expressions without the electrodes, an old alcoholic workman and—Duchenne's principal model—an elderly cobbler who suffered from a mild anaesthesia of the face. In a orderly and exhaustive series of experiments he applied a series of electrical stimulations to these faces and photographed the resulting muscular contractions one by one to produce a wide variety of expressions, some suggesting extremes of emotion. Duchenne took the pictures in a studio (of undetermined location, perhaps his own house), in medium close up against a neutral background with careful attention to all surrounding details of the *mise en scène* and the lighting which he felt could aid in accentuating the relief of the expressive lines.

In 1862 he exhibited the photographs at the International Exposition in London and published them in *Le Mécanisme de la physionomie humaine ou analyse électro-physiologique de l'expression des passions applicable à la pratique des arts plastiques* [*The Mechanism of Human Physiognomy, or an Electro-physiological Analysis of the Expression of the Passions Applicable to the Practice of the Fine Arts*]. He produced the book at his own expense in both quarto and octavo formats, with a different number—from 72 to 88, depending on the edition—of tipped-in albumen prints. He edited the photographs for publication, reducing some, enlarging others and generally eliminating almost all extraneous information, such as dress, in the aim of objectivity. He also masked parts of the images and rephotographed them to foreground individual muscles. Le *Mécanisme* was divided into scientific and aesthetic sections with text and an atlas of photographs for each. The photographs in the scientific section included nine synoptic tables constructed of up to sixteen expressions each, and photographs of antique sculpture whose facial lines Duchenne had emphasized to exemplify how photography could improve upon or correct artistic representations of the emotions. The aesthetic section seems to have been constructed last; it included full-figure photographs of a new model, a half-blind woman posed in ten tableaux illustrating classical literature and scenarios of Duchenne's own invention. These were his only experiments in showing how the whole body--rather than just the face—participated in the expression of feeling, and he did not pursue them.

Duchenne also produced fifty life-sized oval-format enlargements of his pictures mounted on canvas, varnished and framed in gold. These were intended for the education of artists: introduced in 1872 by anatomy professor Matthias Duval (a colleague of Marey), Duchenne's startling photographs were incorporated into the anatomy teaching at the École des Beaux Arts. Six of them were also adapted by Charles Darwin to illustrate his 1872 *The Expression of Emotions in Men and Animal*s.

Otherwise Duchenne's photographs were generally neither well received nor widely disseminated. Critics found his model, the aged cobbler, indecent and undignified, his hideous grimaces unworthy to represent the soul's expressions. The photographs posed a problem. Rather than signs of inner emotions, of consciousness, of what, in fact, separated man from animal, Duchenne's photographs recorded fear, joy, disdain, or terror as mere physiological facts that could be provoked by electricity and captured by the camera. Stimulated by Duchenne's electrodes, the movements of the facial muscles were understood not as signs indicating the presence of a soul, but rather as free-floating signifiers in a cultural semiotics of muscle movements.

In 1862 Duchenne also published *L'Album de photographies pathologiques complémentaire du livre intitulé De l'électrisation localisée* [*Album of Pathological Photographs Complementing a Book Called Localized Electrical Stimulatio*n], generally considered the first photographically illustrated medical book. The sixteen pictures, taken ca. 1860 of muscular dystrophy cases, epitomise Duchenne's belief in photography's role as a diagnostic tool, permanently fixing the object of the clinical gaze. Duchenne was also an expert practitioner of microphotography and among the first to make images of the nervous system seen through the microscopic lens.

MARTA BRAUN

Biography

Guillaume-Benjamin-Amant Duchenne was born in Boulogne-sur-Mer, 17 September 1806, the son of Jean-Pierrre-Antoine Duchenne, and his wife Marie-Denise Lassalle. He was known as Duchenne de Boulogne to distinguish him from the society doctor Édouard Duchesne. He abandoned a successful medical practice in Boulogne after the death of his first wife in childbirth. The surviving infant, Maxime-Emile, was removed by his maternal grandparents but reunited as an adult with his father in Paris. Maxime's death and that of Duchenne's second wife occurred in 1870. Maxime's

widow continued to live with and assist Duchenne for the rest of his life. Duchenne's position in the highly professionalised and hierarchical world of French medicine was peculiar. He had no official post but he was highly regarded as a kind of specialized researcher and allowed to work with patients in a number of hospitals. He never presented himself for election to the Academy of Medicine, but his contributions to medicine were rewarded by a number of important prizes and the Legion of Honour. His publications were well known, and he was received at the court of Queen Victoria. One of the first doctors to use photographs as scientific data, his photographs of facial expressions were left to the École des Beaux-Arts where they had been instrumental in the teaching of anatomy. He died 15 September 1875 of a cerebral haemorrhage.

DUCOS DU HAURON, ANDRÉ LOUIS (1837–1920)

French inventor and physicist

Ducos du Hauron was born 1837 and is known for his very early three-color photographs. In particular, he is known for his subtractive method of color photography by which it is possible to obtain color prints on paper. Throughout his youth du Hauron was interested in the arts, painting and music. At fifteen he was an accomplished pianist. It was not until 1859 that he began to interest himself in color photography.

It is not clear whether du Hauron was influenced by some early color experiments or not. When he started, he was not aware of Maxwell's three-color photographic demonstrations at the Royal Institution in London, which took place in 1861. However, du Hauron was aware of Michel Chevreul's color experiments which demonstrated that over one thousand different colors could be obtained by mixing different proportions of red, yellow and blue pigments.

To make his first photographic color prints du Hauron selected red, blue, and yellow color filters in 1862, which after experimenting with turned out to be incorrect however he later amended this in 1869, by correctly recognizing the primary color filters as red, green and blue. This process involved a viewer rather than prints, with an array of mirrors to combine the three dyed positive images into a single image at the viewing lens. His second photographic negatives were through green, orange-red and blue-violet filters, which were then converted to positives. The positives were printed on three sheets of dichromated gelatin incorporating carbon pigments of red, blue and yellow color respectively, i.e. the complimentary colors to those by which the negatives were recorded. On treatment with hot water, the parts of the gelatin unaffected by light were washed away, leaving red, blue and yellow carbon prints. The three prints, when mounted superimposed, formed a color photograph.

However, rather than converting them into transparencies for projection he dyed each positive with the complementary color of its original filter. Precisely overlapped on white paper, the three films fused into a full color image of the original. The first public exhibition of du Hauron's color photographs took place on 7 May 1869 at the Photographic Society of France in Paris.

Unfortunately, the color sensitivity of black-and-white negative emulsions at this time was rather poor. The film was mainly sensitive to blue and some parts of the green spectrum. There was virtually no red sensitivity at all. Therefore de Hauron's early color prints were less than perfect. Even the most correct theory was bound to lead to unbalanced color photographs until good panchromatic emulsions were available. Du Huron reported that the sensitive of the collodion plate to the three primary colors was 25–30 minutes behind the red filter, 2–3 minutes behind the green filter and only 1–2 seconds behind the blue-violet filter. However, after Vogel's discovery in 1873, that coralline could be used to extend the sensitivity of silver halides into the green

region of the spectrum, du Hauron started to sensitize his plates using dyestuffs. To obtain some red sensitivity, du Hauron started to use chlorophyll.

Ducos du Huron's earliest surviving color photograph, a view of Angoulême, dates from 1877. For example, this photo is reproduced on page 29 in *Histoire mondiale de la photographie en colours*, a book by Roger Bellone and Luc Fellot, published in 1981.

Preceding Ives, Ducos du Hauron developed one-shot prototype color camera, *Photochromoscope*, for recording color photographs.

Already in 1868 du Hauron had described in a letter another potential color photography method which was the *screen plate* technique. However, the letter was not published until 1897. In this process an emulsion is exposed through a screen consisting of a set of very fine lines of red, yellow and blue drawn on glass. Through the red lines only red light could pass and expose the emulsion behind the screen. Likewise, the blue and yellow transmitted only blue and yellow light, respectively. The photographic plate exposed behind the screen was developed and a positive copy made. The positive copy was then overlaid with a similar screen in exact register. The fine, primary-color lines would be blended in the eye so that one could see a the original colors of the object. This technique was first realized by Joly using the correct primary colors and later perfected by the Lumiére brothers when they introduced the Autochrome process in 1907.

In 1897 du Hauron conceived the idea of using a tripack for recording color photographs. Instead of using beam-splitting devices in the camera, he introduced a dialytic selection of the light rays by an alteration of filters and light-sensitive sheets of film or plates. It consisted of a glass coated with a transparent layer of (non-orthocromatic) blue-sensitive silver bromide, next to a yellow filter, to let red and green light to pass to a green-sensitive emulsion, a red filter and then a red-sensitive emulsion. A suggestion of Ducos du Hauron is to manufacture a complete, or *quintuple* (three sensitive surfaces and two screens), set of elements for use in an ordinary dark slide. This set he calls *polyfolium chromodialytique*. After being developed, a yellow print was made from the blue negative, a magenta print from the green negative and cyan print from the red negative. By combining the prints of those complementary colors, full-color reproductions could be made of the recorded tripack plates. However, since no suitable color-sensitive emulsions existed at that time, du Hauron was not able to show the full potential of his invention. It was not really until the 1930s du Hauron's could be demonstrated, when the Kodachrome film was introduced.

In 1899 du Hauron introduced a dual purpose instrument, which was build by Lesueur, the so-called *Mélanochromoscope* which was a combined recording and viewing instrument for three-color photographs.

Hans I. Bjelkhagen

Biography

Ducos du Hauron was born on December 8, 1837 in Langon, Gironde, France. In 1864 du Hauron invented and patented one type of a cinematograph. On February 23, 1869, du Hauron was granted his first French patent (Patent No. 83061, dated November 23, 1868) on additive and subtractive color processes applied to photography, as well as the screen color technique. His first book: *Les couleurs en photographie, solution du problème,* published in 1869, was an important contribution to the understanding of additive and subtractive photographic color processes. His work was exhibited regularly at the Paris Photographic Society from 1869 on. In 1874 du Hauron was granted a French patent on the single-shot photochromoscope (Patent No. 105881, dated December 15, 1874). In 1876 he was granted a British patent on Color Photography (Patent No. 2973, dated July 22, 1876). His patents cover most of modern color photography techniques. Later, in 1892, du Hauron patented also the anaglyph three-dimensional photographic method. His outstanding achievements in photography was acknowledged by being awarded the *1900 Progress Medal* of the Royal Photographic Society for his early work in three-color photography. In 1912, he was made a Chevalier of the Legion d'Honneur. He died 1920 in Agen.

DÜHRKOOP, RUDOLF (1848–1918) AND MINYA DIEZ (1873–1929)

German photographers

Born in Hamburg, Germany in 1848 to working class

parents, Rudolf Dührkoop was an important professional photographer who stepped beyond the conventional rigid poses of traditional portrait photography as he experimented with different lighting effects, while becoming active in art photography and the Pictorialist movement at the turn of the century.

Rudolf Johannes Dührkoop was born August 1, 1848, the only child of the carpenter, Christian Friedrich Dührkoop, working in a cigar factory, and his wife Johanna Frederica Emile. The little family lived on Mattentwiete in the harbor section of Hamburg. Dührkoop received only an elementary school education and in 1870 he went off to war to serve as a private in the infantry in the Franco-Prussian War. Returning to civilian life in 1872, he married Maria Louise Caroline Matzen, on April 28th, the day his first child, Hanna Maria Theresia was also born. To earn a living he worked for the railroad, and in 1873 his second child, Julie Wilhelmine (Minya) was born on June 21st.

By the end of the 1870s Dührkoop left the railroad, worked as a merchant, and had become quite interested in photography, while experimenting with the wet collodion process. By the early 1880's Dührkoop had published his first article, "On the Use of Yellow Light in Developing Bromide Gelatin Plates" in the Berlin periodical, *Photographisches Wochenblatt*, 1882. He applied for a commercial photographer's license in 1882, and in 1883 opened up his first portrait studio on Grosse Bäckerstrasse 26. Quickly successful, he moved to larger studio quarters in 1884 on Hopfenmarkt 18-19, and by 1889 had moved to Ferdinandstrasse 43 and established branch locations in Altona and St. Pauli, suburbs of Hamburg. His daughter Minya became his creative and competent studio assistant at age fourteen. With her assistance their business thrived and in 1906, the Hamburg studio moved to its final location on Jungfernstieg 34, and Dührkoop opened a Berlin studio on Unter den Linden 10.

Dührkoop's sixtieth birthday and twenty-fifth anniversary of his studio in 1908 was marked by celebrations in both Hamburg and Berlin. Dührkoop received a number of awards and honorary memberships, and a Dührkoop "Medal of Progress" was initiated to be awarded annually to two deserving portrait photographers by the Suddeutschen Photographie-Verein.

Dührkoop's career was marked by his ability to bridge commercial and artistic endeavors, as he ran his successful business and at the same time evolved from a traditional commercial photographer to a leading figure in the development of German art photography and the Modernist movement. As early as 1903, when Dührkoop's work was shown at the Ausstellung for Künstlerische Bildnis-Photographie" in Wiesbaden, a reviewer, Hans Spörl, wrote, "In looking at Dührkoop's work, we are hard put to say which of his rich contributions is the most successful. Dührkoop exemplifies best what is meant by 'creating with one's entire conscience.' There is rarely a line in his pictures that does not successfully add to the total image, no tonal emphasis which can be considered misplaced. He has achieved a total harmony of elements; he has determined the play of light and shade, the distribution of mass and the use of movement with complete certainty and total mastery…" (Hans Spörl, "International Ausstellung für Photographie und Graphische Kunst Mainz 1904" *Photographische Kunst 2* 1903–04: 307) Dührkoop's work was critically acclaimed internationally by critics such as Sadakichi Hartmann and Charles Caffin. In 1907 Hartmann wrote, "Dührkoop apparently searches continually for new light effects… He revels in the mysteries of light and shade—one of the greatest problems portraiture has to offer—and makes his prints sparkle with that delightful freshness which is one of the charms of all good pictures." (Sidney Allan, aka Sadakichi Hartmann, "A German Pictorialist-Rudolf Dührkoop," *The Photographic Times*, 39, 1907: 250–251). Hartmann mentions in particular, Dührkoop's masterful portraits of the "Poet Froensen" and "The Lovers" in each of which the elimination of all unnecessary details and the subtle play of light and shadows on the subjects' faces points to a depth of expression that goes far beyond the accurate rendering of facial features.

Following Dührkoop's active involvement in the organization of the 1909 International Photographic Exposition in Dresden, Charles Caffin was to write in *Camera Work* "…the impression thus of the whole exhibit proved upon further acquaintance to be due to the single authority of a few individuals: conspicuously of Rudolf Dührkoop of Berlin and Hamburg; Hugo Erfurth of Dresden, and Franz Grainer of Munich… their work is distinguished by a variety of treatment and a fertility of resource that are in refreshing contrast to the more hackneyed methods of the American group..."(Charles Caffin, "Some Impressions from the International Photographic Exhibit, Dresden," *Camera Work*, October 1909: 38).

Dührkoop's advocacy for increased aesthetic concerns, that was an integral part of the Pictorialist movement, was inspired and enhanced by the work of Alfred Lichtwork (1852–1914), an influential art historian and founding member of the Hamburg Kunsthalle. Lichtwork had become particularly interested in the field of photography through Ernst Juhl (1850–1915), an affluent engineer and patron of photography. Juhl became an avid collector of Dührkoop's work, beginning in 1901, purchasing over a hundred works by 1915. Dührkoop became a close family friend to the Juhls and became the family photographer. Juhl, Lichtwork, and Dührkoop all

viewed art photography as an integral part of a renewed aesthetic reform and education in German society, that would help promote higher cultural standards in an age of increasing industrialization and mass-production.

Dührkoop gained an international reputation travelling as far afield as England and the United States, showing his work in each place, as well as major cities in Italy and Spain. He was elected to the Linked Ring and Royal Photographic Society in England. He traveled to the United States in 1904 and 1911. (He had his work first exhibited in Boston in 1902.) In 1911 he and his daughter Minya were invited to give a series of lectures in the United States, and attended the annual convention of the Photographers' Association of America from July 23–29, in St. Paul, Minnesota. In his address there, Dührkoop emphasized the need for "Truth and Life" in photography, "to elevate the photograph-taking from a mere reproduction of Nature to imbue it with artistic feeling" (*Bulletin of Photography* 23, September 6, 1911, 153–159). On that trip the Dührkoops traveled as far west as Yellowstone National Park, and returning east, Dührkoop was presented to President Taft in Washington, D.C.

By this time Minya had become an important part of her father's work, having learned her skills from close collaboration with her father. She became director of the Hamburg studio in 1906 and part owner of the business in 1907. Minya's own portrait work featured primarily women and children, quite relaxed, often in naturally lit garden settings. In 1894 she had married Luis Diez, a photographer from Malaga, Spain, from whom she was divorced seven years later. After her father's death in 1918, Minya continued to manage both the Berlin and Hamburg studios. In 1919 she became a member of the Society of German Photographers.

Both Rudolf and Minya's work as "commercial" pictorialists was important in its influence on public taste and in the growing recognition of photography as a Fine Art. An obituary written for Rudolph in 1918 might well apply to father and daughter, "The name Rudlolf Dührkoop is firmly connected with the development of modern photography…he will always be remembered as a noteworthy man, who had the will, the power, and the capability of leading his profession" ("Death of Herr Rudolph Dührkoop," *The British Journal of Photography 66*, 1918: 286).

Katherine Hoffman

Biography

Rudolf Dührkoop was born on August 1, 1848, in Hamburg, Germany. He spent his youth in Hamburg, receiving only an elementary school education. He was married on April 28, 1872, the same day his first child was born. His second daughter, Minya, who was to become his photographic assistant at age 14, was born June 21, 1873. He did not become interested in photography until the late 1870s and opened his first studio in 1883. In 1893 the first "Internationale Ausstellung von Amateur-Photographien" was held at the Kunsthalle in Hamburg, and Dührkoop was introduced to the aesthetics of Alfred Lichtwork. In 1899 he won a silver medal at the "Siebte Internationale Ausstellung von Kunstphotographien" at the Hamburg Kunsthalle. In 1901 he began to publish a variety of articles on the reform of portrait photography. In 1902 he had his first exhibit in the United States in Boston, and in 1904 received a stipend from the Hamburg Senate to visit the St. Louis World's Fair and thereafter traveled through the United States, assembling a collection of American commercial photographers' works. In 1906 he opened his Berlin studio. In 1907 he was elected to the post of Photographic Advisor to the German government to consult on issues related to a new copyright law. He was elected to the Linked Ring and Royal Photographic Society in 1908 and was made an honorary member of the London Salon of Photography in 1910. He continued to work in various aspects of photography until close to this death in Hamburg on April 3, 1918. His daughter Minya continued to manage both the Berlin and Hamburg studios. She died in Hamburg in 1929.

DUMAS, TANCRÉDE (1830–1905)

French photographer

The French-born photographer Tancréde Dumas, believed to have been of Italian origin, travelled extensively in Cyprus, Turkey, Syria, Lebanon, Jordan, Rhodes and Egypt, and had studios in both Beirut and Constantinople.

He trained as a banker before taking up photography, and had a studio in Constantinople before 1865. Cartes de visite survive bearing the legend *T R Dumas et Cie, photographes de vues et costumes, prés du jardin des Fleurs, Grande rue Pera 232*. By 1866, he had a studio in Beirut, and by the early 1870s he styled himself as 'Photographer to the imperial and Royal Court of Prussia' having accompanied the Grand Duke Mecklenburg-Schwerin on a voyage to the far east.

His reputation as a photographer is largely based on a body of work produced in the mid-1870s for the American Palestine Exploration Society (established 1870), under the guidance of the archaeologist Selah Merrill, the American-born clergyman and traveller.

A number of Dumas' photographs were included in Merrill's 1877 album *Photographic Views, taken expressly for the American Palestine Exploration Society, during a reconnaissance east of the Jordan River in the autumn of 1875*.

By the early years of the twentieth century, he had returned to his earlier calling as a banker, heading the banking company of T R Dumas et Fils in Paris.

JOHN HANNAVY

DUNLOP, SIR JAMES FRANCIS (1830–1858)

English photographer

Sir James Dunlop of Dunlop was born on 26 August 1830 in London, England. He was the only son of Sir John Dunlop, Baronet, who was the Member of Parliament for the County of Ayrshire, Scotland. His father died when he was nine and he inherited the title and the extensive family estate with its fine mansion near the village of Dunlop in Ayrshire. He attended Edinburgh Academy and may have been introduced to photography by his aunt, Mrs Frances Monteith. There is a photograph of him by his aunt in the Brewster Album in the J. Paul Getty Museum, California. He was associated with the Edinburgh Calotype Club and his photographs appear in each of the extant albums: one is in the Central Library of Edinburgh and the other in the National Library of Scotland. These were taken on a tour of Europe in about 1847-48 in the company of Reverend James Calder Macphail who also produced photographs of similar subjects, which are in the albums. These are of scenes in Italy and Malta. His participation in photography appears to have ended when he became an Ensign in the Coldstream Guards on 7 April 1849. He was promoted to Major in 1855 and served with distinction throughout the Crimean War being awarded the medal and clasps for the battles at Alma, Balaclava, Inkerman and Sebastopol. Due to poor health, most likely caused by the war, he decided to sell his estate and retired to the South of France in 1857, where he died shortly afterwards on 10 February 1858 at Hyeres. He was unmarried. The church in the village of Dunlop in Ayrshire contains a memorial plaque to Sir James Dunlop.

RODDY SIMPSON

DUNMORE, JOHN L. AND GEORGE P. CRITCHERSON (active 1850s–1870s)

In May 1871, the American artist William Bradford (1823–1892) presented a small display of Arctic paintings and photographs at London's Langham Hotel. The paintings were by Bradford himself, and others, while the photographs, although some were credited to Bradford, had been taken for him, and under his direction, by John L. Dunmore, a Boston photographer from James Wallace Black's studio, and his friend George P. Critcherson.

Their place in the history of photography rests on a single body of work, images produced under the harshest of conditions in the summer of 1869 and on Dunmore's enlightening account of their journey and the challenges of collodio-albumen photography in conditions of extreme cold, "The Camera Amongst the Icebergs," published in the December 1869 issue of the *Philadelphia Photographer*,

While little is known of Critcherson except that he hailed from Worcester MA, Dunmore, had joined Whipple & Black as an assistant in 1854, and continued to work with Black at his independent studio after 1860, and later, in 1876, became his partner. Some reports claim the two men became brothers-in-law, but this cannot be substantiated. James Wallace Black had worked with John Adams Whipple as early as 1850, becoming his partner by 1854, although each man retained and operated his own studio. The Whipple & Black partnership lasted until 1860.

Dunmore and Critcherson. Hunting by steam in Melville Bay, the party after a day's sport killing six Polar bears within twenty-four hours.
The J. Paul Getty Museum, Los Angeles

William Bradford was, by the late 1850s, a marine painter of considerable reputation, and in the 1860s, had embarked on a number of voyages researching material for future paintings. Six voyages along the coast of Labrador in the early 1860s had provided him with much useful material, and had triggered and enthusiasm for further, longer and more challenging journeys. His 1869 journey north of the Arctic Circle on board the steam-assisted sailing barque *Panther* was planned to give him material on which to base several years of work back in his New York studio, and took him as far as Melville Bay on Greenland's west coast.

The group left Boston on June 13th, travelling onwards from New York two days later. By that time, one of Dunmore's chests of chemicals had already been smashed and replaced. Arriving in Halifax Nova Scotia on the 19th, Dunmore found his woes were not at an end—two cases containing one hundred glass plates had been broken, and he spent some time sourcing new sheets of glass. With the help of distinguished local Halifax photographer, William Chase, the new plates were albumenised and repacked ready for the journey to Greenland. The steamer *Panther* arrived a few days later and Dunmore supervised the construction of a fifteen by six foot 'dark-closet' on board before the party left on 3rd July.

Along the way, in St John's, Newfoundland, Dunmore took 'twenty-five to thirty views of the beautiful scenery thereabouts.' Arriving in Greenland, the first photographs were taken at Cape Desolation and Julianshaab—where he photographed the local governor and his family, and 'some views of the Esquimaux huts.'

But it was once they had travelled further north to the Glaciers that the finest images were produced. Considerably aided by the highly reflective snow and ice, Dunmore was able to produce perfectly exposed 14 × 18 plates with an exposure time of only two seconds—a combination of image size and exposure which is remarkable. He also refers to taking photographs of bears on the ice flows and taking 'two very good negatives of them from the topgallant forecastle' of the *Panther*—a camera position which would not tolerate long exposures. The crew wished to shoot the animals immediately, but Dunmore persuaded them 'to let me shoot first with the camera.'

From his account of the journey, a picture of his choice of process emerges. At the outset he talks of albumenizing his plates in Nova Scotia before embarking on the *Panther*—suggesting the use of a collodio-albumen dry plate—but at the site of a huge glacier, he refers to the wave created by ice falling into the sea 'which sent the water up twenty feet all over us, and washed away collodion, developing glass, green baize, etc., and came very near to taking us along with it.' That suggests that, in addition to dry plates, he was also coating wet plates while on location—a practice as difficult in the Arctic cold as it was for other travellers in the heat of the Egyptian desert.

The party left Greenland for the last time on September 16th and returned to America.

Dunmore returned to work at Black's studio, while Bradford went to work on his paintings, and Dunmore's name next appears in the media 7th March 1870 issue of the *Philadelphia Photographer*, under the heading 'Sad Accident.'

> On the evening of February 4th while Mr. J. W. Black of Boston, and his worthy assistant, Mr. J. L. Dunmore, were about to commence a lantern exhibition in Lowell, one of the gas bags [the lamp on the lantern projector was gas fuelled] exploded with tremendous force, threw Mr. Dunmore high in the air and burned him sadly about the face and eyes, knocked Mr. Black senseless, drove a stick through the nose of the organist, and damaged the organ-loft, organ and church considerably. Mr. Dunmore at this writing still lies suffering much and very low, but, with great care, it is hoped, may recover his sight.

Dunmore did, indeed, recover both his health and his sight.

William Bradford's portfolio-format book containing 140 of Dunmore and Critcherson's images, was eventually published in London in 1873 in an edition of 350 copies under the title *The Arctic Regions: Illustrated with Photographs Taken on an Art Expedition to Greenland.*

While Dunmore gives no information on his photographic equipment, save for the reference to taking 14" × 18" negatives, the images in the book—tipped-in albumen prints—are predominantly in two sizes, one just under 6" × 9" and the large prints approximately 15" × 11". It is likely therefore that he took at least two cameras.

It was a landmark in the publication of photographically illustrated books, remains one of the most impressive volumes of photographs published in the 19th century.

DURANDELLE, LOUIS-EMILE (1839–1917)

Born in 1838 in Verdun to Jaques Durandelle and Anne Bastien, Louis-Emile Durandelle was among the most accomplished architectural photographers in nineteenth-century France. Little is known of his early training, but by 1854 he operated a studio with Hycaninthe Cesar Delmaet (1828–1862) at 30–32 Chaussée de Clignancourt, Paris. After Delmaet's death in 1862, Durandelle married Delmaet's widow, Clémence Jacob Delmaet, who retained her first husband's surname and actively participated in the running of the studio which continued to bear the name Delmaet and Durandelle. In 1862, the studio moved to 22 blvd des Filles-du-Calvaire; after 1868 it was located at 4, rue du Faubourg-Montmartre.

Although an 1868 prospectus indicates the range of the studio's output, which included *cartes de visite*, enamel portraits, and "artistic and industrial reproduction" of objects, Durandelle is best known for photographs of building projects in and around Paris. While Durandelle undertook relatively modest projects, such as photographing the contruction of a tram station and various private houses in Paris in the early 1860s, he is best known for a magnificent series of about 115 photographs made between 1865 and 1872 that record the construction and decoration of the Paris Opéra.

Designed by architect Charles Garnier and built between 1861 and 1875, the flamboyant Paris Opéra was one of the grandest architectural projects of the emperor Napoléon III's reign, and a symbol of urban planner Baron Haussmann's architectural and spatial modernization of Paris. Durandelle's large-format albumen prints, most made from 38 × 28 cm glass negatives, provided sharp, vivid records of the successive phases of the massive construction project that entailed excavating a large site in Paris's ninth arrondissement. While Durandelle may have made some prints of the Opéra as early as 1862, it was only in 1865 that he began systematically photographing the site and numbering his negatives (Keller, 109). Durandelle's photographs not only documented the progress of the building, but also recorded in close detail the aspects of construction that would later be invisible to the naked eye, including the iron structural supports that were eventually covered by a marble façade and architectural and decorative elements, such as columns, pediments, and decorative sculpture, that were placed high on the building's façade and thus less accessible to the camera or the human eye.

Many of the photographs from the Opéra series were eventually published (uncredited) as *Le Nouvel Opéra de Paris,* a tome that included two text volumes, two volumes of lithographs and engravings, and four volumes of photographs. The four folio albums, *Sculpture ornementale, Statues décoratives, Peintures décoratives,* and *Bronzes*, include 115 photographs by Durandelle and were distributed to architects and designers.

Precise, economical, and accomplished, Durandelle's photographs of the Opéra served multiple purposes: architectural, technical, juridical, bureaucratic, historical, and descriptive. Many possess an almost abstract formalism and dramatic rendering of space and light

that set them apart from other contemporary examples of architectural documentation. The scrupulous directness with which Durandelle approached his subjects, exploring their forms, contours, and the distribution of light and shade across planes, endow the raw materials of construction—beams, windows, planks—with unexpected expressive force. Yet the incipient modernism of this tendency toward abstraction is in part a direct consequence of the technical constraints of both Durandelle's relatively simple equipment and the documentary nature of the project, which required highly detailed, optically sharp, easily readable images (Keller, 112–113).

The firm Delmaet & Durandelle undertook other projects to recording the massive building and renovation programs in Paris and elsewhere in France in the last third of the nineteenth century. These projects included photographing the rebuilding of the Hôtel-Dieu (1868), the building of the Bibliothèque Nationale (1870), the destructions wrought by the Franco-Prussian war and the Paris Commune (1870–71), the renovation of the abbey of Mont-Saint Michel under the architect Edouard Corroyer (1874–8), the construction in Montmartre of Sacre Coeur (1877–90), designed by architect Paul Abadie, and finally the construction phases of the Eiffel Tower, which was begin in 1887 and completed in 1889. Photographs from the latter two projects are included in albums at the Bibliothèque Nationale, *Construction de la Tour Eiffel* (2 vols., 1889), and *Eglise de Sacre Coeur à Montmartre* (2 vols., 1890). Additionally, the firm completed smaller projects, such as documenting the construction of the theater at Monte Carlo (1880), also designed by architect Charles Garnier, and photographing the archaeological excavations of the subterranean space under the Louvre (1882–84).

Durandelle's prints of the Opéra were exhibited to acclaim in the universal exhibition of 1878, Paris. He also won medals in the universal exhibitions of 1878, 1882, and 1889. After the death of Clémence, Durandelle retired to Bois-Colombes in 1890 and married Julie-Eugenie Saint-Léger. He left his studio to Paul-Joseph-Albert-Chevojon, who continued to make industrial and architectural photographs. Durandelle died in 1917.

Major holdings of Durandelle's photographs include the Bibliothèque Nationale, Paris, the Bibliothèque Historique de la Ville de Paris, the Musée d'Orsay, Paris, the Canadian Centre for Architecture. There are no known family archives or correspondence.

SARAH KENNEL

Biography

Born in 1839, Louis-Emile Durandelle was among the most accomplished architectural photographers in nineteenth-century France. Little is known of his early training, but by 1854 he operated a studio with Hycaninthe Cesar Delmaet (1828–1862). After Delmaet's death in 1862, Durandelle married Delmaet's widow, Clémence Jacob Delmaet, who retained her first husband's surname and actively participated in the running of the studio. The firm "Delmaet and Durandelle" was responsible for documenting the construction or rebuilding of some of the most important landmarks in Paris, including the Paris Opéra, the the Hôtel-Dieu, the Bibliothèque Nationale and the church of Sacre-Coeur, and the construction of the Eiffel Tower. Durandelle exhibited photographs in the universal exhibitions of 1878, 1882, and 1889. In 1890, upon the death of Clémence Jacob, Durandelle sold the business and archives to his assistant Paul-Joseph-Albert Chevojon.

DURIEU, JEAN-LOUIS-MARIE-EUGÈNE (1800–1874)

Jean Louis Marie Eugène Durieu (1800, Nîmes, France–1874, Paris, France) was an early French photographer of nudes (male and female), known for making studies for Eugène Delacroix. Some of Durieu's nudes were used by Delacroix to create his own paintings and drawings.

Durieu was a jurist, he served the government during the stormy prelude of the French Second Empire. In 1824 he founded a periodical 'Le Mémorial des Percepteurs.' In 1842 he collaborated on a play 'The Husband of the Widow' which remained in the repertoire of the Théatre Français until 1900. He was also a photographer specializing in daguerreotypes and in 1845 he made astral views with Baron Gros. In 1847 he was leading the administrative section of the, Communes, Ministery of the Interior as Inspector-General of Hospices and Public Utilities. As an administrator he

helped create the Corps of Diocesan Architects. In 1848 he became active with experimenting with calotypes and was appointed Director-general of the Administration des Cultes, by then he was working with the Commission for Historic Monuments, as well as with Prosper Mérimée and Charles Blanc. Together they made a vast inventory of photographs of ancient and medieval monuments in France. Durieu was a friend of Viollet-le-Duc and Eugène Durieu, director of the Administration des Cultes, who was an advocate of the paper negative for recording historical monuments, though critical of it in other respects. Durieu though, produced pictures of artists'models, naked or clothed, Arab slave-girls, Italian characters, and theatrical-style studies. One of his albums belonged to Delacroix, who had no qualms about copying the prints in pencil. Photographs, being 'studies' in the sense used by painters, in order to attempt rendering light, were for Delacroix *'an intermediary charged with initiating us more deeply into the secrets of nature (…) a copy, in some ways false by dint of being exact.'* It was around people such as Durieu and Delacroix that a whole critical theory developed, expounding the difference between photography and pictorial arts while merging together arguments for a renewal of both. This redefining was realized by the sudden success of photography during the 1860s, however it remained unforeseen at that time. Later a definition of 'photography as art' was conceived, based on the need for the photographer to make a personal choice concerning the unity of the image, obtained in a single exposure, and the avoidance of superfluous details, of which both were end results that the calotype process favored.

In 1850 Durieu left the Direction des Cultes and retired, meeting Eugène Delacroix (1798-1863) shortly after. Some painters, including Dante Gabriel Rossetti, made use of photography without revealing its influence. Others such as Eugène Delacroix, saw photography as advantageous to drawing and painting. Delacroix was a leader of the Romantic Movement that rejected classical formalism and emphasized artistic imagination featuring the dramatic, emotional, and personal, often through the use of historic and/or erotic subject matter. Delacroix had nude models posed for Eugène Durieu to be photographed and then he enthusiastically used these photographs as source material. Delacroix claimed that looking at photographs provided him a greater understanding about the human body than the inventions of any 'scribbler.' Drawing, sketching, painting, or modeling the nude has remained a classic problem for Western artists since Masaccio's time, but it did not become the photographer's problem until the 1850s, when artists began to use the new medium as a draftsman's aid. Generally painters and the photographers who collaborated with them cloaked the model in paraphernalia to match the artist's intention, Master Eugène Durieu, for example, draped vaguely exotic materials near the models he photographed for Delacroix.

In 1851 he became a founding member of the Société héliographique. In 1853 Durieu began actually taking the photographs of nude models for Delacroix who supervised the drapings. He was especially known for his nudes and models and thus Nude photography defined as the genre of art photography, whose subject is the representation of the naked (full nude) or partially naked (half nude) human body.

The aesthetic value of nude photography and its boundaries with erotic photography can only be determined with difficulty and on an inter-subjectively level, furthermore it is also affected by its numerous overlaps with pornography. In consequence, nude photography and erotic photography always find themselves branded in multiple ways, and labeled as works of artistic freedom, aesthetics, kitsch, junk or provocation. The boundaries of nude photography, erotic photography and pornography are so undefined and continuously changing that they are always determined and defined by the subjective moral view of the individual and the generally accepted cultural confines of "customs and tradition."

The nude is a classic subject in art. The early high cultures (Egypt, Crete, India among others) already knew nude representations. Its development into other represented forms can be pursued from Greek clay artifacts to the art of the middle ages and on to the European art of the modern age. Since the renaissance era, the study of the nude human body has been an intrinsic part of art education at art academies.

By 1847 the nude also became the object of photography, the first nude photographers included Philippe Debussy, E. Delacroix, Eugene Durieu and B. Braquehais. Models were both professionals and prostitutes, and photographs were both artistic and "spicy," which often raised the aversion of moral and law enforcement officers.

In 1855 Durieu wrote a report on the Société française de photographie (SFP) exhibition and together with the vice-president Paul Périer began a discourse concerning the position of art photography. Between 1855 and 1858 Durieu was the chairman of the SFP. board and offered 8 prints to the SF. and at about the same time he was made an honorary member of the Photographic Society of London. In 1856, it was noticed that his prints at the Brussels exhibition had become very pale, while other prints remained well preserved. In 1857 he left 32 Rude du Bac and moved to 10 Rue des Beaux-Arts, Paris. In 1865 he lived at 170, Rue de Rivoli in Paris.

The Société française de photographie, founded in Paris in November 1854, gave no encouragement to artificial picture making, nor to retouching. Its President Eugène Durieu condemned handwork absolutely. 'To call the brush to the aid of the photograph under the pretext of introducing art into it, is doing precisely the

opposite—excluding *photographic art*.' French painters who took up photography, like Gustave Le Gray, Vallou de Villeneuve and Charles Nègre practiced it for its own aesthetic appeal. They did not go beyond legitimate *genre* photographs of picturesque characters such as on organ grinder by Nègre or some Savoyard street musicians by Disdéri.

Durieu also photographed Clamart and St Valéry-en-Caux between 1851–1855. He used daguerreotype, wet negative paper, wax paper prints, salted, collodion and gold toning. His photographs are now in the collections of the Bibliothèque Nationale in Paris, the S.F.P. in Paris, George Eastman House in Rochester (USA).

DURYEA, TOWNSEND (1823–1888) AND SANDFORD (1833–1904)

Townsend Duryea was born in Long Island, New York in 1823, the eldest son of Hewlett Duryea and Ann Bennett. His younger brother Sanford Bennett Duryea was born in Long Island on 22 February 1833. Townsend started working as a daguerreotypist at 140 Grand St, in Williamsburgh (Brooklyn) in 1840. He was joined in his studio in 1851 by Sanford. After remarrying Townsend left for Australia in 1853 aboard the *Canton,* and established two studios with Archibald McDonald in Melbourne in 1854 and they were then joined by Sanford who arrived aboard the *Nightingale* in August, leaving the New York studio under the control of their nephews Alva Adee Pearsall (b. 1839) and G. Frank E. Pearsall (b. 1841) who both later opened studios of their own in New York. Duryea and McDonald branches were opened in Geelong and Tasmania and they employed Charles Nettleton in Melbourne to perform the outdoor work. The Duryea brothers relocated to King William St, Adelaide in 1855 offering daguerreotypes and ambrotypes. During 1856 they visited country towns and Sanford set up the first studio in 1857 in Perth, Western Australia, before returning to Adelaide in 1859. He made several more visits to Perth, but broke from his brother and returned to America in 1863. Townsend was the society photographer of Adelaide producing fine cartes de visite and training others in photography including Robert Sheppard Stacy and Henry Jones, not to mention his four sons Townsend (b. c.1854), Edwin (b. 1857), Richard (b. 1859), and Frank (b. 1861) who all went on to open studios. Townsend created a massive 14 panel panorama of Adelaide during 1865. He was the official photographer for the Royal visit of H. R. H. the Duke of Edinburgh, Prince Alfred in 1867. A branch studio was opened in Wallaroo in 1873 and then Moonta, operated by Saul Solomon, who later opened another Adelaide branch at 51 Rundle St. On 17 April 1875 the King William St studio and 60,000 negative were destroyed by fire; Townsend relocated to Moonta installing George Bentley as operator, his rebuilt Adelaide studio being taken over by Stephen E. Nixon and Charles H. Manning. Townsend retired from photography at the age of 57, and took up farming in the Riverina district of NSW where he died in 1888. Sanford resumed photography opening a studio at 253 Fulton St, Brooklyn in 1876. Sanford's studio was damaged by fire in 1878 but he rebuilt and he opened a branch at 297 Fulton St in the late 1880s. Sanford's son Hewlett a.k.a. Frederick went to California and became a Kodak agent. His son Chester learnt photography and became a pioneer in the field of radiology. Sanford retired around the age of sixty and died in Long Island in 1904. Henry Augustus Duryea, Townsend's son from his first marriage also worked as a photographer in Brooklyn from around 1880 until his death in 1889.

MARCEL SAFIER

DUTILLEUX, CONSTANT (1807–1865)

French teacher and photographer

Born in 1807 in Douai in northern France, Constant (Henri-Joseph) Dutilleux moved to Paris in 1826 where he worked in a printer's shop and trained at the Ecole des Beaux-Arts. In 1830 he moved from Paris to Arras, where he taught painting, drawing and lithography and ran a lithography firm. Dutilleux, who learned cliché verre technique from Adalbert Cuvelier and drawing professor Léandre Grandguillaume in early 1853, introduced the technique to Camille Corot who, like Dutilleux, was best known for his *en plein air* landcape painting. Working in Arras and, after 1851, in the forest

of Fontainebleau alongside Barbizon artists, Dutilleux produced numerous paintings, drawings, and at least thirteen clichés-verre representing landscape and rural scenes, made in 1853 and again in 1857. Like Corot, who executed his first clichés-verre in collaboration with Dutilleux, the latter's work in this technique epitomizes the close relationship between painting and photography that characterized the Barbizon school. Unlike the linear, graphic qualities of Corot's early clichés-verre, however, many of Dutilleux's clichés verres were made by the painted plate method and exhibit softer lines and a broad tonal range. In 1860, Dutilleux moved to 58 rue st Georges, Paris, leaving his lithography studio to former pupil Charles Desavary. He died in Paris 1865. The Musée des Beaux-Arts, Arras, holds a significant collection of Dutilleux's clichés verre.

SARAH KENNEL

E

EAKINS, THOMAS COWPERTHWAITE (1844-1916)

American painter, sculptor, photographer, and teacher

Eakins was born in Philadelphia, Pennsylvania, and began his career by assisting his father, Benjamin, as a calligrapher and teacher of penmanship. His interests in draftsmanship extended beyond decorative writing, however, and from 1862 until his departure for Paris in 1866 Eakins studied drawing and anatomy at the Pennsylvania Academy of the Fine Arts (PAFA) and Jefferson Medical College in Philadelphia. In Paris, he enrolled at the prestigious Ecole des Beaux-Arts and became a pupil in the ateliers of Jean-Léon Gérôme and Léon Bonnat. Although he likely had gained exposure to photography before traveling to Europe, there Eakins learned about the documentary and artistic value of using photographs as study tools with which to compose and add subtle details to paintings. He also came to believe that an understanding of the mechanics and structure of the human body was the true basis for creating art.

Returning to Philadelphia in 1870, Eakins later joined the PAFA staff as an assistant instructor. In 1878 he was approached by the school's Chairman of Instruction, Fairman Rogers, to help him solve a visual puzzle. When Eadweard Muybridge publicized his motion photographs of racehorses, the size, lack of detail, and inconsistent intervals of the serial images kept Rogers from testing them for accuracy of movement. Rogers hired Eakins to produce drawings of the photographs with which the artist would reconstruct the horses' positions in a consistent series. The two men could then test the results by "reanimating" the photographs in a zoetrope. Eakins applied his results to painting, depicting Rogers riding with his own team of horses in *A May Morning in the Park (Fairman Rogers Four-in-Hand)* (1879–80).

Muybridge later continued his *Animal Locomotion* project at the University of Pennsylvania, and in 1884 Eakins joined him in his work. The two men outfitted a track with a series of cameras whose shutters were tripped at regular intervals as an animal or human subject walked, ran, or jumped through the space in a full period of motion. Rejecting Muybridge's use of sequenced negatives, however, Eakins instead recorded successive exposures of motion on a single negative. In photographs such as "History of a Jump" (1885), he adapted Etienne-Jules Marey's invention of a spinning slotted disk that regularly admitted light to a single point on the open lens of the camera. Muybridge published his photographs in *Animal Locomotion* in 1888 and included a summary of Eakins's research in Professor William Marks's essay, "The Mechanism of Instantaneous Photography."

Eakins had purchased his own camera by 1880 and soon produced photographic sketches of his family members at home and on the beach at Manasquan, New Jersey. Becoming director of the schools at PAFA in 1882, he captured students posed in period clothing and photographed Margaret Harrison in preparation for his painting, *Singing A Pathetic Song* (1881).

By 1881, Eakins employed a magic lantern or another device to project his photographic images onto his painting supports. In his earliest attempts, he traced the outlines of the projected forms in pencil but later abandoned this underdrawing technique and used the projections to incise tiny reference marks onto his canvases. In two versions of *Shad Fishing at Gloucester on the Delaware River* (1881), he utilized multiple projected photographs to compose his paintings with marks made during the various stages of the painting process. (See Tucker and Gutman in *Thomas Eakins*, 2001, Further Reading.)

Beginning about 1883, Eakins undertook three photographic studies of the nude for use in his painting

and his teaching at PAFA and the Philadelphia Art Students' League. Many of these images were made with the assistance of or, often, by his students, including Susan Macdowell, whom he married in 1884. One group of nudes, taken in the studio, was comprised of photographic "académies"—studies of poses echoing classical sculpture and painting—that might be used in the creation of narrative art. Insisting that students should learn from life rather than by drawing or painting only from classical casts, he had them pose for each other in these photographs. Depicting a reclining nude Bill Duckett or an unnamed female model reposed in the manner of an odalisque, he and the students created beautiful and technically useful images.

In 1883 Eakins also pictured his students, professional models, and himself posing in a separate group of images he called the "naked series." "J. Laurie Wallace: Naked Series" and others from the group showed subjects in uniform standing poses seen from seven perspectives. Mary Panzer has linked these photographs to Eakins's motion series, stating that whereas the motion photographs revealed the body's position in action, the naked series showed comparable views of weight shifts in the stationary figure. (see Danly and Leibold, 42, Further Reading). Hanging these images together in the PAFA studio, Eakins and his students used them to determine both the figures' centers of gravity and their differences of physique within identical poses. The photographs helped them to paint, draw, or sculpt figures with lifelike volume and movement.

Eakins's third collection of nudes featured himself and his students together in idyllic communion with nature. These pictures were taken during outdoor excursions to nearby locations in Pennsylvania and New Jersey and provided the backbone for Eakins's paintings *Arcadia* (c. 1883), *An Arcadian* (c. 1883), and *The Swimming Hole* (1884–85). Referencing both a classical past and a present of unashamed camaraderie, the photographs exhibited the bonds of friendship and honest integrity that linked teacher and students

in their drive for artistic professionalism. These bonds were maintained in the display and production of nude photographs at the Art Students' League after Eakins's forced departure from PAFA in 1886.

From the 1890s until his death in 1916, Eakins's interest in photography appears to have diminished as he concentrated his efforts on painting portraits. His work would influence the work of Eva Watson-Schütze and other pictorialist photographers, however. In tribute to his work as a photographic pioneer, members of the pictorialist Camera Club of New York included two images of bathers by Eakins in their 1899–1900 exhibition.

MEREDITH KEY SOLES

Biography

Thomas Cowperthwaite Eakins was born to Benjamin and Caroline Cowperthwaite Eakins on 25 July 1844 in Philadelphia, Pennsylvania. He first studied drawing at the Pennsylvania Academy of the Fine Arts (PAFA) before enrolling at the Ecole des Beaux-Arts in Paris from 1866 to 1869. Returning to spend his career in Philadelphia, he became an instructor and, in 1882, the director of schools at PAFA. He married one of his students, Susan Hannah Macdowell, in 1884. Eakins was dismissed from his director's position in 1886 after he removed the loincloth from a male model posing for a class of female students. Thereafter, he continued to lecture at the Philadelphia and Washington, D.C. Art Students' Leagues, the Women's Art School of the Cooper Union, and the National Academy of Design. Although he showed his painting and sculpture nationally and internationally, the only recorded exhibitions of his photographs were the 1886 display of "History of a Jump" in the Philadelphia Photographic Society annual at PAFA and that of two bathers at the 1899–1900 New York Camera Club exhibit. Eakins was active as lecturer and portrait painter until shortly before his death in Philadelphia on 25 June 1916.

EASTLAKE, SIR CHARLES LOCK (1793–1865)

British patron

Born 17 November 1793 in Plymouth, England, Charles Lock Eastlake was, "the first, and perhaps still the greatest, of that tribe of cultural bureaucrats who…were to become the most significant manipulators of taste and controllers of artistic power…" Sir Charles Lock Eastlake is easily confused with his nephew, Charles Locke Eastlake (1836–1906). The younger Eastlake, also a Victorian taste-maker, was author of two widely known works, *Hints on Household Taste* (1868) and *A History of the Gothic Revival* (1872). Eastlake's initial ambition was to become a painter and to this end, he studied in France, Greece and Italy from 1816 to 1830. During these years, Eastlake was increasingly influenced by a newly emerging German approach to art scholarship that sought to apply a scientific basis to art criticism. He undertook a second career as an art critic and historian culminating in his immensely influential, annotated translation of Johann Wolfgang von Goethe's *Zur Farbenlehre* (1810) as *Goethe's Theory of Colours* (1840)—a publication challenging Newton's seven-color theory with one based on three primary colours. Eastlake's other publications included the first volume of *Materials for a History of Oil Painting* (1847) and a collection of articles entitled *Contributions to the Literature of the Fine Arts* (1848).

While abroad, Eastlake's painting and writing attracted the attention of his fellow expatriates and London critics to the extent that he was elected, *in absentia*, as an Associate to the Royal Academy, becoming a full Academician shortly after his return to England. In 1841, Eastlake was appointed Secretary of the Fine Arts Commission, followed in 1842, by an appointment as Librarian of the Royal Academy and in 1843, as Keeper of the National Gallery. Forced to resign from the Gallery in 1847 over the mistaken purchase of a forged Holbein, Eastlake was nevertheless appointed President of the Royal Academy in 1850. In 1855, he returned to the National Gallery as its first Director, maintaining that post (as well as his Presidency of the Royal Academy)

until his death. Enjoying the full support of both Prince Albert and Parliament, Eastlake greatly expanded the collection of the National Gallery.

Eastlake's knowledge of and interest in photography was at least partly due to his association with the writer and critic Elizabeth Rigby whom he may have met as early as 1843. Rigby was at that time living in Edinburgh where she had both written about and posed for David Octavius Hill and Robert Adamson. As an art critic, Rigby wrote glowingly of a series of Eastlake's portraits, referring to him in her journal of 2 March 1844 as "the Raphael of England." Their professional relationship, as advocates of German art historicism in Britain, evolved into a romance and on 9 April 1849, the middle-aged couple was married at St. John's Church in Edinburgh.

From their position as what Steegman calls a "composite personality"1 atop the mid-Victorian art world, the Eastlakes' support of photography lent considerable prestige to the new medium. The first manifestation of this may have come through Sir Charles' (he was knighted in 1850) position as a member of the Board of Governors of the Great Exhibition of 1851. The Board sanctioned the most ambitious retrospective of photography in the medium's 12 year history, while the Great Exhibition as a whole recognized photography as both an industrial process and a tool for recording of the event itself.

Eastlake's involvement with photography continued in the following year as part of the effort to encourage William Henry Fox Talbot to relinquish his patents on the calotype process. Talbot had agreed to the request on the condition that he would be officially asked to do so by major figures in the British artistic community. Together with Lord Rosse, President of the Royal Society of Arts, Eastlake signed the formal request. Talbot responded with a letter allowing free use of the process by all but professional portrait photographers (both documents then being published in the *London Times* on 13 August 1852). This agreement failed to satisfy the professional photographers, who continued to press Talbot for unconditional release of his patents. It is H.J.P. Arnold's contention that the impasse became an impetus for Roger Fenton's organization of the Photographic Society of London while Gail Buckland asserts that it was Talbot's refusal to relinquish his patents that delayed the Society's formation. In either case, the effort to placate Talbot by offering him the Presidency of the new society was met with Talbot's refusal. At its first meeting on 20 January, 1853, it was instead Sir Charles Eastlake who agreed to become the Society's first President. As Elizabeth would write in her anonymously published 1857 *Quarterly Review* article, "Photography," her husband was selected by the members "in order to give the newly instituted body the support and recognition which art was supposed to owe it."

Eastlake served two consecutive terms as President of the Photographic Society of London (1853–1855). Although Fenton, as the Society's Honorary Secretary, was responsible for most of its organizational activities, there is little doubt that the Society benefited directly from Eastlake's long association with the Royal family. In May 1853, both Queen Victoria and Prince Albert became members and then on 2 June 1853, during the Society's fifth meeting, a letter from Buckingham Palace announced the bestowal of Royal Patronage upon it. Eastlake was among those who escorted Victoria and Albert through the Society's first exhibition in January, 1854 at the Suffolk Street Gallery of the Society of British Artists. As the Royal family's artistic advisor, Eastlake may also be credited with establishing their use of photography as a tool in art historical studies. In 1853, Prince Albert commissioned a systematic photographic record of the Royal family's Raphael drawings, a work later published as *"The Raphael Collection at Windsor Castle.*"

Eastlake's contributions to photography between his departure from the presidency of the Photographic Society and his death in Pisa on 24 December 1865 are more nebulous. Although he and Elizabeth were in close agreement on artistic issues, there is no evidence of his collaboration in her seminal 1857 essay. Perhaps his greatest contribution in those years as before was to lend the considerable weight of the official Victorian art world to at least a consideration of the medium's legitimacy.

Renate Wickens-Feldman

Biography

Sir Charles Lock Eastlake was born on 17 November 1793 in Plymouth, England. From 1816–1830, he pursued a career as painter and art historian in France, Greece and Italy. Upon his return to England, Eastlake was appointed to a series of official positions culminating in President of the Royal Academy (1850) and Director of the National Gallery (1855). Eastlake's interest in photography was encouraged through his association, from the mid-1840s, with the critic Elizabeth Rigby, whom he married in 1849. In 1852, Eastlake helped mediate the agreement by which William Henry Fox Talbot placed his patents in the public domain for all purposes other than portraiture. The following year, he was appointed President of the newly formed Photographic Society of London, a position he retained until 1855. Eastlake's long collaboration with Victoria and Albert was likely responsible for the Society's gaining royal patronage. He died in Pisa on 24 December 1865.

EASTMAN, GEORGE (1854–1932)

The close of the 19th century was a watershed in George Eastman's life (1854–1932): a time when he moved from active, intensive work in photography, from building the factories to market his products and amassing great wealth to a time of relative leisure and the building of institutions to serve humankind through music, medicine, dentistry, philanthropy, racial advancement, and education both technical and liberal. Spanning this watershed was the photographic revolution he initiated.

As a 23-year-old bank clerk in Rochester, NY with a sixth-grade education, Eastman entered hobby photography in 1877, purchasing a collodion wet-plate camera and paraphernalia to record trips. He subscribed to the *British Journal of Photography* in 1878 and in the very first issue, learned about gelatin dry plates. He began producing dry plates for his own use and in 1880, for sale through the E. and H. T. Anthony Company in New York. He also patented machines to coat the plates, first in London (July 1879) and then in the USA (April 1880).

The bank clerk gained a business partner on 1 January 1881 when Col. Henry Alvah Strong, a buggy-whip manufacturer, invested $1,000 in the Eastman Dry Plate Company. Strong would hold the honorific title of president until his death in 1919 with Eastman being the treasurer and general manager (comparable to today's CEO).

Eastman continued working at the bank until September 1881, tending to his dry plate business from 3 PM until midnight and weekends. His reputation for superior plates resulted in a growing business until an emulsion crisis almost closed the business in 1882. He sped to London, photographic capital of the world, "standing in the works" of Mawson & Swan Dry Plate Company for two weeks to learn the reason for the emulsion failure. (His supplier had changed gelatin sources and a vital ingredient—sulfur—was missing.)

Recovering after recalling and replacing the spoiled plates, Eastman soon realized that professional studio photographers and serious amateurs comprised a finite market. In order to grow his business, he would have to target a growing market: everyone. But in the 1880s, hardly anyone entertained the thought of taking pictures himself. Eastman would not only have to simplify photography so that the absolute amateur could take pictures, but he would have to create the desire to do so through advertising and marketing. Part of his genius was combining innovation, simplicity, and quality products with pithy slogans such as "You press the button, we do the rest."

From 1881 on, Eastman pursued transparent, flexible substitutes for heavy, breakable glass, marketing a paper-backed film and roll film holder in 1884. His inability to produce a film without the paper backing led him to hire an undergraduate chemist, Henry Reichenbach, to spend all of his time working on this quandary.

Eastman tinkered until he had constructed a simple, hand-held camera that used the paper-backed film and that anyone, even the rankest amateur, could operate. The Eastman Detective camera (1886) was a dismal failure but the Kodak camera (1888) was a runaway success.

While anyone could take pictures with Eastman's simple Kodak system, developing the paper-backed film was devilishly difficult. So in 1886, he started a photo-finishing business—probably the first in the world. Factory processing of the finished product circumvented the professional photographer and created a vast new market undreamed of by Daguerre and other early photographers.

When the Kodak camera was introduced, it came loaded with a roll of film with 100 exposures. After

the photographer had finished the roll, he could send the whole camera back to Rochester where the film was developed, prints were made and sent back along with the reloaded camera. (Daylight-loading film was invented in 1892.)

Finally in August 1889, Eastman introduced Reichenbach's transparent, flexible nitrate film. The difference in film quality was so obvious that film and camera sales soared again. The 1890s saw the photographic revolution continue with smaller, more efficient camera models culminating in the Brownie camera of 1900, marketed for $1 and taking a roll of film costing 15 cents.

As the first to market film, and the maker of the best film in the 1890s, Eastman was poised to take advantage of the introduction of x-ray photography (1896) and motion pictures. In 1889, Thomas Edison purchased 50 feet of double-thick Kodak film for his Kinetescope, a prototype motion picture machine. When projectors came into use (ca. 1895), they took miles of film. Eastman's company was the only one poised to meet these needs.

The key to Eastman's business success initially was a combination of business and marketing skills and insights, a technological orientation, continuous personal innovation of products, especially cameras, acquiring all patents that related to the company's principal products, and enforcing those patents through lawsuits. Soon he added recruiting employees with technical skills, intense and clever advertising, worldwide distribution of products, the outmaneuvering of competitors, and the raising of capital. The photographic manufacturing business was highly competitive but Eastman was able to win dominance not only in the United States but also in the United Kingdom and on the continent of Europe.

By 1900, twenty years after going into business, the company started by a bank clerk and whip manufacturer was the largest photographic materials business in the world. At the same time, Eastman's own personal technical activities ceased as he delegated many of the functions that he had earlier personally performed. He credited his talented staff with "switching Kodak Park from the empirical to the scientific path."

In 1898, Eastman refinanced the company in London, financial capital of the world, acting as his own broker against the furious opposition of London bankers and brokers, emerging with a personal profit of $1 million. He shared the profit with employees on both sides of the Atlantic—the first Kodak Bonus. This unprecedented move was later institutionalized as wage dividends (1912), savings and loan schemes (1921), stock options, and benefit and pension plans (1929). His reorganization of the Eastman Kodak Company indicated a shift in interest toward the construction of new facilities and finance.

By 1904, Eastman was pursuing techniques of color photography. The most serious effort began in 1914 with the introduction of a two-color color technique named Kodachrome that was good for portraits and still lifes but not landscapes.

The Bayer Company, a large German chemical company that employed 800 research scientists in a prototypical industrial research laboratory founded in 1891, influenced Eastman to change the focus of Kodak's testing laboratory to a research one in 1912.

Because of his burning desire for a better color process, Eastman hired the British research chemist C. E. Kenneth Mees of Wratten & Wainwright to establish the Kodak Research Laboratory (KRL). He considered Mees the world's foremost color authority because of his experience with color-sensitized plates. Mees brought with him a large contingent of Britain's best photographic scientists.

Before Mees, Kodak had a 30-year tradition of technical innovation with Eastman himself handling much of the experimental and developmental work on gelatin dry plates, photographic printing papers, and the new system of roll film. He began to control raw materials through contracts such as that with the General Paper Company. He then gradually built the capacity to produce vitally needed materials, for example, raw paper, gelatin, chemicals, and lenses. In the first decade of the 20th century, he bought twenty major photographic retail stores in large cities across the U.S. and in Canada.

While Mees's knowledge of color photography may have been the main reason that Eastman hired him, he also told Mees that his job was "the future of photography," giving him unbridled leeway to develop research along whatever lines it happened to lead. Mees and other members of Eastman's carefully selected management team ensured the future of the company.

The company's growth was based on innovation, quality control, expansion and the acquisition of know-how purchased from outside sources. Eastman often bought small companies in order to obtain superior products such as the emulsion-making formulas and services of William Stuber. But he recognized that he could not continue this indefinitely in an era when the federal government was investigating him for antitrust violations. Also, the development of new color processes required knowledge that Eastman and his staff did not have and color offered an opportunity to solidify Kodak's leadership position. In addition, Eastman desired that Kodak rank among the corporate trendsetters of his time such as Bayer.

While Eastman's historical importance rests on his roles as business entrepreneur and visionary industrialist; he was also a zealous patriot. Thus, during World War I he directed the Kodak Research Laboratories

(KRL) to lend its resources to the U. S. armed services. This resulted in advances in experimental aerial photography, camouflage (the most effective way to paint a surface vessel to avoid detection by submarines), and colloidal fuels. Most important, Eastman set up a Synthetic Organic Chemicals Department to counteract the utter dependency on German chemicals such as sensitizing dyes and photographic developing agents. By 1921, this department was producing more than 1000 specialty chemicals.

The first major post-war product from the KRL was amateur motion picture film in 1923. Eastman continued pressing Mees to market a color technology (done in 1928, prematurely). In 1920, Eastman had interviewed the young Leopold Mannes and Leopold Godowsky—who would eventually produce the groundbreaking Kodachrome film in 1935 under Mees's aegis, three years after Eastman's death.

Eastman's role as philanthropist is impressive too. His interest in Rochester projects was partly to make the city a "better place for Kodak people to live and raise a family." His rationale for founding the Eastman School of Music—"What you do in your working hours determines what you have; what you do in your leisure hours determines what you are"—could refer to his stimulus for other charitable gifts. Pragmatism and personal appeal were the foundation of his philanthropic philosophy. Trained technicians were important to his business so he became an early fund-raiser for what is today the Rochester Institute of Technology. His reliance on "the good stock" coming to Kodak from the Massachusetts Institute of Technology led him to build a new campus for MIT as an anonymous donor merely known as "Mr. Smith." His concern about preventive dentistry for children had a personal—he and his mother had poor teeth and gums—as well as a community service component. His gift of the Rochester Dental Dispensary led to an Eastman Dental Clinic in five European cities: London, Paris, Rome, Brussels, and Stockholm.

In 1920, when Rockefeller philanthropic interests, led by Abraham Flexner, proposed that he establish a medical school—modeled after Johns Hopkins University—at the University of Rochester, he readily agreed to expand his health care interests. He and Henry Strong's family founded Strong Memorial Hospital and the school/hospital complex continues as the region's largest and most complete medical center and after the Eastman Kodak Company, the area's premier employer.

Eastman owned the only old master art collection in Rochester, bequeathed to the Memorial Art Gallery of the University of Rochester. The university's Eastman School of Music is a conservatory for training performers and teachers and its Eastman Theatre, originally a silent film theater, continues as home to the Eastman-founded Rochester Philharmonic Orchestra. The musical complex had as its goal the training of listeners and the music school often leads the list when "best" music schools in the country are named.

The son of abolitionists, Eastman became his generation's greatest contributor to African American education. His early interest in technical education widened to include liberal arts, education for minorities, music education and women's education—particularly at the University of Rochester.

Despite a myriad of charitable gifts, Eastman considered his major philanthropic contribution to be the company he founded that provided so much work for so many people.

EATON, THOMAS DAMANT (1800–1871)
English

Thomas Eaton was born on 19 January 1800, the only son of Thomas and Mary Eaton (nee Damant). He was educated at Norwich Grammar School and later continued his father's silk merchant's business.

Along with his literary, artistic and scientific interests, he was known as a musician and music critic. He retired from business in 1846 to devote himself to painting and photography.

His first photograph, of a Norwich church, was taken in 1845. He showed a further view of Norwich in the 1852 Society of Arts London exhibition, and three in the Norwich Photographic Society's 1856 show. He was a member of the Photographic Society of London and President of the Norwich Photographic Society and helped organise their impressive 1856 exhibition, which had an entry of over 500 images.

He used the calotype process and later wet-collodion to produce pictures of family, friends, landscape and architecture, which were mostly made in his home city. In the early and mid 1850's he contributed articles concerning photography to both *Notes and Queries* and the *Journal of the Photographic Society.*

The Eaton family were bound up with civic life in Norwich, Thomas was a member of the City Council and awarded the honor of freedom of the city.

Ian Sumner

ECONOMICS AND COSTS

Photography became commercially viable at a difficult economic conjuncture. The recession of the early 1840s deeply effected both Europe and the USA promoting autarchy and protectionism which in turn restricted the circulation of materials and methodologies in the most photographically advanced countries: Britain and France. In the USA early adoption of the daguerreotype process was favoured by the large unemployed masses. Undoubtedly the profession attracted so many since in the 1850s, photography was seen to represent a future in which huge fortunes could be made, and quickly. As in most similar instances, this was true only in a very few occurrences. While serious practitioners spent a few months learning how to make good daguerreotypes, many started completely untrained, tainting the profession's reputation. In any case, with the rapid expansion in the number of practitioners, final quality and revenues suffered, and mass merchandising was finally born.

1840s and 1850s

The first commercial studios opened in New York in 1840, soon followed by London and Paris. For £150

Richard Beard first purchased an annual license to use the process then the rights to adopt the daguerreotype in England; in 1841 opened the first portrait studio in London, and started selling licenses to a number of operators in the provinces for the astonishing sum of £1200. Obviously, it would be unrealistic for a photographer to pay that sum for a licence when the daguerreotype portrait cost one guinea, a little more than the average urban weekly wage; and the costs of setting up a studio was about an average of £1100 for building work, equipment and assistants for a final annual income of £2000. Despite the presence of these and other portrait studios in other cities, commercial photography strained under the restrictive patents covering the daguerreotype and calotype, and Talbot's patent fee for the latter was £100 for the first year and £150 each following year. What was needed to improve the situation was a larger patent-free market, fast and economical processes, and a large public forum for distribution. This arrived in the 1850s, transforming and democratizing photography.

The year 1851 marked the beginning of a new period in photography with Frederick Scott Archer's invention of the wet collodion negative which supplanted all existing methods, and was the fastest photographic process to date, and the first, in England at least, free from patent restrictions. The publication of the unpatented process led directly to the relinquishment of Talbot's patent in 1854 and bypassed Beard's daguerreotype patent by offering a practical alternative for portrait studios. Moreover it made possible to print thousands of photographic positives from a single negative. This development provided the backbone for the stereoscopic and carte-de visite industries and photography progressed from the status of a cottage industry to semi-industrialization. Photographers needed assistants who were paid an average of £150 per year, this rate referred exclusively to first-class men, and the number of talented assistants available was very small, so a percentage of the profit, or sometimes an offer of partnership, was necessary to retain them. Otherwise most assistants were paid near £50.

Manufactories quickly recognised the demand for processing equipment. Some cameras from the 1840s to 1900 were sold with a range of trays, flasks, measuring cylinders, and printing frames, plus full instructions. In 1850s the costs for a rigid camera ranged between 18 shillings and £6 while for an expanding camera was between £1 and £11 and a stereoscopic camera ranged between £3 and £6. More usually, the photographer bought what he needed for the plate size he worked with. The basic requirement was for a glasshouse studio, and a workroom. In the workroom—in which preparation and processing was carried out—daylight was filtered using yellow glass or yellow cloth to create safe conditions. In smaller studios it was not uncommon for a shed to be erected outdoors to serve as a workroom. It was possible to hire fully equipped private glasshouses at the weekly rent of 5 guineas with six lessons. For photographers working on location, or at local fairs, portable darkrooms built around wheelbarrows, darktents, and 'photographic wagons' were available, with price dependent upon the level of sophistication.

The 1850s saw an improvement in hauling transportation which consequently increased output and lowered prices, producing a wave of prosperity lasting until the early 1860s. Portrait photographers did good business in the following years but the days of vast fortunes from photography were still to come. During the whole decade, fashionable West-end photographers charged a guinea for a whole plate portrait, 3 guineas for the same size coloured, and 5 guineas for a large size, coloured. The price for a stereoscopic picture varied from 1 to 16 shillings.

In 1858 in New York, where the daguerreotype was essentially the only process used, only later replaced by the ambrotype, inexpensive and relatively simple to set up, there were two hundred studios, producing a combined annual turnover of $2 million.

1860s and 1870s

A growing consumer market demanded better-quality photographs, made more easily and cheaply, and technologies were adapted to enhance uniformity and affordability. New lenses improved image resolution and reduced exposure times, their costs ranged between 6 shillings and 16 guineas; less expensive glass-plate negatives, which cost between 2 and 6 shillings for a dozen and coated printing paper brought a new generation of inexpensive photographic artefacts. The wet collodion era and, in the U.S., post-Civil War growth attracted many people to the trade, exceeding the demand for offered services and prices plummeted.

By 1861, *carte-de-visites*, tintypes, and stereographs were being produced in their millions, and successful studios were structured like small factories, with standardized procedures and a clear division of labour, They were created with the backing of external capital, collected in the guise of a joint-stock companies, at the heart of which the photographer was at best a major shareholder, but often a merely a salaried employee.

Adolphe-Eugène Disdéri, who was reputed to be one of the richest photographers, taking 1.2 million francs (£48.000) a year, charged 30 francs for 25 *cartes* with two poses, 50 francs for 50 *cartes*, 70 francs for 100 *cartes* and 100 francs for a life-size portrait taken on a plate. In the summer of 1861 33,000 people made their living from the production of photographs and photographic materials in Paris. The same year in London the number of people earning their living from photography

had risen to 2800 and the portrait studios had risen from 66 in 1855 to over 200; in 1866 when the *carte-de-visite* craze had reached its peak there were 284. The average of a wage of a photographer was between £6.000 and £12.000, earned by Mayall who outstripped other English professionals, and the costs for a sitting was 1 guinea for twelve *cartes-de-visite* and £2 for twelve cabinets In Contrast to the impressive sum earned by a large number of photographers, their assistants, who worked from 8 am to 6 pm, received on the average £2 to £3 per week. The top wage for the first-class studio operators was £250 per year. They were required to work both before and after the image had been taken, chemists were needed to prepare negatives, printers to develop the proofs, labourers to colour and stick the prints. In Paris in the mid-1860s the number of studios employing more than ten people was less than ten per cent. Small, family-run concerns, with one or two employees, were still more numerous by far during this period, even though there were photographers like Nadar and Disdéri who employed the up to 50 assistants and 80 assistants respectively.

Photographic art reproductions tapped into the growing middle-class who could afford photographs of themselves in the same elegant and luxurious surrounding of the nobility. They started collecting, and this marked boomed after 1865, when new pigment and photomechanical processes such as carbon and Woodburytype facilitated stable and relatively inexpensive photographic reproductions, even though the patent fee for this process was still high as Goupil & Co. of Paris acquired the rights for France for 150.000 francs (then £6.000).

Mass-produced photographs were finally so inexpensive that only the largest firms could profit from them, and as the market became saturated with each new product type, prices dropped. In the 1860s overproduction and economic stagnation reduced prices and competition was fierce, studios turned to larger formats such as cabinet cards.

At the height of the *carte-de-visite* period, 300 to 400 million *cartes* were estimated to be sold annually in England. So great was the number that more than one Chancellor of the Exchequer contemplated, following America's example, materially adding to the national income by a small tax on each photograph. Between 1864 and 1866 Americans had to affix a stamp to the back of all photographs, ranging in value from 2 to 5 cents. Gladstone considered a penny tax in 1864, and so did Disraeli in 1868, when it was stated that a penny stamp on the roughly 5 million photographs sold annually would help in the prosecution of the Abyssinian war. This lower figure illustrates clearly the decline in the demand of *cartes.*

The situation worsened in the 1870s with a severe depression on both sides of the Atlantic, aggravated by war. In Paris, many studios went bankrupt during the Prussian siege and the mayhem of the Paris Commune drove wealthy clients out to the provinces. The last thirty years of the 19th century were marked by economic fluctuation, with a decline in output between 1875 and 1884, and recession in 1873 and 1893. The photographic market had been held back by the perishability of materials, inhibiting standardization and mass production, and the relative complexity of products had restricted the amateur market.

1880s and 1890s

The market changed again with the commercial introduction of gelatine bromide dry-plate negatives and printing papers in the 1880s. Few photographers had the necessary time or skill to use this process, so commercial manufactures took on the production of ready-sensitized materials, whose adoption was slowed by high prices, technical inconsistencies, and the need to light-proof apparatus and darkrooms. Cameras became simpler and cheaper, their cost ranged between £5 and £32. Eastman's core business was film and paper, and the cameras were essentially vehicles to increase demand; the company's processing and printing services cost up to 50 per cent of the initial outlay for a camera. The prices charged by the leading firms for gelatine dry plate were between 3 shillings to £1 and 6 shillings per dozen, depending on size, in 1880 and between 1 and 10 shillings per dozen in 1890.

From 1880 the growth of the studios in London was in line with the population and fluctuated between 260 and 280 with a pick of 340 in 1900. The amateur market grew steadily, as social mobility and disposable income increased, and a gradual reduction in working hours produced a boom in leisure activities. Existing photographic associations were reinvigorated and new amateur clubs started; their numbers grew tenfold from1880-90. Women became a notable constituency: as early as 1886, women's magazines carried photographic advertisements and from 1889 Eastman publicity illustrated women using Kodak cameras. The importance attached to advertising is indicated by the fact that Kodak in Britain spent nearly £5.000 on advertising to persuade amateur photographers to spend more or to buy their product in preference to another. In the mid-1880s advertising was absolutely crucial in the fledgling market for amateur photography to flourish. Traditionally photographic goods had only been advertised in specialist publications, aimed at a limited audience. By 1900, women made up 30 per cent of British amateur photographers, and the US census listed more than 3.500 female professionals. At the end of the 19th century, with the spread of the dry-plate process and the simplification

of photographic techniques and equipment, the number of amateurs grew considerably.

The later 1890s were generally prosperous, but there remained few patentable mass-market inventions, so profit margins were low and manufactures fought price wars. The professional portrait trade was saturated with *cartes* and cabinet cards, and now also competed with postcards and home snapshot portraiture. The popular press was one of the signal influences of this time, serving more widely enfranchised and educated population. Inexpensive illustrated papers and periodicals were made possible by the new photomechanical processes, which afforded cheap, good-quality reproductions.

Photography finally appeared to have come of age. Technically reliable, in the hands of professionals, sustained by rapidly expanding methods of circulation, it had, within the space of five decades, conquered the principal fields of human activity.

EDER, JOSEPH MARIA (1855–1944)

Austrian technologist, scientist, photo-historian, and teacher

Eder, Joseph Maria was born on March 16, 1855 in Krems on the Donau. He was the son of Karolina from the Borudzkis Polish. Eder was an. He studied natural science at Vienna University, and later at Technischen Hochschule. In 1879 he received his PhD degree, and became an assistant professor in 1887, a professor in 1892, and then became a professor at the department of photochemistry and scientific photography in 1902. From 1882–1924 Eder was a professor of chemistry and physics at a high school (Gewerbeschule) in Vienna. Eder was the founder of and from 1888 to1923, the director of *Lehranstalt für photographie and reproduktionsverfahren,* which is called today Höhere Graph. Bundes-Lehr- und Versuchsanstalt, in Vienna. He directed studies on photometry and x-ray photography.

Under his management the School became the most respectable centre of research within the scientific photography in the world. During his studies he and V. Toth, working with elementary components of chemistry, invented prussian blue, intensifying lead and ferrizyaniden for colour. About 1879 he was worked together with G. Pizzighelli on activity of chlorosilver gelatine: *Die Photographie mit Chlorosilber-Gelatine und chemischer Entwicklung, nebst e. prakt. Anleitung zur raschen Herstellung von Diapositiven, Stereoskopbild. Fensterbild., Duplikatnegativen, Vergroesserungen, Copien auf Papier etc. Wien 1881.* The production of sensitive paper and positive film used in cinema was available because of these two industrial inventions.

J.M. Eder was also interested in sensistometry (Eder-Hecht Wedge in 1919), but prior to the introduction of the DIN speed rating system, it was used in Europe as a component of a standard sensistometer, Eder and Schneider sensistometr, Optical sensynsybilation, method to define panchromatic Eder and Hecht. Chemical and physical developing process—pyrocatechol developer and ferrioxalate. Sensibility properties of erythrosine (1884). His great scientific accomplishment appeared in more than 21 books and 11 articles published mainly by Wilhelm Knapp in Halle am Saale 1878–1932. The book with the largest influence on the world of photography have been: *Ausfuhrliches Handbuch der Photographie*. This compilation went through three editions: 1882–1888 in Halle (13 issues in 8 volumes), 1891–1899 with new material and issues (17 issues in 15 volumes), 1905–1932 another elaboration (18 issues in 11 volumes). The second edition in 1891 was began with *Geschichte der Photochemie und Photographie von Alterthume bis der Gegenwart,* which was a fundamental necessity for the explorers of photography in 1891.This book was published again in 1905 as *Geschichte der Photographie* and was three times larger than the first edition. In 1913 a less known *Geschichte der Photographie in Bildern* and *Quellenschriften zu den fruehesten Anfaengen der Photographie bis zum 18. Jahrhundert*, was published. Eder was the editor of *Jahrbuch für Photographie und Reproduktionstechnik für das Jahr...* Halle 1892–1914 and *Jahrbuch...* und *Reproduktionsverfahren fuer Jahre 1915–1920*. In those periodicals he was talking about the scientific research in the world of photography. From 1888 he was assistant

editor, and from 1903 was a member of the committee of *Photographische Correspondenz.* The first publication, *Ueber die Reactionen der Chromsaeure und der Chromate auf Gelatine, Gummi, Zucker und andere Substanzen organ,* was printed in 1878, and investigated emulsion- gelatin development. On his last work, he collaborated with Adam Trumm's and his editorial abilities in 1932 and created the closing chapters of the book, *Handbuch der Photographie: um Heliogravuere and the Platinotypie.*

Since 1900, he had been delivering lectures on the development of the photography in "Vereins zur Vorbereitung naturwissenschaften Kenntnise" in Vienna. The level of his knowledge facilitated him lecturing about photography at The Science Academy. In 1879–1915 he published five articles in S*itzungsberichten der koeniglichen Akademie*. To this important inventions belonged like the application of pyrocatechol as developer reducer as foung in *Der neue Eisenoxalat- Entwickler und dessen Vergleichung mit dem Pyrogallus-Entwickler. Wien 1880. Verlag der Photographische Correspondenz.*

Together with Eduard Valenta (1857–1937), he published the method of using W. Roentgena's process for taking photographs. Roentgena's photographs were kept as x- rays, "Christiceps argentatus," and the negatives were put in a collection at the Eastman Kodak Company in 1922 from the J.M. Eder and "Aesculap-Snake Vienna 1896" in Private Collection, in Vienna. Another was reproduced in the book *Versuche ueber Photographie mittelst der Roentgen'schen Strahlen. Hersg. mit Genehmigung der k.k. Versuchs- Anstalt fuer Photographie und Reproduktions- Verfahren in Wien. Halle 1896. With 15 Photogravuren in x-rays.* With E. Valenta describing Spectralanalyse in *Beitraege zur Photochemie und Spectralanalyse. Wien 1904* and the methods of research of sensistometric negativebeing published in *System der Sensistometrie photographischer Platten. Wien 1899–1902*, thousands of photographers were using Eder's book *Recepte und Tabellen fuer Photographie und Reproductionstechnik, welche an der k.k. Lehr- und Versuchsanstalt fuer Photographie und Reproductionsverfahren in Wien angewendet werden.* This book too had 25 editions between 1892–1949. *Theorie und Praxis der Photographie mit Bromsilber—Emulsionen unter bes. Beruecks.d. Gelatine–Emulsionsverfahrens. Wien 1881*, had two editions, and from 1884–1888, he wrote four books on the instantaneous photography and he described a new light meter in: *Ein neues Graukeil-Photometr fuer Sensitometrie, photographische Kopierverfahren und wissenschaftliche Lichtmessungen. Halle 1920.* Eder died in Kitzbühel on 18 October 1944.

EDINBURGH CALOTYPE CLUB

The calotype process of photography arrived in Scotland at the time of its invention in 1839 due to the friendship and shared scientific interests of the inventor, William Henry Fox Talbot, and the Principal of St Andrews University, Sir David Brewster. However, it was not just in St Andrews that experimentation with the process began but in Edinburgh where it is claimed the first photographic club in the world was formed: the Edinburgh Calotype Club.

Brewster was instrumental at the start of the Club but in addition helped with it activities, not least by persuading Talbot not to extend his patent for the process to Scotland in 1841 so that it could be freely used by the Scottish enthusiasts.

John Miller Gray, the first keeper of the Scottish National Portrait Gallery, wrote:

> Shortly after the first discovery of the Calotype by Talbot, and its communication by the inventor to Sir David Brewster, a few Edinburgh gentlemen visited the latter, saw his set of Calotypes, and were made aware of the method by which they were produced. On their return they entered eagerly on the study, and formed a little Calotype Club…

A references by Brewster in a letter to Talbot dated 5 October 1841 indicates that the Club may have been active by that time. Despite having Talbot's instructions, problems were experienced in producing successful results by those experimenting with the process. Brewster, in his letter describes the slow progress of Dr John Adamson with the calotype process in St Andrews but also states that "difficulties have been experienced by several persons in Edinburgh."

It is Gray that gives an insight into how the Club was organised when he writes:

> The constitution of the Club was of a very frank and informal kind. The members met at each other's houses, had a friendly meal together, exhibited their productions, and discussed new experiments and their results.

In an obituary to Cosmo Innes, one of the founders and most active members of the Club, the British Journal of Photography reported that "the Calotype Club, thus constituted, continued its pleasant labours throughout the calotype and waxed paper period."

The membership of the Club was small with at least seven principal members, mainly associated with the legal profession, and a few others who were involved from time to time, and one was a woman. The close relationship between the Club and those active in photography at St Andrews persisted and in the two extant albums of the Club there are prints by Dr John Adamson and Sir Hugh Lyon Playfair. There are also prints by Talbot and the most likely source for these would have been Brewster.

The known members of the Club are: John Cay (1790–1865), advocate and Sheriff of Linlithgow; Cosmo Innes (1798–1874), advocate and Sheriff of Moray; George Moir (1800–1870), advocate and Sheriff of Ross; James Francis Montgomery (1818–1897), advocate and later a clergyman; Mark Napier (1798–1879), advocate and Sheriff of Dumfries; John Stewart (1813–1867), estate owner; and Hugh Lyon Tennent (1817–1874), advocate. Associated with the Club were: Sir James Dunlop (1830–1858), student and later soldier; his aunt, Mrs Frances Monteith (1805–1898) who was the wife of Alexander Earle Monteith and advocate and Sheriff of Fife; James Calder Macphail (1820–1908), Free Church divinity student and clergyman; and Robert Tennent (1813–1890) brother of Hugh and owner of land in Australia.

The two known albums of photographs by the Club members and their associates are in Edinburgh. The one in the Edinburgh Central Library belonged to James Francis Montgomery and was acquired from his descendants in 1952. The other is in the National Library of Scotland and was bought at auction in 2001. This is accompanied by an index which has thrown new light on the Club as it gives a description of the images and has a key for the initials that appear beside most of the photographs giving the names of the photographers. There was at least one other album as Gray mentions seeing an album with photographs of places which are not in either of the known albums. The photographs by Mrs Frances Dunlop, which include her nephew Sir James Dunlop, are in an album which belonged to Brewster that is now in the J. Paul Getty Museum, Malibu.

In its loose arrangement the Club survived until 1856 when its members were largely responsible for founding the Photographic Society of Scotland. At the meeting held to consider forming the Photographic Society of Scotland in March 1856, the motion to do so was moved by Cosmo Innes and seconded by George Moir. At the Society's first exhibition later that year Innes exhibited several of his prints by the calotype process.

EDISON, THOMAS ALVA (1847–1931)

American inventor, manufacturer, and cultural icon

The development of a celluloid film band 1⅜ inches wide for the Kinetograph camera and Kinetoscope viewer of Thomas Edison, developed at his laboratory in West Orange, New Jersey, by a team led by William Kennedy Laurie Dickson, is Edison's lasting contribution to the worlds of both moving pictures and photography. Later known by its metric equivalent as 35mm film, Edison's chosen format of 1894 is still the principal moving picture film width after 108 years, and became an ubiquitous format for still photography beginning in the 1930s with the introduction of lightweight single-lens-reflex cameras. The width of this film, and its four perforations per image on both sides of the band, have been virtually unaltered since late 1891, and as early as 1897 this size of moving picture film was referred to as "standard film" or "Edison standard film," even as numerous other formats competed in a still-fluid marketplace. As Paul Spehr has carefully documented (see Further Reading, below), Edison's work on "an instrument which does for the Eye what the phonograph does for the Ear," as the inventor expressed it in a Caveat filed with the U. S. Patent Bureau in 1888, moved through a series of stages: sheet celluloid wrapped around a cylinder, celluloid plates mounted around the edge of a revolving disk, 22mm film perforated on one side running horizontally in the camera, and 1 inch film perforated on both sides running vertically in the camera, which was finally resolved as a thicker 1⅜ inch wide band. In developing their moving picture system and its photographic celluloid, Edison and Dickson had the advantage of working in a unique and intimate relationship with George Eastman and his colleagues in Rochester, New York; no other moving picture pioneer commanded such industrial respect that a major photographic supplies firm entered into the kind of intimate and arduous partnership shared by Edison and Eastman that was necessary to develop a new photographic material.

From their earliest experiments in moving pictures, Edison and Dickson used transparent celluloid covered on one side with a photographically sensitive emulsion.

The celluloid base provided flexibility for the image carrying emulsion, while its transparency allowed the development of a viewing apparatus using transmitted light, where the image carrier moved between the light source and the viewer. The technical considerations in the evolution of 35mm film included making the image area as large as possible for comfortable viewing, while keeping it small enough to produce a compact apparatus, and making the film tough enough to withstand the mechanical stresses of running at 30 to 40 frames per second across the viewing aperture while simultaneously keeping it light enough to have the flexibility to wind through the machine. The changes Edison and Dickson made to the design of their Kinetoscope viewer and Kinetograph camera were direct responses to these constraints: the sheet celluloid film from Carbutt wrapped around a cylinder had images that were too small; the celluloid plates on a revolving disk copied from the Anschütz Schnellseher provided too limited a viewing time; half-inch and three-quarter-inch film perforated along only one side was not robust enough to withstand the stresses applied by the machinery; one-inch film perforated on both sides left too little room for the image. During this period of experiment and evolution between 1888 and 1894 at the Edison laboratory, Eastman also had technical issues to solve, even though his company was the world's most experienced in manufacturing flexible rolls of photosensitised film. Roll film had been introduced by Eastman with an opaque paper backing in 1884, and his Kodak roll film system was an instant success from 1887, so much so that a substitute for its original opaque backing was urgently sought, since the elaborate process of handling this "stripping film" overwhelmed Eastman's developing and printing service. Celluloid nitrate, despite its flammability, was the solution to Eastman's dilemma, but until well into the 20th century every time the photographic emulsion was chemically changed to improve its sensitivity or decrease the grain size and provide better sharpness, previously overcome problems of adhesion between the emulsion and the celluloid base reappeared, often in conjunction with thin cobwebs of exposed emulsion caused by static electricity in the manufacturing process, or other imponderable problems.

The resolution that Edison and Dickson finally made used 35mm wide strips of celluloid-backed emulsion that was slightly thicker than Eastman's still camera film, and was produced and cut—as it was later for other early moving picture companies—to special order by Eastman at a premium price. With the Kinetoscope in use in public from 1894, Edison used this film principally for camera negatives made by the Kinetograph, since was a very clear stock manufactured by pouring out on long glass tables. For positive prints in the Kinetoscope viewer, film from the Blair Camera Company was used since it was slightly translucent and therefore better dispersed the light across the image for the viewer; Blair used a different manufacturing process of continuous casting on a large heated rotating drum.

Although it is often overlooked in studies by film historians, like its predecessor moving picture apparatus, the Schnellseher of Ottomar Anschütz, and like many subsequent moving picture machines such as those of the Lumière brothers, Robert W. Paul, Birt Acres, George W. de Bedts and other pioneers, when the Edison Kinetoscope and Kinetograph system first appeared it was considered revelatory apparatus for the making and exhibition of photographs, and was conceptualised wholly within the enormous technical advances being made by photography in the last quarter of the 19th century. Reviews of the Kinetoscope commonly referred to the astonishing fact that 46 individual pictures were taken in a single second, or that a Kinetoscope view was made up, on average, of over 1200 photographs. Pratitioners in the fast-moving realm of photography, whether manufacturers, suppliers or end-users, had been remarkably agile in responding to new technological developments, including the public fashion for stereoscopy in the 1860s, the expansion of photographic lantern lectures in the 1870s and the introduction of the Kodak system and roll film in the 1880s, but the moving pictures introduced at the end of the 19th century proved to be a step too far for the already prosperous industry, and moving picture work quickly evolved to become a separate realm that would dominate public discourse in the 20th century.

DEAC ROSSELL

Biography

Born in the small town of Milan, Ohio, in 1847, the young Thomas Edison was expelled from school as "retarded" and educated at home by his mother. He went to work at the age of 12, selling candy and his own on-board newspaper to railroad passengers travelling between Detroit and Port Huron, Michigan, where the family had moved. He trained himself as a telegraph operator, took a job with Western Union in Boston, and soon was repairing telegraph apparatus. He executed his first patent, for an electrical vote recorder, in 1868 and the next year became a full-time inventor, moving from Boston to New York City and concentrating on telegraphy. By 1874 his work had created a new duplex telegraph, which allowed a single wire to carry two messages simultaneously, and then a quadruplex system which allowed four concurrent messages, significantly improving both the efficiency and the capital costs of telegraph communications. Now working for some of America's largest corporations, he constructed his own independent research laboratory at Menlo Park, New

Jersey in 1876, the world's first, and began to develop a commercially viable carbon telephone transmitter. He patented the cylinder phonograph in 1877, intending it for office dictation, and his experiments on electric light systems began the next year. Edison's high-resistance carbon filament lamp was patented on 1 November 1879, and over the next three years he patented some 111 electrical devices ranging from generators and batteries to lamps and electric-powered railroads. At the same time he began constructing demonstration electrical stations and commercially manufacturing lamps and other electrical apparatus. Moving his laboratory to larger quarters in West Orange, New Jersey in 1887, his fertile workshop continued to invent and patent a large number of products including storage batteries, magentic ore mining apparatus, and a camera with its moving picture viewer called the Kinetoscope. Amongst the scores of domestic and international firms established to promote and exploit his work, The Edison Electric Light Company eventually evolved into the General Electric Company, and the Deutsche Edison Gesellschaft became the Allgemeine Elektrizitäts-Gesellschaft (AEG). By the early 1900s his advice was sought by businessmen from all sectors of the economy, while his unusual gift for describing new technologies in a simple turn of phrase turned him into a favourite of the press and the public alike. His rags-to-riches story had an immense appeal: the first of many biographies was published in 1879, when he was only 32, and Edison was a leading character in a French science-fiction novel by Villiers de l'Isle-Adam in 1886. His last patent application was filed in 1931, the year he died, and his life and work were promptly memorialised in hagiographic films from Hollywood, first in *Young Tom Edison* with Mickey Rooney as the inventor and then in *Edison the Man* starring Spencer Tracy (both 1940).

EDLER, ANTON (1798–1856)

German daguerreotypist

Anton Edler, born in 1798 in Munich, was first a draughtsman, lithographer and engraver. From 1813 he worked in a surveying office of the Bavarian Army drafting the topographical atlas of Bavaria and maps of Munich. In the process he fell victim to an eye illness and was pensioned in 1850. Although he stoped his drafting work, he continued to photograph, having in 1840 begun practising the daguerreotype, taking mainly portraits. In 1854 he contributed daguerreotypes and calotypes to the *Deutsche Industrieausstellung* [German Industrial Exhibition] in Munich. Edler died on 20 May 1856. His photographic work is preserved in the *Deutsche Museum* Munich and the *Stadtmuseum* Munich.

STEFANIE KLAMM

EDUCATION AND TRAINING IN PHOTOGRAPHY

The roots of photographic education and training go back almost as far as the first public announcement of photography in 1839. By October of the same year, the Polytechnic Institution in Regent Street, London was advertising lectures on the daguerreotype process by its resident chemist Mr. J. T. Cooper three times a week.

In the early days photographers were self-taught. Frequently it was a hit and miss affair but those with backgrounds in chemistry and physics were able to decipher the processes with the minimum of information. J. B. Dancer of Manchester explained the problem: 'The early descriptions of Daguerre's method of proceeding were crude and obscure. In consequence of this I had six weeks of hard work, numerous failures, and accidentally was nearly suffocated by the vapour of iodine before I obtained satisfactory results.' As a 'practical optician' Dancer was able to construct his own camera and lens. By 1841 he was able to supply 'daguerreotype apparatus' and taught the process 'to Manchester gentlemen who became amateur photographers.' (Dancer, 1886)

Photography became a popular pursuit with the relaxation of Talbot's patent in July 1852. With that increase in amateur sales came the need for instruction of the fashionable hobby. By the following spring, classes were available from T. A. Malone at the Royal Polytechnic Institution, Philip H. Delamotte at the Photographic Institution in New Bond Street and Nikolaas Henneman

at the Panopticon of Science and Art in Leicester Square. In this Moorish-style building a lift took visitors to the photographic saloon that was 18 metres long 'enabling family groups of eighteen persons to be taken at once. In addition, completely equipped private glasshouses could be hired by amateurs at a weekly rent. The charge for instruction was five guineas (£5.25) for six lessons. The London School of Photography opened in 1854 at 103 Newgate Street, London. It had branch studios for the taking of portraits in Regent Street, Oxford Street, Poultry in the City, as well as Church Street, Liverpool and Market Place, Manchester.

It was also the written word and word-of-mouth that promoted photography. Alfred Brothers bought 'photogenic paper' consisting of a few sheets ready sensitised with nitrate of silver from a bookseller in Maidstone. He had previously read of Talbot's experiments and had used nitrate of silver and had coated his own sensitive papers. Later, probably in 1855, having seen 'a beautiful photograph on glass' in the window of Casartelli (Opticians) he bought 'a quarter plate camera with a portrait lens and necessary materials' and was shown how to coat a wet plate by them. It was this training and experimentation that allowed him to set up as a professional photographer the following year and by 1857 was invited to take the photographs of the Royal Family at the opening of the Manchester Art Treasures Exhibition.

Photography was taught to the Royal Engineers at Chatham from 1856 at later at Woolwich and other military and naval establishments. This training was invaluable for officers trading in India and was encouraged by the East India Company, acting on instructions from Lord Canning, the Governor-General. Books on the people, landscape and cultural inheritance of India resulted from this open-minded policy with the photographs being almost always being taken by Captains of the Royal Engineers.

The University of London introduced photography into its curriculum at Kings College. A large darkroom was erected and T. F. Hardwich, author of the first manual of photographic chemistry (1855), was appointed. Thomas Sutton, editor of *Photographic Notes*, and Philip H. Delamotte succeeded Hardwick some five years later when the department of photography was split into science and art respectively.

The first examinations in photography were organised by the City and Guilds of London Institute. Photography was one of the seven original subjects examined with a syllabus published in 1880 and the first examinations held in 1881. Three levels of examination were listed: these being at Elementary, Advanced and Honours level. The syllabus itself was theoretical and was divided into eight sections: four of which dealt with the chemistry of various processes, one with optics and cameras, one with apparatus and two with the special applications of photography. These included engraving, typography, lithography, astronomy, microscopy and meteorological recording.

By 1871 one commentator suggests the way forward for the training of the future photographer. The key is 'the art portion of our art-science' and the suggestion is that there is a fundamental difference between the education of the fine art student and the photography student, a discussion that in one form or other has continued ever since. For the photography student it is important that he finds 'that everything in outline and light and shade can be executed by the lens in his camera…. All efforts have to be given to a general cultivation of his thinking powers… and once duly impressed with the conviction it is the head not the hand which has to work, then a steady perseverance in the right direction will… lead to ultimate success.' He continues to suggest the study of pictorial illustration of figure subjects, harmony and outline, light and shade and 'the expression of the hand.'

Considering the photographer of the future in 1873 another commentator observed: 'In order to keep pace with the demands and requirements of an improving public taste, it is essential that the photographer possess other abilities and accomplishments than technical skill. He should thoroughly comprehend the laws and principles that govern all pictorial art, leaving nothing to chance and the camera in that respect. He should not be entirely ignorant of the chemical and optical sciences, and be possessed of a quick and exalted imagination, in conjunction with a profound knowledge of human nature and a practical acquaintance with every grade of social life, that he may understand and be at ease with all sorts and conditions…. In fact to be a successful artist-photographer involves the necessity of perseverance and indefatigable study, without which none ever attained success in any art or science….' (Raven, *The British Journal Photographic Almanac*, 1873).

By 1880 the Polytechnic Institution was bought by Quinton Hogg and renamed the Regent Street Polytechnic. From November 1882 the first technical classes in photography took place on a Saturday evening as a series of thirty lectures. Mr. E. Howard Farmer who was to stay with the Polytechnic as its first head of the School of Photography until 1919 gave these lectures. Outside of the Polytechnic he would best be known for the 'Reducer' named after him. By 1896–97 mention is made of the 'large, highly successful classes at the Polytechnic' while in 1895 the records of the Technical Education Board credit the school of photography with 472 students. (*Greater London Record Office*, July 1895)

While formally outside the timescale of this entry it

is worth noting that in Britain the Professional Photographers Association was formed in March 1901 with the aim of 'Improving the status of those who practice photography in the profession.' In 1905, it prepared a scheme for granting certificates of competency to operators and assistants.

EDWARDS, J. D. (b. 1831)

American photographer

New Orleans photographer J.D. Edwards is best known for a series of photographs of Confederate forts, guns, barracks, shipyards, camps and soldiers that he took in and around Pensacola, Fla., in April 1861.

Born in New Hampshire around 1831, Edwards may have been the daguerreian artist listed with the rooms at 91½ Fourth Street in St. Louis in 1857. His wife, Mary, was a Missourian by birth. In 1860, Edwards was 29, with a wife and young child, working in New Orleans as an "ambrotype portrait" maker. That year, he also made a series of photographs for the government showing the construction of the new Custom House and the Marine Hospital.

In April 1861, with Union forces still occupying Fort Pickens in Pensacola Bay, Edwards traveled there to photograph the burgeoning Confederate presence. After returning to New Orleans, Edwards began selling the images at $1 a copy on May 15. "They are very large and taken superbly," a newspaper advertisement said. A month later, woodcut engravings of Edwards's images appeared in Harper's Weekly. Edwards reported having taken 39 views, but 44 different images are known, and the actual total may reach nearly 70.

All trace of Edwards is lost after 1861; and even the date of his death remains unknown.

BOB ZELLER

EGERTON, PHILIP HENRY (1824–1893)

Philip Henry Egerton is believed to have originated from Wrexham in North Wales, and to have married—for the first of three times—in 1857 before being posted to India as a member of the Bengal Civil Service based initially in Calcutta. He subsequently married again in 1886 and 1890.

It was while he was in India—as Deputy Commissioner for Kangra, North West of Simla in Himachal Pradesh—that he published his only collection of photographs. The 1864 book, *Journal of a Tour through Spiti to the Frontier of Chinese Thibet* was published in London by Cundall, Downes & Co. containing thirty seven tipped in 10" × 8" albumen prints from photographs taken during a three month expedition though the mountains of Himachal Pradesh in the summer of 1863. His journey had been a semi-official trip to explore possible alternative routes for the transport of wool from mountain farmers, and as part of it he visited and photographed the town and people of Spiti, and took the first photographs of the Bara Shigri Glacier a few miles from the town. His photographs of the spectacular mountain-top Kee Monastery attest to his ability with the collodion process.

A complete copy of *Journal of a Tour through Spiti to the Frontier of Chinese Thibet* is preserved in the Harry Ransom Humanities Research Center at the University of Texas, Austin.

JOHN HANNAVY

EGYPT AND PALESTINE

Napoleon's invasion of Egypt in 1798 ignited a Western obsession with the Orient—both ancient and modern—that resonates even today. Much this obsession was focused on Egypt, with its ancient wonders and mysteries, and Palestine, the Holy Land, the land of the Bible. It was manifested by the birth and evolution of Egyptology as a scholarly and scientific discipline, the rise of a popular appetite for anything relating to Ancient Egypt ("Egyptomania") that remains unabated, and in the emergence of an intellectual and artistic fascination with Middle Eastern life, thought, culture and customs included under the broad rubric of Orientalism. Despite the unwelcoming climate and the rigors of travel there, Egypt and Palestine became destinations for travelers of all persuasions—scientists, adventurers, entrepreneurs, but also tourists—and books describing both the sights and experiencing of the Middle East found an eager and steady market. Visual documentation, however, was less available. When photography was introduced in 1839 it was logical and inevitable that the camera would soon be applied to recording the wonders of Egypt and the holy sites of Palestine, despite the challenges of working the early photographic processes in even

the most hospitable conditions. Indeed, photographs –daguerreotypes—were made in Egypt in November 1839, less than four months after the workings of the daguerrotype process were first made public. Over the next 50 years at least 250 amateur and professional photographers are known to have been active in the Middle East, although the actual number was probably somewhat greater; the introduction of amateur roll-film cameras in 1888 undoubtedly increased those numbers substantially by the end of the century.

The history of photography of Egypt and Palestine in the 19th century breaks down into four more or less distinctive but overlapping periods, and the personalities involved include dedicated amateurs, both tourists and residents (who were usually missionaries or diplomats); trained as well as untrained men associated with archaeological or other officially sponsored projects; and professionals, both European and local, some based in Europe, others with studios in Cairo or Jerusalem or some other Middle Eastern city who catered to both the tourist and arm-chair traveler trade. The first period, 1839 to the mid 1840s, is marked by efforts to use the daguerreotype process—some successful, other total failures. The second period, spanning the late 1840s and extending into the early 1860s is defined by photographers using either paper or glass supported negative processes to produce bodies of work usually (but not always) intended for distribution in some form. The third period is marked by the proliferation of local-based professional studios associated with the tourist industry and the production of visual souvenirs that begins in the early 1860s and extends into the late 80s, when the Kodak and similar cameras using commercially made plates and films enable travelers to take their on photographs. The fourth and final period extends into the present day and is marked by the dramatic rise and popularity snapshot photography and the resulting decline and demise of professional studios catering to the tourist trade. Throughout the 19th century, French photographers predominated, with British second, Germans and Austrian third, and other nationalities, including Americans, Greeks and locals (most of whom were Christians) comprising the balance.

The first period was brief and included only a small group of individuals who were able to produce successful daguerreotypes in the difficult conditions of the Middle East. The Frenchmen Frédéric Goupil-Fesquet and Horace Vernet, and the Swiss–born Canadian Pierre Gaspard Gustave Joly de Lotbinière took the first daguerreotypes made in Egypt in November and December 1839, barely three months after the process had been announced in Paris. (Vernet claimed to have taught the Pasha, Mohammed Ali, to make daguerreotypes.) Some of the plates made by these three men were reproduced as engravings in N.P. Lerebours' *Excursions Daguerriennes* (1842), and several views by Joly de Lotbinière of ancient Egyptian monuments were transplated into lithographs for Hector Horeau's slightly earlier *Panorama d'Égypte et Nubie* (1841). These were the first photographically derived—and therefore unquestionably authoritative—representations of Middle Eastern scenes to reach the European public. Joseph-Philibert Girault de Prangey (in Egypt 1843/44) and André-Victor-Alcide-Jules Itier (in Egypt 1846/46) were amateurs who made daguerreotypes to document their travels for purely personal consumption; their collections descended in their families and have remained largely intact into recent years. Goupil-Fesquet, Vernet, Joly de Lotbinière, and Girault de Prangey also included Palestine in their travels and made souvenir views there (Girault de Prangey made more plates of Jerusalem than he did of any Egyptian site), while the only British citizen known to have daguerreotyped in the Middle East, George Skene Keith, a Scot and the brother of Thomas Keith, spent five months in Palestine with his father, a clergyman, and made daguerreotypes views of sites mentioned in the Bible that supposed offered proof of the validity of old Testament prophesies. Keith's plates are known from the steel engraving copied from them that illustrated his father's book, *Evidence of the Truth of the Christian Religion Derived from the Literal Fulfillment of Prophecy Particularly as Illustrated by the History of the Jews and the Discoveries of Modern Traveller* (1844). (French images, even of Biblical subjects, tended to be devoid of religious motives; whereas the work of both British and American photographers often had religious implications.) Few would-be daguerreotypists, however, had the determination or the skill to work the process in the field; a few, among whom was the preeminent German Egyptologist Karl Richard Lepsius, found it impossible. Such practical problems, coupled with the labor-intensive and therefore expensive effort required to produce accurate reproductions of the daguerreotype image for publication, that what photography was done in Egypt and Palestine before the first photographers using negative processes appeared in the late 1840s, had little lasting impact.

The late 1840s into the early 1860s was the Golden Age of photography in Egypt and Palestine, and it generated several bodies of work considered key monuments in the history of photography. This period began when photographers using one of the paper negative processes (calotype or waxed paper processes) began to work in the Middle East; when it ended, they were making glass plate negatives using the wet collodion process. The Rev. George Bridges, an English clergyman who began a seven year Grand Tour of the Mediterranean in 1846, may have been the first make calotypes in the Middles East, although he cannot be placed in Jerusalem until November 1850 or in Egypt until January 1851. Bridges

supposedly made 1700 photographs in the course of his grand tour, and published a number of them as original prints after his return to England, but he was not a technically proficient photographer and most of his surviving prints are in poor condition. Pierre Trémaux, a French architect who spent seven years in North Africa and the Near East beginning in 1847, has an almost equally strong claim to being the first to make calotypes in the Middile East. Trémaux intended a monumental book illustrated with original salt prints made from his negatives, but *Voyages au Soudan Orietental, dans l'Afrique Septentrionale at dans L'Asie Mineure, Executes en 1847à 1854* was apparently never completed, though parts were published. The rare surviving examples of Trémaux's work are in poor condition, and it is clear he was neither especially talented nor skilled, but his *Voyages* was the first of the photographically illustrated works on Egypt, Palestine and other areas of the Near East subsequently by the more gifted photographers of this period. Maxime DuCamp, traveled throughout the Orient 1849-50 in company with Gustave Flaubert, the French novelist. DuCamp sailed up the Nile as far as Abu Simbel in Nubia, and went on to photograph in Palestine and Syria. The result of this tour, *Egypte, Nubie, Palestine et Syrie* (1852), is an album containing 125 salt prints made from the original negatives by Blanquart-Evrard in Lille, that is one of the major—and best known works of 19th century European photography. Félix Teynard, a civil engineer, travelled up the Nile as far as the Second Cataract, above Abu Simbel in Nubia, in 1851–52. He took 160 negatives, and when he returned to France began to sell prints from them in installments. The photographs in *Egypt et Nubie, Sites et Monuments les Plus Interessants pour l'Etude de l'Art et de l'Histoire* (1858) are considerably more beautiful, sophisticated, and compelling than any image in DuCamp's *Egypte, Nubie, Palestine et Syrie*—but because Teynard's album is considerably rarer than DuCamp's, it was forgotten for decades and was overshadowed by it in the histories. The Americans Leavitt Hunt and Nathan Flint Baker became the first Americans to photograph in Egypt and Jerusalem during their Grand Tour of the Orient 1851/52. The trip resulted in about 60 negatives, which Hunt and Baker planned to print and market in the United States; the plan, however, collapsed, very few prints were ever made, and no more than a handful have ever appeared on the market. Hunt's and Baker's images are mostly pedestrian, but their rarity makes them among the most desirable Egyptian photographs. Whether Hunt and Baker encountered Teynard on the Nile is an interesting question. The year after, 1853–54, the French born and Parisian trained American John Beasly Greene, made the first of three trips to Egypt to photograph and excavate. Greene was the first trained egyptologist who was also a trained photographer, and his images include some of the most haunting made in Egypt. Greene intended to publish his work in album form, but the album never materialized even though prints had been commissioned from Blanquart-Evrard. Greene died shortly after returning to Egypt for the third time; he was 24. The Alsatian painter and amateur archaeolgist August Salzmann, spent several months in Jerusalem in 1854, photographing the architecture of Jerusalem; on a second trip, he photographed elsewhere in the Holy Land. Salzmann's *Jerusalem, vues et monuments de la ville sainte de l'époque judaïque au present* was published in 1856. Louis-Constantin-Henri-François-Xavier de Clerq, joined an exploratory mission to Syria in 1859 and used the opportunity to travel throughout the Mediterranean. *Voyage en Orient, 1859–60*, a six volume work containing 222 original prints made by Blanquart-Evrard that is highly prized today. Somewhat later, the American-born German Jacob August Lorent traveled extensively through the Middle East. Particularly interested in photographing buildings endangered by development, Lorent published two noteworthy books: *Egypten, Alhambra, Tlemsen, Algier, Photographische Skizzen* (1861) and *Jerusalem und seine Umgebung. Photograpische Sammlung* (1865). The Englishman Francis Frith is undeniably one of the pivotal figures on this period. Primarily an entrepreneur, Frith made three extended trips to Egypt, in 1856/57, 1857/58, and 1859/1860. He used three different cameras, the largest for plates 15 × 19 inches. *Egypt and Palelastine Photographed and Described by Francis Frith* (1858–60) was the first of seven collections of Middle Eastern photographs published by Frith by 1862. They established his reputation and enabled him to create a picture service that controlled over 4000 images. Other photograophers active in this period include the English amateur John Shaw Smith, who made over three hundred calotype negatives during a two year tour of the Orient, 1850–52, for his own private use. Théodule Dévéria, like his friend John Beasly Greene, was an archaeologist, and a prolific photographer, though much of his work has not survived; and Frédéric Auguste Bartholdi, better known as the sculptor of the Statue of Liberty, who made two extended trips up the Nile. Finally, there was James MacDonald, a sergeant in the Royal Engineers, who was associated with the Ordnance surveys of Jerusalem and the Sinai. These are among the dozens who were active as photographers during this period, most of them making photographs that were meant to appear in publications.

Anton Schranz, a Maltese, opened the first professional studio in Cairo that catered to the tourist and souvenir trade by April 1850, when Florence Nightingale—as she noted in the diary of her trip to Egypt 1849–50—bought souvenir prints from him to give to relatives. By the end of the decade, W. Hamerschmidt, a

professional photographer from Berlin, had established himself in Cairo, where he made excellent quality large format prints to sell to tourists. The opening of the Suez Canal and the introduction of package tours in 1869, created an enlarged market for pictures that could support a lerger, more competitive market. A proliferation of studios followed: Antonio Beato, Henri Bechard, G. Lékégian, J. Pascal Sebah, and the Zangaki Brothers in Cairo, along with Peter Bergheim and Mendel John Diness in Jerusalem. Photographs from these studios survive in great quantities—all generally similar in style and composition, a reflection of the size of the tourist trade, and of the enormous demand for photographs whether for personal souvenirs or for the arm-chair traveler.

By the end of the 1880 these studios were in decline. The introduction of the Kodak and other simple, easy to use cameras, along with the advent of practical and inexpensive photomechanical reproduction technologies, reduced the travelers dependence on outside sources of imagery. By the beginning of the new century, and certainly by the beginning of WW1 and perhaps a lessened obsession with the exotic and the ancient, the school of Middle Eastern photography that arose and flourished in the 19th century had lost its soul.

EICKEMEYER JR., RUDOLF (1862–1932)

Rudolf Eickemeyer Jr. started taking photographs in 1884 while working at his father's engineering firm. In 1889, he joined the local camera club in Yonkers, New York, and began contributing articles on photographic chemistry, lighting, and technique to journals like the *Photographic Times*. He turned professional in 1896, operating a studio in New York City. Eickemeyer relied on commercial work for financial support while continuing to develop his skills as an art photographer. He gained critical acclaim in America and Europe for his pictorialist landscape and portrait photography; his images were often selected by Alfred Stieglitz to appear in the Photo-Secession journal *Camera Work*. But, his best known series of portraits is probably those of the young model Evelyn Nesbit commissioned by her lover, the famous New York architect Stanford White. Shortly before his death in 1932, Eickemeyer endowed a fund for the development of the Smithsonian Institution's Section of Photography and donated a large portion of his personal collection. The donation included important prints, albums, lantern slides, cameras, books, letters, articles, lectures, and awards documenting his long

career in photography. The remainder of his collection was donated to the Hudson River Museum in Yonkers, New York.

MICHELLE ANNE DELANEY

ELLIOTT, JOSEPH JOHN (1835–1903) & FRY, CLARENCE EDMUND (1840–1897)

Photographers

On 29 July 1862, professional photography in the United Kingdom was given a boost by the passing of the Fine Arts Copyright Act, which gave statutory copyright protection to photographs for the first time. If the photograph was made for or on behalf of someone for a 'good or a valuable consideration,' the person giving the consideration (such as the proprietor of a photographic studio, who paid his photographer) was the owner of the copyright.

Moreover, by asking a celebrity to pose for his or her portrait without payment a studio could obtain images that could be sold for a profit to a public filled with the craze for collecting *cartes de visite.* The studio portrait company of Elliott & Fry was founded in 1863 to take advantage of these developments, and subsequently became one of the most prestigious such firms in the country, taking photographs for and selling images of royalty and the aristocracy, political, military and naval leaders, and the stars of sport, music and the stage.

Joseph John Elliott was born in Croydon in 1835, the son of John Elliott and Mary his wife, the daughter of Thomas Brown. Clarence Edmund Fry was born in Plymouth in 1840, the son of Edmund Fry and Caroline Mary, nee Clarence. Clarence Fry had a sister, Lucy Elizabeth born in Plymouth in 1844, who in 1864 married Joseph Elliott in Brighton. How they had met is not known, but it is clear that the connection between the photographic partners was more than a purely professional one. The marriage was followed by the birth of six children, the third of whom, and the eldest son, was Ernest who later succeeded his father in the company when Joseph died in 1903 at his home in Hadley Green near Barnet. Clarence Fry lived in Watford; he died in 1897.

The photographic company was based throughout the later nineteenth century at 55 Baker Street, at premises known as the Talbotype Studios, using the name popularly given to William Henry Fox Talbot's calotype process. From perhaps as early as 1870 it also had a printing works in Barnet, near where the Elliotts lived at the time. This was responsible for production of silver and carbon based prints for clients and for commercial sale.

Sadly little is known about the company since its surviving records were destroyed by bombing during the Second World War. The most detailed information about it comes from an article in *The Photographic News* in January 1880, which described a visit to the Baker Street premises by H Baden Pritchard, who was shown around by Clarence Fry himself. There were three studios at this time, with east-facing window lights and top lights, one small and used mainly for vignettes, the others larger and equipped with a variety of painted backgrounds from which clients could choose. In each studio the camera

Elliott, Joseph John. Before the Ball.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

itself was shaded by an overhead canopy as a giant lens hood, and there were movable shades to all the windows as well as portable screens. The walls of reception rooms and dressing rooms were all covered by paintings and enlargements of photographic portraits 'to try to show what photography can do in vieing with painting in the production of large artistic portraits' . Sittings were relatively expensive by the standards of other establishments (although Pritchard thought the rate quite reasonable), at a guinea (£1 1s) a time, which includedeighteen cartes de visite or six cabinet-size prints. This price compared with a cost of about half a guinea for a seat in the stalls at a West End theatre. Many sitters, though, did not pay. Instead they sat so that the company could sell prints commercially, giving the sitters additional publicity and Elliott & Fry useful income. This was an important side of the business, not only through the sale of prints over the counter but also through their sale for use to illustrate books. Portraits of Wilkie Collins, Oscar Wilde, Joseph Chamberlain, Matthew Arnold and Charles Darwin were all published in books, as engravings or Woodburytypes. Commercial prints were also used to attract new celebrity clients, by sending them copies as samples of what could be achieved, though not all were convinced: the social reformer Samuel Smiles declined, saying that he preferred to own the copyright in any portraits so that he could control their use.

Sitters for Elliott & Fry included soldiers and statesmen, such as Lord Chelmsford, Gladstone, the Shah of Persia and Bismarck, religious figures including bishops and members of the Booth family, artists such as George Cruikshank, Walter Crane and William Morris, writers such as Mrs Humphrey Ward, Thomas Carlyle, Rudyard Kipling and Elizabeth Barrett Browning, musicians such as Clara Schumann and Edvard Grieg, actors such as Ellen Terry, sportsmen such as the Channel swimmer Matthew Webb, and members of the Royal Family from the Queen down. The photographers who actually took the pictures were relatively few in number, but one of them was Clarence Fry himself, who was still working as a photographer until shortly before his death. The most frequently employed during the nineteenth century was Francis Henry Hart of Fitzroy Square and St John's Wood but others were the Chevalier Luigi Beroieri of Chelsea until his return to Italy in 1896; John McLanachan of Hanwell and later Torquay; and Alfred James Philpott of Richmond and Twickenham.

The photographic style of the company throughout the period was simple, with few props (some of which remained in use for many years), and fewer backdrops despite their apparent prominence in the studios. By the end of the century lighting was effectively used to give definition and life to features and to provide impressive depth and detail in costumes and hair. Poses were almost always formal, even with actors in costume, but some individuals, such as J. M. Barrie and the poet Longfellow managed to appear more relaxed.

The company survived until 1963 when it was taken over by Bassano & Vandyck (now the Bassano Portrait Studios). Its surviving negatives and prints were deposited in the National Portrait Gallery, only a small proportion of which date from the nineteenth century. There are however many prints of nineteenth century portraits by the company at The National Archives.

ELLIS, ALEXANDER JOHN (1814–1890)

Alexander John Ellis took some of the earliest daguerreotypes in Italy, but his photographic achievements have been overshadowed by his many other accomplishments: his major interests were in the areas of spelling, pronunciation, mathematics and musical acoustics. The daguerreotypes were never published and he did not develop his flirtation with photography. His intention was to produce accurate representations of familiar Italian views but he was perhaps as fascinated by the technical aspects as by any aesthetic considerations, as also seems to have been the case with his musical interests.

At the age of 26, while travelling on the continent, Ellis decided to undertake an ambitious publishing project entitled *Italy Daguerreotyped*, for which he took a large quantity of landscapes and architectural views in a number of Italian cities. His choice of subjects traded on associations with the Grand Tour and the Enlightenment concern with classical civilisation. Public interest had been stimulated by the opening of the continent to leisure travel after the Napoleonic wars, and the focus of the Ellis collection is on topographical views in the tradition of *vedute*, a repertoire of locations well-known from previous illustrations.

Pictures at this time were often imaginative interpretations. Painters such as Claude Lorrain (1600–1682) had established, and those such as Louis Ducros (1748–1810) had perpetuated, a style that exploited historical and literary associations of established sites,

but often sacrificing accuracy to an artistic configuration. Engravings of such scenes, which were produced in large quantities and of variable quality, were equally unconcerned with an adherence to literal truth. Daguerre's 1839 *History and Practice of Photogenic Drawing* had claimed that his process was indispensable for the traveller and antiquary, as it offered the possibility of topographical precision. Ellis's reference to these categories of potential user in his proposal outlining the book's contents suggests that he was familiar with Daguerre's book. Ellis stressed that his concern was faithfulness of detail, to ensure that future visitors would not have their expectations aroused by prints, only to be disappointed by the reality.

Despite his amateur status, Ellis undertook the project with professional commitment and a great deal of energy. As well as Rome, he visited Pompeii, Pozzuoli, Paestum, Naples, Pisa, Florence and Venice, most of them several times, between April and July 1841. During this period he took 137 daguerreotypes. With little experience upon which to draw, he proceeded by trial and error. He brought to the task the systematic approach that he utilised in his later scientific activities, analysing such variables as climate, chemistry and time of day in order to refine his technique.

The value of the collection is enhanced by the notes that he took. For each daguerreotype, Ellis recorded the date, place, view, the time exposure began and ended, atmospheric conditions, his rating of how successful the exposure had been, and general observations. All were taken using Daguerre's original process and Ellis probably corrected lateral reversal by using a mirror in front of his lens, both factors accounting for the length of exposures, the recorded one of which ranged from 6 to 73 minutes.

In addition to his own daguerreotypes, Ellis purchased a number from Achille Morelli and Lorenzo Suscipj (1802–1855). The latter took nine of the daguerreotypes in the collection in 1840, thus predating Ellis's. Both Morelli and Suscipj were responsible for miscellaneous views, but notably each took a panorama of Rome, Morelli taking thirteen from the Capitol Tower (forming a complete circle) and Suscipj eight from San Pietro in Montorio. Each of these sequences was made in June 1841, suggesting that the pair were commissioned by Ellis. However, the fact that Suscipj produced daguerreotypes before Ellis indicates that he played a more significant role than suggested by Gernsheim (1982) who stated that Suscipj and Morelli "assisted" Ellis, and indeed by Ellis himself, who referred to his unnamed "aides."

Ellis's proposal for *Italy Daguerreotyped* describes it as "a collection of Views, chiefly architectural, engraved after Daguerreotypes in the possession of the Editor" (i.e., himself). It was intended to comprise 60 engravings faithfully copying the originals. Thirty-two pictures were to be of Rome, alternating with those of other cities, each accompanied by a short description specifying the point from which it had been taken, the date, and the name of every public building shown. Ellis chose large 150mm × 205mm plates because they needed to be able to contain the requisite detail that would allow the engraver to transcribe them accurately. The work was to be published in twenty monthly parts at a price of 1/- or 1/6 each number, commencing 1 January 1845, but the project was abandoned and Ellis put the plates aside.

There are a number of possible reasons why the book was not produced. Gernsheim claims that it was because of the expense of engraving the pictures. In addition, *Excursions Daguerriennes*, comprising engravings based on daguerreotypes taken in Europe and the Near East, was published in Paris between 1841 and 1844 by Noël-Marie Paymal Lerebours (1807–73), and Ellis may have decided that the sense of novelty had been lost. More importantly, *Excursions Daguerriennes*' engravings did not do justice to the originals, and Ellis perhaps felt that the same fate would befall his project. Finally, he may have not had time to see *Italy Daguerreotyped* to fruition because during this period he was immersed in his philological researches, publishing *Phonetics* in 1844 and *The Alphabet of Nature* the following year.

Instead, the 159 whole-plate daguerreotypes, along with the accompanying documentation, were given to the Science Museum by Ellis's son Tristram upon his father's death in 1890 and subsequently transferred to the National Museum of Photography, Film and Television in Bradford (which reproduces many of them on its website). Becchetti and Pietrangeli's *Roma in Dagherrotipia* (1979) prints all of the Roman views. Together, images and notes form a significant collection from this period, providing both a documentary record of facets of those cities, and insights into the technical aspects of recording them with an infant medium.

TOM RUFFLES

Biography

Alexander Ellis was born in Hoxton, Middlesex, on 14 June 1814. His name was originally Sharpe, but he changed it to his mother's maiden name in 1825. This was a condition imposed by a relative of his mother for Alexander to receive significant financial support, giving him lifelong security. He was educated at Shrewsbury, Eton and Trinity College, Cambridge. He married in Naples in 1840 and after periods in a number of places, including Dorking, Bath and Bristol, he and his family settled in Kensington, west London. Author of many works on spelling, pronunciation, acoustics and mathematics, he corresponded widely and was associated

with numerous learned societies, notably being a fellow of the Royal Society, the Society of Antiquaries and College of Preceptors. He was awarded an honorary doctorate by Cambridge University four months before his death, which occurred on 28 October 1890. None of his obituaries mentions his daguerreotypes.

ELLIS, WILLIAM (1794–1872)
English missionary, botanist, and photographer

The Reverend William Ellis originally embarked on a career as a gardener before his ordination at the age of twenty-one. He became a missionary, in Africa and in the South Pacific, eventually becoming the Chief Foreign Secretary of the London Missionary Society.

By the late 1820s he was publishing accounts of his missionary activities and travels—notably in 1826 a book on his experiences in Hawaii—but he was in his late fifties before his first encounter with photography, learning the skills of the art in preparation for a series of journeys to Madagascar between 1853 and 1856—ac-

Ellis, Reverend William. Portrait of Black Couple.

companying another missionary photographer, James Cameron. His account of his travels and photography was published in *Harper's Monthly* in April 1859.

Believing that visual material would support his missionary activities even more than the printed word, his camera became a powerful tool, and in his accounts of his travels, he recorded the reaction of the natives to seeing their own likenesses for the first time. He was taught photography by Roger Fenton.

Ellis was also a botanist, and is credited with the discovery of a number of species of orchids in eastern Madagascar during further journeys to the islands in the late 1860s.

His images survive in a number of major collections in the US and Britain.

JOHN HANNAVY

EMERSON, PETER HENRY (1856–1936)

English photographer and writer

Peter Henry Emerson was born in Cuba on 3 May 1856. His American father, Henry Ezekiel Emerson, distantly related to the author Ralph Waldo Emerson, owned a sugar plantation on the island, but due to his poor health, the family moved in 1864 to Wilmington, Delaware. Three years later, however, Emerson's father died and after a short stay in Cuba the young boy's mother took the family back to Wilmington where he began his formal education. In 1869 the family again moved, this time to England, where Emerson spent the rest of his life, taking the option of British nationality that was open to him via his English grandfather. His academic progress was impressive both at school and subsequently at university in London and Cambridge. He studied medicine, gaining his MRCS in 1879 and his MB in 1885. Despite being considered one of the best medical students of his generation, Emerson, who was fortunate in having a private income, decided not to practise medicine and devoted himself instead to a variety of interests. In 1881 he purchased his first camera and it is for his photographs and for his writing that he is now best remembered. All of his published photographic work, with minor exceptions, appeared between 1886 and 1895. He continued to write, however, on his family history and on a variety of other subjects, to the end of his life.

Emerson was married in June 1881, to Edith Amy Ainsworth, a nurse whom he had met during his medical studies. At the end of that year, the couple took a holiday in Italy. It seems to have been here that Emerson began to develop his strongly-held views on art and nature. In August 1883 he took a holiday in the coastal town of Southwold in Suffolk, in the part of England that was to become the inspiration and location for most of his subsequent work. Also in that year he joined the Photographic Society Club, London. Two years later, in 1885, Emerson returned to Southwold and, together with his brother, hired a yacht for a cruise on the Norfolk Broads. On this cruise he met the painter Thomas Frederick Goodall (1857–1944). Goodall, a Norfolk man, had trained at the Royal Academy of Arts in London and was an exponent of the French-influenced 'Naturalistic' style of painting with which Emerson had strong sympathies. Emerson and Goodall became firm friends and artistic collaborators and for the following six years Emerson's photographic activities were concentrated mainly in rural Norfolk.

In 1886 Emerson, with Goodall as co-author, produced *Life and Landscape on the Norfolk Broads*, a large book of forty platinum prints, with a text describing aspects of life in and around the inland waterways of Norfolk. Two more books followed in 1887; *Pictures from Life in Field and Fen*, and *Idyls of the Norfolk Broads*. These were illustrated with photogravures made, Emerson stated, directly from his negatives. The platinum prints of *Life and Landscape on the Norfolk Broads* had been made in Scotland by Valentine and Sons, of Dundee. These prints were of variable quality and it was possibly this experience that contributed to Emerson's choice of photogravure for all his subsequent publications, although the close relationship between the methods and materials of photogravure and of the artistic medium of etching was probably a more influential factor.

In the introduction to *Pictures from Life in Field and Fen*, Emerson claims, of the photogravure: "If successfully performed, it is purely an automatic process, so that the resulting copper plate is a facsimile of the negative, no translator stepping in to mar the work." It is clear, however, that considerable retouching has been carried out on these images, which was the normal practice of reproductive printmakers at this time. Emerson, while deploring this practice, had little control over it. In the same introduction he states: "The plates are, as a rule, entirely free from retouching, and any hand-work that has been introduced is a cause of regret to us, and we are in no way responsible for it, for our idea of a perfect photo-etching or engraving process is one in which the resulting copper plate is entirely the effect of chemical action."

In 1888 followed *Pictures of East Anglian Life*, illustrated with thirty-two photogravures and fifteen small half-tones in Collotype. Then in 1889 came the book that was described by one of Emerson's contemporaries as having the effect of "a bombshell dropped into the midst of a tea-party." Emerson's first edition of *Naturalistic Photography for Students of the Art* set out, in uncompromising fashion, his views on art and on photography, on the characteristics of the eye, on contemporary artistic practice, and the consequent

implications of these for a photography founded on Naturalistic principles. Detailed instructions were given on every aspect of photographic practice. A second, slightly revised edition followed in 1890.

In *Naturalistic Photography* Emerson was addressing those who wished to emulate him. He was also aiming to align photographic practice with contemporary movements in British art with which he identified. This brought him into direct conflict with the photographic establishment, personified by Henry Peach Robinson (1830–1901), whose composite, sharply defined photographs were the epitome of all that Emerson despised, and whose book *Pictorial Effect in Photography*, published in 1869, had been a major influence on those whose photography had artistic pretentions.

Naturalistic Photography, in which Emerson prescribes methods, materials and techniques to be used by the student who wishes to follow his lead, would appear to describe, by implication, Emerson's own working practice. A study of his published work, however, reveals this to be only partially true. He advised, for instance, the use of long-focus lenses, to avoid the 'false drawing' given by lenses with a wide angle of view, yet many of his photographs show just this effect. He also frequently ignored his own rules on Naturalistic Focusing.

Emerson's theories of Naturalistic Focusing caused controversy and confusion. Quoting the work of the German scientist and medical researcher Hermann von Helmholtz, Emerson advocated the use in photographs of a restricted depth of field as analogous to that of the eye, and, reasoning that photographic lenses were capable of greater definition than the eye, advised that "... it is always necessary to throw the principal object slightly (often only just perceptibly) out of focus, to obtain a natural appearance...." This, of course, simply shifts the focal plane elsewhere and Emerson's contemporaries, even if sympathising with his aims, were well aware of the practical difficulties of achieving them. In many of Emerson's published photographs, an area of sharp focus may be found that, given his antipathy to retouching, he was unable to disguise. In 1889 he asked his friend T.R. Dallmeyer to design a lens "like the eye," but Emerson found that it did not produce the effects he required. Other photographers, notably George Davison, while initially in favour of Emerson's principles, subsequently adopted the more diffused images of Impressionistic Photography, of which Emerson disapproved, causing some acrimonious exchanges in the photographic journals.

In 1890 Emerson published a folio entitled *Pictures of East Anglian Life*, comprising a selection of ten prints from his book of the same name. It was intended as a supplement to *Naturalistic Photography*, to show in pictorial form the results that the student should aim for. Also in 1890 appeared *Wild Life on a Tidal Water*.

During the second half of 1890 Emerson was approaching a crisis in his artistic life. He had begun to have some doubts about the artistic status of photography and his correspondence with painters, notably George Clausen, had not been encouraging. Clausen pointed out to Emerson the limitations of photography as an artistic medium; limitations of which Emerson had previously been dismissive.

In May 1890 Hurter and Driffield had published the results of their photo-chemical investigations into the characteristics of dry plates. An important conclusion was that once the plate had been exposed, the ratios of the of the image densities were fixed and could not be altered during development. Until then, photographers believed that tonal relationships could be altered by selective development, and indeed this subjective intervention was fundamental to Emerson's claims for the artistic status of photography. He spent three months during 1890 testing, in practice, Hurter and Driffield's laboratory results and reluctantly concluded that they were right.

Emerson's justification of the status of photography as an artistic medium relied on the ability of the photographer to select and frame a subject; to adjust the focus and the focal plane to emphasise some parts of the subject and suppress others; and, most importantly, to adjust the tonal relationships on the negative to match those as visualised by the photographer. He wanted the freedom of the artist's subjective transcription of tones, even if this was at variance with their relative luminance. Science, however, denied him this freedom. In Emerson's words: "I thought once (Hurter and Driffield have taught me differently) that true values could be obtained and that values could be *altered at will* by *development*. They cannot; therefore, to talk of getting the values in any subject whatever as you wish, and of getting them true to nature, is to talk nonsense" (Emerson's italics).

Emerson came to the conclusion that photography was not and could not be art and in consequence he published, at the end of 1890, a pamphlet entitled *The Death of Naturalistic Photography* in which he gave his reasons for this renunciation, as he called it: "... misgivings seized me after conversations with a great artist, after the Paris exhibition; these were strengthened after the appearance of certain recent researches in psychology, and Hurter and Driffield's papers; and finally the exhibition of Hokusai's work and a study of the National Gallery pictures after three-and-a-half months' solitary study of Nature in my house-boat did for me."

Emerson's 'great artist' has not been identified. Both Whistler and Clausen have been suggested, but on the available evidence it seems unlikely that Emerson would have had the opportunity of "conversations" with Whistler.

The reactions to this renunciation were polarised

Emerson, Peter Henry. Rowing Home the Shoof-Stuff.

between the dismay of those who had followed his teaching and the delight of those whom he had antagonised. Emerson recalled unsold copies of the second edition of *Naturalistic Photography* and wrote to his friend, the sculptor James Havard Thomas that he was considering giving up photography entirely. "I wish to God I had never seen a camera..."

But Emerson was resilient and his correspondence in the spring of 1891 with Joseph Pennell, the American artist and illustrator, shows him arguing vigorously that photographic images, printed as photogravures, could legitimately be considered as art. Pennell politely disagreed.

Emerson did not give up photography and continued to publish his work. In 1893 he published *On English Lagoons*, and in 1895 *Marsh Leaves*. He made the photogravure plates himself for these, his last two illustrated books. As opposed to his earlier large-format photographs, frequently showing rural scenes and agricultural workers, his post-renunciation photographs are smaller, contain progressively fewer human figures, tend to concentrate on distant subjects and, frequently, the effects of the mists and frosts of autumn and winter on the landscapes of rural Norfolk.

Emerson's last attempt to influence his contemporaries was his publication, in 1899, of the third edition of *Naturalistic Photography,* from which all references to the artistic status of photography were excised. Despite his earlier public renunciation of photography-as-art, he retained his conviction that photographs should share the materials and methods of the artist-printmaker. He wrote:

> ... we feel that the day is not far distant when every one who expresses himself by photography will also bite his own plates and make his own blocks, and the prints will be published by print-dealers as etchings are now. This, in my opinion, is the only method which can give fullest satisfaction.

It is clear from Emerson's correspondence with Alfred Stieglitz that he continued to take photographs into the 1920s, but no evidence of this output seems to have survived. Apart from the published work, many examples of which still survive, thanks to their publication in bound volumes, there exists a number of unpublished photographs by Emerson that were donated to George Eastman House, where they remain as the only significant collection of his unpublished work in a public collection.

P.H. Emerson died in 1936, one day short of his eightieth birthday.

David Stone

Biography

Peter Henry Emerson was born in Cuba on 3 May 1856, to an American father and an English mother. Following the death of his father in1867, his mother moved the family to England, where he completed his education, qualifying in medicine in 1885, having married in 1881. There were five children, born between 1882 and 1892.

His photographic subjects were concentrated mainly in the English county of Norfolk and published in a series of books and folios combining text and photographs, some co-authored with the painter T.F. Goodall.

Emerson exhibited his photographs from 1882 onwards.

His main publications are:

1. *Life and Landscape on the Norfolk Broads* (1886) with T. F. Goodall
2. *Pictures from Life in Field and Fen* (1887)
3. *Idyls of the Norfolk Broads* (1887)
4. *Pictures of East Anglian Life* (1888)
5. *Naturalistic Photography for Students of the Art* (1889/1890/1899)
6. *Pictures of East Anglian Life* (1890)
7. A portfolio of 10 prints selected from the book of the same title *Wild Life on a Tidal Water* (1890)
8. *The Death of Naturalistic Photography* (1890)
9. *On English Lagoons* (1893)
10. *Marsh Leaves* (1895)

EMPEROR PEDRO II (1825–1891)

Pedro de Alcântara João Carlos Leopoldo Salvador Bibiano Francisco Xavier de Paula Leocádio Miguel Gabriel Rafael Gonzaga de Bourbon Habsburgo e Bragança was born in Rio de Janeiro on December 2, 1825. His father, Emperor Pedro I, abdicated in 1831. Pedro II purchased a daguerreotype camera in 1840, the year he was declared an adult and enthroned. He also learned to use it, thereby becoming the first Brazilian-born photographer. As a patron, he encouraged the development of photographic methods, spent vast sums on photographs and albums, and in 1851 created the post of Imperial Photographer, an appointment held by Buvelot & Prat (1851), Insley Pacheco (1855), Christiano Junior (1857), Klumb (1861), Stahl & Wahnschaffe (1862), Lopes Cardoso (1864), Ferreira Guimarães (1866) and Gutierrez de Padilla (1889). Pedro II traveled extensively and collected European photographs, while ensuring that Brazilian photography featured prominently in his country's pavilions at Universal Exhibitions in London (1862), Vienna (1867), Philadelphia (1876) and Paris (1889). Deposed and banished in 1889, he died as Pedro de Alcântara in Paris on December 5, 1891. His collections, including albums by Benjamin Mulock and Victor Frond, are housed at the National Library in Rio and the Imperial Museum in Petrópolis, Brazil.

EMULSIONS

Strictly speaking these are "Suspensions" but the name has stuck. A true emulsion is a stable mixture of two incompatible liquids, salad cream then a familiar example of oil and vinegar. The original weird and wonderful concoctions also used egg albumen as a stabiliser and had a similar appearance and texture. In the course of time it has changed to mean both the liquid and the dried material on a negative or paper print.

Today we tend to think only of gelatin emulsions although in the 19th century it was used for fewer years than albumen or collodion.

The word was unknown at first, the sensitive matter being deposited in paper rather than onto it, Talbot's original process of dipping then drying. This was used for both the negative and positive and it was not until Niépce de St. Victor invented the albumen process in 1848 any real improvement was possible. There were two crucial inventions here. The first was a rigid base, a glass plate. The real breakthrough was the prior preparation of a light sensitive mixture applied to the plate, then dried, the emulsion. This invention has remained essentially unchanged.

Niépce opened up the way for major improvements in associated camera and lens technology because huge negatives needed them. A positive could only be made by contact printing and the glass plate solved the other inherent problem with paper, its opacity. Once the concept of applying an emulsion as a transparent sensitised layer to a transparent inert base had been established, photography as we know it started. Fuzzy images and long exposures gave way to a faster and sharper process.

However, it's important to understand that whilst every worker, then Company, has their own 'secret' emulsion recipe, the basic principles haven't changed since 1848. A mixture of silver halides is made or mixed in a solution of a transparent substance which when applied to the plate, dries to a stable light sensitive coating. Precise details of selecting, preparing, mixing, and spreading seem like witchcraft today, but remain familiar in any modern factory using gelatin. This is then exposed, developed and used to make any number of prints.

With this key bit of technology established it soon became apparent that an emulsion applied to paper also greatly simplified print making. A prior albumen application made the paper both more rigid but also kept the sensitive emulsion where it was most needed, on the surface. The albumen in the emulsion also added a sheen to the final image and acted as a protecting or "anti-scuff" surface.

In the same year 1848 that Niépce introduced albumen, R. J. Bingham of the Royal Institution, London, gets the credit for first suggesting gun cotton or collodion for photography. As a synthetic material it had many obvious advantages. Scott Archer prepared his first negatives that year, then disclosed his collodion process in 1851. By 1855 collodion had largely displaced albumen when Mayall published the then most widely used albumen system. The two systems ran in parallel for a long time and albumen continued for decades after collodion had been replaced in turn by gelatin.

Albumen had a number of practical disadvantages, not least bacterial spoilage and uncertain quality but when dry it also stood up to abuse much better than the other obvious natural alternative, gelatin. It was not for another 30 years that this problem was solved and even then albumen prints remained a firm favourite right up to recently, and for large glass lantern slides at the turn of the century nothing today really excels for tonal quality.

Like albumen, collodion emulsions found very wide application in both negative and positives. Its main practical advantage was the ability to prepare and store stock solutions without decomposition. Even after a century and a half some samples from the period are still usable and the technology might not have moved on much were it not for a severe disadvantage of collodion, its unsuitability for scientific measurements. When dried, the emulsion became very insensitive, and nearly all negatives were created from the "wet collodion" process. For precise work needed for the Transit of Venus in 1874 the wet process was totally inadequate.

The Royal Greenwich Observatory gave W. de W. Abney the task of solving this and he modified and combined both the emulsions of the time. He used the stability of dried collodion as a base and albumen as a sensitive layer. He cured the decomposition problem with an unlikely ingredient, stale beer. This beer albumen process paved the way for all modern photography because it illustrated two fundamental clues to progress. The first was that prior chemical treatments of dry plates could yield huge increases in sensitivity and gave long-term storage as a bonus. Second, it was possible to modify the colour sensitivity of the emulsion. Abney's two critical discoveries led to everything we know today, high speed panchromatic, then colour films.

Once this groundwork had been established the time was ripe for another major step forward in emulsion technology, better alternatives to inflammable collodion and decomposing egg white. Gelatin had been tried since Talbot's invention but the stuff was simply not well enough defined to be reliable. With Abney's initiative, better gelatin consistency was sought and quickly found to be vastly superior. By the 1880s gelatine had become the major ingredient in emulsions but even as late as 1896 R Child Bayley still hadn't fully solved the specification problem in a paper to the Royal Photographic Society. Gelatin emulsions had become the standard photographic medium for the next Venus transit in 1882, and Abney's special additives had increased sensitivity way beyond anything thought possible a decade before.

Emulsion technology hasn't changed much from that time because of a peculiarity of gelatin, it contains natural components which actually sensitise the emulsion. No synthetic substitute comes anywhere near that unique property. Making an emulsion falls into several stages, laid down in the 1880s.

Gelatin has to be critically quality controlled for consistency, then mixed with water to make the basic ingredient. To this is added, or it is added to a solution of halides. The ratio of bromide to chloride and iodide, determines the photographic properties and the gelatine controls the grain size when silver nitrate is added to the mixture. Then follows a period known as "ripening," still a very much mysterious situation when the emulsion reaches an improved sensitivity. When that process is over, the emulsion is coated onto the negative or positive and allowed to dry. At all stages before use many special ingredients can be added to confer special properties, and there may be washings to remove some or all of these. That is one reason why no two batches of photographic emulsion behave exactly the same.

The only major change towards the end of the century was to flexible film instead of glass plates introduced by George Eastman. That led ultimately to an emulsion expansion into the present mass market through ever smaller formats and convenience in use.

ENGLAND, WILLIAM (1816–1896)

British photographer and inventor

William England is arguably one of the forgotten giants of 19th century British photography and, regretfully, his work is largely ignored today. Born in London in 1816 England began his photographic career in the early 1840s as a daguerreotypist, going on to use both the wet and dry collodion processes and printing with albumen. After building a reputation as both a gifted technician and portrait photographer of some talent, he eventually abandoned portraiture to join The London Stereoscopic Company, upon its founding in 1854. England soon became the company's principle photographer and leading technical innovator. England was largely responsible for building London Stereoscopic Company's global reputation over the next decade and his travels took in a wide variety of foreign destinations such as Ireland (1858), the U.S. and Canada (1859) and Paris (1860 and 1861). It was primarily these 'exotic' views that captured the imagination of the public and contributed greatly to the rapid rise of London Stereoscopic Company in the 1850s and 60s when stereography was at the height of its popularity. Originally founded by George Swan Nottage, London Stereoscopic Company produced a wide variety of stereoscopic views that were all the rage during the Victorian era and London Stereoscopic Company were one of the very first companies to license their imagery for commercial reproduction on a global basis. Staff photographers such as Reinhold Thiele and William England traveled the world in their mobile, horse-pulled darkrooms shooting a variety of subjects and views for commercial reproduction by London Stereoscopic Company. Aside from his outdoor work England produced a variety of subject matter including formal portraiture and London Stereoscopic Company's renowned 'Comic' series which included the hugely popular 'ghost' stereographs, employing double exposure techniques. England left London Stereoscopic Company at the height of their popularity in 1863 to concentrate on a freelance career though his last major project on behalf of London Stereoscopic Company was as the exclusive photographer for the International Exhibition od 1862 in London. England's collection of some 15,000 stereoscopic plates have survived relatively intact over the years and was once 'saved' from being turned into greenhouse glass shortly after London Stereoscopic Company ceased trading in the early 1920s.

The invention of 3-D photography (stereography) first received popular acclaim at the Great Exhibition of 1851 in London and within 10 years stereographs had entered almost every home in Europe and America as a new form of entertainment. England's most important series for London Stereoscopic Company were taken during his American journey in 1859. He traveled from New York, up the Hudson river and through the Catskill's to Niagara into Canada, capturing over 230 views along the way, as well as other locations including Philadelphia and Washington D.C. where he shot the Capitol under construction. His focus was on both urban and engineering works including the railroads as well as the dramatic scenery of the rivers and waterfalls and this series the first American views to be commercially available in Europe. His memorable shot of Blondin crossing Niagara Falls on tightrope became one of the best selling stereographs of all time—allegedly selling some 100,000 copies worldwide. The majority of England's stereo views were taken on a single short focus lens 'pocket' stereoscopic camera which was introduced by London Stereoscopic Company in 1858. The entire apparatus was a mere 20cm long × 12 cm wide × 5cm deep and, weighing in at just over half a kilogramme, meant it was eminently mobile and suited England's travels perfectly. The only problem with this type of single lens design was the fact the whole camera needed to be laterally moved along a groove or track, after the first image had been taken on one half of the plate. Though the camera movement could be varied up to a distance of 33cm, scientists of the day advised this not to be any more than the distance between the pupils of the eyes—about 6cm—for the proper stereo effect to be achieved. The single lens camera was soon superseded by the development of the 'binocular' or twin lens camera which took both images simultaneously which significantly accelerated the picture taking process.

As well as being a fine photographer with an instinct for style and composition, England was also a great technician and a number of London Stereoscopic Company's developments in photographic apparatus—particularly those connected with stereography—were largely due to England's technical expertise, for example he developed a shutter with variable openings in 1861. After leaving London Stereoscopic Company in 1863 to pursue a freelance career, England continued with his stereo work, capturing views all over Europe; France, Switzerland and Italy in particular. The many Alpine views taken by England were considered to be some of his finest and were very much his forte, those taken of the Chamonix Glacier being particularly sought after and the resulting stereographs sold all over the continent as well as in Britain. In 1867 England erected a photographic

printing studio at his home in Notting Hill, London ostensibly to print from his landscape negatives but continued to travel throughout Europe, and at his peak, England was regarded as one of the leading landscape photographers in Europe. However this did not help him during the Franco-Prussian War of 1870, when he was arrested in the Rhine region of Germany and accused of being a French spy. England was eventually released but not before the authorities had initially confiscated his lenses, though these were later returned. England is perhaps one of an elite band of photographers who spanned the whole evolution of photography from the daguerreotype to the roll-film and seemingly adapted to each phase with relative ease. Throughout his career his advice and patronage was much sought after and he was a member of several photographic societies. England died in August 1896, at the age of 80 and is arguably *the* greatest of a number of unsung British photographers of the Victorian era whose work is often overlooked.

A great proportion of England's work—the views taken on behalf of London Stereoscopic Company—are currently in private hands and housed in west London. Together with the stereoscopic negative plates, the collection also includes the original day books, contact prints and catalogues. Taken as a whole, the collection constitutes an invaluable photographic document of the period—not only for their historical significance but also for their image clarity, striking detail and technical brilliance. A unique view of the Victorian era…and all in glorious stereo.

MATTHEW BUTSON

Biography

William England was born around 1816 in London, England. Ran a daguerreotype portrait studio from 1840. Abandoned portraiture in 1854 and joined London Stereoscopic Company. First overseas trip on behalf of London Stereoscopic Company to Ireland in 1858. In 1859 traveled to USA and Canada producing the *America* series. In 1860 (approx) joined London Photographic Society. In 1861 visited Paris and in same year invented camera with variable shutter openings. Photographed International Exhibition of 1862 in London and the Dublin Exhibition of 1863 last major commissions for London Stereoscopic Company. 1863 onwards focused on freelance career producing his first views of Switzerland. Between 1863 and 65 took views all over Europe, though chiefly in France, Italy and Switzerland—specialising in Alpine views—with patronage and financial support of British Alpine Club. In 1865 published first major album containing seventy-seven panoramic views of Switzerland, Savoy and Italy. Erected a printing studio in Notting Hill, London in 1866. In 1867 published second album—seventy-two views of the Rhine. In 1871, England made a member of the London Photographic Society and in 1886 became President of the Photographic Society of Great Britain. In 1889 was one of the judges at the Universal Exhibition and later became vice-president of the jury. Later the same year he became chairman of the West London Photographic Society. In 1890 he ran the Solar Club of Great Britain. Died in London on 13th August 1896.

Exhibitions

1865 Dublin International Exhibition, Ireland.
Eleventh Annual Exhibition of the Photographic Society of London.
1867 Royal Cornwall Polytechnic Exhibition—Photographic Dept., Cornwall, England.
Paris Universal Exposition, Palace of the Champs de Mars, Paris, France.
Thirteenth Annual Exhibition of ther Photographic Society of Great Britain, London.
1868 Fourteenth Annual Exhibition of the Photographic Society of Great Britain, London.
1870 Neuvieme Exposition de la Societe Francias de Photographie com Palais de I'Industrie Aguado, Paris, France.
1872 Seventeenth Annual Exhibition of the Photographic Society of Great Britain, London.
1873 Eighteenth Annual Exhibition of the Photographic Society of Great Britain, London.
1874 Dixieme Exposition de la Societe Francias de Photographie com Palais de I'Industrie Aguado, Paris, France.
1875 Nineteenth Annual Exhibition of the Photographic Society of Great Britain, London.
1876 Centennial Exposition, New York, USA.
1877 Twenty-second Annual Exhibition of the Photographic Society of Great Britain, London.
1878 Twenty-third Annual Exhibition of the Photographic Society of Great Britain, London.
Exposition Universelle, Paris, France.
1881 Photographic Society of Great Britain Exhibition, London.
1883 Photographic Society of Great Britain Exhibition, London.
Exposition Internationale de Photographie, Palais des Beaux-Arts, Paris France.
1884 Photographic Society of Great Britain Exhibition, London.
1888 Royal Photographic Society Exhibition, London.
1890 Royal Photographic Society Exhibition, London.
1892 Photographic Society of Great Britain Exhibition, London.
1893 Thirty-eighth Annual Exhibition of the Royal

Photographic Society, London.
1895 Exhibition of Photographs, Process Work and "Black and White," City Art Gallery, London.
Third Annual Photographic Salon—The Linked Ring, Dudley Gallery, England.
Fortieth Annual Exhibition of the Royal Photographic Society, London.
Special Exposition of Photography Arts and Sciences, Imperial Institute, London.

ENLARGING AND REDUCING

In photography's first decade, the practice of enlarging or reducing a negative image was largely unknown, although several pioneers had suggested the idea, and even practised it. John Draper had proposed making enlarged copies of daguerreotypes as early as 1840, and Alexander S Wolcott patented an enlarging camera in March 1843. In June of the same year, Henry Fox Talbot patented a calotype enlarger, and therefore has priority claim to the invention of a system for making an enlarged print from a negative. None of these early devices achieved widespread popularity, due in the main to the length of exposure necessary.

By the end of the century, however, such procedures were a commonplace part of the photographic process, with 'enlarging lanterns'—enlargers—available powered by gas, petroleum, limelight, magnesium and even electricity. The half-century in between was a period of invention and innovation, during which a range of instruments were patented and marketed.

Intriguingly, the practice of reducing image size evolved more rapidly than that of enlarging. The pioneer in this respect was John Benjamin Dancer of Manchester, England who, in May 1853 produced a micro-photograph, 2mm in diameter, of a memorial tablet to William Sturgeon, a pioneer in the science of electricity, from a 5" × 4" (125mm × 100mm) negative he had taken the month before.

It is interesting to note that Thomas Sutton, on seeing his first micro-photographs, commented that they were "of little or no practical utility" and "somewhat childish and trivial." Their uses proved to be anything but childish and trivial, and micro-photographs, produced by René Prudent Patrice Dagron (1819–1900) proved an effective means of getting messages out by pigeon post during the siege of Paris 1870–71. Dagron's technique involved reducing messages to microdots of just over 1mm diameter, a reduction of up to 100 times.

The micro-photograph also found a perhaps trivial but nonetheless engaging application in the "Stanhope," the invention of the same Rene Dagron who, in 1859. combined a tiny lens—invented in the late 18th century by Charles, the 3rd Earl of Stanhope—with a micro-photograph to form a single miniature magnifying unit which he called his "cylindre photomicroscopique."

Reduction frequently involved the use of a camera. During the carte-de-visite era, photographers such as Francis Bedford produced large photo-montages of captioned scenic views which were then copied on to small negatives and contact printed and mounted for sale as cartes-de-visite.

At the other end of the scale, initial approaches to enlarging in the early days of photography rarely involved negatives—enlarging daguerreotypes could be effected by using a copy camera—a sliding box camera designed to permit photography at a scale greater than 1:1.

With the introduction of the collodion negative in the 1850s, and increased availability of smaller format cameras, Achille Quinet invented a vertical enlarging camera in 1852, but it was an inefficient light-gatherer, and required very long exposures. In an attempt to resolve that problem, David Acheson Woodward designed and patented the idea of the solar enlarging camera in 1857, able to make enlarged life size prints from quarter plate and half plate negatives with an exposure of about forty five minutes. The camera used a mirror and condenser lens to focus sunlight on to the negative, the image being projected on to the paper via a copy lens. Patented improvements to the solar enlarger, in the 1860s and 1870s saw it equipped with a heliostat—a clockwork motor to rotate the mirror—thus ensuring that the light beam remained concentrated on the condenser lens throughout the exposure.

A modification of Woodward's design was introduced in 1864 by Desiré Charles Emanuel van Monckhoven. It was the first instrument to really look like an enlarger. Fitted into the wall of the darkroom, it gathered light in the same way as Woodward's apparatus, but used a more complex lens assembly to correct for spherical aberration and thus produce a sharper more evenly illuminated print.

J.F. Campbell's 1865 enlarger was the first vertical design, built into the studio roof and gathering daylight from above. The vertical enlarger, illuminated by artifical light, would not become commonplace until the 1890s.

Alphonse Liébert's enlarging apparatus was introduced at about the same time, and was used by fellow photographer Nadar to create his first enlargements that same year. Liébert's design eschewed reflected light in favour of direct solar illumination, while retaining a geared drive system—hand-cranked—to keep the condenser lens pointing directly towards the sun. This direct illumination system significantly reduced exposure times.

Gaston Tissandier, writing in the second edition of his *History and Handbook of Photography*, translated by John Thomson, noted that "enlargements, it is true, offer certain inconveniences; the details of the enlarged proof have often a disagreeable effect; they are exaggerated and seem as though seen under a magnifying glass. It would, however, be unjust, in spite of these defects, to underrate the importance of the results obtained.

Perhaps because of these 'defects'—presumably grain and imperfections in the collodion coating of the negative—solar enlargements, on to either paper or canvas, were often over-painted by studio artists, creating a combination of photography and painting which was sometimes highly successful, but often rather less so!

In the 1870s, numerous photographers advertised this service—offering enlargements from carte-de-visite prints and daguerreotypes as well as existing negatives. Typically, prices in London ranged from two shillings for a 10 × 8 print, up to three pounds for a life size bust "finished in oils." In 1878, R. L. Elliot & Co., of London's King's Road advertised that they could produce prints up to 25" × 20" from quarter plate negatives. Elliot's particular boast was that his enlargements were made using limelight – an illuminant first suggested by John Benjamin Dancer.

The combination of the relatively fast bromide and chloride papers as a replacement for albumen in the 1880s, and more efficient light sources, spurred a number of developments in enlarger design. Early artificial light enlargers were horizontal, looking much like lantern slide projectors, with the image projected on to an easel. With light sources such as limelight, gas or kerosene, the equipment was fitted with complex light baffles and a tall chimney to vent the noxious fumes out of the darkroom.

As the new century dawned, electric lighting was starting to make inroads into daily life and electrically powered enlargers became available, albeit at a very high price compared with their oil or gas-fired alternatives.

ENSLEN, JOHANN CARL (1759–1848)

When Johann Carl Enslen took up photography at the beginning of 1839 at the age of 80, and became the first person to make photographic paper prints in Germany, he had already retired—twice—from a career as one of the most remarkable showmen of his generation. His earlier career(s) exemplified the same curiosity and skilled craftsmanship that he brought late in life to photography. At the age of 22 and seemingly without prior experience, he built a *montgolfière* 80 feet high, in which his financier François Xavier Adorne made the 11th successful manned baloon flight from the Finkmatt in Strasbourg on 15 May 1784. Between 1785 and 1800 he travelled throughout Europe with an astonishing collection of flying sculptures, intricate aerostatic figures in life-size and over-life-size made from gold-beaters' skins that were a pinnacle of rococo design and were exhibited hung from threads in large halls with the circulation of an admiring public below causing just enough of a draft that they swayed gently in the air. If the circumstances were right, meaning that tickets could be controlled or underwriters be found, Enslen released his figures in "air hunts" across the city: one performance in Berlin in 1796 attracted some 80,000 of the town's 121,000 inhabitants, and equally extraordinarily crowds were found in London, Vienna, and other cities for his air chases involving a wild boar chased by two dogs, and a stag chased by another dog with a man on horseback behind. His figures, some 30 of which fitted neatly into a hand satchel, also included Mercury, an Aerial Nymph, and Cupid, with the goddess Diana seated in a Roman coach led by two stags his

pièce de resistance, described in contemporary sources in blushingly superlative terms. Around 1788 he began to construct and exhibit automata, and in the 1790s after reputedly buying the apparatus of Paul Philidor in Vienna, gave phantasmagoria ghost-raising shows in Berlin. For the coronation of Franz II in Vienna, he released a gigantic baloon in the form of a colossal temple surrounded by genies and allegorical figures. Enslen's illusions, including a room-sized *camera obscura* entertainment, were always meticulously constructed and brilliantly performed. An admiring Prussian King gave him a large estate near Danzig, where Enslen retired at the age of 46 and turned to astronomical observations of the Aurora borealis, scientific experiments, and the making of moon globes, as a sideline taking over the local iron foundry, expanding it into the largest regional factory with about 60 workers. When Napoleon's troops confiscated his lands and his ironworks in 1807, Enslen returned to the life of a travelling showman, together with his son exhibiting 1 × 4 meter half-panoramas in Germany, central Europe and Italy, retiring for the second time in 1834 to Dresden. Here he published the first of his two monographs on the nature of light and returned to the study of the moon, making seven half-spherical moon globes which were given to the leading observatories of the day, including Greenwich.

Early in 1839, while Daguerre's process was still secret, Enslen began to experiment with photography. He said then and in later years that he followed Talbot's methods, which were first partially communicated to the Royal Society on 31 January 1839, but his inability to fix his images permanently until sometime after March, 1839 has led the historian Stephan Oettermann (see further reading, below) to suggest that at the beginning Enslen was actually following the earliest work of Thomas Wedgwood, and was again, as with his other Dresden activities, picking up one of the scientific interests that had intrigued him during his first retirement at Danzig. From April through the end of the year, Enslen made numerous photogenic drawings by laying out complicated arrangements of pressed ferns, feathers, butterflies and leaves on his salted paper, in a kind of early Biedermeier design. A portrait of Frederick the Great, a head of Christ, a Mary and Child, a view of the market in Dresden, or of the Frauenkirche in Dresden, some also surrounded by ferns and other natural objects, were prepared using engravings made transparent by soaking them in varnish and then laying them out on his photographically sensitised paper, as Niecephore Niepce had done in the 1820s. Enslen's experiments were reported beginning in April, 1839 in newspapers in Leipzig, Dresden, Vienna and elswhere; he assiduously sent photographs to many friends and acquaintances, including one by unknown means to Talbot at Laycock Abbey, a print which despite being properly inventoried there toured America in 1988 as an original Talbot image. Enslen seems to have remained active as a photographer only for about two years: a planned 1841 publication *Anleitung zur Verfertigung von Lichtbildern auf photogenischem Paper* (Instructions for the Preparation of Light Pictures on Photographic Paper) was never printed and its manuscript is now lost. His interest in photography, although indubitably motivated in part by his unflagging curiosity about all kinds of illusions, seems to have been not in exactly reproducing the natural world, but rather in photography as a reproductive process that could replace the printing press and again, like his aerostatic figures, be carried in a hand satchel. He therefore never used a camera but remained dedicated to photogenic drawing.

DEAC ROSSELL

Biography

Johann Carl Enslen was born in Stuttgart on 21 May 1759, but the events of his youth, education and early work remain obscure. Around 1782 he moved to Strassbourg, where just a few months after the first baloon ascent by the Mongolfier brothers the young 24-year-old seemingly without prior training built the first German Mongolfière, in which the eleventh manned flight took place from the Finkmatt on 15 May 1784. From 1785 to 1800 he travelled across Europe with an array of what he called "aerostatic sculptures," baloons fashioned in splendid Rococo style of gods and animals, with which he captivated the leading courts in Paris, London, Vienna and Berlin and whose flights in "air hunts" attracted tens of thousands of spectators. About 1788 he began to construct automats, including a piano player, a mechanical bird and a flute player that inspired Emanuel Schikaneder to form the character of Papageno in his libretto for Wolfgang Amadeus Mozart's "The Magic Flute." Continuing his experiments in physics, optics and mechanics, he opened a theatre in Berlin and gave elaborate and skillful exhibitions of white magic using mirrors, a room-sized camera obscura, and some of the earliest Phantasmagoria lantern apparatus. Wealthy and famous, Enslen retired at the age of 40 and moved to his estate near Danzig, where he took up astronomy, constructed a globe of the Moon and made optical experiments. He became interested in the making of iron and by 1804 owned the largest iron foundry in the Danzig area, with some 60 employees. Three years later his works was confiscated by Napoleonic troops, and after losing his estate he returned to Berlin in 1811 and re-started his career as a showman, building automats, projecting microscopic objects with a solar microscope, and exhibiting a huge relief model of Paris. From 1816 he painted and exhibited a new form of panorama with his son, a half-round panorama about 1 meter by 4 me-

ters, traveling across all of Germany and central Europe and spending 1823 to 1826 in Italy. Around 1834, at the age of 75, Enslen retired for the second time, moving his residence to Dresden. Again taking up astronomy and physical experiments, he published two monographs on the nature of light in 1834 and 1841 and began to experiment with photography in early 1839. Working on paper printing methods he devised his own fixing solution and began producing photogenic drawings in March, 1839, becoming the first practicing photographic pioneer in Germany at the age of 80. His last work was a large copper engraving of a café garden in Dresden; he died on 10 December 1848.

EPSTEAN, EDWARD (1868–1945)

Photoengraver, book collector, and translator

Edward Epstean occupies an unconventional position in the historiography of early photography. Neither a collector of images nor academic, nevertheless his elevated linguistic skills and decades-long professional experience as a photoengraver enabled him to become a foremost scholar and disseminator in the interwar years. His translations of key French and German works into English meant that Epstean's influence stretched far beyond his professional circles. Furthermore, thanks to his foresight as a bibliographer and bibliophile, generations of scholars have benefited from Epstean's research collection, donated to Columbia University in his native city of New York.

Edward Epstean began his career in photoengraving in 1892, and therefore lived through the period which saw a huge expansion in halftone printing. His scholarly bent gave him the impetus to constitute a personal library in the field: "It was the need for a thorough theoretical understanding of the reproductive processes by photography, in which I have been engaged for some forty-five years, which led me to bring together these books" (Foreword, *A Catalogue of the Epstean Collection*, New York: Columbia University Press, 1937). However, a cursory glance at the subject matter of his collection makes plain that it had long outgrown the requirements of a working library to encompass the full scope of photographic science, history and applications. In fact the photomechanical processes and colour printing comprise barely a fifth of the collection.

Epstean's breadth of vision was matched by the assiduity with which he set about constructing his collection, in particular literature from the earliest years of photography. His professional contacts enabled him to add to his holdings the libraries of Stephen H. Horgan, William Gamble and Josef Maria Eder. His French holdings were consolidated with the acquisition of a private French library, including duplicates from the collection of Gabriel Cromer (1873–1934) gathered by Kirkor Gumuchian (1886?–1949), then a bookseller in Paris but who would move his stock and selling operation to New York City on the eve of the second world war. Epstean was ably supported in his endeavours by John A. Tennant, a New York bookseller and publisher of *The Photo-Miniature* from 1899 to 1939. When Epstean decided to place his collection, he was fortunate in having as a negotiating partner Hellmut Lehmann-Haupt (1903–1992), an outstanding historian of printing and rare books curator at Columbia University from 1930 to 1937. Lehmann-Haupt recognised the significance and value of Epstean's library for research and oversaw the integration of The Epstean Collection, as it became known, into Columbia University library in 1934. A bibliography of the collection was published in 1937 while Epstean, viewing the collection as a work-in-progress, continued adding to the holdings and provided annual funds for further acquisitions. By the time of his death, the collection numbered some two thousand titles comprising three thousand volumes.

In parallel to his collecting activities, Epstean undertook a series of translations, introducing the English-speaking world to important photohistorical studies by Victor Fouqué, Georges Potonniée, Erich Stenger and, most notably, Josef Maria Eder. The impulsion came on a visit to Eder in Austria in 1932, and by 1934 Epstean had completed a draft translation in longhand of the fourth edition of Eder's monumental *Geschichte der Photographie* (History of Photography). For copyright reasons and "the changed political conditions in Germany," the work was not published by Columbia University Press until 1945. Epstean used the interval to ensure full revision and technical editing by several leading photographic scientists, with the result that Eder's work, in Epstean's translation, gained broad acceptance in the English-speaking world as the standard work in the field. It had no peer as a single-volume comprehensive survey until Gernsheim's *History*, and even sixty years later has not been fully superseded.

Epstean was conscious of the pitfalls of translating technical texts, stating that he found it "extremely

difficult to steer a middle course" between literal and stilted transliteration and freer interpretation which risked traducing the author's intent. He rose to the challenge both in translations from German and from French, publishing successively two key texts on the origins of photography: Fouqué's work on Niépce *La Vérité sur l'invention de la photographie* (The Truth Concerning the Invention of Photography) in 1935 and Potonniée's *Histoire de la découverte de la photographie* (History of the Discovery of Photography) a year later. Epstean's manages to respect the source texts while rendering them in readable English. Integrity of another kind was required of him in his final translation, that of Erich Stenger's *Die Photographie in Kultur und Technik: ihre Geschichte während hundert Jahren* (The History of Photography: its Relation to Civilization and Practice). He steered it through the press in 1939, a year after the German original, in the teeth of mounting opposition, not least from the American publishers. Epstean was a proponent of the universality of scholarship, and placed his personal commitment above political antipathies. As a concession to Anglo-American sensitivities, the preface to the German edition by Heinrich Hoffman was omitted, but otherwise the source text remained unaltered.

Epstean's contribution to scholarship was recognised in his lifetime with the award of the Davanne medal by the Société française de photographie and honorary fellowship of the Royal Photographic Society. After his death, Epstean's archive was turned over to Columbia University library. It contains material relating to the acquisition and donations of his books, typescripts and offprints of his articles and speeches as well as the typescript and galley proofs of the Eder translation.

STEVEN F. JOSEPH

Bibliography

Edward Epstean was born in Bohemia on 19 September 1868. He emigrated to the USA in 1888 and received his naturalisation papers five years later. In 1889 he went to work for the electrotyping firm of Hopkins & Blaut, founding their photoengraving department in 1892. In 1898 Epstean set up, with H.L. Walker, the Walker Engraving Company, incorporated in 1928, of which he became director and treasurer. Epstean married Josephine A. Kupfer (died 1942) in 1890. Epstean died at his home in New York City on 7 August 1945.

ERMAKOV, DMITRI (c. 1845–c. 1916)
Chronicler of the Caucasus

Ermakov was born between 1845 and 1848 in Tbilisi, the son of Ludwig Cambaggio, an Italian architect, and a Georgian mother of Austrian descent, who was a noted pianist. She remarried with one Ermakov, whose name her son Dmitri took.

Among the schools where Ermakov as a young man received training was the Military Topographic Academy at Ananuri, at the foot of the Caucasus Mountains, 102 kilometers north of Tbilisi on the Georgian Military Highway. In Ermakov's estate various albums are to be found with photographs of this military highway and a number of views on and around this route. Most likely Ermakov took his first steps toward his future profession as photographer while at this academy. By that time every military academy in Europe had its photographic department, to serve the needs of cartography and for the production of maps and topographic files. Moreover, experiments were being done at these institutions with new photomechanical reproduction techniques for the production of map material. Photography was also found extremely well suited for reconnaissance in conflict situations and regions.

Ermakov left the military school toward the end of the 1860s. Shortly thereafter, around 1870, he opened his own photographic business in Tbilisi, the city of his birth and the capital of Russian-controlled Georgia. The studio was located on the Dvortsovaya, a street where various photography studios had been established for many years, and which drew many visitors. As early as 1846 a photography studio had been opened there, operated by Henry Haupt and I. Aleksandrovski. The photographers V. Khlamov and A. Roinashvili followed in the ensuing years. Ivanitski also set up there in 1863. Roinashvili was in fact the first photographer of Georgian extraction. He called his studio "Rembrandt," a good indication of his ambitions and the seriousness with which he practiced his trade. It has been suggested that Ermakov took over some of Ivanitski's stock, particularly the many portraits of ethnic types, and also stock from Roinashvili. Such files of negatives were, after all, the most important business capital for photographic studios, and often remained in use for decades. It is thus quite possible that Ermakov took over an existing studio, and/or all or part of an older inventory. That was the accepted practice in this period, during which professional photography studios were taking off in a big way all over the world.

Several years after opening his studio Ermakov became a member of the Société française de photographie (SFP) in Paris, the most prestigious photographic association in Europe. Who had nominated Ermakov for membership—there was after all a strict admissions

policy—is, alas, unknown. He submitted work for the SFP's biennial exhibition in 1874, reporting Trebizond, on the Turkish coast of the Black Sea, as his address. That could mean that he had opened a branch or second studio there, because he had already photographed considerably in that region. All the pictures that he sent to the Exhibition in Paris—17 in total—were made in that area. According to the catalogue they were prints from wet collodion plates. For the rest, this was the only time he submitted work for the SFP exhibitions in Paris. A couple of years later, in 1878, the took part in the Anthropological Exhibition in Moscow, where he received an honorable mention. He would also receive distinctions at photography exhibitions in Turkey, Persia and Italy.

In the years 1877 and 1878 Ermakov received an exceptional commission: he was added to the General Staff of the Caucasian Army, in the Field Photography Section, to record military movements in the Russo-Turkish war. None of the photographs he produced for this have been located.

During his working life Ermakov must have traversed huge distances. If we look at the photographs in the albums in his collection, it would appear that he had a great interest in geography and ethnography in the whole of Eurasia. In addition to Georgia itself, he traveled through Turkey and Persia, to Kazakstan and Uzbekistan to visit the ancient cities of Bukhara and Samarkand, through the southern Russian republics of Dagestan, Ingushetia, North Ossetia, Cherkessia, up to Krosnodarskij and through the Crimea, to the north of Georgia. Apparently here he was himself at work with one or more assistants. It is also possible that he sent his co-workers to these various places. Perhaps some of the photographic material in the albums also comes from other photographers, from whom he purchased negative plates. The result was an enormous photographic oeuvre which can be termed extensive and multifaceted. He records the inhospitable, snow-capped mountain ranges of Svaneti, the oil fields in Baku and the construction of drilling rigs, the 1905 pogrom in Baku, the architecture, churches and monuments in all these regions, art reproductions and extensive surveys of the peoples from these areas in long series and detailed reportages. All these series and still many more other subjects are to be found in Ermakov's 126 sales albums. They contain an almost incalculable treasury of information about a number of regions and peoples in the Caucasus, Turkey, Russia, Persia and the surrounding area.

These trips were no simple undertaking. The photographer worked with large glass plates (often handled wet), employed cameras of various formats, and always had to have his chemicals and darkroom near at hand. Ermakov in fact worked with glass plates of up to 50 × 60 cm. In the 19th century photography had not yet mastered enlargement. All prints were produced in the same dimensions as the negative plate; Ermakov thus must have used a mammoth camera. This also means that for his work he must have had a sort of caravan with him in order to carry all his apparatus, as well as a mobile darkroom. It is reported that Ermakov himself specially designed such a mobile laboratory. To have carried out all the work of his that has been located, that was certainly no unnecessary luxury. He returned from an expedition to the mountains of Svaneti in 1910 with as many as 1500 negatives. It is obvious that Ermakov also did business elsewhere for periods of time, or had multiple branches, as in Trebizond, mentioned earlier, but certainly also in Teheran, where he received the title of Court Photographer to the Shah of Persia. Photographs by Ermakov are to be found at the University of Teheran.

Ermakov ultimately operated a large photographic business over the remarkably long time span of about 45 years. Over this period he must have produced at least 25,000 negatives: that is, after all, the number that have been found in his estate. His interests, however, also ran well beyond photography. He was an honorary member of the Caucasian Section of the Moscow Archaeological Society and the Association for the Advancement of the Visual Arts, and he was given the freedom of the city of Tbilisi. It is not known precisely when Ermakov died; it must have been around 1916/1918. His extensive estate was sold to the University of Tbilisi by his widow and in 1930 eventually handed over to the Simon Janashia State Museum in Tbilisi.

HANS DE HERDER

Biography

Dmitri Ermakov was born between 1846 and 1848 in Tbilisi (then called Tiflis) Georgia. After his initial education in his hometown he joint the Military Academy in Ananuri, an old town and fortification along the Georgian Military Highway. This route is one of the eldest pass ways through the Caucasus mountains and connects Tbilisi with Vladikavkaz, capital of North Ossetia. After serving as a military photographer he established his own firm in downtown Tbilisi. He traveled extensively through the Eurasian continent and he was the Persian court photographer for a number of years. Back in Tbilisi he educated and later collaborated with Antoin Sevruguin who became a known Persian (although not from Persian descent) photographer. Little is further known at this moment about Ermakov's whereabouts. The estate is researched and conserved for the future since 2000 and will be presented to Unesco to be listed on the World Memory List expected in 2007.

Collections

The main body of Ermakov's heritage can be found at the Simon Janashia State Museum in Tbilisi, other parts are at the Museum of Tbilisi's History and the Museum of Art, the Tbilisi City Archive has a small collection as well, although this may have been destroyed during the civil war in the 1990ies. From his days as court photographer to the Persian Shah, prints and albums can be found at the Golestan Museum in Tehran.

A substantial print collection can be found at the Russian Museum of Ethnography, St. Petersburg, Russia.

Smaller collections are at the Rijksmuseum, Amsterdam, the Netherlands and at the Phototheque in Paris, France.

EROTIC PHOTOGRAPHY

The production of erotic photography is nearly simultaneous with the invention and development of the photographic medium. Almost immediately, this new technology made clear the erotic nature of visual imagery and the heightened pleasure of looking at images with a direct documentary link to the experienced, both real and imaginary. This "indexical" relationship made erotic photographs far more provocative than nude paintings but also became a central impediment to their production and circulation. Though erotic pictures in the form of lithographs and frescoes had long existed,

Abigail Solomon-Godeau suggests that photographic technologies inaugurated an entirely new vocabulary of sexual imagery.

Residing somewhere between visual pornography and the photographic nude, erotic photography may be most clearly distinguished through an analysis of its production and consumption, with particular focus upon issues of subjectivity and spectatorship. Unlike the explicit sexuality of pornographic representation, erotic photographs leave something to the imagination, generally favoring strategic covering and subtlety over excess and consummation. Though erotic photography expresses interest in eliciting a sexual response from the viewer, it refrains from depicting sexual activity.

Whereas nude photography makes no pretense to narrative or fantasy, erotic images often use staging and posture, props and fetishes. Rejecting the academy figure's demure and modest view-from-behind, erotic photography depicts a model whose more direct engagement with the viewer—or voyeur—sets the libidinal terms of the exchange. Many critics contend that the boundaries between visual pornography, erotic photography, and the academic nude cannot be clearly determined and therefore recommend situating these genres along a spectrum rather than in strict categories. To be sure, even the fully clothed body, landscapes—such as those by Pictorialist Clarence H. White (1871–1925)—and the elegant corporeal curves of the domestic still life may also stage the viewer's desire, provoking emotional responses not unlike those evoked by erotic photography's staple image of the female body.

Erotic photographs first appeared in France around 1845 and soon after in England. Despite mechanical complexities and a delicate product, daguerreotypes featuring erotic images were soon sold by Paris opticians and art dealers. The daguerreotype process was available to the French public without franchise and, recognizing the enormous commercial potential of erotic photography, an underground market quickly blossomed. The use of *études photographiques* by painters such as Edgar Degas, Gustave Courbet, and Jean-Auguste-Dominique Ingres legitimized the production of nudes, though typical erotic photography was not concerned with classical ideals, proportional exactitude, or, necessarily, the beauty of the human form. As early as 1845, Eugène Delacroix and others used *académies*—academic studies of nude or partially dressed models—in lieu of living models, and it was not long before non-artists used them as objects of voyeuristic gratification.

Inevitably, soft-core pornography was sold under the misonomer *académies* in order to circumvent bans on such material. According to Elizabeth Anne McCauley, by 1852 and 1853 French laws against photographic nudes were "inconsistent and poorly defined" with recourse made to pre-existing laws such as the eighteenth century prohibition against "obscene images, prints, or drawings" or the 1810 Code Napoléon, an injunction barring the sale and distribution of visual or written material without the name of its creator. Circuitous methods of controlling such images—such the extension of copyright laws and mandatory registration of photographic prints at the Ministry of the Interior—were meant to compensate for otherwise permissive attitudes about depictions of nudity. "Artistic studies" of nudes, unlike transactions around "obscene material" were legitimate as long as they complied with "certain unstated and ambiguous rules of posing." Public condemnation was more prevalent than prosecution, though seizures of

photographic nudes were made and police increasingly used registries to follow the manufacture and distribution of nude and erotic images.

In an effort to articulate the qualities of erotic photography, critics note its characteristic proximity; where nudes are compositionally featured at a distance, erotic photographs play with closeness as a means of alluring the viewer. Michael Koetzle builds upon erotic photography's tactic of the "strategically veiled," identifying the integral role of stockings, veils, garter belts, and fans in what he calls erotic photography's "boudoir effect." In such images, a closely cropped visual field constrains the woman in its space, offering her up to a viewer who then sees her body as would a voyeur peeking into a boudoir, and who may construe the proximity as an invitation to intimacy with the titillating possibility of tactile interaction.

Because all erotic photographs before 1860 were daguerreotypes, they served as pleasure commodities for those who possessed both capital and space in which to collect and display such material. Indeed, social advocates showed the greatest concern for the effects of such images on the lower class population, as its lack of education and refinement translated into deficient moral probity. As such, class-related concerns with virtue and morality increased as advances in technology rendered erotic photography accessible and affordable for practically everyone. As models were often also prostitutes, actresses, and dancers in vaudeville shows, their socioeconomic status only served to confirm class biases.

Improved and cheaper technology popularized the medium, allowing the exploitation of its commercial potential and, by extension, the images it produced. With the development of the collodion process and other chemical and technical innovations, the daguerreotype's labor-intensive one-offs were supplanted by negative/positive process enabling the limitless production of one image. New technology and professionalization facilitated new formats in which to circulate erotic photographs, and soon images appeared as *cartes-de-visite* and stereoscopic photographs.

Prevailing interest in colonial documentation, ethnography, and the orientalized "other" occasionally manifested in erotica in the form of "exotic" tableaux. Animal skins, feathers, beads, tapestries, and scarves converged as coded intersections of the foreign and the erotic. The relaxed sexuality of Baron Wilhelm von Gloeden's (1856–1931) albumen prints of Sicilian boys lounging in the sun on leopard skins exemplifies this interest in the eroticized Mediterranean "other," as well as the medium's preoccupation with prepubescent bodies and homoerotic representation. Baron von Gloeden's models epitomize the docile and feminized eastern male of nineteenth century colonial imagination. Still, the female body was almost without exception the central preoccupation of nineteenth century erotic photography. As John Pultz notes, photography itself attended the shift away from the male nude, whose smooth, muscular physique had exemplified beauty since classical antiquity.

Perhaps fear of prosecution or social stigmatization accounts for the dearth of historical records on those who actually produced the genre's profusion of images, for both the Kinsey Institute's archive and the Uwe Scheid collection contain abundant erotic photographs by anonymous artists. Still, the work of Lewis Carroll (1832–1898), Julia Margaret Cameron (1815–1879) and Viscountess Clementina Elphinstone Hawarden (1822–1865) reveals the Victorian era's interest in the vulnerability and sexuality of children. Even while such work is considered artistic photography, soft light and mirrors conjure a sensual ambience, demonstrating a shared vocabulary with erotic photography. Foregrounding the link between commodity culture and "woman-as-spectacle," nineteenth century erotic photography serves as milestone in the history of a prosperous and enduring industry.

ETHNOGRAPHY

From its beginnings photography was considered as a handmaiden of arts and science and was widely used as an instrument for the gathering and cataloging of the scientific data so prized during 19th century. People were no exception to this cataloging which could take place with never before seen tribes of dark Africa, as well as with western countries peasant, or even urban lower class populations. Commercial and amateur photographers, scientists and explorers all were engaged in this picturing of the other, creating and perpetuating stereotypes of childlike Africans, vice burdened Chinese, noble savage North American Indians or southern Pacific Venuses. Even if the scientific value of this view of the other by the "Euro American" eye has been questioned for a long time; these images have now an increased significance.

After all are not all photographs of ethnographic value, don't they all show habitats, behavior and costumes of human groups?

Since the 15th century Westerners had traveled though the world. No continent or ocean seemed to be unknown to 19th century cultured people. However everything was again to be discovered, with new media, including the mass use of press and photography which allowed new forms of knowledge and a wider audience for that knowledge. The white man was, for the first time, discovering interior Africa; North America, Asia and Australia had yet to be explored fully. If new lands with high waterfalls, huge mountains and rivers interested the public nothing could be of greater curiosity than their inhabitants; people with strange habits, odd clothing (or no clothing at all). These people were to be found in all continents, from dark, wet and warm Africa, to arid and dry Central Asia, exotic Far East, high South American mountains, or even North American prairies, not to mention European countryside. They all were enduring the shock of being found by modern civilization, they all were to disappear, at least as bearers of those exotic and inferior habits.

This idea of photographing a vanishing world was of greater importance for these photographers and connected the images of these exotic peoples in far away places with folk habits and costumes that were closer to home.

Ethnography and photography were not only children of the same century, but also of the same decades. They both came to public eye around 1840; they were both the products of 19th century's scientific obsession. It is impossible to image ethnography without photography, but it is also hard to imagine 19th century photography without its ethnological uses, where art and science were very hard to tell apart.

Ethnographic photography was a tool both for colonialism and imperial ambitions, of national identification and nationalist construction. All parts of the world were the subject of this photography pursued, like one of the most important missions of photography, by amateurs and professional photographers, by travelers and scientists. In these images persons were not seen as individuals, but rather as representing ethnic, regional or professional types. The ambition was to gather a worldwide catalogue of races, ethnic groups and types, which, after all was not far from happening. Louis Figuier, author of the 1873 book, *Les Races Humaines*, wrote about the need of an ethnographic collection obtained by means of photography, by the same time T. H. Huxley was commissioned by British Imperial authorities to create a photographic fund of all the races of the British Empire.

Scientists and explorers used photography as an instrument for the research and knowledge spreading they pursued. Its objectivity would allow the most accurate record of people and places they were exploring. However photography could also be seen as the power demonstration of the western white power over the barbaric non-white, and as a means of bringing light, another way of spelling Christianity and civilization, over these peoples. Being a godlike, light based, technology, photography was seen *per se* as able to bring the light of civilization to the darker, uncivilized parts of the world.

The control over those photographed enforced by the photographer was a part of the white upper class westerner power over the other. The power needed to make people pose to the photographer was a part of the wider colonial or ruling class power. The eye of the photographer and the eye of the camera were analogous to the eye of the surveillance needed to ensure control over lower class and colonial people.

One of the first references of the use of photography for the study of other people was made as early as 1852, in the *Manual of Ethnological Inquiry*, published in 1852 by the British Association for the Advancement of Science, nevertheless the real uses were not yet common, due to the technical problems of using photography in the field. However, the camera was a mandatory piece of equipment for late 19th century explorers, scientists and travelers, photography was much easier with dry-plates and handheld cameras.

When in 1885 Luanda based commercial photographer published his book on Portuguese western Africa, Luciano Cordeiro, a well-known writer stated this work to be not only a crucial one in Portuguese colonial aspirations, but also the first such work to be carried in the depths of the Dark Continent. He was, of course, wrong, black Africa was not the primary focus of photographers, but expeditions carried out since the 1850s has been using photography has a mean of documentation and report about places and people found. David Livingston's Zambezi Expedition, in 1858–64, has Livingston's brother, Charles as the official photographer for the expedition. Livingston's idea was to use the expedition as means to increase knowledge about Africa. Photography was to be instrumental in that goal so he instructed his brother to have the equipment ready to "secure characteristic specimens of the different tribes." Unfortunately, only the photograph of a baobab tree survived.

Some decades latter, John Kirk, also exploring Zambezi River also used photography, in his images people were displaced from their environment, and places were photographed as if they were empty of people.

James Chapman also used photography as part of his hunting and trade expedition in South Africa's interior in the years 1859–63. Luciano Cordeiro was, indeed wrong stating Cunha Moraes work to be the first in Dark Africa's interior, however, he was not wrong when describing the enormous difficulties endured by an 1870's photographer inside dark, humid and warm Africa. At the time the biggest colonial power (British empire), and the least powerful one (Portugal) rivaled about some African territories and being first was important, even if the words of Luciano Cordeiro are, most likely, a proof that these early African photographs were never widely known.

All these images of Africa were important to enforce already existent ideas of African people as idle and childlike, due to the fertility of the land. Europeans had a mission, bring civilization to these childlike retarded people. They were also important in the creation of a colonial ideal in European powers.

America, opposed to colonial Africa, was composed of independent countries, all of them recently created by the descendents of European settlers, with European cultures and languages. These new world countries had much different situations for their Indian population. Some of them had already destroyed most of their native population, some were in the process of doing so, while in others, such as the Andean countries, Indians were an important part of the population. Photographing South American Indians was not an enterprise for the explorers, but mainly to commercial photographers. Most of these established themselves in South American countries coming from Europe and using the photography of the native as a commercial venture. Photographs were being made to generate profit, as they were sold as *carte-de-visite*, stereographic views and later as postcards. The main goal for most of these images was a commercial one, but these images were important in the building of national identities for those countries. The context of their production and circulation would make them closely linked to the cultural stereotypes already present for those people. These links with existent stereotypes would also show in the idea that images could be, when not available, created. Margarita Alvarado, in her study on the Chilean Mapuche Indian image, found pictures with white people appearing in Indian costumes, composed images, in what she calls the construction of an imaginary image. This imaginary image was the product of the same commercial photographers, mostly European newcomers, who were making the portraits of white people living in Chilean small towns. Brazil, had to deal with three different kinds of population: The little known Indians, the Negro slaves and slave descendents and the new European migrants. All of then were potential subjects to ethnographic photography, all of then were in need of surveillance and control. José Christiano Junior, himself a Portuguese migrant made studio portraits of slaves in the 1870s, at about the same time, Militão Augusto Azevedo, a S. Paulo native, although based in Rio, photographed non slave Negroes. These were commercial photographers and these photographs were made using the same techniques used on their portrait sitters. The photographs of Brazilian Indians were quite early in photography's history; the E. Thiesson expedition of 1844 came with full face and profile daguerreotypes of Botocudo Indians, complementing skeletons, now in Paris Museé de l'Homme.

The North American West was, during 19th. Century, less known than South America. White settlers were starting their western migration. Much of midwestern land and of their peoples were unknown to east coast society. Exploration photography was of great importance to the knowledge of the west, and to the building of United States and Canadian identity. Even if there were a huge number of different people, the North American image was made, above all with landscape photography. There is an exception in the huge survey on the American Indians made by Edward S. Curtis, even if it is mostly a 20th century enterprise, is close enough to 19th century ethnographic photography. The photographs made of California Indians from 1900 by Alfred Koeber have similar goals, although a smaller scope. These surveys were made not on a vanishing world, but on an already vanished world, since American Indian were all but destroyed as autonomous entity by 1900. This may explain the small number of Indian photographs in 19th century Western images, including surveys on New Mexico, Utah and Nevada Indians,

Uncatologued (Photographer). Indian peasent young woman holding twigs on her head.
The J. Paul Getty Museum, Los Angeles

and some anthropometric photography carried out by W. H. Jackson. Indians were seen has hostile savages; there was a war waging on them, they had no place in the new civilized world being built by the white man. The fact that some of 19th century photographs would show Indians in "civilized" costumes is a confirmation of this idea. As they were physically exterminated, they had little or no place in photography. In the early 20th century the Indian was no longer a treat, but little more than a memory, or a folk character, so Curtis could photograph to preserve that already vanished world. His work was a huge exploit, consistent with the idea of having all the races and tribes in one nationwide catalog, however his Indians would not, most of the times, use those costumes or live in the way depicted by his photographs. His pictorialistic approach is also seen as a handicap to the ethnological value of his photographs, even if it does enhance their art value.

The main interests of European photographer were, however, focused on the old world. Orientalism was at his height and photographers saw in the Holy Land, Egypt, but also Far East, a first choice location for photographs. The mideastern landscape was in focus, as well as mid eastern people, whose habits and costumes were, 2,000 years later, reminders of biblical scenes, many of these photographs actually ended up being used as biblical illustrations. More than in any other places of the world, most of these stereotypes were drawn from the previous repertoire of themes known to Orientalist and biblical scene painting. Western view of mideastern historical significance was, also, of major influence in the way its inhabitants were perceived and photographed. Religion was a major force driving mideastern ethnographic photography. In complete opposition of this use was the construction of a mideastern erotic image, being built over the exotic beauty of Arab women, the image of the harem and supposedly scantily clad belly dancers and odalisques.

Mid eastern photographic tours were early in the history of the medium, one of the better known was Maxime du Camp's expedition to Egypt and Palestine in 1848 and 1849, with novelist Gustave Flaubert. Even if his published images were mostly of monuments, there are also images of local people in those monumental

surroundings. Venturesome Europeans had in North Africa and the Middle East a place to visit, particularly after the opening of the Suez Canal, and photography was a particular resource for these travellers; monuments might be the main focus of these amateur photographers, but local people were also an important subject.

Commercial photography had a fast growth in mid eastern societies; one of the best known studios was the Bonfils family in Beirut, which, by 1876 had a mail order catalogue with views of places and people to supplement their portrait studio revenues. The part of revenue generated by these views seemed to be greater than in other places of the world, as there was a good market for them.

Anthropometric photography did also take place, even if it was less common than in Africa, India or other parts of Asia. Ernest Chantre published his *Recherches Anthropologiques dans l'Afrique Orientale: Egypte,* in 1904, based on comparing almost a thousand of modern Egyptian photographs, taken in 1898 and 1899, with measurements made from mummies. The main difficulty was in photographing women, which unfortunately, for anthropometrics, but fortunately for ethnographers, are sometimes photographed wearing their usual face and head covering.

Handheld Kodak cameras in the hand of tourists, or amateur explorers were of more importance in the Middle East then in other farther away places, so much of ethnographic photographs from 1890 on are the product of such amateurs.

Adrien Bonfils, second in the already mentioned Bonfils family generation, wrote that after twenty centuries Palestine was unchanged. That view of the Middle East as an unchanged land, living in a sort of a time warp, is reflected in images of romantic nostalgia. Ethnographic photography here was not in the quest of the unknown, but of the biblical past.

India and the Far East were by their resources in the view of European powers. India was already the jewel in the crown of the British Empire, however its multitude of powers and different people was of great concern to British rulers. *The People of India* was one of the most ambitious of all photographic surveys of racial types, resulting in 8 volumes of almost 500 photographs each, was started as a collection for Lord Canning, India's Governor-General, from 1856–58. However after the Indian rebellion in 1857, it became an official project for the Political and Secret Department of the India Office, showing the close connections of science and surveillance. John Bourne photographed northern India's landscape and people, being his Indian rulers picture series very popular as a souvenir for British officers returning home. In fact local rulers were a major focus for ethnographic photography.

A commercial photographer working in the Far East, John Thomson experienced the magic powers of photography, as felt by the other. He describes how his camera was perceived like a magical thing, and himself like some kind of necromancer. Some of his photographs, and his latter description of a systematized methodology for race type photography would detach his images from ethnography, however he also photographed people engaged in their activities. His images, and accompanying words do also provide negative moral judgments, which were needed as China could hardly be described as an inferior civilization, so the burden of cataloging Chinese as inferior to Euro Americans would have to be put on vice and moral inferiority. China had been opened to Europeans after the mid-19th century Opium Wars, and Felice Beato was one the first and better-known European photographers working in the Far East; China and, since 1862, Japan, where he made his famous photographs, mostly studio portraits, of Japanese society.

European photographers pursued the same sort of "exotic" type photography, they were making in other continents, in southern Europe. Local people, costumes and habits were in focus the same way landscapes and monuments were. The photographs of English photographer C. Clifford and French photographer J. Laurent in mid-19th century Iberia set the standard for photographs of that nature. By the same time Thomas Annan was commissioned by Glasgow City authorities to photograph the city slums before a major renewal, his photographs were mainly of buildings, however some showed their inhabitants. Russian and other Eastern European photographers focuser on their far north or Asian type population. Photographers of the same country produced images of rural and even urban types in Europe, even if they were higher in the hierarchy of races and types. Countries would have their own regional and professional popular types hierarchy, fishermen might have a "higher" position than peasants; some regions, particularly the southern part of Mediterranean countries had a lower position within those countries. Western countries were in the process of industrialization, the rural society was decaying. Like in the images of people recently discovered by "civilization" this entire world was being photographed before it would disappear under the wells of progress. As a matter of fact some had already disappeared and was being recreated just for the picture.

As nationalism emerged as the main political ideology, there was a need to create elements of national, and even of local identification, what E.J. Hobsbawm calls the "Invention of Tradition." Photography played a major role in this; local habits and costumes, real and not so real were the subject of countless photographs from a countless numbers of amateur and professional photographers. Every European country had his major

editions of local and regional popular types in postcards, newspapers, and magazines. Some photography publishing houses relied upon this market for a good part of their sales.

A small part of theses photographs were the product of organized travels, using the train or even bicycles, some were made in response to newspaper-launched campaigns, sometimes reflecting the idea of gathering a collection of all national or regional types. However, local photographers, to supplement the income from their portrait studios, were producing much more. The stress is no longer on racial issues, even if they are sometimes present to tell a country apart from his neighbour, but on professional or local types. Peasants, water carriers, fisherman and even beggars all were in the focus of the photographer. Some types were more in favor of photographers, country women washing in the streams, is one example, the old long bearded fisherman, another, they more the result of a culturally constructed choice than of reality. The Russian empire had the most organized attempt on this nationalist use of ethnographic photography, the *Moscow Ethnographic Exhibition* of 1867, showed, mainly with photographs, the different peoples and professional types of the empire with a pan Slavic imperial idea.

For all these images there were a multitude of different uses, from scientific research to the family albums, postcard and magazine publication. They seemed to be an important part of some local photographers revenue, but there were also amateur photographers mainly concerned with photographing their hometown or village.

Arguably the images made for research are less linked to cultural stereotypes than those made by commercial photographers and amateurs. However, the similitude of ethnographic photographs from around the world is a proof of photography's international character and of its origin in 19th century's ideology. The stereotypes created by 19th century ethnographic photography are sometimes still alive, and had an important influence in how people around the world are perceived. In places from Portuguese fishing villages to Moroccan roads people stand dressed up waiting to get some money from the tourist photographer, they are doing no more than allowing the persistence of 19th century ethnographic type photography.

EUGENE, FRANK (1865–1936)

American photographer

Born Frank Eugene Smith in New York, Frank Eugene's long engagement with photography began while studying painting in Munich between 1886 and the early 1890s, and his photographic work echoed many of the stylistic qualities of the pictorial movement of the period. Initially he saw himself as a painter, with photography no more than an abiding hobby.

By the late 1890s, however, he was being described as a 'painter photographer' a term coined specifically for him, as his work bridged the two mediums. His photography often involved extensive afterwork on the negative, using scraping tools and paints to modify the images.

Eugene first came to public prominence in 1899 when an exhibition of his unique approach to pictorial photography was mounted at the Camera Club of New York, and several images were included in the London Salon of that same year. Sadakichi Hartmann observed that "he is essentially a painter, and looks at photography merely as a new medium to express his artistic individuality."

Four examples of Eugene's work was featured in Alfred Steiglitz's journal *Camera Notes*, and he later became one of the most regularly featured photographers in *Camera Work*.

In the 20th century, Eugene became one of the 'American Links' of the Brotherhood of the Linked Ring, and in 1902 a founder member of the Photo-Secession.

John Hannavy

EVANS, FREDERICK HENRY (1853–1943)

British bookseller, photographer

In a lantern slide lecture in 1886 before the Photographic Society of London (since 1894, The Royal Photographic Society of Great Britain), Evans showed photomicrographs made, not for scientific purposes, but as images reflecting his "life-long love and study of 'the beautiful.'" George Smith, proprietor of the Sciopticon Company, had sold Evans a microscope and a camera and produced these lantern slides from platinum prints. Smith stressed the pure or straight approach in photography, and Evans, who lacked art skills, embraced this approach which would define much future photographic art.

The photomicrographs included images of minute shells and sea creatures including a lantern slide titled 'Spine of Echinus,' c. 1886, a cross section magnified 40x which readily suggests lace work, a mandala, or a rose window. The Photographic Society recognized the aesthetic achievement and awarded Evans their medal in 1887.

Evans, a respected London bookseller, turned his camera from photomicrography to cathedrals, where he often used an 8 × 10 inch plate camera with a lens selected to fill the frame before making a lengthy exposure. He claimed to practice "cathedral picture making" rather than "mere photography."

Evans immersed himself in cathedral towns for days as he experienced the sacred buildings emotionally while noting locations and lighting for eventual picture making. Perfectionism might have led to sterile records, but he was aiming for platinum prints, platinotypes, which would convey the same emotional response in the viewer that the original evoked. While interested in Emanuel Swedenborg's mysticism through James Garth Wilkinson's writings, Evans maintained his photography concerned beauty, not devotion.

Sprituality through symbolism, however, seems integral to this beauty, as seen in the soft grey tonal passages from dark to light that frequently suggest upward progression.

An example is "Lincoln Cathedral Stair in the S. W. Turret," 1895, which shows narrow spiral steps countered by pointed rib arches, an image suggesting theories of coincidence in nature from Charles Baudelaire to Symbolist poet and critic Arthur Symons whom Evans photographed. "Cathedral picture making," then, relates to the Symbolist photographs of Alfred Stieglitz, and find kinship with such Edward Weston images as "Chambered Nautilus," 1927, and "Artichoke Halved," 1930.

Lincoln Cathedral was the subject of some 120 lantern slides shown at the Royal Photographic Society in 1899. Among the images was "Lincoln Cathedral: From the Castle," 1898, where the dark patchwork of rooftops gives way to the light filled hazy view of the massive cathedral as a sign of the sacred Medieval world contrasting and towering above the profane industrial age.

This photographer's quest for beauty and the ideal included the grotesque wall sculpture in cathedrals which he photographed from slightly below to convey the viewer's perspective. Such photography without resort to dramatic effects treads a narrow line between record and artistic interpretation.

Recognition of the grotesque and its resolution in portraiture is found in "Aubrey Beardsley," 1894. Evans was attempting a portrait of the artist , whose career he helped launch, and supposedly likened the gaunt young man to a gargoyle, whereupon Beardsley struck the pose of a grotesque on Notre-Dame, Paris. The resulting photograph is equally a portrait of the artist's elongated hands—suggesting gothic ribs—and his beak-like profile with the overall image communicating Beardsley's avowed commitment to the grotesque.

Though Evans's portraits are mostly of friends, he believed that portraiture, more than architecture, offered photography's greatest potential for art. He wrote in the *Amateur Photographer*, "What is wanted in portraiture is the portrait, and nothing more; no obvious intrusion, that is, of the personality of the producer; a true portrait, of course, an evocation, true to the spiritual and mental as well as the physical" (Evans, 11 Feb. 1908, in Hammond, Texts, 101).

Evans's approach to landscape is reflective of pictorialism with its continuation of the picturesque. When photographing woods, however, Evans expressed a Symbolist idea of seeing natural forms as relatable to cathedrals, and so *In Redland Woods*:

> Surrey, 1894, a pathway forming an orthogonal is surrogate for a nave with the tall trees rising to a leafy vault. For some of his landscapes he used a soft focus portrait lens, such as New Forest, 1891, showing intertwining trees whose forms suggest the strainer arches in Wells Cathedral.

While Evans favored the vertical format, he framed the picturesque 'Kelmscott Manor from the Thames,' 1895, with curving road, river, and silhouetted trees leading to this home of William Morris, leader of the arts and crafts movement. Evans knew Morris and photographed Kelmscott's interiors including the attics ca. 1897. In these photographs he transfers his sense of light and form from great architecture to the vernacular of private spaces and was no doubt influential on Paul Strand and Walker Evans. Though bound to a modern, mechanical medium, Evans shared much of Morris's philosophy along with that of John Ruskin and the Pre-Raphaelites with their detailed rendering of the natural world as metaphor for the spiritual.

The quest for "cathedral picture-making" is demonstrated with Evans's dissatisfaction with the photograph "Wells Cathedral: Stairs to Chapter House," 1899. He

Evans, Frederick. In the Attics. *The Metropolitan Museum of Art, Purchase, David Hunter McAlpin Fund, 1968 [68.519 (26)] Image © The Metropolitan Museum of Art.*

tried again c. 1900, this time framing a more unified sweep upward and through the light-filled passageway. Finally, he achieved the noted "A Sea of Steps," 1903, that takes a lower viewpoint and emphasizes the rhythms of the foreshortened stone steps while stabilizing the image with the engaged columns terminating with the light-bathed Tudor arch.

In 1898, Evans retired from his bookstore . His stature as an internationally renowned photographer was recognized with his election to the Linked Ring Brotherhood with whom he exhibited and designed innovative exhibitions. He was the first British photographer published in *Camera Work*, in 1904, and Stieglitz proclaimed him the leading architectural photographer. In this period he accepted commissions from *Country Life* magazine for landscape and architectural photography in France. He published some 100 articles on technical and aesthetic issues, many for the *Amateur Photographer*.

By the start of World War I, Evans's health had worsened, and it was difficult to obtain platinotype paper, and so, he retired from photography. In 1928, he was elected an Honorary Fellow of the Royal Photographic Society. Following his death in 1943, the Society held an Evans symposium and published memorial articles which launched a renewed interest in this photographer whose images and writing helped establish pure photography as art.

JOHN FULLER

Biography

Frederick Henry Evans was born 26 June 1853. He worked in a London counting house, but poor health led him to bookselling, where his self-acquired knowledge attracted noted writers including George Bernard Shaw, a strong advocate for photography as art. Evans began photography in 1883, at first photomicrography and then architectural, landscape and portrait work.

Lacking traditional art skills, he practiced pure or straight photography, and published over 100 articles mostly on photography. He retired from bookselling in 1898, and moved with his family to near Epping for health and photography. His photographs won international acclaim, and in 1900, he was elected to the Linked Ring Brotherhood. Evans's exhibit design and multiple mounting techniques showed relationships to the arts and crafts movement. He was recognized as the greatest architectural photographer. By World War I, he essentially retired from photography, and in 1928, he was elected a Fellow of the Royal Photographic Society of Great Britain. He died in London 24 June 1943, two days before his 90th year.

EXHIBITION OF THE WORKS OF INDUSTRY OF ALL NATIONS, 1851: REPORTS BY THE JURIES

The Great Exhibition held in Hyde Park in London between May and October 1851 acted as a milestone both for the rise of photography and for its position within international industrialisation. It provided the first major display of photographs to have a significant effect on an international scale. It also spawned one of the landmarks in 19th century photographically illustrated books, the special presentation copies of the four volume *Report by the Juries. Great Exhibition of the Work of Industry of All Nations* published in London by the Commissioners for the Exhibition of 1851 (Royal Commission) in 1852.

Photography had already had a significant effect on the creation of illustrations to printed publication on the Crystal Palace prior to the publication of the *Report by the Juries*. John Tallis had used Daguerreotypes taken by E. Fehrenbach, Richard Beard, W.E. Kilburn and J.J.E. Mayall to create steel engravings for the illustrations for *Tallis's History and Description of the Crystal Palace* (3 vols.) John Tallis, London and New York [1852]. In June 1851 photographs by Philip Henry Delamotte (1820–1889) of the exhibition building in its different stages—and of pieces of the sculpture to be exhibited were displayed at a *conversazione* of the Society of Arts in London. However, Delamotte's images were not used to illustrate the *Reports by the Juries*. This honour was bestowed on probably three photographers. Some forty-three of the photographs can be accredited to the Frenchman Claude-Marie Ferrier (1811–1889) while a further twenty-eight can be attributed to Hugh Owen (1808–1897), an amateur photographer and the Chief Cashier of the Great Western Railway. Owen worked with paper negatives, Ferrier with glass, using Niépce de St Victor's albumen process. The France-domiciled English photographer Robert Bingham printed the photographs used for the illustrations.

The idea of producing photographically illustrated presentation sets of the jury reports probably came from Prince Albert. Henry Cole noted in his diary in July 1851 that the "Prince [Albert] suggested that Talbotypes should be prepared to illustrate the report of the Jurors, and that 100 copies should be taken of each negative to be distributed to Public Libraries and foreign countries exhibiting." Subsequently, the Royal Commissioners decided at their meeting of 26 July 1851 to reserve £1,000 for "*Photographs of Articles exhibited, to be preserved as permanent memorials of the Exhibition*." At their next meeting, in August 1851, they formulated a letter to all foreign committees in which they mentioned the proposal of "transmitting to the Governments of their respective countries, through the Foreign-office, a complete set of the Medals and a copy of the Reports of the juries, illustrated by photographs of articles exhibited, in commemoration of the part taken by them in securing a representation at the Exhibition of the produce of their National Industries." The complete presentation set was to consist of the four mentioned volumes of the jury reports, three volumes of the *Official Descriptive and Illustrated Catalogue* (illustrated with engravings) and one volume of the *First* (and Second) *Report of The Commissioners for the Exhibition of 1851*.

By November 1851, William Henry Fox Talbot noted he had agreed with the Executive Committee, responsible for the production of the *Reports by the Juries,* that he would receive 15 copies of the presentation copies, of a value "roughly estimated at £30 per copy" in compensation for the printing not being contracted to Talbot and his former manservant, Nicolaas Henneman, who had set up a photographic establishment in London in 1847. Henneman was to be given "a present of £200 to compensate him for his trouble and disappointment." A list of 122 governments and institutions and individuals who were to receive complimentary copies was agreed and recorded in the minutes of the 52nd meeting of the Royal Commissioners in March 1852.

The production of the photographically illustrated copies of Reports by the Juries represented a monumental logistical challenge the like of which had not been previously attempted. Over 20,000 photographs would need to be individually printed at an average of 80 per day—using daylight—and then mounted. In the event, many of the photographs were printed in Versailles, where Robert Bingham had set up a printing establishment for this purpose. Bingham had the negatives on loan from the Royal Commission. When the project was finished in 1853, he was obliged to send them back to England because the time allowed by the French customs to keep them in France had expired. Captain Henry Charles Cunliffe Owen of the Royal Engineers was a key player in the organisation of the production of the presentation copies and in April 1852 he contacted the British Museum to advise on the mounting of the photographs on paper supports. According to Edgar Bowring, secretary of the Royal Commission, Captain Owen did not contend himself with any inferior execution and workmanship and was therefore largely responsible for the excellent condition of the presentation copies which made them a "handsome & highly finished present."

From the illustrations lists, printed in the volumes, it can be derived that jury reports were intended to have 154 photographs. However, the number of images in individual copies varies. A survey of the subject matter of the photographs in the *Reports* is revealing. Over fifty are of free-standing pieces of sculpture exhibited within the Crystal Palace thus giving a disproportionate perspective, considering the thirty classes of the exhibits and the exhibition's overall character. However, sculpture figured prominently in the exhibition, being placed at eye-catching spots in the Crystal Palace. These objects, like August Kiss' *Amazon* and Hiram Powers' *Greek Slave*, proved to be very popular with the public and were given much attention in other publications. Sculpture also made good subjects for the photographers who could show off their ability with interesting compositions and dramatic lightening. There are around ten general views of the building and the remainder of photographs document individual exhibits, including a view of Prince Albert's model house for families—subsequently rebuilt in Kennington, south London. In the process, the Royal Engineers were given the task of gaining permission from the exhibitors to

have their objects and goods photographed, using a special form.

The allocation and geographic distribution of copies is significant. Some 50 copies were presented to British individuals associated with the Great Exhibition; Royal Commissioners, members of the Executive Committee and seven officers of the Royal Engineers who had been key players in the organisational operations. Some British institutions, such as the British Museum, the School of Design and the Society of Arts received copies as did the 'national' libraries in Dublin and Edinburgh. Some parts of the British Empire were favoured with copies; Malta, the 'Cape of Good Hope,' 'Barbadoes' [sic], Trinidad, British Guiana, Canada, Nova Scotia, New South Wales and New Zealand. It seems that nine Indian Maharajahs and rulers received copies presented directly by the East India Company.

The remainder of presentation copies were presented to foreign governments. Some 'countries' fared better than others. In 1851 Germany was made up of a confederation consisting of thirty-eight sovereign states and four free cities. Twenty-seven of these were listed to receive presentation copies, probably reflecting the connections of Prince Albert with the country of his birth and his close interest (if not direct involvement) in the creation of the photographically illustrated copies of the *Reports.*

The presentation sets were produced by a joint venture of Spicer Brothers, a mayor wholesale paper company in London, and the printing firm of William Clowes and Sons. Together they had been responsible for all the official printed matter for the Great Exhibition. The volumes were bound by Robert Rivière, one of the foremost bookbinders in London. The production and the distribution of the presentation copies points to a significant period of elapsed between the decision by the Royal Commissioners in January 1852 as to who would be presented with copies and their actual delivery. This delay was partly caused by a fire at the printers, which destroyed the complete production of the printed texts. The first copies were ready in January 1853 and 44 copies were dispatched the following March. However, Talbot received his 15 copies in April 1854.

A full evaluation of the impact of the photographically illustrated copies of the *Reports by the Juries* has yet to be undertaken and the location of all extant copies is as yet unknown.

EXHIBITIONS OF PHOTOGRAPHY

Nineteenth century exhibitions of photography were held by a wide range of groups, from national governments, mechanics' institutes, and museums to commercial studios and amateur photographic societies. The purposes and audiences for photographic exhibitions were similarly diverse. Exhibitions were used to promote the political and economic interests of imperial nations, to entertain and educate the public, to publicize commercial studios, and to promote the practice of photography as an art form, among other reasons. Exhibitions of photography had an impact on social conventions and cultural practices and, at the same time, ideas about photography were shaped by exhibitions.

World's Fairs, also known as Great Exhibitions and Expositions Universelles, were the largest of the early major venues for the public circulation of photography. These international exhibitions were celebrations of industrial production and imperial expansion, where the products of industrial nations were displayed to mass audiences. While the first exclusively photographic exhibition was held at the Society of Arts in December 1852, photography was included in the first Great Exhibition at London's Crystal Palace in 1851. Included major contributions of from Britain, France, Germany, and the United States. Commercial photographers, who exhibited work that promoted their studios, showed portraits, genre scenes, city views, and landscapes. At the 1876 Philadelphia Centennial Exhibition, photography and related goods were displayed together in their own building for the first time. However, at all of the international exhibitions, photographers also submitted contributions to other sections. For example, photographs of anthropological specimens and racial types were part of colonial exhibits, and photographs of public works projects, historic monuments, and urban views were shown in national displays. International exhibitions were spectacular events that were designed to entertain and educate the public, and they played a significant role in popularizing photography.

Mechanics' institutes were among the earliest venues for exhibiting photography in Britain and the United States. These institutes were commercial organiza-

tions that aimed to educate working-class men and to improve the quality of consumer goods. Mechanics' institutes held annual fairs where commercial goods and new technologies were exhibited together with the fine and decorative arts. Photographs were often exhibited alongside photographic equipment and new technology, but they were ranked among the fine arts in the system of awards. Portraits, an important source of income for commercial studios, were the most common subject matter of the photographs shown at these industrial fairs. Prizes were awarded and photographers often used awards to promote their businesses. Although smaller in scale than the international variety, these exhibitions were aimed at a similar, popular audience.

Photographs were also exhibited in the waiting rooms of commercial studios. During the early decades of photography, these displays were an essential part of creating a theatrical atmosphere that drew clients in to the illusion that photography was a mysterious and magical process. These informal exhibits were used to sell the work of the studio, but they also helped to establish an aesthetic environment by aligning photography with art. For instance, from the 1860s, Montreal-based photographer William Notman displayed photographs, along with paintings, drawings, and sculpture by local artists, in the reception area of his studio.

In the nineteenth century, photography was generally not shown in art galleries, but it was collected and displayed by museums concerned with design and industrial products. Henry Cole, the founder of the Museum of Ornamental Art in London (1852), which later became the South Kensington Museum (1856), and still later, the Victoria and Albert Museum (1899), began collecting and exhibiting art photographs in the late 1850s. Cole collected work by photographers such as Roger Fenton and Julia Margaret Cameron for its artistic merit, while studies, such as Eadweard Muybridge's photographs of animal locomotion, were valued as aids for artists. In the 1850s, proposals were put forth in Paris and Berlin for museums of photography, where reproductions of works of art from major collections, such as the Louvre, could be shown. Although these plans did not come to fruition, photography was used to reproduce works of art in museum collections. In the United States, the Smithsonian Institution began collecting and exhibiting photography in the 1870s as part of its Department of Graphic Arts. Like the South Kensington Museum, the Smithsonian attempted to educate visitors with its displays.

Exhibitions by photographic societies were important in the struggle to have photography accepted as a fine art. In the 1850s, photographic societies, such as the Photographic Society of London and the Société française de photographie, held small exhibitions of their work. At first, they followed the conventions of academic salons, with images hung from floor to ceiling, but this method proved impractical for viewing the fine detail and subtle tones that were valued by the photographers. In the 1890s, when photographers broke away from traditional photographic societies and formed new art-focused groups like the Linked Ring, the Photo-Club de Paris, and the Photo-Secession, new spaces for the exhibition of photography and new modes of display emerged. The Linked Ring salons in London from 1893–1909 were extremely prestigious, and a jury selected the best work from an international group of photographers. Here, photographs were framed in an increasingly uniform way with lighter frames, and there was more focus on individual photographs. Collectors could purchase the work, and reviews of the shows were published in photographic journals. In 1893, the Japan Photographic Society held its first *Foreign Photography Exhibition* in Tokyo, and the pictorialist work from abroad delighted amateur and professional photographers. This show encouraged photographers in Japan to experiment with new directions in art photography and to develop a Japanese pictorial style. The Philadelphia Photographic Salons, held in 1898–1901 were the first American salons equivalent to their European counterparts, as well as the first American photography exhibitions held in an art institution, the Pennsylvania Academy of Fine Arts. Many of the original members of the New York-based Photo-Secession exhibited and met at these influential salons.

During the nineteenth century, the social and cultural value of photography was negotiated through exhibitions. While, in its early years, photography was exhibited as a product of industry, towards the end of the nineteenth century, it became increasingly common to display photographs as works of art.

EXPEDITION PHOTOGRAPHY

As an activity both enabling and symbolizing the advance of modern industrial economies, expeditionary enterprise in the nineteenth century was based upon a new empirical quest for knowledge and a political will to establish civil order and authority according to Western ideologies. An expedition might seek places that few had previously probed to any great extent within the geographical neighborhood of the expeditionary party's own place of origin. With respect to expeditionary photography, Auguste-Rosalie Bisson's successful ascent of Mont Blanc in 1862 is a good instance of a physically challenging goal relatively close to home. In the nineteenth-century sense of the term, however, expeditions usually entailed a journey by one or more individuals to explore a region or to reach a destination generally at some remove from Western metropolitan centers and their cultural and social extensions in cities and towns in other lands. This essay examines the emergence and development of photography as an agent of visual documentation that became integral to exploration or expeditionary activities largely associated with notions of progress, nationalism, and imperial design. Because photography was a practice adopted by inhabitants of other regions penetrated by the often unwelcome advances of Western society, an additional study outside the scope of the present discussion might examine photographers of non-European ancestry who undertook journeys of importance to their own cultures.

By the late eighteenth and early nineteenth centuries, overland journeys and sea voyages involving extensive exploration had begun to accord a place to artists. Two instances are the British painter William Hodges on James Cook's second voyage to the South Pacific (1772–75), and the Frenchman Dominique Vivant-Denon, for whom it was "imperative to describe everything," while depicting antiquities and terrain under Bonaparte on his Egyptian campaign (1798–1801). Both of these cases established a lineage of scientific and scholarly pursuits on the one hand, and exploits of strategic political concern on the other. They illustrate the scope of expeditionary work, which could take the intrepid traveler over expanses of land and water to regions whose geographical and physical character had been only poorly known at best. The apparatus of support might be private, or sanctioned by governmental authority, or a collective venture with a combination of both. As such, expeditions must necessarily be understood to have multiple functions; because they were costly and fraught with risk, explorers needed to demonstrate the value of their journeys to their sponsors back home. Reports and journals recording the encounters of the expedition became common by the 1830s, together with hand drawn delineations of places and their inhabitants, geological formations, fauna, and flora.

Despite difficulties in obtaining successful results in the field in its first decade or so, early adherents of photography recognized its implications as an astounding new form of visual documentation more exacting in its faithfulness to the subject compared to conventional practices. By 1841, in the spirit of Denon's delineations of Egypt, a transitional work appeared by the architect and Egyptologist Hector Horeau, *Panorama d'Égypte et de Nubie*, with aquatints after Pierre-Gustave Joly de Lotbinière's daguerreotypes made in Egypt. (Joly de Lotbinière also contributed to Lerebour's, *Excursions Daguerriennes*.) Photographers would henceforth push into areas considered exotic and that, although still given liberal interpretation by Romantically inclined painters, would undergo increased scrutiny through the lens of the camera.

Maxime du Camp had realized the implications of producing photographs of environments rich with associative and historic significance when in 1850 he traveled with the writer Gustave Flaubert to Egypt and the Middle East. Du Camp had received an official commission from the French government, privileging him to access the lands of the Pharaonic dynasties, which resulted in over 200 negatives. These comprise images of monumental Egyptian sculpture and edifices with a clarity and perceived quality of scientific observation that signal a new aesthetic of exploration relative to prior modes of depiction. Du Camp's research also revealed an ethnographic interest in his representations of Arab culture, and an indication of the psychological and social complexity of encounter symbolized in the photographs of the people. Several indications of future directions are thus present in Du Camp's achievement: he contributed to the initial stages of a cumulative photographic archive important for geopolitical, scientific, and scholarly study; helped to rationalize France's geopolitical presence in the Orient, and hence reinforce its nationalistic identity as an industrial power; and assisted in popularizing Egypt in the European imagination

through various publications that included Du Camp's pictures. One of these was *Egypt, Nubie, Palestine, & Syrie*, published in 1852 by the printing establishment of Blanquart-Evrard. In short, Du Camp and others such as Félix Teynard, John B. Greene, and later Francis Frith contributed to a growing ethos in Western culture, in which entrepreneurship united with the acquisition of visual knowledge to entertain as well as to inform a fascinated public.

Photography was adopted in the following decade as an important agent in civil and military exploration and reconnaissance. This could be a matter of either individual initiative or team effort. Officers in the British administrative, medical, and military establishment in India were encouraged to use the camera as early as 1856. Two of the earliest known cases of photographic expeditions in the Indian Himalayas were solitary missions by an army engineer, Captain Melville Clark, and a deputy commissioner, Philip Henry Egerton. Their explorations of 1861 and 1863, respectively, resulted in singular publications that augmented the conventionally produced pictorial records of previous explorations in the Himalayas while offering the novelty of authenticity associated with photographic documentation. Clarke's *From Simla through Ladac and Cashmere* (1862) provides a glimpse of the terrain and the types of habitations encountered on his journey, from the higher arid regions with their Tibetan settlements—where the photographer engineer makes clear his astonishment that anyone could dwell in such "desolate country"—to the more hospitable Srinagar, the former Mughal summer capital in the Kashmir valley. Egerton's photographs and accompanying narrative in his *Journal of a Tour Through Spiti, to the Frontier of Chinese Thibet* (1864) indicates the author's interest in geology and ethnography, and is also explicit in proclaiming his confidence in English commerce and civilizing mission.

Photography's contribution to nationalist interests and imperial designs can be easily overstated, but its deployment as an instrument in tactical missions to remote areas leaves little doubt that such motives were at work. The Abyssinia Campaign of 1867–8 yielded upwards of 1500 photographs produced by specially trained Royal Engineers. The venture is important for understanding the politics of science as a facet of Britain's imperialistic project during the age of Victoria. Sir Roderick Murchison, President of the Royal Geographical Society, who had already initiated David Livingston's Zambezi Expedition of 1858–64, once again wielded his formidable authority by making certain that the scientific community would benefit from geographic knowledge acquired by the expeditionary party that was sent ostensibly to gather military intelligence and seek stability in the region. As it had for the Zambezi Expedition, photography proved a significant validation of Murchison's geographical and strategic concerns in support of empire.

The study of photography's place in the exploration of the American West in the years following the Civil War offers further opportunity to study the sometimes conflicting agendas of scientific and utilitarian enterprise. George M. Wheeler, a first Lieutenant in the Army Corp of Engineers, spearheaded the US Geographic Surveys West of the One Hundredth Meridian. Wheeler had the Army's support based on his ultimate (but unrealized) objective to produce a comprehensive engineering map of the Western Territories. Nonetheless, he engaged the services of scientific and other non-military personnel on his campaigns beginning in 1871, including the photographers Timothy O'Sullivan and William Bell. Beginning in 1869, with government sponsorship, Ferdinand V. Hayden led the US Geological and Geographical Survey of the Territories, in which the civilian scientist and his associates pushed into Colorado, Wyoming, Utah, New Mexico, Idaho, and Montana to survey and ascertain the natural resources of these vast expanses. Hayden, however, well exceeded the practical objectives mandated by the latter with his overriding concerns for the scientific and social value of his explorations. Here the significance of photography was understood through the prolific work of William Henry Jackson, which, together with the art of Thomas Moran, were able to convey better than words to the public and a skeptical Congress the incredible beauty and fantastic features of places like the geologically dynamic Yellowstone region. The concept of wilderness, seemingly limitless, yet perceived as fragile and subject to radical change through future settlement was brought home through Hayden's efforts and the witness of images, leading to the establishment of Yellowstone National Park in 1872, the first in the U.S. national park system.

A critical facet of the production of photographs during such arduous journeys was the photographer's subjective achievement in the act of exploration, discovery (or re-discovery), and successful securing of images under the duress of environmental extremes. A well-outfitted party might have twenty porters or more to transport supplies and equipment, depending on the planned duration of the expedition. The exploration of desert and mountain wilderness areas made trekking with the camera particularly challenging, not only owing to dramatic changes in climate and altitude and the uncertainty of route conditions, but also because the labors of making photographs on the spot demanded a physical constitution and agility well beyond the skills of most practitioners. The degree to which expeditionary photographers would push themselves and their entourage to get the view is astonishing, particularly in cases where the operator either was the very man responsible for taking the lead or else given license to

venture out from the main group. This is driven home particularly well where one has occasion to read the written accounts of intrepid artists like Samuel Bourne, Timothy O'Sullivan, or William Bradford. Each in his own way was able to successfully capture the essence of a personal encounter with the wilderness, though with larger implications for study: Bourne on his three Himalayan Expeditions in the 1860s; O'Sullivan on his campaigns with Clarence King in the American Great Basin in the late 1860s and early 1870s; and the painter Bradford in the Arctic region and Greenland in 1869 with the photographers John L. Dunmore and George Critcherson. In Bradford's case, for instance, the iceberg was the chief feature that epitomized his experience, and photography became the enabling medium for this as clearly evident in passages from his account of the expedition in *The Arctic Regions* (1873): "The wild, rugged shapes, indescribable and ever-changing, baffle all description, and nothing can do them justice but the sun-given powers of the camera" (Bradford, 49).

Although the "conquest" of the terrain by the photographer is implicit in the image appearing before the viewer, the implications run much deeper than is evident in a single image. First, any immediate aesthetic regard related to the aging Romantic standards of the picturesque and sublime must be tempered by the knowledge of photography's transcriptional powers, of almost magical character to nineteenth-century observers and to the artists themselves. The attainment of geophysical locations remote in space and time was authenticated by their appearance in the pictures, but the representations themselves corresponded to shifting sensibilities toward the empirical: raw attributes of rocks, fissures, fossils, glaciers, ice caves, and the like paralleled scientific directions that placed high importance of the gathering of firsthand evidence in the field. Moreover, the experience was greatly augmented by the systematic effort of a number of photographers to produce multiple interrelated views at a specific location, including panoramas and sequenced pictures, to better represent the space-time continuum of place through careful study and imaginative reflection. The peoples encountered on these voyages were also assigned to a text and image realm, frequently integrated into ethnographic studies as a representation of disappearing cultures only too readily taken as part of the aesthetic experience. Thus, expeditionary photography, beyond matters of taste and the pleasure of looking, engaged the cultural and political dynamics of the age.

EXPOSITIONS UNIVERSELLE, PARIS (1854, 1855, 1867 etc.)

The Paris Expositions Universelles and the other world's fairs of the nineteenth century were curious and spectacular cultural events. Sponsored by the host country's government, they were well-orchestrated public relations campaigns as well. These exhibitions provided the ideal forum for the host country to promote its notions of progress, nationalism, imperialism, unity, education, culture, entertainment, and commerce. They also served as some of the largest and earliest public venues for the exhibition of photography. Thus, the Expositions Universelles of 1855 and 1867 are rich points for study of particular moments in photographic history.

The first French exposition universelle was held in the center of Paris along the Champs Elysées from May 15 to November 15, 1855. It was also the first international event where art was shown together with industrial products, albeit in separate buildings—art in the Palais des Beaux-Arts and industrial products in the Palais de l'Industrie and its Annexe. Photography was exhibited in the industrial division, in the same building as steam engines, gloves, animal skins, lacework, ironwork, food,

and animal products, among other things. This classification made a strong statement about photography's accepted role and applications. It was clearly celebrated as one of the most important inventions of the nineteenth century with Louis Daguerre's name being carved on the façade of the Palais de l'Industrie along with other great men. Photography's status as an art form was, however, hotly debated.

Photography was categorized in the twenty-sixth industrial class, "Letter and Block Printing, Photography" and had its own subcategory which included both photographic equipment and photographs. The submissions were selected by each country's subcommission and were exhibited in different locations throughout the Palais de l'Industrie as the exhibition space was divided between the different countries. An element of competition was created by the fact that an International Jury awarded four levels of prizes (grand gold medal, the first class medal, the second class medal, and honorable mention.). Interestingly, half of the jury was French and the other half of the jury was comprised of members from foreign countries proportional to the number of exhibitors. Not surprisingly, French exhibitors greatly outnumbered any other country and made up the majority of the prize winners. Approximately 180 different photographers were represented at the 1855 Exposition Universelle; 92 of them were French. The others came from Britain, other European countries, the British colonies, the United States, and Turkey.

There was a great focus on the latest technical innovations in photography in the countries' exhibitions. The 1850s were a period of much experimentation and progress in the field with France and England leading the way. By 1855 daguerreotypes were losing popularity and paper photography, both colotypes and collodion, were seen as the wave of the future because of their reproductive capabilities as well as their non-reflective, easier to view surfaces. This trend was reflected in the entries at the Exposition Universelle.

The types of photographic works shown embodied popularly-held contemporary views of acceptable applications of photography. They can be divided into three broad categories: scientific and documentary aids, industrial and commercial applications, and artistic tools. In the scientific and documentary category, Dr. William Reade's photographs of the moon and William Sherlock's studies of clouds were touted in much of the Exposition Universelle commentary for their applications to astronomy and meteorology. Auguste Adophe Bertsch and Camille Arnaud's microscopic photography of insects, wood, and vegetable fibers were also highlighted. Dr. Hugh Diamond's photographs of mental patients' facial expressions were praised for their important applications to the study and care of mental illness. Louis Rousseau and F. Jacques Moulin reinforced the concept that photography could be used in the field of ethnography by showing images of Hottentot men and women who were seen as ethnological objects of fascination in the mid-nineteenth century. Works by photographers of the Mission Héliographique, a project sponsored by the French government to document the country's architectural patrimony were complimented as ideal examples of photography's documentary uses.

Photography was also celebrated for its industrial and commercial uses. Adolphe Braun was awarded a first class medal for his floral studies, which he used in his wallpaper and textile design business. Louis-Désiré Blanquart-Evard and A.A. Fockeday were praised for developing a technique that enabled them to produce infinite numbers of prints from the same negative, thus greatly affecting their illustrated book publishing business. A number of portraitists also exhibited at the Exposition Universelle, including André-Adolphe-Eugène Disdèri, Nadar, and Mayer and Pierson. Photography offered an inexpensive alternative to the oil-painted portrait, affording a much larger portion of the population the opportunity to have a portrait made.

Photography's application as a study tool for artists was widely supported in the 1850s. Examples by photographers such as Gustave Le Gray, André Giroux, Henri Le Secqq, and John Dillwyn Llewelyn of reproductions of works of art as well as portraits and landscapes which could be used by artists as an aid in their painting and sculpture were also exhibited.

While the focus at the 1855 Exposition Universelle was on the marvels of the technology itself and photography's role and function as an important tool in a range of fields, there was a strong undercurrent in the exhibition's reviews, reports, and other commentary that also discussed photography's status as an art form in its own right. Many of the same works discussed above for their applications in the various fields were also promoted by some critics for their aesthetic merits. Similarly, a contingent of critics expressed great disappointment in the fact that photography was relegated to the Palais de l'Industrie rather than the Palais des Beaux-Arts, a position which would have granted it more recognition as an art form. While opponents of photography's artistic qualities focused on the mechanical elements, proponents emphasized the degree of choice and creativity involved in composing a photograph from the angle, to the lighting, to the framing. On a side note, there was also a great aesthetic debate in the 1850s which found its way into Exposition Universelle commentary surrounding the retouching of photograph. Many saw retouching as deterring from an image's veracity and sincerity.

The next exposition universelle to be held on French soil was thirteen years later from April 1 to October 31, 1867. In the intervening years, photography had made significant technical advances and had exploded in

popularity with studios going up everywhere, extending further throughout the world. At the same time, photography still had not been fully recognized as an art form. Though photography was accepted into the 1859 Salon, it was isolated from the other artistic media, which were exhibited concurrently in the same building. The photography component, which was officially the third exhibition of the Société française de photographie, could only be accessed through a separate entrance. It was comprised solely of photographs; there was no equipment. The two exhibitions had their own catalogues which were similar in format, but neither mentioned the other exhibition.

The 1867 Exposition Universelle embodied the general consensus on the status of photography in the 1860s. It was held again in the center of Paris on the Champs-du-Mars between the Quay d'Orsay and the Ecole Militaire. This time the fine arts and industry were housed in the same main Palais which was surrounded by many smaller exhibition buildings that formed an exposition park. Photography was placed in Classe 9, "Material and Application of the Liberal Arts" in its own section, "Photographic Prints and Equipment." Physically and psychologically, photography held a position somewhere between art and industry. The exhibition space was again divided by country, but all photography exhibits were located along the same gridded ring in the Palais making it easier to compare the different countries' submissions. Over 650 exhibitors showed in this category. The majority was French and British, with other entries from numerous European countries, Russia, the United States, Canada, Algeria, and Turkey. The photographs shown were generally similar in type to those found at the 1855 Exposition Universelle. Some of the new types included equestrian portraits, geographic views, images of China, and greatly enlarged panoramic photographs. Many of the same photographers who had also exhibited in 1855 exhibited or participated as jurors in 1867.

Much of the 1867 commentary highlighted the technical achievements. There was great concern about the vulnerability of photographs and a strong desire to increase their longevity. New carbon techniques which promised permanency were exhibited. The Woodburytype was seen as another important technical development. Other photographers were experimenting with diverse materials and uses for photography including: miniatures that could be used for jewelry, photographs on enamel, and portraits on porcelain. The firm Geymet and Alker was developing new, more portable equipment that could be used by the "tourist photographer." A Mr. Johnson from the United States exhibited a panotoscopic camera that could be used for groups and landscapes at a great range as well as to better capture skies and clouds.

The photography exhibitions at the 1855 and 1867 Expositions Universelles brought photography to the attention of a public that was larger and geographically more far reaching than ever before. They promoted a fairly broad range of photography's potential applications and also served as a forum for the ongoing nineteenth-century debate over its status as an art form.

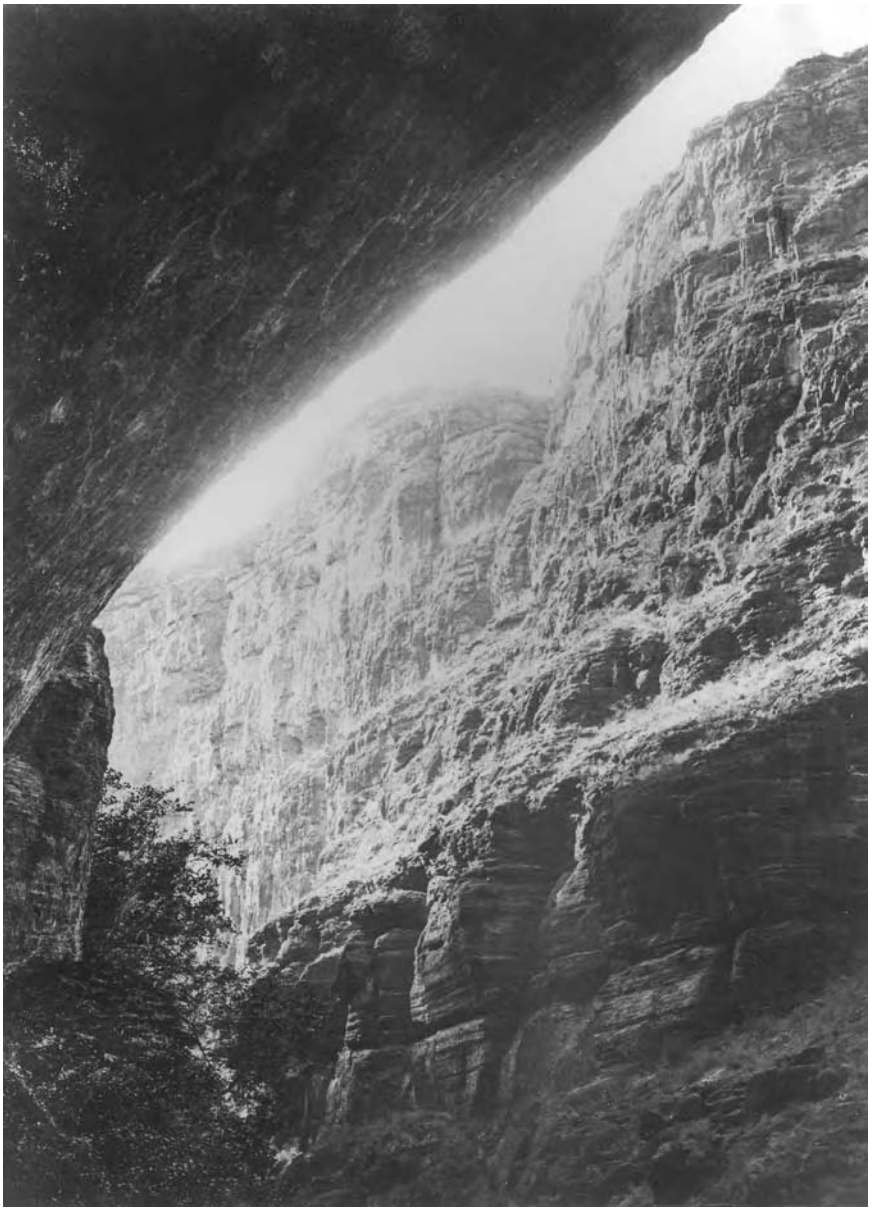
EXPOSURE

In photography, common understanding of the term "exposure" suggests simply exposing a film, plate or paper to light. More scientifically, it can be defined as the effect produced on a sensitised material by light, which is proportional to the product of intensity and time. Correct exposure depends on four variable factors; the quantity of light, the nature of the subject, the aperture of the lens, and the sensitivity or 'speed' of the negative material.

Long exposure times severely limited the scope of the photographic pioneers. The first process used successfully to produce a permanent image, the heliographic process of Joseph Nicéphore Niépce, required an exposure time of several hours and was therefore of very limited potential. The first practicable processes, the daguerreotype process of L.J.M. Daguerre and W.H.F. Talbot's photogenic drawing, both announced in 1839, required shorter exposures but still long enough to severely limit the photographer's subject. The earliest daguerreotypes requiring minimum exposures of five minutes and often up to thirty, depict almost exclusively, static landscapes, architectural views and still life subjects. The subject matter of Talbot's surviving photogenic drawings is even more limited. Most are *shadowgraphs*, as Talbot described them or what we would call photograms today. Surviving camera pictures are rarer and again show static subjects. Exposure times were probably a little longer than contemporary daguerreotypes. In *The Pencil of Nature* (1845–46),



Bell, William Abraham. Canyon of Kanab Wash, Looking South. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift [2005 2005.100.585 (10)] Image © The Metropolitan Museum of Art.*

Talbot claimed that he produced camera pictures in ten minutes "during the brilliant summer of 1835." On the other hand, his notebook of 14 August 1839 records "… a picture made by the camera in an hour, on a dark day." Exposure times of both processes were reduced, particularly by improvements in the chemistry of the sensitive materials. In 1840 John Goddard in England found that Bromine vapour increased the sensitivity of daguerreotype plates. The same year Talbot discovered that gallic acid added to silver nitrate produced a latent image after a brief exposure, which became visible on development. The consequences were dramatic. With exposure times reduced to a few minutes, the exciting prospect of photographing living people became reality. By the end of 1840 it became evident that commercial portrait photography could be achieved using either process and the first studios opened a year later. However, exposure times still limited the photographer's craft. The streets of Talbot's London calotypes (c 1845) are peopled by ghosts or eerily empty because the exposures of two or three minutes were too long to capture the city bustle.

In 1851 Frederick Scott Archer introduced the wet collodion process, an innovation which combined some of the best elements of the pioneer processes and reduced exposure times to a few seconds. Wet collodion soon superseded both earlier processes and promoted an explosion of popular interest in photography. A wider range of subjects became possible, yet the length of exposure still imposed limitations. Victorian portraits usually show solemn faced sitters because it was difficult for them to smile naturally for several seconds. Action shots remained problematic, most movement being recorded as a blur. Thus, Roger Fenton**'s** Crimean War photographs (1855) often have the appearance of empty stage sets. Tripods were essential to keep the camera steady and exposure technique remained primitive, involving removing the lens cap for a period measured by counting or timing with a watch. Photographers made life more difficult for themselves by failing to deal systematically with the known factors that affected exposure. The attitude of William Lake Price in his *Manual of Photographic Manipulation* (second edition 1868) was typical. "No fixed data can be given for duration of exposure,… Still, by practice, a sort of instinct grows on the photographer,…" Using specialised apparatus and techniques, photographers such as Thomas Skaife, Thomas Sutton and George Washington Wilson, did manage to reduce exposure times to fractions of a second and capture small but sharp images of moving subjects. Lenses of large aperture and short focal length were essential, as was ideal light and careful processing. Even so, as William England recorded in *The Photographic News* (April 11, 1862), to produce these so-called `instantaneous' photographs "a very large amount of patience is necessary, and failures are very plentiful."

All this finally changed in the 1870s with the introduction of the fast gelatine halide dry plates that readily allowed exposures of fractions of a second. The technological spin-off was enormous. Shutters became an essential adjunct to the camera, which themselves became smaller and could be held in the hand. Exposure meters first began to be widely marketed in the late 1880s. The development of new artificial light sources was stimulated. Roll film became practicable and with it moving pictures and the cinema. At last, photography in a wide range of situations, night or day, was simplified, action could be recorded and John Herschel**'s** 1860 dream of 'snapshot' photography became a reality.

Suddenly a new world was opened to photographers. New insights into the natural world were provided by the motion studies of Muybridge and Marey. Unposed pictures taken without the subject's knowledge became possible for almost the first time and Paul Martin**'s** street life photographs of the 1890s are a landmark of the period. The rapid growth of a new amateur market and the loosening of photography's ties with the graphic arts brought a fresh stimulus to the debate about photography's role as an art form. One of the most influential photographers to exploit the new technology, P.H. Emerson**,** wrote passionately on the debate in his book, *Naturalistic Photography* (1889).

The widespread introduction of the gelatine dry plate and its consequences marks the beginning of modern photography. During the twentieth century, steady improvements in equipment and sensitive materials contributed to further small reductions in exposure times. Nevertheless, improvements in the twentieth century were small and incremental compared to the great strides made at the end of the nineteenth. Determining optimum exposure times continues to be a key factor in making good photographs today but current practice and style is largely made possible by technological developments made a century earlier.

EYNARD, JEAN-GABRIEL (1775–1863)

Born in 1775 in France, Eynard fled to Switzerland in 1793 to escape the excesses of the French Revolution. An illustrious career as a merchant, international financier, and diplomat ensued, enabling him to amass a large fortune, much of which he devoted in the 1820s to helping Greece win its independence.

Eynard was sixty-three when the invention of the daguerreotype was announced in 1839. He exercised his prodigious energy to learning the process, and in 1842 made eight daguerreotypes of the French king, Louis-Philippe, and his family, images now seemingly lost.

Free from financial constraints, Eynard chose his subjects at will. Not surprisingly, he drew from the life immediately around him: his family, friends, servants, houses, carriages, the city of Geneva, and the stage sets of his private theater. He selected his settings, arranged the poses, and, with the help of his valet, Jean Rion, included himself in many images. These carefully composed, technically accomplished, and elegant documentations of Eynard's life collectively comprise, in effect, an extended family album at once both sophisticated and artful.

As they were made for private delectation and were not subject to the vicissitudes of the market place until well after his death in 1863, a surprisingly large number of his daguerreotypes have survived.

GORDON BALDWIN

F

FALLOWFIELD, JONATHAN (1856–2005)

English chemist and photographic chemical supplier

Jonathan Fallowfield was born in 1835 and established himself as a chemist. By 1856 he was advertising as a 'photographic chemical and material warehouse.' From the early 1870s the business primarily sold cameras and photographic materials for use with the wet-collodion and, later, dry plate processes offering professional and studio equipment such as portrait cameras and carte-de-visite lenses. In 1885 the Fallowfield premises and business was valued at £18,000. Jonathan Fallowfield had a reputation for hard work and he recalled that during one period of twenty-four years he only took one week's holiday. He died in London on 23 February 1920 leaving an estate of £51,360 13s 7d.

In 1888 the business was purchased by F W Hindley (1856–1925) who significantly expanded its retail activities and in 1890 the business moved to 146 Charing Cross Road, London, where it remained until 1923. From the early 1890s the firm expanded the range of equipment offered by it and commissioned products which it retailed under its own name, most significantly the Facile camera patented by Frank Miall in 1889, which was produced in several models until the end of the 1890s. It is unlikely that it undertook any extensive manufacturing on it's own account.

After the 1919 the firm concentrated on retailing equipment made by the major equipment and sensitised materials manufacturers and its own brand cameras and equipment disappeared. Jonathan Fallowfield became a limited company in 1921 and by the 1930s the firm had diversified into selling radio equipment. During the 1950s it began to concentrate on British wholesale and export orders only.

The company remained a wholesale photographic business becoming part Sangers Photographics Wholesale Ltd in 1987 and Sangers Ltd in 1996. The Fallowfield company exists in name only as part of Quadnetics Group plc.

MICHAEL PRITCHARD

FAMIN, CONSTANT ALEXANDRE (FRENCH, 1827–1888)

French photographer

Constant Alexandre Famin (sometimes confused with Charles Famin, a painter) was a French photographer who operated two studios in Paris (5, rue de Fleurus; 20, av. d'Orléans). Famin primarily photographed landscape and rural subjects, and was among the group of photographers to work in the forest of Fontainebleau and its environs in the late 1850s, 1860s, and 1870s. His rural photographs, and in particular his studies of peasants and farm animals, may have been intended as aids for painters, but even among these, Famin's eye for complex, intriguing composition and his sharply detailed prints distinguish his work from that of other photographers of rural life. He also appears to have made architectural photographs at Bourges and Paris. The bulk of Famin's known work is represented in the Bibliotheque Nationale, Paris, where, under the rule of the *Dépôt Légal,* he made two large deposits of his work in 1863 and 1874. Though he primarily produced albumen prints from collodion negatives, a group of stereoscopes deposited in 1859 at the Bibliothèque Nationale, Paris, under the name J. Tongue but now thought to be by Famin, suggests a greater diversity to his output than previously acknowledged.

SARAH KENNEL

FARADAY, MICHAEL (1791–1867)

Michael Faraday was closely associated with some of the most important pioneers of photography. He worked hard to improve Britain's glass production, especially important for large lenses. He also discovered phenomena related to the optical behavior of materials that became of use in the 20th century. He is, however, more remembered as the single person most responsible for the modern technology for the generation and management of electric power. He also made many contributions to chemistry. But his greatest importance for photography was arguably his work on the relation between electricity and magnetism. While this was fundamental to the generation of electric power it was also the basis on which James Clerk Maxwell (1831–1879) built his theory of electromagnetic waves, which explains much of the behavior of light and its relatives, radio waves, infrared, microwaves, ultraviolet, x-rays and gamma-rays.

Faraday was born to a father who was in trade as a blacksmith, and had a short term of formal education, which included essentially no mathematics. He apprenticed to a bookbinder at age 13 and became increasingly interested in chemistry and electricity. Eventually he was able to construct experimental equipment, based on what he had read, using extremely simple materials. By 1812 he had constructed, for example, a machine to generate static electricity and accumulate an electric charge, as well as a voltaic pile, what we would now call a battery.

In the winter of 1810–11 Faraday attended a series of public lectures on chemistry. He took careful notes, which he illustrated. He presented these to his employer, and not long after a patron of the store noticed them and took Faraday to a public lecture at the Royal Institution by its laboratory director, Sir Humphrey Davy (1778–1829), one of the most well known physicists of the time. Faraday was enthralled, and when his apprenticeship was up some months later he handed his notes of the talks to Davy and requested employment as Davy's assistant. Some months later Faraday was hired and began his career at the Royal Institution, his main affiliation until his death.

A year after Faraday was hired he accompanied Davy on a tour of major science laboratories on the Continent. Faraday met scientists in Germany, France and Italy, including Ampere, Humboldt, Gay-Lussac, and Volta, the inventor of the voltaic pile. The people he met he remained in contact with upon his return to the Royal Institution.

The Royal Institution was a learned society established in 1799 to promote organized research and disseminate new knowledge. The former goal was supported by the creation of a laboratory and a set of research professorships, and a major research library. The diffusion of knowledge was to be carried out both by courses offered by the research professors. Faraday founded a series of six talks at Christmas time for juveniles and carried them out himself for 19 years.

Faraday's work for the first several years was largely in chemistry. He performed analyses for Davy and published a number of short papers on them.

In 1820 Oersted, a Danish physicist discovered that an electric current flowing in a wire would orient a compass needle at right angles to the wire. Repeating Oersted's experiment re excited Faraday's interest in electricity and magnetism, one which he eventually became heavily involved with.

In 1821 Faraday married Sarah Barnard. He applied for and received an addition to his rooms in the Royal Institution. The couple occupied these rooms for the rest of his career.

The same year he showed that a magnetic needle could be made to rotate around a wire carrying an electric current. This is the principle of the electric motor, though it took some years for practical designs to follow, mostly because no source of large amounts of electric power existed. Such sources awaited Faraday's discovery of the electric generator idea a decade later.

In the years immediately following he performed mostly chemical experiments, including the 1825 discovery of Benzol, which later became the basis of a number of the aniline dyes, which still later came into use as photographic sensitizing dyes.

Faraday became involved with glass production in the following way. In the early 1800s the British had dominated the supply of high quality optical glass and the instruments, such as *camera obscuras*, telescopes and microscopes, made from it. But in the 1810s and twenties a new supplier, a young German named Fraunhofer, began to produce much better glass of considerably larger diameters, and through using the glass in large prisms discovered that the spectrum of the Sun was a rainbow crossed by dark lines at fixed colors (founding modern spectroscopy). These lines in turn he was able to use as high precision sign posts to measure the quality of his glass, and to give it precise specifications for his customers. Fraunhofer became the world leader in supplying large lenses and prisms.

This naturally concerned the British and the Joint Committee of the Board of Longitude and the Royal Society for the Improvement of Glass for Optical Purposes was established in 1824. It at first included a number of well-known physicists, such as Humphrey Davy, Thomas Young, and Sir John Herschel as well as lens maker George Dolland and glassmakers Pellat and Green were added. Faraday was engaged to do a chemical analysis of samples of Fraunhofer's glass. This he did and handed the derived compositions to the glassmakers, working on the assumption that this

piece of reverse engineering was the key to reproducing Fraunhofer's success. But their attempts to use these formulae repeatedly failed. It became evident that the conditions of manufacture, including the materials and shape of the melting pots, the temperature progression of the furnace, and the stirring techniques and materials were also important.

In 1825 a subcommittee of Dolland, Herschel, and Faraday was set up to closely supervise the glassmakers. In 1827 it was deemed necessary to move the furnace operations to the Royal Institution so that Faraday could supervise them directly. The results continued to be imperfect, yielding glass with bubbles and striae. It became clearer that the stirring technique was crucial to getting uniformity in the glass, but this goal eluded Faraday. The few successes Faraday achieved were not reproducible. In May 1830 he resigned the Committee. Fraunhofer had meanwhile died in 1826, and his secrets, known to former associates as well as some of his coworkers, were carried abroad. They were put to use in Switzerland and then in France. The expertise eventually found its way back to England that led to a revival of British optics.

In the 1820s Faraday noticed, while experimenting with a manganese-doped glass of purple color, that the glass turned darker if exposed to sunlight. It could turn lighter again if removed from the light. This must be one of the earliest descriptions of photochromic behavior, and is directly related to photography. He never tried to produce an image with this material, though he could have. A silver halide-doped glass with the same ability found practical application in darkening/clearing sunglasses in the late 20th century.

As mentioned above Faraday was a close associate and became a friend of Sir John Herschel, and likely through him got to know Henry Talbot. In 1839 when Talbot wished to describe his work on photographic images Faraday provided the first public announcement of his photogenic drawing process on the 25th of January before the Royal Institution. He gave the first talk on the details of the process (see the *Literary Gazette* of Feb. 2, 1839). Faraday supported Talbot in his admission to the Royal Society, but later opposed the granting to him of a baronetcy. Faraday connected to many others in the circle of early photographers and sat for a number of portraits, including one by Mayall.

Faraday had always thought that symmetry of action in physical phenomena was important and should apply to electricity and magnetism. He had demonstrated in 1821 the electric motor principle, as outlined above. He thought at the time that the reverse should work and that there should be a way for a changing magnetic force to cause an electric current to flow in a conductor. In 1831 he resumed his electrical experiments. He demonstrated that rotating a coil of wire between the poles of one or more magnets would induce an electric current to flow in the coil. This is the basis of the electric generator. With this discovery the modern age of electricity began.

In the 1840s and 50s Faraday taught chemistry and continued his electrical and optical researches. He discovered that magnetic fields could affect the properties of light both as it traveled in the vacuum and through matter. He demonstrated that strong magnetic fields could rotate the plane of polarization of polarized light as it traveled through glass placed between the poles of a large magnet (Faraday rotation"). This clearly hinted, based on the earlier discovery of the link between electricity and magnetism that light's nature was both electrical and magnetic.

In pondering the fact that electric charge and magnets could exert forces on things the charge and magnets do not touch (as is the case for matter and gravitational attraction), Faraday dropped the old term of action-at-a-distance, and began to speak of this influence as evidence for electric and magnetic "fields," existing in and influencing the properties of space. The magnetic field could easily be visualized by sprinkling iron filings on a sheet of paper under which was placed a magnet. This now common experiment, and a similar one that can map electric force, made it easy to speak of field lines or lines of force, with their own reality, more or less independent of their sources in electric charges and magnetic poles.

The magneto-optical phenomena demonstrated by Faraday and the field idea were picked up, elaborated and mathematized by Maxwell in the 1850s and 1860s into a self-consistent set of equations which described static electric charge, currents in the vacuum and in conductors, and the consequent electromagnetic fields generated by the latter sources. He showed that electric and magnetic fields could propagate each other as waves and derived the waves' speed of propagation from the known electrical properties of conductors and the vacuum, and showed that this speed was in agreement with the previous best measurements of the speed of light. This established the electromagnetic wave nature of light and allowed Maxwell to predict the existence of radio waves and the rest of the electromagnetic spectrum. This foundation to the electromagnetic wave theory of light is Faraday's single greatest contribution to traditional photography and the newer digital photography.

Faraday did experiments until 1855 and lectured until 1861. His health declined during that time and he died in 1867.

FARDON, GEORGE ROBINSON (1807–1886)

American and Canadian photographer

Fardon was born in 1807 in Birmingham, England. No information is available about his ancestry or his early life there, nor when he emigrated to the United States. Internet genealogical Web sites suggest people bearing the name Fardon in the Birmingham area were Quakers. Fardon first appears in North America as a commission merchant at 42 Maiden Lane (*Daggett's New York City Directory*, 1848–49); he lived at 84 Greenwich Street. How or when he learned photography is not known. He appears to have been attracted to California by the 1849 gold rush. Although his arrival date in San Francisco is still a mystery, he was, judging by the photographs published in his *San Francisco Album* (1856), active by the mid-1850s. His Victoria obituary, which credits him with introducing the wet-plate process to San Francisco, possibly as early as 1852, also suggests he arrived in California in 1849. Fardon's reputation as a photographer in San Francisco rests upon his landscape and architectural views. According to Peter Palmquist and Thomas Kailbourn (2000, 223), this set him apart from his contemporaries. Some of Fardon's landscape images clearly depicted the photo studio facades of James May Ford and Robert H. Vance. Fardon, however, did not advertise as extensively as these contemporaries. There is even some evidence that he either learned photography from Ford or acquired some his San Francisco views (Palmquist and Kailbourn, 2000, 224, note 3).

Like many photographers in other urban settings hoping to boost their sales and promote their home, Fardon created a seven-part panorama of San Francisco in May 1855 (*Bancroft Library, University of California Berkeley* and *J. Paul Getty Museum, Los Angeles, California*; cited in Palmquist and Kailbourn, 2000, 224). During 1855 and into the early summer of 1856 he continued to produce striking photographs of the city's architecture from street level and elevated vantage points atop buildings and various hills. These photographs, including the seven-part panorama as separate images, were compiled into a book, *San Francisco Album: Photographs of the Most Beautiful Views and Public Buildings of San Francisco*. First advertised in September 1856 by Herre & Bauer (William Herre and John Bauer), this publication is considered the earliest work about an American city illustrated completely with photographs. Each copy was unique and contained between 30 and 33 salted-paper prints from wet-collodion negatives. Only nine copies are known to exist today (Fardon, 1999, 173). Marvin R. Nathan's catalogue raisonné of every extant San Francisco view by Fardon totals 65 (Fardon, 1999, 135–171). Some of Fardon's San Francisco landscape photographs, including a second panorama from around 1860, have not survived and are known only through artistic representations. Two examples are "The Merchants' Exchange, San Francisco, California," published in *Ballou's Pictorial Weekly* on May 23, 1857 (*Huntington Library, San Marino, California*; cited in Fardon, 1999, p. 118; this view may be based on a photograph, "Views in California" no. 8, *California Historical Society, San Francisco*), and "San Francisco in 1860" published by Hutchings & Rosenfield (*Bancroft Library, University of California Berkeley*; cited in Fardon, 1999, p. 115). Among the images in *San Francisco Album* is one depicting "Fort Vigilance," (also known as "Fort Gunnybags"), the Montgomery Block Building on Sacramento Street, with sandbags lining its front and guards on the rooftop. Fardon took at least two other photographs of this building which headquartered the Vigilance Committee: one view, taken May 22, 1856, depicts the moment after the lynching of two men accused of homicide, while the other is a side view of Sacramento Street from Front Street which also shows the fortifications erected by the Vigilance Committee. The lynching photograph is considered one of the earliest examples on the North American West Coast of photographic reporting (Fardon, 1999, 166). William Herre, one of Fardon's publishers, was a member of the 1856 Vigilance Committee.

Fardon competed in public exhibitions of his photographs at least three times in his career. The first two occasions were in San Francisco at an Industrial Exhibition sponsored by the Mechanics' Institute in 1857 and 1858. At the latter exhibit he was awarded a bronze medal for his nine patent leather photographs. These same photographs may have subsequently formed the centerpiece of his photographic display, which included other examples of studio and outdoor group portraiture, landscape and architectural views taken in Victoria, British colony of Vancouver Island, and shown at the 1862 London International Exhibition. Fardon was a member of the very large committee which oversaw the donation of materials for the exhibit. He did not win any prizes for his contribution. Frances George Claudet, his colleague in New Westminster, capital city of the neighbouring

colony of British Columbia, won honourable mention. The jury for the photographs included Claudet's father, Antoine-François-Jean Claudet.

Fardon did not remain in San Francisco very long and relocated to Victoria, the capital city of the British colony of Vancouver Island. The date of his move is still uncertain, but appears to have been in 1859 or 1860 at the latest. Evidence from one of his customer's diary and a copy of *San Francisco Album* owned by this same customer, James de Fremery, places him in San Francisco in early March 1859 and possibly as late as July 1859 or January 1860 (Fardon, 1999, 171). Evidence for Fardon's earlier physical presence in Victoria is provided by a receipt issued to Fardon on May 3, 1859 for a first installment payment on the purchase of two city lots at auction in Victoria. These lots, however, may have been bought on his behalf for his half-brother Alfred John Langley. Langley, himself having moved to Victoria from San Francisco in 1858, could also have purchased them for Fardon. One of these lots, Lot 1616 (southwest corner of Yates and Langley Streets), was rented on May 10, 1859 by Langley to two Victoria merchants who were also to construct a brick building on the lot. This building housed Fardon's studio in the late 1860s and early 1870s. Fardon sold the second lot, Lot 1617, on December 15, 1859 to his three half-brothers (A.J., James, and Charles Langley); the sales agreement does not provide a geographic location for either party. Fardon also owned a third lot, Lot 1620, in the same block on Langley Street, which he sold, along with Lot 1616, in May 1867 to A.J. Langley (Langley family papers, BC Archives, MS-0180, box 2, files 17 and 18; *Gazette* [Victoria], May 5, 1859, notice of sale of Lot 1616 and 1617 to "J.R. Fardon").

Although Fardon was a Victoria property owner on paper in 1859, he was not listed as a voter in the December 1, 1859 voters list, nor was he listed in the 1860 business directory. The first unequivocal instance of Fardon's presence in Victoria is a ship arrival notice for the steamer *Pacific* from San Francisco on June 15, 1860 on which "Mr. Fardon" is listed as a passenger (*Daily British Colonist* [Victoria], June 16, 1860). Fardon was assessed and taxed under the Vancouver Island colony's Trade Licenses Act on January 1, 1861 as a photographer on Government Street. He may also have been the "photographist" responsible for photographing a corpse and charging the widow $20 for expenses (brandy, cologne and three handkerchiefs) to keep himself from fainting (*Daily British Colonist*, October 23, 1860). The only other known photographer in Victoria at this time was Stephen Allen Spencer (1829?–1911), who may also have had the commission. One of the first known Victoria newspaper ads for "Fardon's Photographic Gallery" was published on March 2, 1861 in the *Daily British Colonist*. On March 28, 1861 the same newspaper noted the addition of "G. Farden" to the membership of the Industrial Exhibition Committee which began planning the previous month for the Vancouver Island colony's submission to the 1862 London International Exhibition. One of the photographs Fardon contributed, a multi-part panorama of Victoria, was reproduced as a wood engraving in the *Illustrated London News* on January 14, 1863 (*National Archives of Canada, Ottawa, Ontario*).

While Fardon continued to produce a few outdoor photographs in Victoria, the mainstay of his business was portraiture. He photographed many of the city's founding families, as well as visitors, such as members of the British Royal Engineers detachment, from the mainland colony of British Columbia. Fardon's earliest portraits generally see the customer standing with a headstand for support. The studio backdrop is plain, with a wide floorboard moulding and carpeted floor. Sometimes a curtain, tied back, appears on the right. In some of these early Victoria portrait photographs Fardon appears to have encouraged a relaxed attitude with his sitter lounging in a chair next to a table. A few early portraits are also group shots of two or three individuals, sometimes family members, sometimes civil servants. Later portraits contain more elaborate props and backdrops. In addition to these carte-de-visite full-figure views, he also produced head and shoulders portraits. Unlike his time in San Francisco, Fardon placed newspaper and book advertisements indicating his portrait specialties: "Cartes des visite. Likenesses on patent leather, paper, or glass. Children under 5 years, $3." (*Daily British Colonist*, October 4, 1862). Besides the nine patent leather portraits now owned by the *Victoria and Albert Museum, London, England*, which were exhibited at London International Exhibition in 1862, only one other such portrait can be attributed to Fardon. This is a full-figure carte-de-visite size studio portrait of Sarah Crease, wife of H.P.P. Crease, a lawyer, judge and knight (*British Columbia Archives, Victoria*). The carpet pattern and plain studio wall match several other portraits taken in Fardon's studio; based on information accompanying the photograph it was taken before June 1863. Two other photographers in Victoria in 1862 who advertised patent leather photographs were S.A. Spencer and Blacklin & Bristow.

In October 1863 Fardon relocated his studio to a brick building on the corner of Langley and Yates Streets. Fardon returned to England between July 1865 and July 1866. He hired Noah Shakespeare (1839–1921) to manage his studio. When Fardon returned, Charles (Carlo) Gentile hired Shakespeare in August 1866. One of Fardon's last newspaper ads started appearing in the *Daily Colonist* in mid-September 1869. When Benjamin F. Baltzly, an employee of Montreal's William Notman, visited and photographed in and around Victoria in July 1871, he captured a sign advertising Fardon's business

on the side of the building housing his studio (*Notman Photographic Archives, McCord Museum, Montreal, Quebec*). Fardon retired from photography in Victoria in the early to mid-1870s and in 1876 moved to Oakland, California. He operated a photo studio with William H. Bluett (Bluett & Fardon), then left the field permanently upon his return to Victoria in 1877. Fardon died on August 20, 1886 and was buried in Ross Bay Cemetery, Victoria, British Columbia. A very weathered white marble headstone marks his grave (Block F, plot 32 W 21A) which is near his half-brother A.J. Langley's grave (Block F, plot 32 E 21).

Biography

George Robinson Fardon was born in 1807 in Birmingham, Warwickshire, England. By the late 1840s he was living and working in New York City as a commission merchant. He was in San Francisco, California, by the mid-1850s. Where or when he learned photography is unknown. In September 1856 Herre & Bauer published Fardon's *San Francisco Album*, believed to be the first photographic compilation depicting an American city. Fardon exhibited some of these views in the Mechanics' Institute's First Industrial Exhibition (1857). The next year he was awarded a bronze medal for his display which included portraits on patent leather. Following the discovery of gold on the Fraser River, British Columbia, Fardon made a number of trips to Victoria, Vancouver Island, where he purchased property, chiefly on behalf of a relative. Fardon first advertised as a photographer in Victoria in 1861. As part of the Vancouver Island entry to the London International Exhibition (1862), he submitted at least portraits on leather taken in Victoria. Although primarily a studio portrait photographer, Fardon's outdoor work included group portraits, buildings and a multipart panorama of Victoria (*London Illustrated News*, January 14, 1863). Following his retirement from his Victoria photographic in the mid-1870s, he moved to Oakland, California, where he had a brief photographic partnership with William H. Bluett (Bluett & Fardon). Fardon subsequently returned to Victoria where he died on 20 August 1886. He is buried in Ross Bay Cemetery, Victoria, BC.

FARMER, ERNEST HOWARD (1856–1944)

English physicist and photographer

Ernest Howard Farmer was born in Brighton in 1856, the second son of Robert Farmer, one of Brighton's early portrait photographers who had opened 'Mr Farmer's Daguerreotype Rooms' in the town in 1853. At the time of Ernest's birth, the family was resident at 59 North Street, Brighton, described as 'Mr Farmer's Old-Established Photographic Rooms' despite the studio's relatively short existence. By 1859, Robert Farmer was dead, and Howard, one of three children was brought up by his mother Harriet. He was the only one of the three children to survive into adulthood and, by the 1881 Census he was resident in Lambeth, London, his occupation listed as physicist, with his widowed mother living at the same address. Harriet's occupation was listed as 'charwoman.'

While still a young man, he became interested in amateur photography, his scientific training fuelling a curiosity about how the photographic process worked.

After his appointment as a teacher of photography, Farmer was appointed the first Head of Photography at the Regent Street Polytechnic, and is remembered as the inventor of 'Farmer's Reducer,' the mixture of potassium ferricyanide and sodium thiosulphate which is still used today to lighten excessively dense negatives and prints. He published the formula for his reducer in 1883.

JOHN HANNAVY

FENTON, ROGER (1819–1869)

British photographer

Born into the security of a wealthy Lancashire family, Roger Fenton was under no pressure to pursue a challenging or financially rewarding career. Despite that, he

Fenton, Roger. Still Life with Fruit. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 (2005.100.15) Image © The Metropolitan Musem of Art.*

chose to study and practice law, and to engage with the emerging profession of photography. After undertaking some initial tuition in painting in both London and Paris, he qualified as a lawyer and took up the new art of photography, initially as a hobby. Photography became his abiding passion for many years, during which time he emerged not only as one of the pre-eminent professional photographers of his day, but also as a major driving force and guiding hand in the foundation of organised photography in the United Kingdom.

The impact of Fenton's involvement with early British photography was considerable and enduring—both from the point of view of his skill and vision as an image maker, and his involvement in the establishment of The Photographic Society of London, and its publication *The Photographic Journal*. Driven by his enthusiasm for discussion and debate, and the exchange of information between practitioners, he helped establish the model of photographic fellowship that endures to this day.

An interest in art remained with Fenton throughout his life, and influenced his approach to photography and photographic composition. In the years before he turned his attention entirely to photography, his friendships with Charles Lucy and Ford Madox Brown were clearly significant factors in the type of paintings he exhibited. In each of the three years 1849, 1850 and 1851 he had a painting exhibited at the Royal Academy, but after 1852, he appears only to have exhibited photography.

With Lucy and others, he was instrumental in the establishment of the North London School of Drawing and Modelling in 1850, and helped secure for that school the patronage of the Prince Consort, Prince Albert. Albert's acquaintance with Fenton and his work later developed into an enduring interest in the work of the Photographic Society of London, and led to Fenton taking on the role of instructor to the Prince in the rudiments of photography.

It is not certain when Roger Fenton's interest in photography first began, although it is likely that its genesis may be traced to his time in Paris in the mid 1840s. His earliest dated images, taken using a modification of Gustave le Gray's Waxed Paper Process, were produced in 1852, and thirty-nine of them were exhibited at London's first photographic exhibition organised at the Society of Arts in December of that year. These included three images from his recent trip to Russia, views taken around his home in Albert Terrace, London, at various locations in Gloucestershire, and of his birthplace—Crimble Hall in Lancashire.

Circumstantial evidence supports the long-standing opinion that Fenton was a founding member of the Photographic Club (often referred to as the Calotype Club) in 1847, but his name is notably absent from early references to this group. However, membership included Peter Wickens Fry, Peter le Neve Foster, Frederick Scott Archer, Joseph Cundall, Hugh Owen, Dr Hugh Diamond, Edward Kater, Robert Hunt, Charles Vignoles, F. W. Berger and Sir William Newton, many of whom became Fenton's lifelong friends.

No surviving images have yet been traced to support Fenton's practical involvement with the calotype process. Despite this, the evidence for including him in the

group remains persuasive, although just when he joined is unclear. His name was included in a list of six Photographic Club members in 1852 who approached William Henry Fox Talbot in an attempt to persuade him to waive licence fees for the calotype process. However, as Talbot at that time claimed patent jurisdiction over both the waxed paper and wet collodion processes, Fenton's membership as late as 1852 did not in itself establish him as a user of the calotype, by which time his enthusiasm for waxed paper was well documented.

In that same year the 'Organising Committee' or 'Provisional Committee' which steered the establishment of the Photographic Society of London (later The Royal Photographic Society) comprised the same six men—Fenton, Peter le Neve Foster, Sir William Newton, Peter Fry, Robert Hunt and Frederick Berger.

On a visit to Paris in October 1851, Fenton met Gustave le Gray, inventor of the waxed paper process, and two other accomplished photographers—Vicomte Joseph Vigier and Monsieur Pulch, both of whom published and used variants of le Gray's method. By April of the following year he was successfully exploiting the process in his photography in Gloucestershire, and by August had overseen the publication of his treatise "Photography on Waxed Paper" published in the fifth edition of W. H. Thornthwaite's *A Guide to Photography*, London, 1852. In that text he refers to Pulch's process as one he has used with considerable success.

Declining to recommend le Gray's formulation on account of the perceived weakness of its solutions, he detailed both Vigier's and Pulch's variants. In addition, he drew attention to the French preference for English papers—especially the thin paper produced by Whatman & Co—and the British preference for French papers, especially those produced by Lacroix and Canson.

In the following months, Fenton was in Russia, using waxed paper to photograph work on Charles Vignoles' bridge over the River Dneiper at Kiev, making a series of stereoscopic views intended for viewing through Charles Wheatstone's Reflecting Stereoscope.

Authorship of a treatise on a relatively new process, and the production of a series of accomplished images both in England and in Russia both point to Fenton's initial engagement with photography having taken place well before the spring of 1852. The absence of any images from before that time, however, is curious.

The preparation for, and the journey to Russia in the autumn of 1852 was almost certainly Fenton's first involvement with stereoscopy, but as an amateur photographer. The professional photographer in the team was J. C. Bourne, and Fenton's work for his friend Vignoles in Kiev can be assumed to have been quite separate from Bourne's professional assignment.

Fenton prefaced the journey with some experimental photography at Regent's Park Zoo, evaluating methods of producing effective stereoscopic imagery. His subjects included a dead stag which was photographed using a series of different approaches to produce the optimum stereoscopic effect. Three surviving pairs of images from large format waxed paper negatives attest to these experiments, and the separations range from less than a metre to several metres. In the subsequent stereoscopic pairs produced in Russia, the distance between the two taking positions appears to be in the region of one to two metres, resulting in images which create a slightly exaggerated stereo effect when viewed in the Reflecting Stereoscope. On location in Kiev and Moscow, Fenton's experimentation provided the foundations for some remarkable stereoscopic views of Vignoles' bridge construction site in Kiev, and of the buildings in the Kremlin, Moscow.

The Russian images mark a significant change in Fenton's photography, and the journey produced the first images which significantly contributed to his enduring reputation as a major image-maker. One photograph, *Domes of the Cathedral of the Resurrection, Kremlin*, is now considered by historians and collectors to be an icon of early photography. Intriguingly, it does not appear in the list of photographs by Fenton exhibited at the exhibition in December 1852. Yet, included were images such as *Pittevilla Spa, Cheltenham* and *The Old Well Walk* which had been less than well received when first published in *The Photographic Album* earlier that year.

Fenton's enthusiasm for establishing a British photographic organisation in London predates his earliest dated images by some months—again attesting to an already established enthusiasm for photography.

The Societé heliographique, the world's first (but short-lived) photographic society, was established in Paris in January 1851 with Baron Jean-Baptiste Louis Gros as President, and in October 1851, Fenton travelled to France to meet the society's founders, and learn of their aims and objectives. His paper 'Proposal for the formation of a Photographic Society' appeared in *The Chemist* magazine in March 1852, and was an abridged version of a much longer paper which recent research has attributed to Antoine Claudet. Fenton and Claudet were both ardent advocates of a forum in which photographers could discuss and progress their art, so a degree of collaboration in the development of such a proposal is not surprising. By June 1852, an Organising Committee, formed to promote the establishment of the new society, had elected Fenton as its Honorary Secretary, and it is clear that many of the fundamental principles which guided their efforts originated with Fenton—particularly the establishment of a regular journal which would disseminate papers on new development in photography,

and encourage interaction between members in dealing with the medium's challenges and constraints.

At the Society's inaugural meeting on January 20, 1853, Fenton read a number of important papers on how the new society might conduct its business. He was elected as Honorary Secretary and, three weeks later, with Hunt and Vignoles, established the Publications Committee, becoming co-publisher with Dr John Percy of the *Journal of the Photographic Society*.

Fenton's decision to turn his hobby into a profession was taken in the summer of 1853, and seems to have been provoked by a request from the British Museum for advice on the establishment of a photographic studio and darkroom. Independently, both Fenton and Philip Henry Delamotte were asked to advise, and both agreed willingly. Each man also offered his services to the museum as photographer—Delamotte in August 1853 and Fenton two months later. On the recommendation of Wheatstone's Fenton was appointed, and for the next six years he maintained an important association with the museum.

Fenton produced a wide-ranging body of work, much of it photographed on the 'leads,' a flat roof area where a makeshift open-air daylight studio could be set up. The manhandling of rare works of art and historical artefacts up to this location, and dusting them with chalk to reduce reflection, suggest that the value of creating photographic images for dissemination throughout the world at times overruled the normal considerations of conservation.

In his business dealings with the museum, he introduced a number of innovative marketing approaches, including an agreement to produce negatives without charge in return for the right to sell prints himself made after the museum's orders had been fulfilled. This culminated in the establishment of a sale kiosk in the museum foyer, where images were sold to the visiting public by Fenton's staff. The success of this venture, in addition to substantial print orders from the museum trustees themselves, kept a number of staff at Fenton's printing establishment occupied.

While his work with the museum was proceeding, Fenton was also moving into other areas of photography. In early 1854 he was commissioned by Queen Victoria to produce a series of formal and informal royal portraits, resulting in some of the most atypical and striking portraits of the Queen ever produced. His abilities as a portrait photographer and as a creator of informal 'tableaux vivants,' which is evidenced by a body of work produced at Buckingham Palace, Balmoral Castle and Windsor Castle, were considerable.

Later in 1854, during a photographic trip to Yorkshire, he field-tested the photographic van with which he would subsequently travel to the Crimea. The 360 Crimean War images, which he produced between March and June 1855, ensured that the legend 'first war photographer' would invariably be attached to his name.

The Crimean War images, produced for commercial sale through the printsellers Thomas Agnew & Sons and P. & D. Colnaghi, were photographed to an agenda which avoided confronting Victorian sensibilities, and which was more than a little conscious of the political importance of the story being told. Fenton's letters home—to Agnew and to his wife Grace—established the true story of the war as seen through the photographer's eyes in a way his pictures did not.

While photography was undoubtedly limited in what could be captured—considering the low sensitivity of the wet collodion process, and the cumbersome nature of the equipment—Fenton's images contain little of the drama found in photographs by James Robertson, and others. Only on one occasion, in the chilling *Valley of the Shadow of Death* is there any suggestion of the real nature of what has been described as the last medieval war, and the first of the modern era. Otherwise the body of work for which Fenton is most widely known consists of finely executed camp scenes, harbour scenes and military portraits. As a commercial venture they enjoyed limited success, as the war was over before they were made widely available to the public. The long-term damage to Fenton's health from the cholera he contracted while in the war zone contributed to his early death.

It is interesting to observe that despite the often highly critical published reviews of his architectural and landscape photographs in the early 1850s, Fenton rose to a position of pre-eminence in these branches of photography in the mid and later 1850s and early 1860s.

His mastery of light and of composition take his images well beyond the obviously picturesque, although clearly paying homage to the Victorian ideals of the romantic landscape. Abbeys, priories, great houses and castles, and the rolling landscapes of Lancashire and Yorkshire were frequent subjects—often taken during visits to his family or his wife's families—while views in the Scottish Highlands date from his visit to Balmoral.

Several visits to North Wales resulted in a fine series of large views, and an extensive collection of images for the Brewster stereoscope, later published both as books, and as sets of stereocards. In these majestic images, the wet collodion negative process and albumen printing paper were often pushed to their limits to capture the fleeting subtleties of light and shade. In Ribblesdale, his subject matter ranged from the impact of industry on the landscape—the *Bobbin Mills at Hurst Green*—through to the delicate tones and hues of *Morning, the Keeper's Round*, where shooting into the low sun, Fenton captures a gamekeeper, seemingly oblivious to the camera, walking his dawn round.

In the several versions of the series, *A Vista, Furness Abbey,* again shooting into the light, strong shadows pull the viewer through and past a figure, or figures, standing in the archway towards a more distant animated group. With notable exceptions, figures in Fenton's landscape and architectural photographs are relatively rare, usually appearing only to add scale to a building or an expanse of landscape. However major assignments demonstrated that he was just as accomplished in the photography of the animate as the inanimate. The royal portraits (1854–1857), the Crimean War images (1855), ghillies and gamekeepers in Scotland and Lancashire (1856–1859), a cricket match (1857) and the Queen's Cup shooting match at Wimbledon (1860) all serve to demonstrate the breadth of his understanding of his medium. His exceptional achievement in figural photography is a series of studio compositions exploring exotic and middle eastern themes produced in the late 1850s, with titles such as *Nubian Water Carrier* and *Pasha and Bayadère.* Inspired by a Victorian fascination with the mysterious east, these images sit somewhat apart from the main body of Fenton's work. Recent researches in the USA have thrown much fresh light on the extent of this work, its inspiration and its reception amongst Fenton's peers.

Towards the end of his relatively short photographic career, Fenton embarked on the production of a series of elaborate still lifes, exploring the textures and patterns of fruit, game and other often unrelated objects. Considered to be the height of photographic art when first exhibited, these images also mark the zenith of his technical achievement with the medium. These images won him many awards and plaudits, including a medal at the 1862 International Exhibition. It was in a text accompanying a stereoscopic pair of just such a composition that the *Stereoscopic Magazine* in 1862 announced Fenton's retirement from photography, and his return to the legal profession.

An auction sale of all his work—negative and prints—resulted in the major proportion of his landscape and architectural views being purchased by Francis Frith, and subsequently published as a series of themed bound volumes—*The Works of Roger Fenton*—including such titles as *Cathedrals* and *Landscapes*. Frith continued to publish some of the views until the end of the nineteenth century, and sections extracted from several others continued in print as postcards until well after the Great War.

JOHN HANNAVY

Biography

Roger Fenton was born in 1819 at Crimble Hall, near Rochdale in Lancashire, one of seventeen children born to his mother and stepmother. The family's wealth came from mills and banks in the Rochdale and Heywood areas of Lancashire. His father, John, became the first Member of Parliament for the newly created Rochdale constituency in 1832, and for a few years sat on the same side of the house as the Whig (Liberal) MP for Chippenham, William Henry Fox Talbot.

At the age of seventeen, Roger was enrolled at University College London, to study mathematics, Greek and Latin, and graduated with the degree of Bachelor of Arts in 1840. In the same year, he enrolled to study law at UCL, and also developed an enduring interest in drawing and painting. In 1843 he married Grace Maynard, by whom he had five daughters and one son. Both his eldest daughter and his son died in childhood. By 1844 Fenton was studying art in Paris, and upon his return to England, developed friendships with Ford Madox Brown, Charles Lucy, and other leading painters of the day. Despite being called to the Bar in 1851, Fenton continued to practise as a solicitor for some years, with offices in King William Street in the City of London. He is also believed to have kept chambers in the Temple from 1852/3 until 1865, although his work as a professional photographer occupied him full time from 1854 until 1862, when he resumed his law practice. For much of his married life, the family lived at 2 Albert Terrace, Regent's Park, London. He died at his home in Potter's Bar, Hertfordshire in 1869 at the age of fifty.

FIEBIG, FREDERICK (active 1840s–1850s)

German lithographer and photographer in India

Although unlisted in the Calcutta commercial directories (apart from presumably being the 'Feibig' recorded as a piano teacher in the 1849 and 1850 editions of *The Bengal and Agra Directory and Annual Register*), Fiebig is known to have been active as a lithographer in the mid-1840s, when he published a number of topographical views of the city. In 1846 he also visited Singapore, where he sketched a now-lost panorama of the town, with the apparently unrealised aim of selling lithographic copies to subscribers (*Singapore Free Press*, 2 April 1846). The only contemporary reference to his photographic work appears in a short article recording his visit to Madras in early 1852 ('Photography in Madras,' *Illustrated Indian Journal of Arts*, Madras, part 4, February 1852, 32). This confirms his German origin and notes that he had taken up photography 'nearly three years' previously. During this period he had become a prolific calotypist, producing the first extensive photographic documentations of Calcutta and Madras. The writer of the article attests to having been shown between seven and eight hundred views of Calcutta alone and also mentions Fiebig's photographic activity in China and Burma, although no examples from these locations have come to light.

By 1856, Fiebig was in England, where he succeeded in selling a collection of nearly 500 hand-colored salted paper views of Calcutta, Madras, Ceylon, Mauritius and Cape Town to the East India Company (British Library, India Office Records, Miscellaneous Letters Received, vol. 193, 1856). The views of Ceylon appear to have been taken in the course of his visit to South India in 1852, while the Mauritius and Cape material must have been taken during the voyage back to Europe. No further information on his movements has been traced.

Apart from the large series of prints now in the British Library, only a few small collections of his work have surfaced at auction in recent years. The rich tonality of these uncolored images perhaps gives a better indication of Fiebig's sophisticated skills as a calotypist, than the more lightly printed and sometimes crudely colored views held in the British Library.

JOHN FALCONER

FIERLANTS, EDMOND (1819–1869)

Belgian photographer and photographic publisher

Edmond Fierlants was born in Brussels on 20 July 1819. His father Nicolas Fierlants was a lawyer and joint founder of the Université libre de Bruxelles in 1834. Edmond was brought up as a member of the upper bourgeoisie, and was probably of independent means. In the late 1840s, he married a woman considerably younger than himself, Isabelle Nieuwenhuys (born in 1831). They divided their time between Brussels and Paris, where their first child Hélène was born in 1850. A son, Albert Jean, was born in Brussels in 1852.

During his stay in Paris, Fierlants learnt the rudiments of photography, and completed his technical apprenticeship under Hippolyte Bayard, whom he would thereafter refer to as his "authority." Guided by the experienced Bayard, Fierlants acquired a reputation as a technically proficient researcher, and in 1854 became one of 93 founder members of the Société française de photographie, the only Belgian on the list. In 1855, the Society's *Bulletin* refers to him as one of the "*habiles experimentateurs*" [skillful experimenters] of the Taupenot process. Fierlants pursued his research, drawn to the process for its use in landscape and architectural photography, and published an article detailing the process' advantages in the *Journal of the Photographic Society* [of London] in 1856.

Fierlants showed his work in public for the first time in 1857. His reproductions of paintings at the exhibition of the Société française de photographie were well received, and, on the strength of a growing reputation, he was invited to join the jury at the industrial arts exhibition in Brussels that same year. Fierlants was planning a return to Brussels in order to make photography a full-time occupation, an unusual step for a man of his background in the Belgium of that era. However, the Belgian state, created as recently as 1830, was in search of its national identity, one strand of which was a cultural heritage rich in art and architecture. This heritage needed its spokesmen and popularisers, and Fierlants conceived it as his mission to undertake this task within his chosen medium.

In a revealing correspondence to Martin Laulerie, secretary of the Société française de photographie, Fierlants outlined his plans. He wrote of his aim to photograph the paintings in the museums of Brussels and Antwerp, enlisting his colleagues' help to promote his "*entreprise*" [enterprise] and adding: "Je dis mon entreprise, c'est trop dire. C'est justement ce qu'il faut obtenir et vous savez que nul n'est prophète dans son pays, quand j'habitais la Belgique il y a quatre ans je ne m'étais jamais occupé de photographie…" [I call it my enterprise, but that's claiming too much. The aim is precisely that, and you know about a prophet being without honour in his own land—when I used to live in Belgium four years ago photography never interested me…] (undated letter written from Aix-la-Chapelle).

In fact, Fierlants proved more than successful in promoting his cause. Buoyed up by the encouragement of his peers, and the judicious use of his family's influence in government circles, Fierlants returned to Brussels

on 5 May 1858, and immediately began lobbying the Ministry of the Interior for support. The liberal minister Charles Rogier, sympathetic to Fierlants, referred the matter of the Académie royale de Belgique [Royal Academy of Belgium], which gave a favorable opinion: "…l'Académie comme le Gouvernement, comme le pays, doit désirer que la gloire de nos vieux maîtres soit popularisée par tous les moyens possibles" […the Academy, as the Government, as the country, must fervently wish that the glory of our old masters be popularised by every means possible] (*Bulletin de l'Académie royale de Belgique*, 2nd series, 5 (1858): 77).

Fierlants had already begun his campaign in the field, taking nineteen studies of Bruges architecture and making a request to the mayor of Bruges to photograph the art works in the Hospice of St John. He concluded an agreement with the publisher Victor Didron in Paris to publish his output. Appearing under the series title *Les grands peintres avant Raphaël, photographiés d'après les tableaux originaux* [Great painters before Raphael, photographed from the original paintings], the prints were praised for their size and accurate capture of surface tone and texture, at a time when most photographic reproductions of paintings were not made directly from the originals (unlike Fierlants' work), but were rather copy prints from engravings.

The momentum was unstoppable. Armed with favorable reviews and the goodwill of the Belgian government, Fierlants received successive commissions to record the historic art and architecture of the towns of Antwerp (165 views taken in 1860), Brussels (114 views taken between 1862 and 1864) and Louvain (39 views taken in 1865), full-plate images characterised by compositional rigour. He regularly exhibited his work, most spectacularly a life-size model of the Saint Ursula reliquary at the London international exhibition in 1862, on which Memling's panel paintings were represented by Fierlants' albumen prints, perhaps hand-coloured.

Fierlants founded the Société belge de photographie in 1862, trading from custom-built premises at rue Keyenveld 69 (renumbered 73) in the commune of Ixelles. He moved in with his family on 25 July 1862, and it would serve as his studio, photographic publishing house, office and residence for the next five years. The company was granted a royal warrant in 1863, and the Société royale belge de photographie Ed. Fierlants et Companie published a stock catalogue in 1865, running to nearly 1400 items. But by this time, municipal support was drying up; in the wake of missed deadlines and unpaid bills, Fierlants turned to his final sudsidised project, an edition of the life-work of Belgian artist Antoine Wiertz (1806–1865), whose singlemindedness in pursuit of his monumental art must have chimed well with Fierlants' own driven outlook.

At the end of 1867, divorced and in debt, Fierlants opened a branch portrait studio at Montagne aux Herbes Potagères 4, moving there alone on 31 December 1867. The studio did not enjoy commercial success, and Fierlants was forced to relinquish control of his company. He died at the studio, a ruined man, on 21 December 1869. Under the directorship of Alexandre de Blochouse (1821–1901) from 1869 to 1885, the Société royale belge de photographie outlived its founder's vision of popularising Belgium's cultural heritage, operating as a middling photomechanical printing press.

The municipal archives in Antwerp, Brussels and Louvain house their respective commissioned series of town views and monuments. These are complemented by substantial holdings in the Bibliothèque royale Albert Ier— Cabinet des estampes, Brussels. The Rijksmuseum —National Photography Collection, Amsterdam, has a comprehensive run of books photographically illustrated by Fierlants. The municipal archives, Antwerp, also has a contemporary set of wet-plate negatives, probably supplied by Fierlants as part of his commission.

STEVEN F. JOSEPH

Biography

Edmond Joseph Marie Fierlants was born in Brussels on 20 July 1819 into a prominent family. In the late 1840s, he married Isabelle Nieuwenhuys (born in 1831), and had two children. Fierlants learnt photography in Paris under Hippolyte Bayard. Founder member of the Société française de photographie, Fierlants won a reputation as the photographer of Belgium's cultural heritage rich in art and architecture. Fierlants received commissions to record the historic monuments of Antwerp, Brussels, and Louvain. Fierlants founded the Société belge de photographie in 1862, trading from rue Keyenveld 69 (renumbered 73) in Brussels-Ixelles. Granted a royal warrant in 1863, the Société royale belge de photographie published a stock catalogue in 1865. In 1867, divorced and in debt, Fierlants opened a portrait studio at Montagne aux Herbes Potagères 4. The studio did not bring success, and Fierlants was forced to relinquish control of his company. He died a ruined man, on 21 December 1869.

FINLAND

Advance reports in Swedish-language newspapers ensured that a single daguerreotype would be a sensation when displayed in Turku, and Helsinki, Finland, in the New Year of 1840. The local doctor of Turku, Henrik Cajander (1804–1848), acquired details of the process while travelling in France, and produced Finland's first photographic image on his return in 1842. Thereafter, photography was influenced by political and economic aspirations as Finland sought independence from Russia, of which it remained a province until 1917.

The first notable Finn was a bookbinder, Fredrik Rehnström, who was born in Mäntyharju and in 1844, established a business based on skills learned in St Petersburg. For seven years, he travelled the country as an itinerant photographer offering daguerreotype portraits, which were popular because he photographed his customers in familiar locations, (rather than studio settings). On retirement, Rehnström moved to St Petersburg.

Other early photographers were foreigners, attracted by the market of Finland, but who introduced important skills. Two Estonians, Beno Lipschütz and Baptist Tensi offered daguerreotypes in Helsinki, Turku and Viipuri in 1848, and three years later a German, Friedrich Mebius, introduced the calotype to Helsinki. Two Danes ran successful studios for many years—Petter Christoffer Liebert began in 1842, and lasted for over twenty years, whereas countryman Charles Riis, took over the thriving business of Karl Eugen Hoffers when the latter returned to Prussia in 1871.

Hoffers had been in competition with Carl Adolph Hårdh of Sweden since 1860. Both men ran successful businesses in Helsinki and had established reputations, especially when working out of doors. Hårdh died in 1875 and a Swedish colleague, Fritz Hjertzell, ran the studio on behalf of his widow (whom he later married).

During the 1860s, famine was eradicated from Finland and improved prosperity coincided with a phase in which the *carte-de-visite* became popular. The system had been introduced by the Borchardt brothers of St Petersburg, who launched the service in Helsinki by asking high prices, but with improved incomes, Finnish people enjoyed patronising the professional studios. An attraction of the *carte-de-visite* was the twelve copies that were provided at one sitting; this had initiated an enthusiasm for collecting portraits to create albums of families. Simultaneously, the working classes began to have a say in running the country and to many, the possession of a self-portrait by the economical ferrotype process symbolised power and ownership.

In 1859 the newspaper *Wiborg* reported that a merchant's widow, Caroline Becker, had opened a portrait studio in Viipuri, and in the same year, Hedvig Keppler, the clockmaker's daughter, advertised in the *Åbo Underrättelser* newspaper to announce her studio in Turku. Trained in St Petersburg in the ambrotype process, she traded during the summer of 1860, "until the waters freeze." When she married a baker, Carl Fredrik Löfman, the couple moved to Salo and she terminated her photographic career.

Only large towns, such as Helsinki, Turku, Viipuri and Oulu (in the north), were able to support a business but the introduction of the cabinet photograph allowed studios to promote an alternative to the increasingly popular *carte-de-visite*. An apprentice scheme coped with the demand for assistants, many of whom were engaged to colour photographs by hand.

A Norwegian influenced Helsinki photographic circles when he set up his studio in the capital in the summer of 1877. Nineteen-year-old Daniel Nyblin had studied in Oslo and the United States, and had been running Riis's studio for two years. He quickly established a reputation for attractive poses which made use of studio accessories. For the next ten years, he photographed academics, civil servants, tradesmen, artists, citizens, artisans and the gentry, as well as many of the visitors passing through Helsinki *en route* to and from St Petersburg, and his cabinet-sized portraits of well-known people were successfully sold to the public. His cousin Georg enhanced the Nyblin reputation by opening a studio in Turku in May 1885.

Daniel Nyblin also pioneered the marketing of albums of photographs featuring Finnish life. Some of the photographs were reproduced from paintings, others were coloured by hand, and the sets proved to be popular in remote areas. Whilst travelling in Europe, Nyblin had become aware of the value of exhibitions and worked hard to unite amateur and professional photographers within the Amateur Photographic Club of Helsinki,

which had been founded in 1889. A successful exhibition was held in 1892 when 24 members exhibited 375 photographs, and soon similar clubs were established in Turku, Viipuri, Vaasa and Tampere.

Nyblin's pre-eminence was challenged in 1889 by the arrival of K E Ståhlberg, and by Christmas 1890, Ståhlberg adopted Nyblin's ideas and offered his customers photographs of the countryside. He printed them larger than the familiar cabinet-size urban views and they had immediate appeal. To consolidate his idea and increase the coverage of the country, he recruited travelling photographers, which included Into Kondrad Inha and Samuli Paulaharju. At the time, Finnish law required identification to be incorporated on the contact prints, details of author, studio, date and location of the photographs have survived. For indoor photography, Ståhlberg freed himself from the inferior natural lighting of Nordic winters by equipping his studio, the Atelier Apollo, with electric light in 1900.

In 1870, the Finnish Literary Society had awarded a scholarship to Reinhold Theodor Hausen to assemble a photographic record of historical monuments, and with the advent of dry plates, photography become an important aspect of the official expeditions, which explored and surveyed Lapland between 1877 and 1887. The Finnish Polar Expedition (1882—84) had a remit to study the northern lights at Sodankylå but no useful records were obtained by the expedition engineer, Karl Granit, on account of limitations in the materials and equipment.

The value of photography was further recognised in 1890 when Helsinki Observatory participated in an international study of the heavens and Anders Donner recorded the stars during the next twenty years. The success of an exhibition of photographs, staged by the Geographical Society of Finland in 1894, provided the basis for many important studies in the 20th century.

FISHER, GEORGE THOMAS (dates unknown)

The chemist George Thomas Fisher Jr. authored one of the early popular manuals on photography—*Photogenic manipulation, containing plain instructions in the theory and practice of the arts of photography: calotype, cyanotype, ferrotype, chrysotype, anthotype, daguerreotype, and thermography*. First published as a 50 page book in 1843 by George Knight of London, it ran to three editions in two years. In the following year, the book was translated into German and Dutch and editions published in Leipzig by Händel, and by Stenfert Kroese in Arnhem.

In 1845, expanded to 56 pages, the book was split into two sections, with section two dealing exclusively with the daguerreotype. Published in both Great Britain, by Knight, and the US by Carey & Hart of Philadelphia, it was even more successful than the original. In 1848, the book was completely rewritten by Robert Bingham, still using the title *Photogenic Manipulation*, Part 1 at 72 pages and part 2 at 58 pages, running to many subsequent editions into the mid-1850s.

In September of 1851, an article by Fisher appeared in the *Photographic Art Journal* on "Thermography—Electrical and Galvanic Impressions."

Little is known of Fisher's life except that he styled himself, at the time the first edition was published, as 'Assistant in the Laboratory of the London Institution.' Gernsheim (*Incunabula of British Photographic Literature*, 1984) states that the authorship passed to Bingham in 1848 after Fisher's death, but the 1851 article in the *Photographic Art Journal* would seem to question that.

JOHN HANNAVY

FISKE, GEORGE (1835–1918)

George Fiske was born to farming parents in New Hampshire, and trained as a banker in San Francisco, before turning his attention to photography. He is reputed to have joined Robert Vance and Charles Leander Weed—the first person to photograph in Yosemite as an assistant, and an assistant to Carleton E Watkins as well.

Fiske moved to Yosemite with his wife in 1879, devoting the remainder of his working life to studying and photographing the landscape, alongside Galen Clark, who had become the first Guardian when the national park was created in 1864. When Clark's book *The Yosemite Valley: Its History, Characteristic Features, and Theories regarding Its origins* was published by Nelson L. Slater in 1910, the majority of the illustrations were by Fiske.

Living in Yosemite all year round, he was the first to photograph the valley in winter, creating dramatic

photographs which sold widely. A house fire in 1904 destroyed many of his negatives unfortunately.

Fiske, reportedly 'tired of living,' killed himself in 1918, and but for the interest of the young Ansel Adams, many of his images might have been lost. Adams printed from the surviving large format negatives in the 1920s, and campaigned for their proper conservation but was ignored. The plates, stored in the attic of a Yosemite Park Company sawmill were destroyed in another fire in 1943.

JOHN HANNAVY

FITZGERALD, LORD OTTO AUGUSTUS (1827–1882)

Lord Otto Augustus Fitzgerald was a man of many talents. Apart from attending most high society parties and functions, he was also a composer. He composed a piece in the 1840s called The *Spirit of the Ball*. Fitzgerald married Ursula Lucy Grace Bridgeman, formally known as the Dowager Lady Londesborough, on December 14, 1861. Fitzgerald held numerous posts in his lifetime: he was a Lieutenant in the Lancashire Hussars, a Treasurer of the Household in 1866 and an MP for Kildare. Fitzgerald was also a founding member of the Dublin Photographic Society. Along with other keen photographers, Fitzgerald regularly attended meetings at the premises of Mr. W. Allen, a local chemist who resided at 48 Henry Street, Dublin. In 1854 the group named themselves the Dublin Photographic Society and Fitzgerald was appointed to be its President. He held this position for four years, from Nov. 1854–1858. From 1857 the society held exhibitions, which continue today. It is the second oldest photography society in the world, and many of its early members went on to immeasurably influence photography and its development. An example of Fitzgerald's own work is an image that he took and printed himself in the inaugural year of the society, entitled 'The Meeting of the Waters, Killarney.'

JO HALLINGTON

FIXING, PROCESSING, AND WASHING

The impetus for work on fixing, processing, and washing was motivated by the problem of image stability in photographs. From 1798 until 1839, Thomas Wedgwood and Humphry Davy, Joseph Nicéphore Niepce, William Henry Fox Talbot, and Louis-Jacques-Mandé Daguerre all encountered difficulties in fixing their photographic images. Yet the answer was established as early as 1777, when Carl Wilhelm Scheele published a dissertation on the chemical action of light, in which he observed that ammonia checked the light sensitivity of silver chloride. In 1819, John Frederick William Herschel discovered

Durieu, Eugène. Nude.
The Metropolitan Museum of Art, Gilman Collection, Purchase, Mr. and Mrs. Henry R. Kravis Gift, 2005 (2005.100.41) Image © The Metropolitan Museum of Art.

the solubility of silver chloride in ammonia hyposulphite. Herschel's published results (1821) led Joseph Bancroft Reade, in 1839, to test the properties of sodium thiosulphate in fixing silver chloride images on paper, and it has been suggested that Reade apprised Herschel of his work. In 1839, Herschel proposed sodium thiosulphate (termed 'hypo') as a photographic fixing agent and made his results known to Talbot. Like Daguerre, Talbot was fixing his photographs in a concentrated solution of sodium chloride, which inactivated the unexposed silver chloride but did not remove it, so that the photographs remained somewhat light-sensitive. But whereas Daguerre adopted hypo once he learned of Herschel's discovery in 1839, Talbot used potassium iodide and, later, potassium bromide to fix his calotype negatives, and only in 1843 did he try sodium thiosulphate, in a heated solution.

Sodium thiosulphate became the standard fixing agent for silver halide processes and was used for wet collodion negatives. However, the gelatin silver prints and dry plate negatives of the 1880s and 1890s carried thicker photo-sensitive coatings, and the action of the

fixer had to be more vigorous; an acidified fixer of ammonium thiosulphate was eventually substituted. When used with alkaline developers, this required an intermediate acidified 'stop bath.' Organic developers (such as pyrogallol, hydroquinone, and eikonogen) required an acidic clearing agent to eliminate fogging. In 1889, Alexander Lainer discovered that sodium bisulphite could be added to sulphurous acid for a one-stop fixing bath. Non-silver processes (such as cyanotype and platinum prints) require different fixing or clearing baths: cyanotypes are cleared in plain water, and platinum in a weak solution of hydrochloric acid.

The fixing of a silver image necessitates dissolution of the unexposed silver halides, which remain photosensitive after development. To stabilise the image, a chemical fixer is used to convert the halides into soluble silver compounds that can be removed by washing. Washing may not clear all residual silver complexes, or remaining fixer: the former may be stabilised by toning, while the latter requires a hypo clearing bath.

By 1855, it was recognised that silver photographs had poor archival permanence, and in May of that year both the Photographic Society of London and the Société française de photographie set up committees to investigate the fading of positive photographs. Both efforts had been inspired by Louis-Alphonse Davanne and Jules Girard, whose initial analysis was presented to the Société in March and April 1855. Contributions were also made by Baron Humbert de Molard, Eugène Durieu, Thomas Hardwich, Thomas Malone, and George Shadbolt. It was discovered that residual fixer carries sulphur compounds, which convert the metallic silver of the image to silver sulphide. Silver sulphide is yellowish in colour and has half the density of metallic silver, producing irreversible yellowing and fading in the image, particularly in the highlights and mid-tones. In 1866, John Spiller reported that in albumen prints, residual sulphur compounds in the egg-white coating exacerbated deterioration.

Sulphiding could be prevented by gold-toning, as discussed below, but also crucial was the proper removal of the fixing compounds, achieved by prolonged washing in clean water and the use of clearing agents. Many hypo clearing agents were suggested, with the most effective being a weak solution of sodium sulphate, or ammonia combined with hydrogen peroxide. Silver prints on paper typically require about an hour to wash out the fixer, although in 1855, Thomas Sutton recommended several hours for paper negatives, and up to twenty-four hours for positive prints. Numerous chemical tests for hypo were proposed, with potassium permanganate, mercuric chloride, and silver nitrate being the most accurate.

In 1840, Hippolyte Fizeau discovered that treatment of a silver photograph in a solution of gold chloride would partially replace and partly plate the silver particles, producing a stable silver-gold alloy. Toning often preceded fixing, but Fizeau combined both, using gold chloride and hypo in a ratio of one to three-hundred. Both alkaline and acid toning baths were used, and in the 1890s, combined toning-fixing baths were introduced for self-toning silver gelatin and collodion papers, with the addition of potassium and ammonium thiocyanate, or the substitution of lead acetate for the gold chloride. More recently, it has been established that there is a protective effect to residual silver sulphide, which is actually more stable than pure metallic silver.

The mechanics of fixing, processing, and washing influenced the design of studio and field darkrooms. However, the processing environment and problems of ventilation, consistent temperature and humidity, water supply, and contamination were largely unaddressed until the late 1880s, when industrial photographic printing works established large-scale, rapid processing and washing facilities.

FIZEAU, LOUIS ARMAND HIPPOLYTE (1819–1896)

French physicist

Fizeau was born in Paris on September 23 into a well established family. His father had been a professor at the Faculté de médecine de Paris, where he taught pathology since 1823. As a boy he spent his youth between Paris and the family property of Suresnes. With the end of his secondary studies at Stanislas college, during the years 1840, he worked many jobs, but Leon Bernard Foucault, who was independently weathly, enabled him to fully devote himself to the study of sciences such as medicine initially, then physics, and later optics at the Collège de France, where he attended the lectures of Victor Regnault, and at the observatory of Paris under the direction of François Arago. He was undoubtedly influenced by the surgeon Alfred Donné, who he knew through his friendship with Foucault. Fizeau became interested in the Daguerrian process, in which he made great efforts to become very quickly accomplished.

In August 1840 he presented, in front of the Académie des Sciences, his process to improve testing methods by covering them with a thin metal gold varnish, obtained by a dissolution of gold chloride mingled with soda hyposulphhee. This method, provided the advantages of considerably reducing the mirror effect of the daguerrian plates by raising the tone of the images, and of making the images more resistant to damage caused by friction, abrasions, and oxidations. This major innovation gave him recognition nationally and internationally within photographic communities. In 1841, Fizeau began working on an original method of engraving the daguerreotype, of which Sir W.R. Grove presented on the same topic that year at the London Electronical Society. Fizeau's method, however, combined the use of acid, fatty oil and gold, and enabled him to transform the plates into matrices for engraving.

In 1842, this complex process of engraving was used for three illustrations of the second volume of the *Excursions daguerriennes* celebrated in Lerebours' publication. The following year, after various improvements, Fizeau protected his invention through the use of a patent, and also that year, Claudet introduced the process in England. At the same time, Fizeau became interested in the reduction of exposure times and introduced in 1841, an accelerating agent similar to bromine, which enabled him to produce images in approximately 15 seconds. This solution was undoubtedly suggested to him by engraver Augustin-François Lemaître, who was the former collaborator of Niépce and Niépce de St-Victor. But Lemaître was not the only engraver consulted by Fizeau in his research. Fizeau collaborated with Louis Henri Brévière, the director of the engraving of Royal Printing works.

Until 1849, Foucault and Fizeau, probably encouraged by Arago, jointly worked together to find the exact analysis and the measurement of various photographic light sources. It was probably within this framework that they obtained on August 2, 1845, at the observatory of Paris the first daguerrian image of the Sun, in 1/60th of second. The following year, with other regular collaborators from the observatory, like N.P Lerebours and Secrétan, Fizeau published *Traité de photographie*. In 1847, he appeared at the head of the list of the "most remarkable daguerreotypists" determined by Thierry in his shortened general History of photography. In 1848, *Histoire générale abrégée de la photographie* awarded him a medal for his research.

At the same time though, the essence of his work in the field of photography seemed to be complete. His last known images, from the experiments of heliographic engraving done in collaboration with Lemaître and Hurlimann, went back to 1849, and this same year, Fizeau, abruptly ended his collaboration with Foucault. Both Fizeau and Foucault conducted research on speed determination based upon opposite theories. In 1856, the Institute awarded him the prize Triennal before electing him, and four years later, he became a member of the Academy of Science, general physics. For a time he was superintendent at the Polytechnic School of Paris, and was named, in 1875, as a foreign member of the The Royal Society, London, and decorated with the Legion of Honor the same year. In 1878, he became president of the Academy of Science and entered into the prestigious Bureau of Longitudes of the Observatory of Paris. His activities within the Academy proved that his interest for photography remained wholly intact at the beginning of the years 1870. For example, he brought to life the commission formed to observe the passage of Venus in front of the Sun and was, on this occasion, one of the defenders of the use of the daguerreotype for this event. A few years later, in 1887, he supported the photographic project of creating a chart of the Sky for the international congress of astrophysics of Paris.

In 1853, Fizeau married Thérèse Valentine de Jussieu, from a famous family of botanists. Together they had two girls and a boy. Following the death of his wife in 1863, he withdrew to the Château de Venteuil à Jouarre in the Seine and Marne. It was there that he died of a cancer on September 18, 1896. Four years earlier however, several of his images had been presented in the historical section of the International exhibition of photography of Paris. To reconstruct the exact photographic production of Fizeau would be difficult today for example, an image is made up of numerous daguerreotype plates,

some having been used for engraving tests, and tests on paper. The principal subjects photographed were, in addition to some monuments of Paris and of the Normandy coast, images of the Parisian roofs, or the residence of the street of Cherche-Midi, some scientific topics (Sun, reproductions of insect), but also, a number of portraits and reproductions of objects also caught Fizeau's interest.

His images are today, in Paris' Carnavalet museum, the museum of the national Academy of arts and trades, the national Bibliothèque nationale de France and the photographic archives of the Patrimoine. It seems that a part of the files and its collection disappeared in plundering from the castle from Venteuil, which happened during the First World War. Certain manuscripts, original work, and letters however were given in 1935 to the files of the Academy of Science by M.Ramond-Gontaud, but no photographs were included. A part of his collection was put on sale in London (E.P. Goldschmhet) during the 1950s which included in particular, more than fifty of images signed by Fizeau himself, such as the dedicated specimen of *The Pencil of Nature*, and 17 original tests of Talbot. For about fifteen years, several important sets of his daguerreotypes and engraving tests were sold to Chartres (Gallery of Chartres 3.12.89; 6.10.91; 7.3.93), Paris (Drouot, 12.12.97; Sotheby' S, 16.03.2002) and London (Sotheby' S, 27.10.99).

FLACHÉRON, COUNT FRÉDÉRIC A. (1813–1883)

French engraver and photographer

Jean François Charles André Flachéron (called Frédéric Flachéron) was born in Lyon on 26th October 1813. His father, Louis Flachéron, was a famous architect. On 31st March 1836 Frédéric enrolled at the Royal School of Fine Arts in Paris. In 1839 he won the second Great Prize of Rome for engraving on medals and semi-precious stones, but later decided to leave for Rome. He belonged to the French artistic circle and was especially close to the painter Ingres. Flachéron took photographs of Rome from 1848 to 1853 using the calotype process. He always signed and dated his salted paper prints. In the early 1850s at the Caffè Greco he often met other well-known photographers such as Giacomo Caneva, James Anderson, Eugène Constant. In 1851 at the Great Exhibition in London he showed seven panoramic views of Rome and won a medal. In 1852 he participated in the photographic exhibition held at the Society of Arts, London. He also kept in touch with an important collector from Montpellier, Alfred Bruyas (patron of Gustave Courbet), who was in Rome in 1846 and in 1848. Bruyas collected many photographic views of Rome by Flachéron, dated from 1848 to 1852. In 1866 Flachéron went to Paris with his family and he died there on 28 June 1883.

Silvia Paoli

FLORENCE, ANTOINE HERCULES ROMUALD (1804–1879)

Draftsman, painter, and typographer

Florence was born in Nice, France on 29 February1804 but passed his childhood in Monaco. As a young man he worked as draftsman, painter, typographer and later as inventor. He went to Brazil in 1824. He worked in the trade and in printing media, before taking share with Langsdorff, forwarding as draftsman from 1825 to 1829.

Baron von Langsdorff (1773–1853) who had the position of consul-general of Russia in Brazil hired him as an illustrator and topographic draftsman for an expedition in the Amazon. Florence was on the same boot as the German painter Johann Moritz Rugendaz en de French illustrator Adrien Taunay.

In 1830, he married the Brazilian Maria Angélica de Vasconcellos and settled in Vila de São Carlos, current Campinas (near to São Paulo) where he would stay till his death on 27 March 1879. His wife died in 1850 and left him 13 children. Four years later he married the German immigrant Carolina Krug with whom he had 7 children.

From 1830 on, Florence devoted himself to his numerous projects of invention. During the Langsdorff expedition, he had developed a new system of using musical notation to record the songs of birds and vocalizations of other animals, which he named "zoophonia." In 1830, when he was searching for a simplified way of printing his more than 200 illustrations performed during the Langsdorff Expedition, other than using expensive and time-consuming engravings on wood and metal (xylography and lithography). In 1830 he invented a new process, similar to the mimeograph, which he named "polygraphia," and began using this commercially in his printing office. In 1832, with the help of a pharmacist friend, Joaquim Correa de Mello, he began to study ways of permanently fixing camera

obscura images, which he named "Photographia." He developed a technique of visual representation on paper sheets that tiny holes bored into it, creating little light reflections. The originals were then placed in front of an opening and exposed to the light of the sun, inside an obscure part. Then, the image acquired was fixed as the external images projected in this camera. In 1833, they settled on silver nitrate on paper, in a process very similar to that developed by Niépce and Daguerre. Unfortunately, partly because he never published the invention adequately, partly because he was an obscure inventor living in a remote and underveloped province, Hércules Florence was never recognized internationally as one of the inventors of photography. He wrote a letter concerning "photographie" in his newspaper at the date of January 15, 1833. Five days later, he made a report of his first experiment with the obscure room but, unfortunately, none of the further images were successful. In 1842, he launched "O Paulista" the first newspaper in the State of São Paulo—and in 1858, "Aurora Campineira," the first newspaper of Campinas. His multiple talents drew the attention of the emperor Dom Pedro II (1825–1891) who visited him in 1876. Florence also wrote several books about his expeditions which were published in 1875.

FLOYD, WILLIAM PRYOR (active 1860s–1870s)

British photographer

Little biographical information, beyond his professional activities, is available for one of the most successful Hong Kong based photographers of the mid-1860s–70s. Floyd first appears in China in 1865, in the employment of the Shanghai photographers Shannon and Co, but by the following year he had transferred to Hong Kong to work as a photographer for Silveira and Co, whose business he acquired shortly afterwards. By 1868, trading under the business titles of both W. P. Floyd and Co. and the Victoria Photographic Gallery, he was advertising views of both Hong Kong and mainland China, but the bulk of his work was firmly based in the British colony. Contemporary reviews compare his work with John Thomson (some of whose negatives he appears to have acquired and marketed on the latter's departure in 1872) and while the range of his output was certainly more limited, he seems to have enjoyed similar commercial success. Portrait and genre studies apparently formed only a minor part of his output, which was predominantly focussed on satisfying (in the words of the *China Mail* of 8 August 1868), a 'common desire to obtain memorials of a locality in which some of the best years of our life have been passed.' A technically competent, if not unduly inspired photographer, Floyd's surviving work nevertheless provides an extremely valuable historical record of the colonial topography of Hong Kong, with a particular emphasis on the documentation of individual public and commercial buildings, clubs and European domestic architecture. Floyd left Hong Kong in 1874, his business and premises taken over by Emil Rusfeldt.

JOHN FALCONER

FLY, CAMILLUS SIDNEY (c. 1849–1901)

On October 26th 1881, a gunfight took place across the street from the studio of Camillus Samuel Fly in Tombstone Arizona. Although now known as the "Gunfight at the OK Corral," the gunfight between the Clantons and Wyatt Earp took place on some open land rather than in the corral itself. According to some eyewitness accounts, the photographer himself disarmed the wounded Billy Clanton after the gunfight was over. Fly had previously photographed Ike Clanton, Earp and Doc Holliday in his studio. His restored studio, displaying many of his images, is part of the OK Corral historical site.

Born in Missouri c. 1849, Fly moved to California as a child, and to Tombstone with his wife Mary immediately after their wedding in 1879, where they operated a photographic studio and a twelve room boarding house at 312 Freemont Street.

Fly photographed a meeting between General Crook and Geronimo and his Apache followers early in 1886, taking individual portraits of Geronimo, and groups of Indians and U.S. Cavalry. Some of his pictures were used as the basis of illustrations in *Harper's Weekly* in April 1886 (No. 1531).

The *Tombstone Epitaph*, in 1887 noted that "Mr. C.S. Fly, the well known photographer, leaves today for Florence, Phoenix and other points in the Territory" and that "during his absence, Mrs. Fly also an accomplished photographic artist, will conduct the gallery in this city as usual." Travelling in Mexico that year Camillus photographed the devastation after a major earthquake.

JOHN HANNAVY

FOCIMETER

Antoine Claudet (1797–1867) first demonstrated the Focimeter in 1849, and exhibited the instrument at the Great Exhibition in London in 1851. His Focimeter was one of three distinctively different instruments of the same name designed in the nineteenth century to perform different but associated functions. Claudet displayed the device as part of a group of instruments he had designed to enhance the predictability of the photographic process. Alongside the Focimeter, he showed his Photographometer, an early light measuring device, and the Dynactinometer which measured the relative powers of lenses. The Focimeter was developed as an aid to photographers in achieving perfect focus on the daguerreotype plate when using the achromatic lenses then currently employed in photography. In the words of the text accompanying the display of the instrument, Claudet wrote

> It is impossible to obtain well defined photographic pictures without previously ascertaining the exact position of the photogenic focus, which is easily done by taking the image of the focimeter on a photographic surface, and comparing the segments of the apparatus with the image, then on the ground glass and the photographic surface.

The narrow spectral sensitivity of the daguerreotype plate meant that chemical and optical focus did not always coincide when using optics which were not fully corrected. Alongside the instrument itself, Claudet exhibited a group of daguerreotypes demonstrating *the differences between the visual and photogenic focus and their variation*, underlining the effectiveness of the Focimeter in achieving perfect chemical focus.

The instrument consisted on a series of numbered 'flags' located radially around a short pole. The Focimeter was set up at the subject position, and the pole aligned along the axis of the taking lens. The flags were separated along the pole at fixed distances, and the camera was focussed on the central one, usually numbered '4.' The exposed and processed plate was checked to ascertain which of the flags was most precisely in focus. If flag 4 was sharpest, then a fully corrected lens was in use. If flag 4 was not the sharpest, then the difference between optical and chemical focus could be ascertained by checking the distance between flag 4 and the sharpest flag.

Michael Faraday gave the same name to a device he designed in 1860 for Trinity House—the body responsible for British lighthouses—to test the precision of lens manufacture and the accuracy of lens and lamp alignment in lighthouses. His Focimeter was made for him by William Ladd, the London-based optical instrument and microscope maker, and the device greatly increased the effectiveness of lighthouse beams.

By the end of the nineteenth century, a third device had emerged, once again being normally referred to as a 'Focimeter.' The origins of this third 'Focimeter' can be traced back to Thomas R Dallmeyer's 'Focometer' which was an optical test bench designed to ascertain lens focal length and check the extent to which aberrations had been corrected. It is unclear when 'focometer' gave way to 'focimeter' as the normally used term.

A sophistication of that device, for measuring the strength and characteristics of ophthalmic lenses, is now an established tool of the science of optics, and 'focimetry' or 'focometry' is a branch of that science.

JOHN HANNAVY

FOCUSING

Ensuring precise focus has always been one of the fundamental challenges of photography. However, the ability to focus an image on to a surface predates photography by centuries.

While the earliest descriptions of the *camera obscura*, in use since the eleventh century, did not include a means of focusing the image, by the late 18th century, the focusing camera obscura was a relatively common artist's tool. While some camera obscura designs included a limited facility to focus the lens, the majority were, like the much later 'box camera' of fixed focus construction—being focused on infinity. By the years immediately preceding the invention of photography, however, the typical camera obscura was, like the early production models of photographic cameras, of sliding-box construction with two boxes sliding, one inside the other, to enable the operator to select the required plane of focus.

On the focusing camera obscura the larger box, the camera body, normally contained the viewing screen, while a sliding lens box moved in and out of the front. With the photographic camera, however, the design was generally reversed, with the lens panel and camera body (the larger box) remaining fixed to the tripod while the rear box carrying the focusing screen and sensitive material was moved in and out to achieve precise focus. Once focus had been achieved, the two boxes were 'locked' together with a thumbscrew. That was the design adopted by Alphonse Giroux for the first production model of the daguerreotype camera in 1839, and one which dominated camera design in the early years, despite its bulk.

There were, however, several cameras in which the box carrying the lens was movable—including one of the first cameras to be fitted with a focusing scale, designed by George Smith Cundell in 1844.

In contrast, several of Henry Fox Talbot's first and smallest cameras—his 'mousetraps'—were of fixed focus designs, although others did incorporate lenses which could be focused in a sliding sleeve.

One of the first cameras to be fitted with a mechanism for assisting precise focusing—focus being adjusted by

Clifford, Charles. Courtyard of the House Known as Los Infantes. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Mr. and Mrs. Hentry R. Kravis Gift, 2005 (2005.100.504.46) Image © The Metropolitan Museum of Art.*

a rack and pinion system and checked with a magnifying glass—was Voigtländer's all-metal camera design of 1840. Fitted with Petzval's remarkable f3.7 doublet lens, and taking circular daguerreotypes of 80mm diameter, this camera was, probably, the first camera to permit truly precise control over focus. The considerably reduced depth of focus afforded by the faster lens, of course, made precise focusing a much greater necessity than the smaller aperture lenses used on other, larger-bodied, contemporary cameras.

Voigtländer's rack and pinion focusing system reappeared on the Bourquin daguerreotype camera of 1845—as did Petzval's doublet portrait lens.

During the 1840s, it became normal for cameras designed for external use to be focused by simply sliding the box. For studio cameras, with their faster lenses and larger apertures, where more precise focus was desirable, the camera would first be crudely focused using the sliding box, then fine focused using either a rack and pinion adjustment on the lens barrel, or a simple helical device.

A radically different approach was that taken by Alexander S Wolcott, whose camera design eschewed the whole idea of a lens in favour of a concave mirror—a system used in generations of reflecting telescopes. The mirror, fixed inside the camera body, collected the light rays and focused them on to a small daguerreotype plate—never bigger than 1/9th plate. To achieve sharp focus, it was the plate carrier that was adjusted along a sliding track inside the camera body.

George Knight marketed a variation on the 'American Camera' in the early 1840s, the two sliding boxes being of sufficient length, when extended, to enable 1:1 focusing. Knight's catalogue described the camera as offering "great variation in the length of focus and may be used for copying daguerreotypes where the focus is required to be the same length as the object to be copied is distant from the object glass."

With the introduction of bellows in the 1850s, rack and pinion focusing along baseboard rails eventually became the norm—with some cameras offering lens panel focusing and others adjusting the focus by moving the back panel. By the 1860s, cameras appeared permitting adjustment on either standard.

The introduction of lens designs offering variable apertures—designs by Waterhouse, Quinet, Chevalier and others were introduced in the 1850s and 1860s—gave photographers hitherto impossible control over the depth of field, and thus gave them control over the plane of focus itself. It was 1886, with the introduction of Lancaster's *Rectigraph* lens of 1886, before a lens with an iris diaphragm was first widely marketed.

With the introduction of enlargers, and the progressive reduction in negative sizes towards the end of the 19th century, the establishment of precision in focusing became paramount.

Technical issues of image sharpness occupied a disproportionately large part of critical reviews of early photography—where the creation of pinpoint sharpness in all planes of the image was deemed an essential. Photographers with their blue sensitive plates initially struggled with understanding key issues about the difference between optical and chemical focus, but as the art matured, and pictorial ideas about soft focus, or selective focus, rather than sharp focus became talking points, the challenges which faced photographers expanded.

In this more mature environment, focus became something the photographer could control, adjust and

adapt to suit the artistic or creative requirements of the photograph.

One of the first to put this new approach into practice—albeit by accident according to her son—was Julia Margaret Cameron. Writing in her brief biographical manuscript *Annals of My Glass House* in 1874—of her first 'success' in photography almost a decade earlier—she recalled that "when focusing and coming to something which, to my eye, was very beautiful, I stopped there instead of screwing on the lens to the more definite focus which all other photographers insist upon."

The Cuban-born Peter Henry Emerson took matters yet further, proposing that only the central subject of the photograph should be in sharp focus, the remainder being allowed to recede into a softer focus to draw the viewer to the picture's central purpose. 'Naturalistic Photography,' as proposed by Emerson, sought to replicate the manner in which the human eye—and therefore the photographer himself—saw the scene while contemplating photographing it. "In this mingled decision and indecision, this lost and found" he wrote, "lies all the charm and mystery of nature."

FOELSCHE, PAUL HINRICH MATTHAIS (1831–1914)

Australian police inspector and amateur photographer

Foelsche was born in Germany on 30 March 1831. Shortly after migrating to Adelaide in 1854, he enlisted in the mounted police. In 1869, Foelsche was commissioned to lead a new force at Palmerston (Darwin) where he developed an enthusiasm for wet-plate photography. An avid contributor to International exhibitions, his entries received a number of awards. Foelsche retired from the police force in 1904, and died in Darwin on 31 January 1914.

Foelsche developed an enthusiasm for wet-plate photography and scientific collecting following his appointment as the Northern Territory's first police inspector in 1869. Most active between 1873 and 1896, he produced over 500 images of the colony and its Aboriginal peoples initially for International exhibitions, but later in the making of photographic albums.

His accomplishment and range extended with his change to the dry-plate process: from buildings and industry to picturesque scenes of rivers, escarpments and remote settlements. His portraiture became increasingly influenced by the new science of anthropology and is comprised of over 300 plates and accompanying records of Aboriginal people.

TIMOTHY SMITH

FONTAYNE, CHARLES H. (1814–1901)

At the Great Exhibition of 1851 at London's Crystal Palace, a panorama of the Cincinnati waterfront was exhibited. Comprising eight separate whole plate daguerreotypes, the panorama measured over five and a half feet in length, and was of a quality so high that historians have been able to identify every vessel moored along the banks. The panorama was photographed across the river from the rooftop of a building in Newport, Kentucky, by Charles H Fontayne and William Southgate Porter (qv) in September 1848.

The two photographers had resumed a partnership earlier that year, after Porter had moved from Baltimore where, from 1844 until 1846, they had operated a successful studio at 268 Baltimore Street.

Fontayne, who had first practised photography in 1841, left the Baltimore studio in early 1846, moving to Cincinnati where he worked on his own until Porter rejoined him in his studio at 30 West 4th Street.

He was working on his own by 1854, when he offered a reward in *Humphrey's Journal* for the return of stolen cameras, and in the following year he claimed to have produced the world's first life-sized photograph. By 1856 he was at Ryder's Gallery, Cleveland, Ohio.

In the 1860s he developed equipment for the large-scale production of prints, and dryers for completing the process.

Still active in the 1890s, he claimed that in the 1840s, he had been suffering from consumption, until the chemical fumes apparently cured him. He died in Clifton New Jersey in 1901, after several years of working in New York.

JOHN HANNAVY

FORBES, JAMES DAVID (1809–1868)

English physicist and glaciologist

James David Forbes was Professor of Natural Philosophy at the University of Edinburgh from 1833 to 1859

and Principal at the University of St Andrews from 1859 until his death in 1868. In 1838 he was awarded the Royal Society's Rumford medal for his discovery of the polarization of radiant heat; his later research, on glaciers, earned him the sobriquet "explorer and surveyor of the Alps."

Forbes's importance for the history of photography lies in his contacts with the inventors of the new art. On 27 February 1839, Talbot sent Forbes a "lace specimen of Photogenics," together with two pieces of prepared paper. Three months later, within the space of a few days in May, first in London and then in Paris, Forbes saw specimens of Niépce's heliographic process and examples of Daguerre's plates. Forbes was in fact one of the first British scientists to see Daguerre's photographs, and he described the experience in detail in his journal and in a letter to his sister. The day after he met Daguerre, Forbes met Isidore Niépce, who explained his father's process "circumstantially and … no doubt correctly."

GRAHAM SMITH

FORRESTER, BARON JOSEPH JAMES DE (1809–1862)

English

Joseph de Forrester was a port wine merchant, artist, antiquary, and author, who went to Portugal in 1831 to work in the port business, eventually revolutionizing the production methods. His important work in surveying the Douro River helped make it more navigable—a further aid to the wine-shipping trade. He published *Portuguese Scenery with Illustrative Notes* in 1835 and *The Portuguese Douro and the Adjacent Country and So Much of the River as Can Be Made Navigable in Spain* in 1848. He illustrated these works with his own lithographs and maps.

He became a partner in the firm Offley and de Forrester and was made a Baron by the Portuguese Government in recognition of his work in promoting the port trade with Britain.

He started making calotype views of the River Douro and the surrounding areas in the early 1850's as an aid to his survey of the river. In all he is known to have made at least 220 photographic studies.

He was a member of the Photographic Exchange Club and the Photographic Society, as well as the Society's select dining club.

He drowned in his beloved Douro river, near the Ponto do Cachuo rapids on 12th May 1862, his body was not recovered but a tombstone was erected in his memory at the Anglican church of St James at Oporto.

IAN SUMNER

FOSTER, PETER LE NEVE (1809–1879)

English barrister, mathematician, keen amateur scientist, and early photographer

Peter le Neve Foster was one of a small group of men who met informally in each other's houses from c. 1847 to share their early enthusiasm for photography. Now often referred to as the Calotype Club, the group included Peter Wickens Fry, Frederick Scott Archer, Hugh Diamond, the engineer Charles Blacker Vignoles and others.

Born in Lenwade, Norfolk, in 1809, and called to the bar in 1836, Foster subsequently met Roger Fenton, and with their shared interests in both the law and photography the two men's association lasted many years.

Foster was one of the moving forces behind the restructuring of the Royal Society of Arts in the 1840s, serving as its Secretary for 25 years. With Fenton and others, he was one of the organisers of the first exhibition of photographs held at the Society, in December 1852.

He was a founder member of the Photographic Society of London in January 1853, and served on its first Council. He would later also serve as a member of the group sent by the Society to negotiate with William Henry Fox Talbot for the relaxation of his calotype patents for amateur photographers.

JOHN HANNAVY

FOUCAULT, JEAN BERNARD LEON (1819–1868)

Jean Bernard Leon Foucault was born in Paris on September 23, 1819, son of Fortuné Foucault, editor and bookseller, and Nicole Lepetit. The family settled in Nantes and remained there until the beginning of the 1830s, then moved to Paris. In 1834, the father, suffering a mental illness, was admitted to a hospital and died in 1839. This family history partially explains why Foucault never married. His interest in science and technology was evident as a young person. As an adolescent he seemed to have built scientific toys, revealing an early a taste for instruments and scientific experiments based on scientific facts.

In Paris, Foucault was registered with the Stanislas College where he showed little enthusiasm for his studies. Due to poor health, he studied with a tutor. During this period, he became friends with another pupil of the college, Hyppolite Fizeau, with whom he invested from 1844 to 1849 the majority of his research in the field of photography and whose courses offered more than one similarity to his.

After receiving his baccalaureate, Foucault directed himself towards medicine. He wanted to become a surgeon, but his phobia of blood eliminated that initial

vocation. During this period he met professor Alfred Donné, whom he followed to the Medical school and attended microscopy courses, before becoming a professor there himself. The two men remained very close. In 1845, Foucault succeeded Donné as the scientific writer of the *Journal des Débats*.

Since 1839, Donné had an interest in the daguerreotype and its possible applications in the field of medicine. Undoubtedly under his influence, Foucault started work on the technique and, according to his biographer Cornu, "built an apparatus from his hands." With Donné, he attempted to take daguerreotypes of enlarged globules from 20 to 400 times actual size by using a solar microscope-daguerreotype. Summarizing several years of work, these images appeared in 1844 in *l'Atlas du cours de microscopie*. The edition included 80 plates based on daguerreotypes taken by Foucault, and were published in 4 successive editions. The same year, the two men presented their photoelectric microscope, used by Donné at the time of its conferences.

In parallel, in collaboration with another doctor, Doctor Belfield-Lefevre, Foucault undertook research on the sensitive layers of the daguerrean image. In August 1843, the two men spoke in front of the Academy of Science of Paris on the preparation of the sensitive layer that received the image, and again in October 1846 noting the process that made it possible to reproduce, with equal perfection, the brilliant and obscure tones of the model.

It is hard to determine with certainty the date of the beginning of Foucault's collaboration with Fizeau. In 1841, an echo of previous searches, Foucault developed one slide with bromine allowing an application of uniform bromide. However, in April 1844, Foucault and Fizeau agreed for the first time to speak in front of the Academy of Science (research on the intensity of carbon light). Until 1849, probably encouraged by Arago, they jointly continued their experiments to analyze and measure the light required and involved particularly in the phenomenon of the interferences between two rays of light and in the action of the solar spectrum on sensitized surfaces. On August 2, 1845, they obtained at the Observatory of Paris the first daguerrienne image of the Sun now known in Paris as CNAM.

Their research became more directed towards the questions of pure physics in particular, relating to the determination the speed of the light. In 1849, an estrangement between the two men put an end to their collaboration. This same year, Fizeau determined the speed of light and Foucault determined the relative speed of light in air and water. Soon after Foucault presented a photoelectric apparatus to the Academy of Science, and continued to be interested in various questions related to optics as on the first stereoscopic process.

His activity in the field of photography slowed down; however, Foucault continued his work in the field of physics. In 1851, he built his famous "pendulum" making it possible to highlight gravity. The experiment received the recognition of his peers and he became an international celebrity, starting a true "pendular fashion."

Four years later he was appointed to a recently created position at l'Observatoire de Paris, where he was responsible for the study of the sun and the construction of new instruments to observe it, and tried with little luck to develop the ability to photograph it. In 1862, he was named a regular member of the prestigious Bureau of Longitudes and a foreign member of the Royal Society, London from which he had received in 1855 the Copley medal. In 1865 finally, he was elected as a member of the Academy of Science of Paris, (section of mechanics), of Berlin. Every Thursday morning, his scientific discussion would attract off the street of Assas the national and international scientific celebrities who would discuss scientific matters in his living room.

Even if his activity as a photographer seemed to be finished, his interest in photography and questions regarding optics remained. In 1854, he became part of the founding members of the Société française de photographie and became a member of its board of directors. He remained in this position until his death in 1868. In 1860, he was sent to Spain to photograph, on behalf of the Observatory of Paris, the total solar eclipse. Two years later, he developed a heliostat for photographic enlargement, which was built by his son-in-law, the Dubosq optician. Suffering since 1861 from incurable and progressive paralysis, he died in Paris on February 11, 1868.

His photographic production now known, consisting of daguerreotypes of Paris and a still life of a bunch of grapes, is extremely small, with the exception of the scientific images concerned with the Sun and microscopy. In the public collections today, this work is mainly preserved at Paris, the Société française de photographie, and the musée du Conservatoire national des arts et Métiers.

FOWKE, FRANCIS (1823–1865)

Captain Francis Fowke, RE, was a captain in the Royal Engineers, but is primarily remembered as an architect. He planned the International Exhibition in London in 1862 and was responsible for the original designs for, amongst other buildings, London's Albert Hall, Edinburgh's Royal Scottish Museum, and London's Natural History Museum, although that was modified and completed after Fowke's death by the eminent architect Alfred Waterhouse. Fowke also designed the first phase of London's South Kensington Museum, which evolved into the V&A.

Fowke's interest in photography brought him to use the medium to record aspects of the construction of his buildings, and images survive showing such aspects as the testing of the strength of new cement used in the construction of brick arches during the construction of the South Kensington Museum.

That interest in photography can be traced back to the early 1850s, and by 1856 he had designed and patented a novel compact folding camera for his own use. The camera was used by several military, and government-employed, photographers. It was later manufactured and marketed by Ottewill as an ideal instrument for the travelling photographer, due to its ability to be collapsed into a very compact form. Built of teak, the solid wooden design, however, was superseded by Kinnear's lightweight design using folding bellows.

JOHN HANANVY

FOX, EDWARD (1823–C. 1899)

British landscape and architectural photographer

Fox was born, probably in London or Sussex, England in 1823. He was the eldest of four brothers. His mother, Sarah, was a milliner. His father, also named Edward, was a painter and printmaker of picturesque landscapes who specialised in views of Brighton and its surrounding topography. Edward Fox senior exhibited paintings frequently at the Royal Academy from 1813, and at the British Institution from 1820, until the early 1850s. The young Edward followed his father in the arts and is listed in the 1851 census at the family address in Middlesex Street, St. Ann's, Sussex, as a "decorative painter." However, by 1861 the census lists him in Brighton as an "artist-designer, photographer." His earliest known photographs are calotypes dating from around 1856.

Fox took as subjects many of the local scenes of Brighton and the outlying villages, towns and landscapes painted by his father. In Brighton he photographed the street scenes, fishing boats and fisher-folk on the beach, shops, civic buildings, hotels, churches, the Theatre Royal and the Royal Pavilion. These images constitute the earliest comprehensive photographic survey of the town and are important historical documents. He also made many calotypes of a picturesque character in Sussex localities such as Mayfield, Bramber, Shoreham, Ditchling, Preston, Battle, Rottingdean and Chichester. Up until around 1860 he printed on albumen paper from calotype negatives and thereafter began using wet collodion on glass negatives. He used various sized negatives ranging from 12.7 × 10 cm (5 × 4 in); 17.8 × 22.8 cm (7 × 9 in); 21.6 × 28 .5 (8.5 × 11.25 in) and 16.5 × 19 cm (6.5 × 7.5 in). A series of views of Brighton's Marine Parade, King's Road and beach exist trimmed to a panoramic format.

Sometime in the early 1860s he set up a photographic business at 44 Market Street, Brighton from where he promoted himself as a "Landscape and Architectural Photographer" as the stamp on some of his prints shows. He registered the copyright of many of his photographs from 1862. Some of these are reproductions of paintings. However his commercial activity encompassed work of a primarily documentary nature of local interest and also artistic photography. Some of Fox's architectural photographs appear to document the recent completion of buildings. It is possible that these were made as sources for engravings or lithographs in the architectural press. An auction announcement for the sale of the villa and gardens of Queen's Park estate Brighton, 1863, is illustrated with lithographs credited as from photographs by Fox (V&A Photography Collection files). He also issued stereographs and topographical cartes-de-viste. These reveal his eye for newsworthy subjects. In 1860 he photographed the beached hull of the French brig *Atlantique* of Nantes which was wrecked off the Albion Hotel, Brighton. At the marriage of the Prince of Wales in 1863 he documented Brighton's Market Street decked out with bunting. Fox must have hoped that these and other subjects, in accessible stereograph and carte-de-visite formats, would have a wide commercial and local appeal. Presumably he sold many copies but very few examples have since come to light.

Fox's more artistic intentions are shown in what appears to be a personal album (private collection, London) made around 1864. It shows the village of Mayfield, its half-timbered buildings, the ruins of the archbishop's palace and scenes of haymaking, evocatively inscribed "E. Fox. Studies of Effect." His ambitions of this kind were captured most fully in his "instantaneous photographs" of sea and sky made in an oval format in 1865. Gustave Le Gray had pioneered the notion and image of the instantaneous photographic seascape during the mid-1850s in France yet few British photographers met the challenge as well as Fox. It is likely Fox's seascapes that were shown at the Photographic Society Exhibition in November 1869 and described by the *Photographic Journal* (vol. XIV, 172) as "Foreground and Cloud studies."

Perhaps Fox's most significant contribution to art was his systematic study of trees published as: *The Anatomy of Foliage. Photographed examples of the principal forest trees, each taken from the same point of view in winter and in summer; enabling the student to trace the limbs when hidden by the masses of foliage. Arranged by Thomas Hatton. Photographed by Edward Fox*. The set was issued from 1865 to 1866 in eight monthly parts each containing one pair of plates. The sixteen photographs consist of eight pairs of trees: *The Oak, from Friar's Oak, Clayton Sussex; The Elm, from St. John's Common, Sussex; The Sycamore, from the Valley of Preston near Brighton; The Horse-Chestnut, from the Rectory, Clayton, Sussex; The Spanish-Chestnut, from Buxted Park, Sussex; The Beech; The Ash* and *The Lime*.

The *Brighton Gazette* (23 November 1865) noted in its perceptive review of *The Anatomy of Foliage*:

> The principle puzzle in sketching trees from nature was *what to leave out* … Now here the photographic art has the advantage. The photograph *leaves out nothing*. It gives at once multiplicity and mass: it shows the general distribution of light and shade without losing detail. It is true that hitherto photographs of trees have not been satisfactory. From the tremulous character of the sprays … the clearness of the foliage has been lost and a black, unmeaning mass has often been the rendering of the most beautiful and delicate tracery. But the art advances. Our townsman, Mr. Fox, has done wonders … And in the summer just gone by the same enchanter has compelled the monarchs of the forest to stand before his magic lens and deliver up their treasures.

The work was deemed exemplary for students for "the details, if examined with a lens, are of the most minute description, showing the very veins in the leaves of the horse chestnut and the spine on its fruit." The review went on to record "the fact that the work is in use at the Government School of Art at South Kensington is an evidence of the estimation in which it is held by some of the highest authorities in the kingdom." The Department of Science and Art purchased two copies in October 1865 for £3.0.0 from Hatton who sold the prints for Fox from his premises at 3 Ship Street, Brighton. As well as being invaluable documents for the draftsman the photographs were also exhibited and praised in their own right. They were shown at the soirée of the Photographic Society of London, King's College, in June 1866 as studies of trees, "in and out of leaf" (*Photographic Journal* vol. XI, 67).

Fox participated in a number of the exhibitions of the Photographic Society of London, showing mainly views of Brighton and its surroundings, in 1863, 1864, 1876, 1877, 1878 and lastly in 1880. By the 1890s his photographic activity appears to have stopped. On 4 June, 1892 he placed a notice in the *Brighton Herald*: "Mr. E. Fox, Artist & Landscape Photographer (Late of 44 Market-street), has removed to 15 Havelock Road, Preston Park, where he respectfully solicits a Visit from his old Friends and others to inspect his collection of oil paintings and original photographs, which he is desirous of disposing of at exceptionally low prices. On view from 10 to 5 daily." At the age of seventy-nine, Fox was clearly taking stock. The exact date of his death is not known.

Martin Barnes

Biography

Fox was born, probably in London or Brighton, England in 1823. His father, also named Edward, was an artist who specialised in views of Brighton and its surrounding topography. The young Edward followed his father in the arts and is listed in the 1851 as a "decorative painter." His earliest known photographs are calotypes dating from around 1856. Fox took as subjects many of the local scenes of Brighton and the outlying villages, towns and landscapes painted by his father. Around 1860 he began using wet collodion on glass negatives and set up a photographic business at 44 Market Street, Brighton where he promoted himself as a "Landscape and Architectural Photographer." His commercial activity also encompassed local views of a documentary and topographical nature which he issued as stereographs and cartes-de-vistes. In 1865 he made "instantaneous photographs" of sea and sky in an oval format. Between 1865 and 1866 he issued *The Anatomy of Foliage*, pairs of photographs of trees taken from the same vantage point in summer and winter. These were devised as aids for students of drawing and were used by the government school of art.

FRANCE

Photography began in France as early as 1816 when Nicéphore Niépce, wrote to his brother Claude, about his success of fixing on white paper images of his garden's aviary. That was, as he himself said, still a defective process of which no prints remain. The objects appeared

Le Gray, Gustave and Auguste Mestral. The Ramparts of Carcassonne. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Harriette and Noel Levine Gift, 2005 (2005.100.34) Image © The Metropolitan Museum of Art.*

white on a dark background. Nevertheless Niépce wrote, underlining his faith in his research that, "something could be changed in the way of arranging colors." Using the *camera obscura*, he made in his text a direct parallel with engraving and painting and even used the word "picture" [tableau] to characterize his first trial. After many tests made between 1816 and 1824 he obtained on metal and stone the first images from his house's window, which he called *héliographie*s (*The View from Le Gras Window*, 1827, Austin, University of Texas). Jacques Louis Mandé Daguerre heard, possibly from the optician Chevalier, of Niépce's trials. Daguerre, a skillful stage designer, and successful inventor of the *diorama*, had been trying for some years to stabilize images that became visible within the *camera obscura*. Perhaps because of the many differences between them, they didn't work cooperatively earlier with each other as Niépce thought Daguerre suspicious, however the two men began a venture in 1827. Unlike Niépce who was in search for reproducibility and whose model was engraving, Daguerre was keen to achieve precision and clarity. The quest for a precise print remained his *motto* after Niépce's death in 1833; he conducted their first researches alone at first, and then after 1836 with the young architect Eugène Hubert. Daguerre's work remained quite hidden despite rumors within artistic circles.

In 1838, he sought support for his new invention and started to show his first images made on silvered copper plates made sensitive to light after exposed to iodine salts. Daguerre called these images "daguerreotypes." He quickly gained the support of François Arago, a physicist, and member of the French Academy of Science and delegate to the Chamber of Deputies. Daguerre's prints raised Arago's enthusiasm, saying "Mister Daguerre's invention offers a great interest for its newness, its artistic usefulness, the rapidity of its execution and for its valuable resources that will soon be borrowed by science (...)" (François Arago, *Report to the French Chamber of Deputies,* July, the 3rd, 1839). Arago's first announcement of *daguerréotype* at the French Academy of Science the 7th of January 1839 remains the official birthdate of photography in France as in the rest of the world. By revealing his discovery on this day, he preceded England's William Fox Talbot who was carrying on his own experiments on paper.

Nevertheless such an announcement within the scientific circle had long lasting effects on France's photographic reception. Even though some months later (the 19th of August 1839) Arago made a thorough presentation of daguerreotype in front of the two French Academies—one of Science and the other of Fine Arts—the latter maintained some distrust toward photography.

Despite Daguerre himself belonging to mainly just artistic circles and Niépce to none, daguerreotypes and later negative/positive photography were considered scientific inventions, both under political, psychological and aesthetic matters. It had been disclosed by a physicist that Arago and Daguerre simplified Daguerre's process as much as possible for other users and in doing so reduced the operator's involvement. "Images came by themselves in the *camera obscura*" wrote Daguerre in 1838. Such a statement could not have been worse in a society where artistic achievement was based upon the artist's mind and not his hand. Photography had become almost mechanical. Last but not least the precision of the daguerreotype eliminated the need for

most scholars. The clear metallic plate succeeded in reproducing every detail. Enhancing both the main and unwanted details of the subject went against the pictorial theory of sacrifice. A long story of uncomfortable relationships between artistic institutions and photography had then been opened. Photographers had to wait until 1859 to see their works be shown at the perimeter of the official Salon in Paris. Meaningfully, photographs have been admitted into the French Academy of Fine Arts since only 2006.

Indeed such an opinion was not shared by everyone and did not prevent the new invention from developing quickly in France thanks to its wide-spread availability since Daguerre and Isidore Niépce were funded by the French State for their invention. At the beginning of the 1840s, daguerreotypists opened studios in Paris (around ten in 1841, mostly in the Palais Royal area) and in the major cities of Camille Dolard in Lyon, Desmonts in Marseille, Finck in Strasbourg. Some Academics even showed their interest in photography. If Paul Delaroche's too famous sentence is not true ("From now painting is dead!"), then his opinion toward daguerreotype was indulgent, if not enthusiastic. As Arago reported: " Line's accuracy,," Mister Delaroche said, "and form's precision are as consistent as it could be thanks to Mr. Daguerre 'drawings' [*dessins*] (...) Painters found in the new process a quick way to create a whole collection of sketches they could not get otherwise without time and patience" (Arago, op. cit.).

In September 1839 Horace Vernet and Frédéric Goupil-Fesquet sailed to Egypt; the optician Lerebours had given a camera and daguerrian products to Fesquet. Unfortunately all the plates he made are lost today. From 1842, Lerebours published in two volumes *Les Excursions daguerriennes* [*The Daguerrian Excursions*] with plates engraved from daguerreotypes. Arago's dream, to reproduce accurately all the world's marvels, came almost to life just few a years after his announcing his plan. Jules Itier, Joseph Philibert Girault de Prangey, and the Baron Jean-Baptiste Gros were among the passionate amateurs who practiced daguerreotype and made beautiful plates on their trips to China and around the Mediterranean Sea. Stanislas Ratel and Louis Choiselat traveled the South of France in the mid-1840s. Durig their traveling they took outstanding panoramic views of cities and countryside. Their panorama of Toulon Harbor made of five daguerreotypes was the first photograph made of famous roads.

Daguerre's acknowledgment by the French State established the daguerreotype as the first photographic process and left the other researches in the shadows. Hippolyte Bayard showed his first direct positives on paper to Arago in May 1839. The faithful Daguerre's supporter seemed to have ignored them. In July Bayard took part in a charity show in favor of Martinique. After seeing Bayard's tests Raoul-Rochette, secretary of the French Academy of Fine Arts, was far more enthusiastic in his support of Daguerre's invention: "Mister Bayard's drawings look like old masters drawings, beautifully used by time." (Désiré Raoul-Rochette, "Académie Royale des beaux-arts, rapport sur les dessins produits par le procédé de M.Bayard" ["Royal Fine Arts Academy, Report on drawings made thanks to Mr. Bayard's process"], *Le Moniteur universel,* November, 13th. 1839, 2009–2010).

An important factor in developing images was paper smoothness, which appealed to Academicians. They were also attracted to an image built upon light and shade. Bayard himself, Humbert de Molard, Blanquart-Evrard researched on paper during the 1840s. The latter managed to perfect Talbot's process around 1844. Blanquart-Evrard's own calotype formula spread in France from 1847 among artistic circles. Artists were drawn to the process for its closeness to engraving, thanks particularly to image reproduction. Several painters from Paul Delaroche's studio—Gustave Le Gray, Charles Nègre, Henri Le Secq—were among first adepts. Le Gray played a central role in the diffusion of photography among Parisian artistic circles. Many of the first French calotypists had been his pupils in his Barrière de Clichy's studio from 1849–1850, like Maxime du Camp, Joseph Viguier, and Alexis Lagrange. Léon de Laborde, an archeologist, and curator for sculpture at the Muse du Louvre, had also been his pupil. Impressed by the quality of prints Le Gray showed at the 1849 *Exposition des Produits de l'Art et de l'Industrie* [*Industrial and Fine Arts Products Exhibition*], de Laborde had been one of his active supporters among cultural circles. In Sèvres, in the West suburb of Paris, Victor Regnault—director of the French China Manufacture—and Louis Robert—head of painting studios—led one of the most active and creative groups working on photography during the Second Empire.

In 1851 the first photographic institution was born. The precise role of the Société héliographique [The Heliographic Society] was not easy to define. Nevertheless the association which gathered painters (Eugène Delacroix, Jules Ziegler), architect (César Daly), critics (Champfleury, Francis Wey, Léon de Laborde) and photographers (Gustave Le Gray, Henri Le Secq, Charles Nègre, Maxime du Camp, Edouard Baldus, for instance) played a central part in the recognition of photography (André Gunthert, "Le roman de la Société héliographique" ["The Heliographic Society novel"] in *Etudes photographiques,* no. 12, November 2002, 37–64). The Société heliographique had been founded around Bayard and Le Gray to promote paper photography and its aesthetic in front of daguerreotype, which was still the leading process at that time, both in industrial and critical terms. The active part of the

association did not last more than six or seven months. Its publication *La Lumière*—first issued on February 9th, 1851—played a crucial part in promoting paper photography as well as its models and aesthetic qualities in common with painting, architecture and sculpture until the end of the 1850s when the publication ended long after the dissolution of the Society.

The year of 1851 was also key in terms of international acknowledgment for French photography. The first World Exhibition in London within the impressive Paxton Crystal Palace had been one of the major international events of mid-19th century. It gave photography a place to be shown in conjunction with paintings, sculptures and architecture, and for photographers one of the first opportunities to publicly exhibit their skills and gifts. Many daguerreotypes had been shown from different countries. The show emphasized the quality achieved by the first photographic processes and French calotypists illustrated how well they improved Fox Talbot's invention.

Blanquart-Evrard opened his photographic printshop that same year in Loos-les-Lille. Between 1851 and 1855, he published more than twenty portfolios gathering salted paper prints such like *L'Album de l'Artiste et de l'Amateur, Etudes d'après nature, L'Art religieux.* Many famous French and Belgian calotypists worked for him: Hippolyte Bayard himself, Charles Marville, Henri Le Secq, and Victor Regnault for instance. In 1852, *Egypte, Nubie, Palestine et Syrie* [*Egypt, Nubia, Palestin and Syria*] was the first book with photographic illustrations which included Maxime du Camp's photographs taken in 1849 and 1850 during his trip with Gustave Flaubert. Despite the aesthetic qualities of Blanquart-Evrard's images, the factory closed in 1855, only four years after its opening. The cost of fabrication—the overall process involving the participation of many skilled workers—was high and well above engraving costs. Additionally, in spite of the care given to print photographs nothing could be done to prevent the salt paper prints from fading with time.

France's largest photographic exhibition during this time took place in 1855 within the Exposition Universelle, Paris.' Organized by the Société française de photographie [the French Photographic Society] this event was not considered a part of high art, and as such had not been permitted for inclusion in the Fine Arts division and instead was categorized as an Industrial device. Founded in 1854 the Société française de photographie gathered many members of the Société héliographique. Victor Regnault was honorary President, Eugène Durieu was the first President until 1858. A periodical *Bulletin* was issued and it reported on photographic events but also on the association's activities. General assemblies as well as Board meetings proved to be central places for French and Foreign photographers to show their work or to present their technical innovations. The key role played by Alphonse Davanne when he became President in 1867, as he enhanced the association involvement in scientific, economical and political circles. In 1859 the fourth exhibition of the Société française de photographie was permitted within the rooms of the Annual Salonfor the first time.

Portraiture still remained the main photographic subject and the core of French photographic industry. In his rue Saint-Lazare studio Nadar welcomed between 1854 and 1860 most of the major artists of his time. Thanks to his acute judgement, and the attention he gave to his sitters, he made sensitive portraits where psychological likeness supported by physical likenesses. At the end of the Second Empire more than 1200 photographers were registered in Paris. Photographers' studios gathered enough tables, chairs, tools, and toys to furnish a large Parisian flats. These studios typically had wide windows to let as much light in as much as possible for better photographs. The wooden walls of the studio were often painted to create the illusion of varied landscapes of gardens, forests, and seasides behind the sitter. Beside the *bric-a-brac* stood Nadar in his commercial boulevard des Capucines studio where all the walls were red as were the furniture and even the photographer's clothes. In 1850s the invention of the *carte de visite* boosted portraiture business. Celebrities' portraits were sold to be kept in albums. Such an economical success lured many people. During those years photographers careers went up and down with financial success often being followed by bankruptcy. Gustave Le Gray, Mayer and Pierson, and Nadar met financial difficulties and closed their Parisian studios for a while, or even permanently. Furthermore, after years of success where the many in high Parisian society had came to sit for photographs in his studio, Disdéri died destitute at the end of the 1880s.

Since the end of the 1840s many improvements had been made to photographic technical process. The waxed paper negative devised by Gustave Le Gray gave the print both density and precision. By the mid-fifties the collodion glass negative invented by Frederick Scott Archer was used by most French photographers for the short exposure times it allowed and the quality of the final print. As early as 1839 the new invention raised many dreams reinforced by Arago's public announcement. Photography appeared as the ideal way of reproducing the whole world and its marvels. It seemed to be the most efficient assistant to scientific research as well. French photographer's ability combined with their connections to both artistic and scientific circles made this almost true. In 1851 the French *Commission des Monuments historiques*, founded in 1837, hired five photographers—Gustave Le Gray, Auguste Mestral, Edouard Baldus, Henri Le Secq and Hippolyte

Bayard—to make the first photographic inventory. *La Mission héliographique* was born within the Société héliographique; the five photographers as well as Léon de Laborde, one of the most influential members of the Historical Monuments administration, were all members. At the end of the 1830s Prosper Mérimée traveled throughout French territories and documented monuments needing restoration and photography provided best illustrative accuracy. The aesthetic qualities of these prints were outstanding. The French Administration did not publish the prints it ordered. They have been kept in the files gathered on each building for the Historical Monuments architects which roused Francis Wey's indignation. *La Lumière* critic as well as most members of the Heliographic Society had seen La *Mission héliographique* demonstrate French mastery of the paper negative and regretted that these images had not been shown as a whole. Nevertheless the five photographers were free to sell the prints they had kept after having fulfilled the *Commission des Monuments historiques* request.

Several other architectural recordings were requested of photographers during the Second Empire. Between 1854 and 1857 Edouard Baldus followed the Louvre reconstruction by Hector Lefuel. In the 1860s the city of Paris hired Charles Marville to photograph the transformations of Paris in the same way the city of Marseille commissioned Adolphe Terris. The young New Opera architect, Charles Garnier asked Hyacinthe César Delmaet and Louis Emile Durandelle to produce images all the building stages. Afterwards, their photographs were been published in albums designed by the architect to promote his work.

In spite of scientists' enthusiasm, scientific photography remained sparse during the Second Empire. In 1868 two doctors—Hardy and Montméja—from the Saint Louis hospital in Paris published the *Clinique photographique de l'hôpital Saint-Louis*, which contained their own research on skin diseases. From this, a photographic studio was opened within the hospital. The most outstanding medical photographic testimony was Duchenne de Boulogne's publication *Mécanisme de la physiologie* (1852–1856). Thanks to the photographic illustrations, he realized a nomenclature of facial muscles which directly corresponded with the emotional expressions they caused. The success of this work had been influenced both by the quest of scientific objectivity and by the aesthetic heritage of Charles Le Brun's *Traité des Passions* creating another use for photography for both scientists and artists.

Although photography's reception within the French Fine Arts Academy remained unenthusiastic, photographers as soon as the mid-1840s, started working with models. Nude photographs—*Etudes d'après nature*—underline the high art/low art relationship between the Fine Arts and the new invention. Most of the nude daguerreotypes belonged in erotic or even pornographic genres, nevertheless, some academic nude daguerreotypes had certainly been artistically made. These photographers imitated academic poses and deliberately eliminated or minimized eroticism. The line between erotic photography and academic studies remained difficult to establish and to avoid any trouble with the strict legislation on *images galantes* circulation photographers started in 1852 to register their works at the Imperial Library as studies for artists. The first to do so was Jacques Antoine Moulin who had run into legal trouble because of these types of images in 1850. Poses were closed to academics only and imitated *Venus, Danae, Susan,* or nymphs. The woman usually stood or reclined and was obviously not the ideal feminine reconstruction the Academy desired. The model was the only woman and after coming into the studio, took off her clothes which were deliberately shown on the photograph—and posed in front of the camera. The confusion many critics of the time felt when looking at nude photographs came from the twofold faithfulness to *Le Beau idéal* and to realism.

Photography was not allowed at the *Ecole des beaux-arts* until the end of the 19th century when Paul Richer was appointed as anatomy and morphology professor. Nevertheless many photographers—among them Moulin, Julien Vallou de Villeneuve, Louis Camille d'Olivier, Auguste Belloc—sold nude studies to artists. Some even claimed as Gaudenzio Marconi did to be *Photographe officiel de l'Ecole des beaux-arts*. Several photographers like Jean-Louis Igout for instance offered catalogs of poses to artists with both male and female models.

Etudes d'après nature included landscapes, rural scenes and seascapes. Constant Alexandre Famin made many countryside views showing animals, farmers, and wooden houses. Charles Aubry designed in the 1860s beautiful images of fruits and flowers to serve as models for La Manufarcture des Gobelins craftsmen. Since 1877, Adolphe Giraudon sold studies where women posed as gleaners, goose keepers, shepherdesses. He also offered photographic reproductions of works of art. Art reproduction was one of the very first subjects of photography in France. Nicéphore Niépce made some engraving reproductions in the 1820s and the first of Bayard's direct positive prints showed sculptures in his studio. At the beginning of the 1850s when paper photography took over, daguerreotype art reproduction was one of the main challenges for photographers. To demonstrate the photographic ability to copy paintings was the way of gaining a place among fine arts. In 1851 Francis Wey underlined photography's accuracy compared to engraving interpretation. Photographic reproduction of paintings was not easy to achieve. The need for strong and uniform light was difficult to achieve

as was the need to reproduce faithfully, if not the colors, then at least the tones. Indeed if the collodion glass negative enabled blue tones to show, some colors such as red and yellow would not as easily be seen. Robert Jefferson Bingham—the British photographer of the 1851 Great Exhibition in London—came to Paris in 1855 and settled there. He became one of the most talented photographers in France for fine arts reproduction. In 1858 he made reproductions of Paul Delaroche paintings for the first *catalogue raisonné* ever illustrated by photographs, which was published by Goupil. Once a lithograph and engraving dealer, Adolphe Goupil started to print and sell photographs at the beginning of the 1850s. One of his first publications was in 1853, and was Benjamin Delessert's photographs of Raimondi engravings. By the end of 1884, Goupil's *Galerie photographique* had reached 1759 entries. Adolphe Braun, an Alsatian photographer who made photographs of fruits and flowers for his hometown's textile industry, also turned to art reproduction. At the end of the 1860s he successfully used carbon prints to copy the huge Michel Angelo paintings of the Sixtine. French museum curators' attitude toward photographic reproductions was not keen. Many of them were reluctant to move the works they kept. They saw photographic products—glasses, wet collodion—as dangerous and dirty for pictures sake. In 1866 Nieuwerkerke then *Surintendant des Beaux-Arts* forbade the Louvre entrance to exhibit any photographs. Charles Marville managed to escape the interdiction and even took unofficially the title of *Photographe du Musée du Louvre.* One had to wait until December 1883 to see a contract signed between the Fine Arts administration and the Braun company, who was given the project of photographicly reproducing works of the Louvre collections for thirty years.

There had been no formal aesthetic inventions during the 1870s. Improvements had not been made in terms of genre but to support photographic industrialization and development. Among them finding a way of fixing images had been crucial for printers and publishers since the 1850s. Photomechanical process had been mostly chosen and used. Charles Nègre and Edouard Baldus devised their own methods around 1850 and Nègre saw in the photographic engraving "the essential complement for photography." In 1857 the Duc de Luynes set up a competition within the Société française de photographie to find the best way of fixing photographs. Alphonse Poitevin won with his carbon prints. Most of the photomechanical processes designed after 1865 were modeled after his invention. The replacement of photographic prints by photomechanical images caused higher print numbers and reduced publication costs. Goupil adapted the woodburytype designed in 1865 calling this *photoglyptie* and used it despite its complexity. The collotype, invented by Albert in 1868 however was easier to handle and was mostly chosen by photographers after 1870.

Reproducing colors had been one of the first challenges for photographers since it was invented. Despite their commercial success most critics were reluctant toward hand-colored daguerreotypes or paper photographs. In 1862 Louis Ducos du Hauron started to work on a camera which allowed color photography. Six years later he licensed his invention, which positioned three different images made from colored filters and papers. At the same time Charles Cros conceived of a process similar to Ducos du Hauron's. Thanks to his theory on color addition the final image was made by superimposing three negatives of blue, orange, and green. Both techniques did not find at their time commercial developments. Additionally years later, Lumière's autochromes had been found in color. In 1878, Dalloz published the first book illustrated with colored photographs *Le Trésor artistique de la France*. Léon Vidal made photographs of the works of art kept in the Gallery of Apollo in the Louvre and used his *photochromie*, based on chromolithography and woodburytype.

Reduction of time exposure enabled photographers to reveal a still hidden world to human eyes. As the astronomer Pierre Jules Janssen observed, photography had then became a valuable asset to scientists. It became, he wrote, "the scientist's retina." In 1874 he designed a photographic revolver that allowed the reproduction of the different stages of the transit of Venus'. Astonishingly he used daguerreotypes and not collodion to do so. He chose this then forgotten technique for the precise images it took.

The main innovation of the end of the century was not French but its use deeply changed photographic uses and habits in France. In 1871, the Englishman Richard Leach Maddox invented the gelatin dry plate silver bromide process. Improved by Désiré Van Mockhoven in Belgium, the new technique quickly took over in France during the 1880s. The reduction of time exposure being less than one tenth of a second, allowed photographers to take on new subjects. Fixated on motion, photographers took images of waves, horses galloping, running trains, and steaming ships. Charles Grassin made several photographs of waves and ships in the Boulogne harbor in 1882. It has been said that his photograph of the steamer Folkestone leaving Boulogne had an exposure below 1/82th of a second. Louis-Jean Delton photographed horses races in Auteuil and Muybridge's work on animal locomotion drew high interest in France when they were published in 1878 in *La Nature*. Jules-Etienne Marey devoted his life to movement analysis and gave up traditional anatomical studies of the dissection of dead bodies' for research to help the living. Inspired by Muybridge's process he conceived his own photographic device to observe movement, chronopho-

tography. Within the *Station physiologique* he opened in Auteuil he designed not only a photographic process (based first on glass negatives then on celluloid films) but also a complex and ingenious laboratory where every attempt was made to avoid any distortion of observation. His works raised French artists' interest and although a doctor himself, his aim being scientific, he nevertheless always had been keen on artistic representations. A soon as 1873 he wrote *La Machine animale*. In 1878 he gave a lecture *where* he pointed out how unrealistic representation of horses pace by painters and sculptors had been until then. He published in 1893 the *Album de physiologie artistique, n°1, des mouvements de l'homme*. If Edgar Degas chose to keep a traditional representation of movement in his paintings, his sculptures of dancers and horses showed an interest for movement analysis close to Marey's experiment. In 1882 Albert Londe created the photographic department within the Parisian hospital of La Salpêtrière. From 1888 his images reproducing Charcot's work on hysteria were published in *Nouvelle iconographie de la Salpêtrière.* This medical photography marked another use for photography and union between science and photography.

Instantaneous images did not go move beyond to show a moving world. Although they depicted previously unseen stationary images, they failed to reproduce movement. Snapshots showed human beings, vessels, trains and waves as if they were stopped. As André Gunthert wrote: "Instantaneous fixed an index of surprise and accident." Commercialization of the Kodak Pocket camera from 1888 enlarged such an index. Its low price and its easy handiness gave many people the chance of buying and using it. Millions of every day life incidents and surprises had been reproduced: kids' games, jumps, falls, dives, and even hide-and-seek parties. Photography had entered thousands of people's livese.

Maurice Guibert, a close friend to Henri de Toulouse-Lautrec, joined an association of amateur photographers, *La Société des excursionnistes photographes.* His photographs showed friendly groups of men laughing, joking and teasing. Pierre Bonnard and Edouard Vuillard both used the Kodak Pocket as well. Bonnard's photographs show the happy and noisy games of his sister's kids in the family's house. All hi simages were not of simple daily events, and around 1900, he took several nude photographs of Marthe, who became his wife some years later. Bonnard's photographs often raised emotions and relayed the intimacy between the photographer and his model, which is enhanced by his painter's sense of composition and light. He also took more photographs of Marthe in his garden at Montval. Bonnard kept her movements beautiful and poses freedom. She walked from sunlight to shadow, at ease within nature as a nymph.

Edouard Vuillard photographs are closely related to both his work and his life as well. The painter called himself "a day-to-day life explorer." For most of his life, he painted family and friends often with an outstanding acuteness of judgment. His Nabis paintings made in the 1890s are deeply influenced by his stage sets and by his familiarity to Ibsen or Maeterlinck plays. His choice for unbalanced compositions, his taste for decorative panels and the way he emphasizes how uneasy communication is between people underlay his photographs as well. He bought his camera in 1897 and kept photographing until the 1930s. He often mentioned photography in his diary. More than just images of games and incidents, his photographs show long lasting attitudes and links between people. His photographic work echoes his painting.

Edgar Degas' photographs can not be related to snapshot aesthetics. It has often been written that as a photographer he composed still, almost severe yet strongly enlightened images. His photographic practice only lasted some months around 1895 as he was already quite old with a long career behind him. The images, however all show his close friends—Stéphane Mallarmé, Auguste Renoir, the Rouart and Lerolle families. Degas obliged his models to long poses. His prints were under his control enlarged by Guillaume Tasset who designed contrasting images.

Aside from painter's photography, pictorialism developed in France at the end of the century. Pictorialism was born among amateur circles. The Parisian *Photo Club* gathered from 1890 consisting of Constant Puyo, Robert Demachy, Hachette, de Singly. In 1894 they organized rue des Mathurins in Paris, the first *Exposition d'art photographique.* They claimed that photography should be recognized as an art; however they still used techniques mainly taken from painting and drawing. Pictoralists chose to show a world far away from modern life's agitation and as such they could be compared to symbolist artists. In 1899 Robert de la Sizeranne published his manifesto *La Photographie est-elle un art?* ("Is Photography an Art?"). In 1903 Puyo launched *La Revue de photographie* where the photographs shown in the Photo Club exhibitions were published. Photo Club members kept close relationships with pictorialist photographers abroad and participated in foreign exhibitions and publications.

Eugène Atget has been, seen since Berenice Abbott discovered the man and his photographs in the 1920s, the French forerunner of "pure photography." Surrealists, Man Ray at first, is also highly praised his images. Atget was born in Libourne and came to Paris in 1878. After having tried to work in theaters as a painter he settled as professional photographer in 1890. On his door was written: *Documents pour artistes*. Some years later he started his systematic survey of Parisian streets and buildings. He sold his photographs to public institutions like the Bibliothèque nationale, Musée

Carnavalet as early as 1898, at that time purchasing them for documentary purposes. Atget's photographs reveal an old Paris where shops and boutiques have today disappeared.

December 28th, 1895, saw a new invention which was offered to Parisians on boulevard des Capucines, in the Indian salon of the Café de Paris. Auguste and Louis Lumière, manufacturers from Lyon, showed ten short moving stories on a white screen, among them *L'Entrée en gare de la Ciotat, La Sortie d'usine* or *Le Déjeuner de bébé*. Almost sixty years after Daguerre's invention the Lumière brothers succeeded, as had Marey some years before, in reproducing movement.

FRANCK; FRANÇOIS-MARIE-LOUIS-ALEXANDRE GOBINET DE VILLECHOLLES (1816–1906)

French photographer and professor

French photographer, his studio was at 15, Place de la Bourse from 1859 to 1862, and 18, rue Vivienne from 1861 to 1880 in Paris. He was a Professor of photography at the Ecole Centrale in 1862, and was also a teacher at the Ecole Impériale centrale des arts et manufactures in 1863.

He was a member of the Societé française de photographie, becoming a member of the board of directors of the society from 1882 to 1900, a member of the Committee of organization of the international congress of Photography in 1888, and a member emeritus of the SFP in 1900. He was also a member of the jury of the Exposition Universellle of 1878. Additionally he was a Knight of the Royal Orders of Wasa (Sweden) and of the Crown of Italy.

Franck was born 21 December 1816 at the Château de Voyennes in the Somme department in France. He first embraced a literary career and he became interested in photography in 1845 with daguerreotype. From 1849 to 1857, he left the French republic and took refuge in Barcelona. From this period date photographs of Spain and Germany on salt paper and stereoscopy, and an album in four volumes untitled *Topographie d'Espagne.* From 1859 to 1880, Franck set up as photographer in Paris. He offered official and artistic portraits, artistic reproductions, industrials, views, monuments and later lessons in photography and illustrations for books. In 1862, he was professor at the Ecole Centrale of Paris and began his "Galerie universitaire contemporaine." Next year, he became the photographer of the high schools Polytechnic, Normale, Mines, Saint-Cyr and published group portraits until 1975. In 1864, Franck, apparently close to the power, photographed the Bishopric and the Legislative Corps. In 1865, he reproduced famous art collections displayed at the exhibition of the Central Union of Fine Art applied to Industry at the Industry

Palace in Paris, containing decorative art, ceramics, weapons, goldsmith's, tapestry and, among others, the Nieuwerkerke's collection. He gathered a hundred views in an album untitled *L'Art ancien.* In spite of his interest for art, Franck was above all a witness to the men and the changes of his time. In 1866, he published an *Album contemporain contenant les biographies de 300 personnages de notre époque* containing conventional portraits. After the Paris Commune in 1871–1872, he photographed the ruins of Paris and its surroundings.

In 1880, he sold his establishment at Chalot and devoted himself to the manufacture of opaline plates for slides. Ten years after, he retired in Asnières, 7, rue Saint-Denis. He died 16 January 1906 at Asnières.

FRAUDS AND FAKES

The initial celebration, by William Henry Fox Talbot and others, of the superior "truth and fidelity" of photography gave way in the second half of the nineteenth century to an increasing awareness of the potential duplicity of photographic images and of photographic operators. Starting in the 1860s, questions of fraud and fakery emerged in relation to controversies and legal cases involving spirit photography, and in response to darkroom printing tricks that allowed photographers to alter a figure's setting or identity. Concerns about photographic deception followed advancements in techniques such as double exposure, combination printing, and the like. By the 1890s the notion that photographs cannot lie was routinely dismissed in print. In 1889, one critic went so far as to argue that, "in every case a photograph is but a deceptive representation of the object photographed" (Woodbury, 1898, 283). Similarly, in the context of aesthetic debates about photographic manipulations by the Pictorialists, Eduard Steichen wrote in 1903 that, indeed, "every photograph is a fake from start to finish" (Steichen, 1903,107).

In fact, the camera's special ability to deceive had been discussed as far back as Giambattista della Porta's sixteenth-century treatise on natural magic, in which he recommended using a walk-in camera obscura (literally: dark chamber) for presenting fantastic scenes for the astonishment of viewers, who "cannot tell whether they be true of delusions" (Porta, 1957, 364–365). Reframing the issue of natural magic in the nineteenth century, Scottish physicist Sir David Brewster amplified upon della Porta's observation that the optical image was in itself neither true nor false, but because it seemed true offered an especially potent agent of deception; only knowledge of the laws of Nature could enable one to test and verify potentially misleading sense impressions.

Talbot's 1844 *The Pencil of Nature* celebrated photography for its special grasp of "truth and reality," thus obscuring the ability of photographs to create false impressions. But, as inadvertently demonstrated by the example of Talbot's own *Scene in a Library* (actually shot out of doors in full sunlight), the circumstances under which a given photograph was made might not be immediately apparent in the image itself or in the statements made about the image (Charlesworth, 1995, 214–215). From studio portraits with false tree swings to Alexander Gardner's notorious civil war images of the "Rebel Sharpshooter" whose corpse has been rearranged by the photographer, nineteenth-century photographers frequently contrived aspects of the reality that they pictured. A famous 1883 portrait of Walt Whitman showing the poet with a butterfly perched on his finger, subsequently used as the frontispiece for *Leaves of Grass*, prompted skepticism during Whitman's own lifetime; it would seem that a cardboard butterfly had been rigged up for the occasion (Mitchell, 1992, 196).

Two of the most widely publicized cases of outright photographic fraud involved spirit photographers, the American William H. Mumler and Frenchman Édouard Isidore Buguet, who purported to be able to capture faint images of spirits along with living sitters on their photographic plates. Mumler was arrested in New York for fraud and larceny in 1869, but after a lengthy preliminary hearing, the case was dismissed, owing to the fact that neither the truth nor the fraudulence of his images could be proved beyond a doubt. But the widely reported hearing, including a deposition by the celebrated showman P.T. Barnum, raised public awareness of the many techniques for manufacturing fake photographs. The idea that photographs might provide questionable or false evidence and so needed to be viewed with skepticism thereby gained new currency (Leja, 2004, 57–58). In France, Buguet admitted to trickery and was convicted of fraud in 1875, serving jail time based on his discredited spirit photographs.

The technique for creating a ghostly apparition through double exposure ("for the purpose of amusement") had been laid out in Brewster's 1856 treatise on the *Stereoscope*, prior to the first publicized spirit photographs. In 1860, Oscar G. Rejlander used a double exposure to create a ghostly visage in his *Hard Times*, and, more important, had ambitiously elaborated on the possibilities of combination printing in *Two Ways of Life* of 1857. His *OGR the Artist Introduces OGR the*

Mumler, William H.. Untitled Portrait. Unidentified woman seated with arms of a "spirit" over her head.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

Volunteer, c. 1871, appears to show Rejlander twice in the same scene at the same moment—a trick that would come into a certain international vogue in the 1890s, notably in an image of Henri de Toulouse-Lautrec posing as both artist and model.

In the political realm, photomontage techniques were used in the 1860s in Italy to show the exiled Queen of Naples in compromising positions with contemporary religious leaders, and to place the head of Abraham Lincoln onto a variety of figures in various settings (Mitchell, 1992, 204–209). Along with the increasingly sophisticated use of such techniques there developed growing suspicion about photographic evidence.

Thomas Hardy 1885 novel, *A Laodicean*, featured a plot device whereby a photographic portrait of the story's hero was libelously manipulated in order to show him in a state of intoxication (Henisch and Henisch, 1984, 313). In 1894, British jurist Ernest Arthur Jelf used a constructed photograph in which former Prime Minister William Gladstone appeared to stand at the door of a London Pub to illustrate the "worthlessness" of photographic evidence (Tucker, 1987, 378–9). Similarly, the theme of entertaining but potentially misleading "Photographic Lies" was amply illustrated in an 1898 London magazine article with several "faked photographs," including one entitled, "Showing how a man can be in two places at once" ("Photographic Lies," 1898, 262).

At the same time, accusations of fakery were being leveled at photographers who manipulated their prints for purely artistic effect, prompting Eduard Steichen's sarcastic response in the first number of *Camera Work*. Addressing himself to "Ye Fakers," Steichen dismissed criticism that artistically manipulated prints were "faked" and argued that "faking" was present "in the very beginning" of the photographic process, the exposure itself. If all photographs were "fake from start to finish," then what mattered to Steichen was achieving authentic expression, not preserving the inherent truthfulness of the unmanipulated photograph, which for him, as for others of his day, was but a myth.

FRÉCHON, EMILE (1848–1921)

Emile Fréchon is considered an orientalist photographer. Fréchon moved to Algeria with the rapid development of tourism in search for exotism. Born in Normandy, in 1848, he worked as a journalist until Jules Gervais-Courtellemont asked him—in 1887—to come to Algeria to manage his photographic company.

Fréchon photographed the desert and was one of the first to do so. In the beginning of the 1890s Fréchon photographed the oasis of Biskra that he later published in *L'Algérie pittoresque et artistique* which was released by Gervais-Courtellemont in 1892. In 1895, he finally established his own studio and sold his images to European tourists. In addition to maintaining his own studio, he continued to trade with another studio in Etaples, located in the North of France and spent his time between both countries.

The Photo-Club de Paris, which displayed pictorial work in France, received his work and exhibited it in 1894 and 1895 in their Salon and published his photographs in their Bulletin. Fréchon developed a style close to that of the drawings typical France's naturalistic paintings. Critics called him the "photographic Millet." Indeed, he prefered landscapes to the urban aesthetic and liked to play with the oriental light to obtain backlighting. He died in 1921.

Marion Perceval

FREDERICKS, CHARLES DEFOREST (1823–1894)

According to Frank Leslie's *Illustrated Newspaper,* 11 September 1858, "Frederick's Photographic Gallery, 585 and 587 Broadway, was brilliantly illuminated with colored lanterns. The words 'Photographic Temple of Art' were formed by hundreds of lamps, covering a semi-circular arch of sixty feet in curve. The windows and balconies of these magnificent Daguerrian rooms were crowded during the day with spectators, almost to the interruption of business. There is no more popular photographic gallery in New York than this, and nowhere are portraits obtained with greater fidelity."

Having learned the daguerreotype process from Jeremiah Gurney—from whom he bought his first camera—Fredericks travelled and photographed throughout South America for nine years before briefly operating a studio in Paris in 1853.

His first New York studio opened in 1854, and for a short period 1855–56 he and Jeremiah Gurney were in partnership.

One of the first to introduce the carte-de-visite into America, Fredericks, for a time, also held the US Patent rights for the family album with its familiar slots. His studio had a prodigious output of both carte and cabinet format images, and continued in business until c. 1890.

Woodblocks based on his portraits of eminent figures—such as Samuel Walker, President of Nicaragua, and Commissioner Simeon Draper of the New York Police—regularly appeared in Leslie's *Illustrated Newspaper.*

John Hannavy

FREEMAN, ORRIN ERASTUS (1830–1866)

American photographer

Born in Boston, Massachusetts, Freeman was listed in the 1857 City Directory as a saloon keeper. His great grandfather had been a colonial governor and local lawyer, his grandfather a surgeon and his father was a house builder. Encouraged by stories of his younger brother Albert's financial success as a merchant in Shanghai, Orrin accompanied his mother and other brother, Melvin, on a four-month journey to China, arriving in March, 1859. He arrived in Shanghai with ambrotype equipment, determined upon starting a career in China as a photographer. Oddly, he chose the inland city of Soochow (present-day Suzhou), rather than Shanghai, to open his first studio. That seems to have been unsuccessful and he then advertised his studio's re-location to Shanghai in July 1859. Although moderately successful, he decided to move to Japan. By early 1860 he was operating Yokohama's first commercial studio and also trading in photographic equipment and other goods. Within a year of establishment, he was approached by Ukai Gyokusen, a wealthy merchant, who made Freeman a substantial offer for his ambrotype camera, equipment and lessons. Ukai would become the first professional Japanese photographer and Freeman, no longer connected with photography, would go on to amass a fortune as a Yokohama merchant. He died suddenly of paralysis in 1866 and is buried in the Yokohama Foreigners' Cemetery. [One of his ambrotypes is held by the *Numazu City Archives of Meiji History*, Japan.]

Terry Bennett

FRÉNET, JEAN-BAPTISTE (1814–1889)

French painter, photographer

As a young man he entered the Academy of Fine Arts in Lyon; in 1834 he went to Paris where he attended

the Academy of Fine Arts and trained in the atelier of Ingres. When Ingres took up his post at the French Academy in Rome, Frénet followed. After his return to France in 1837 he worked for some time in Paris; then settled outside of Lyon where he undertook regional commissions. Frénet, a committed Republican, became politically active after the revolution of 1848. He was the mayor of his small community and ran afoul of the authorities for falsifying election returns in the plebiscite of 1851. This effectively ended any hope for official painting commissions. He appears to have taken up photography in the early 1850s, perhaps as a response to the limitations to his career as a painter. Working with the paper negative, salted paper print process, Frénet made domestic portraits and intimate studies of informally posed family groups, as well as a small number of landscapes. Examples of his photographic production date to the 1850s and are limited to the paper process.

KATHLEEN HOWE

FRESNEL, AUGUSTIN JEAN (1788–1827)

French scientist and inventor

Fresnel was born on 10 May 1788 in Broglie, France. His father, Jacques Fresnel, was an architect who went on to work on harbour construction at Cherbourg. In 1794 the political situation in France led to work on the harbour being halted so the Fresnel family went to Mathieu, a village north of Caen, where young Augustin Fresnel spent the rest of his childhood. His parents were Jansenists, and Augustin was brought up with strict values in a stern atmosphere which would strongly influence him throughout his life.

After elementary education by his parents, and secondary education in Caen he entered the École Polytechnique in Paris in 1804 with a career in engineering in mind. Two years later he progressed to the École des Ponts et Chaussées, qualifying as a civil engineer. He was employed first in the Vendée and then on the building of a major road through France connecting Spain with northern Italy. However, he had a hobby: he was fascinated by light and undertook experiments in 1814. In 1815, when Napoleon landed at Cannes with some of his guards, Fresnel was so upset that he left his engineering job and offered to fight for the King against Napoleon. By 20 March Napoleon had reached Paris putting Fresnel in a difficult position. As a consequence he lost his engineering post and was put under police surveillance. He had few options left but to return to his home in Mathieu. In fact circumstances had conspired to give Fresnel the free time he needed to concentrate on his experiments with light. His work on optics soon convinced him of the validity of the wave theory of light which was, at that time, totally disregarded in favour of the corpuscular theory. After Napoleon was defeated at Waterloo, Fresnel was reinstated into his old engineering appointment. He was then only able to undertake research on light in his vacations. He was transferred to an engineering post in Rennes but continually requested leave so that he could go to Paris to continue his scientific investigations.

By applying mathematical analysis to his work Fresnel removed many of the objections to the wave theory of light. He knew little about the contributions by other scientists. He experimented with diffraction, making a breakthrough when he attached a piece of black paper to one edge of a diffracter and observed that then the bright bands within the shadow vanished. From this he correctly deduced that these bright bands were produced by light coming from both edges of the diffracter but since bright bands outside the shadow remained he deduced that they must result from light reflected from only one edge of the diffracter. He published his first paper in October 1815 on his wave theory of light, making a first attempt to explain the phenomenon of diffraction. He then applied the same mathematics which worked for his diffraction experiments to give theoretical results on interference patterns obtained by reflecting a light source with two mirrors. He verified the theoretical results by experiment. Much of this early work was already essentially known, but Fresnel next developed a new theory, publishing tentative results in July 1816. After working for a while on polarisation of light during 1817, he returned to his theories of diffraction when the Académie des Sciences announced that the Grand Prix for 1819 would be awarded for work on that topic. He was confident of his theory since his mathematical deductions from the one simple hypothesis led to results which he had verified experimentally. In his submission he calculated the intensity of light at every point behind the diffracter using what were later called Fresnel's integrals.

In 1819 the committee to judge the Grand Prix met consider Fresnel's submission but most members including the chairman Arago and Poisson believed in the corpuscular model. However Poisson was fascinated by Fresnel's mathematics and discovered further consequences beyond those which Fresnel had deduced. Poisson showed that a bright spot would be seen in the centre of the shadow. Arago asked that Poisson's remarkable predictions based on Fresnel's model be tested. Indeed the bright spot was seen exactly as Fresnel's theory predicted and the Grand Prix was awarded. Fresnel zone plates, used in photography, rely on this work. Despite this triumph for wave theory, polarisation of light produced by reflection still provided a strong argument in favour of the corpuscular theory. Fresnel and Arago, now very confident that they could explain this effect with Fresnel's theory, undertook further

work on polarisation. Fresnel discovered what was later called circularly polarised light. No hypothesis led to the experimental results obtained other than that light is a transverse wave and, in 1821, Fresnel published a paper in which he claimed with certainty that light is a transverse wave. This went too far for most, even Arago, but Fresnel stunned his critics when he next showed that double refraction could be deduced from the transverse wave hypothesis.

After 1824 he devoted less time to his researches on light. He was employed by the Lighthouse Commission and as part of his effort he invented so-called *Fresnel lenses* which were made by splitting a large lens into stepped concentric rings and mounting them in the same plane. These quickly replaced mirrors for lighthouses and lenses as large as 3 metres in diameter have been constructed using this method. This invention has found numerous other applications, including the lenses in theatre lights, collimators in overhead projectors and the lenses in the view-finders of SLR cameras.

Fresnel died of tuberculosis in on 14 July 1827 in Ville-d'Avray, France at the age of 39. He had struggled throughout his life against ill health but it is remarkable that he was able to undertake an exceptionally high workload despite suffering from severe fatigue. Perhaps it was the strict religious upbringing by his parents which gave him the strength to overcome his illness for so long.

The unit of optical frequency has been named after Fresnel. One *fresnel* is 1012 hertz (one *terahertz*).

FRESSON AND FAMILY, THÉODORE-HENRI (1865–1951)

French inventor of carbon paper Charbon-Satin

Agronomist by profession, Théodore-Henri Fresson also worked on electronics and with military technology. In 1899 he presented before the French Photographic Society "Photographic proofs printed on carbon paper that can be developed without transfere." His process came from Charbon-Velour (Victor Artigue. 1889) commercialised in 1893. The composition of the Charbon-Velour Paper was a secret and so was the formula for the Charbon-Satin (with the exception of the inventor family, the photographer José Ortiz Echague and the workshop Luis Nadeau in Canada).

By the 1900's and thanks to the efforts of Maria, the wife of Fresson, and their sons Pierre and Edmond, the Charbon-Satin was manufactured and sold. Fresson's product was more reliable than the Artigue process it was in competition with it.

Thereafter, the advent of small format negatives forced Pierre Fresson to adapt the procedure for enlargements. From 1947, the Fresson brothers, aided by their children (Micheline and Jacques for Edmond, Colette and Monique for Pierre) achieved prints production themselves in their workshop at Dreux. The sale of monochrome prepared papers progressively decreased around 1950. In response to this, Pierre Fresson, helped by his son Michel, adapted the process to quadrichromy (the first process for the production of permanent colour images). In the sixties, their main clients were advertising photographers. Since the seventies, the 'Atelier Fresson' has been prized by artists and photographers such as John Batho, Bernard Plossu and Bernard Faucon. In 1978, the son of Michel, Jean François Fresson, joined the team, continuing a one hundred year family tradition.

LUCE LEBART

FRESSON PROCESS

The genesis of this process takes us back to Alphonse Poitevin's carbon process of 1855, whose original patents (Fr. Pat. 24,592, Aug. 27; the Engl. Pat. 2,816 of Dec. 13, 1855 is not as complete) covered both carbon printing and collotype. The carbon process takes its name from the carbon black pigment that Poitevin used in his early experiments. Any permanent pigment mixed with potassium dichromate and a colloid such as albumen, gelatin or gum arabic, will result in an emulsion sensitive to light. Exposed under a negative, a dichromated pigment coating will become insoluble proportionally to the amount of light it receives. Parts of the image which are protected by the dense areas of the negative will remain water soluble and will reveal clear highlights after development has taken place in cold or hot water, as required by the nature of the colloid used. This process, which does not involve a transfer of the emulsion before development (unlike the carbon transfer process), is referred to as "direct carbon."

Few people used the original Poitevin direct carbon process as the resulting images produced a short scale with excessive contrast which most photographers considered inferior to the silver prints of those days. This technique remained largely dormant until it was revived, under the name of gum printing, ca. 1894, by Rouillé-Ladevèze in Paris. In the meantime direct carbon was used for the reproduction of tracings and architectural drawings and one particular variant, introduced by Frédéric Artigue, around 1878 was adapted by

his son, Victor, for the production of continuous tone photographs, in 1893.

To achieve this, the removal of the unhardened pigment emulsion had to be effected by the use of a solution of plain water and sawdust, the latter acting as an abrasive. The Artigue paper, marketed as Charbon-Velour, could provide beautiful prints with a matt surface but the process was far from perfect for commercial use.

Théodore-Henri Fresson (1865–1951) was an agronomist by profession and a man of many talents. Throughout his life he worked on agronomy, electronics, photography, military technology and other technologically advanced processes. Around 1893, he saw the carbon paper Artigue Charbon-Velour advertised in a photography store. That paper was the first commercial attempt at producing a carbon paper that did not require transfer prior to the development in order to maintain a perfect gradation of the image. The Charbon-Velour, however, was not entirely satisfactory. No two batches were alike, due mainly to the large number of uncontrollable factors in the manufacturing of the paper.

Fresson became interested in the problem and after several years of research began the manufacture and sale of his Charbon-Satin around 1899. The paper was available in 20 colors on various types of textured bases. Absolute secrecy was maintained as to the details of the process which was used strictly by members of the family from one generation to the next. Exceptions in recent years have been the late José Ortiz Echagüe and this writer. No patents were taken for further secrecy.

Fresson paper was imported and sold in America by Edward Alenius, between 1927 and 1939. After the War, the Fresson family concentrated its efforts on printing for other photographers, instead of selling the paper for outside use, although it has been made available from time to time.

The best known exponent of the Fresson process was the late José Ortiz Echagüe (b. 21 Aug. 1886–d. 7 Sept. 1980), whose fabulous work can be seen in the collections of major museums, including that of the Royal Photographic Society of Great Britain, now located at the National Museum of Photography, Film & Television, in Bradford and the Metropolitan Museum of Art in New York city. There are about 1,000 of his prints in North America, 3,000 world-wide. He is considered the most important Spanish photographer of the 20th century. After his death, his family donated his photographic negatives and prints to the University of Navarra in northern Spain.

Ortiz Echagüe bought the Fresson formulas and equipment necessary to manufacture the paper from a relative of the Fresson family, in 1966.

The transaction was carried out secretly to avoid the wrath of the rest of the family. After lengthy and tumultuous negotiations, Luis Nadeau in Canada acquired the process through him in 1979, shortly before his death.

C. Puyo and Robert Demachy, in France, and Léonard Misonne, in Belgium, were some of the early pictorialists who used the Fresson process. More recently, Frank Horvat, Bernard Plossu, Lucien Clergue, Sheila Metzner, Sarah Moon and Tourdjman, have had some of their work printed by the Fresson family. Most modern work is printed by the four-color version (quadrichromie-Fresson), introduced by Pierre Fresson in 1951. The color variant of this process has never been used outside France.

The highly coveted Fresson process has attracted considerable attention, as it can provide beautiful and light-fast prints, and is the last, early proprietary photographic process of importance still jealously guarded by a handful of people, namely the descendants of the inventor, in France, and this author, in Canada. It is currently the only true photographic process commercially available that can produce a permanent color print without a photomechanical screen.

FRIESE-GREENE, WILLIAM (1855–1921)

English photographer

Born William Edward Green, 7 September 1855 in Bristol, England. Father James Green, metal craftsman.

Became William Friese-Greene after marriage to Victoria Mariana Helena Friese in 1874. Apprenticed to photographer Maurice Guttenberg of Bristol. Became owner of portrait studios in Bath, Bristol, Plymouth, London and Brighton. In partnership in the 1880s with Esmé Collings. Inspired by J.A.R. Rudge's glass-plate moving images, Friese-Greene patented two sequence cameras for flexible materials: one (1889) with engineer Mortimer Evans, another (stereoscopic, 1893) from a design by Frederick Varley. Paper (and later, celluloid) 'films' taken with his cameras, including a view of Kings Road, Chelsea, were at a slow rate, and projection was unsuccessful. Helena died 1895. He devised, with John Alfred Prestwich, a flickerless projector (1896). Married Edith Harrison in 1897. Patented a color motion picture process (1905). Other patents through 1921—some practical, others unworkable—included electrical devices, X-Rays, inkless printing, and color photography. Poor financial control led to two bankruptcies. He died 5 May 1921, London. Claimed to be, and posthumously championed as 'The Inventor of Kinematography,' he was subject of an unreliable biography, *Friese-Greene: Close-up of an Inventor* (Ray Alister, London: Marsland 1948), and a romantic biopic *The Magic Box* (1951).

STEPHEN HERBERT

FRANCIS FRITH & CO.

In 1884 the British photographer Francis Frith wrote his memoirs of the first sixty-two years of his life, the first words of which were as follows: "I am what circumstances over which I have had little or no control from my very birth have made me." Such modest words open the autobiography of a man who had amassed a fortune in the grocery business by the time he was thirty-four and then went on to become one of the pre-eminent travel photographers of his day and founded F. Frith & Co., a photographic printing firm and archive in England that was the largest of its kind in the 19th century.

While not the only photographer of his era to publish scenic views of exotic places and monuments commercially, Frith was arguably the most prolific, and an integral figure in the popularization of the travel photograph specifically, and commercial photography generally. His reputation as a photographer was established largely on his photographic work from his three expeditions to the Near East between 1856 and 1860. Indeed, the critical and commercial success of these photographs allowed Frith to start Frith & Co., whose vast photographic archive would survive well into the 20th century and become Frith's greatest legacy.

Francis Frith Jr. was born on October 7, 1822 in Chesterfield, Derbyshire to Francis and Alice Frith. The second of three children and the only son to a prosperous wine merchant, Francis Frith Jr. grew up in a liberal yet devout Quaker household. He spent the first decade of his life in Chesterfield, spending much of his youth exploring the bucolic hills and woods surrounding his home. At the age of ten Frith was sent off to a Quaker boarding school where he remained until the age of sixteen. In 1838, upon the completion of his studies and at the insistence of his father, Frith began a five-year apprenticeship in a Sheffield cutlery firm.

Frith never completed his apprenticeship, however, as he had what can best be described as a nervous breakdown around 1843 and returned home for an extended convalescence. After regaining his health Frith traveled the towns and countryside of Scotland and Wales for the better part of two years. At trip's end Frith reentered the world of business, this time in the thriving, industrial seaport of Liverpool, where sometime around 1845 he and a partner started a wholesale grocery business provisioning transatlantic vessels. The company flourished, and Frith eventually sold the business and used the proceeds to finance a small printing company around 1850, which also proved successful. By 1856 Frith sold his printing firm as well and, having amassed a small fortune from his two business ventures, retired a wealthy man at the age of thirty-four.

It was apparently during his time in Liverpool that Frith first took an interest in photography, so much so that in 1853 he became one of the founding members of the Liverpool Photographic Society. When Frith finally left Liverpool after the sale of his printing firm and moved to Reigate, a town south of London, he continued his photographic activities and even exhibited a number of his photographic portraits and landscapes at the Photographic Society of London in January 1856.

Soon after relocating to Reigate, however, Frith decided to travel, and in September of 1856 he set sail for Alexandria, Egypt on the first of three life-changing photographic expeditions to the region. His itinerary combined his enthusiasm for photography and travel with an astute entrepreneurial awareness of the eager market in Victorian Britain for photographs of the Near East, at that time a region known mostly through written accounts and the drawings and lithographs of the Scottish artist David Roberts. Accompanying Frith on his expedition to the Near East was Francis Herbert Wenham, a friend and engineer who advised Frith on the mechanical and optical aspects of photography.

Frith and Wenham traveled to archeological sites across Egypt with an entourage of assistants and staff and a small convoy of wagons needed to transport the sizable photographic outfit required by Frederick Scott Archer's recently introduced wet-plate collodion process and Frith's three different cameras: a standard full-plate (200 × 250mm), a mammoth (400 × 500mm) and a small stereoscopic camera. Frith preferred the clarity provided by the wet-plate system's glass negatives and

its capacity to produce multiple high-quality prints, despite the logistical problems posed by the elaborate equipment and the collodion process's demanding system of on-site preparation and development of the photographic plates—a complex procedure made all the more difficult by the Near East's difficult terrain and often inhospitable climate.

Despite these and other hardships endured along the way, Frith managed to photograph scores of ancient archeological sites, monuments and topographic views throughout Egypt, especially in the area around Thebes. Using his three cameras, he often shot the same subject in multiple formats and from several perspectives to enhance their future commercial possibilities. Among Frith's finest photographs from this expedition are those of the Sphinx and Great Pyramid of Giza, the pyramids of Dashoor and of the colossal sculpture at Abu Simbel.

Frith returned to England in the summer of 1857, where his photographs appeared in an album published by James S. Virtue of London. The London-based firm of Negretti and Zambra also distributed a well-received series of his stereo views. Frith's cache of remarkable topographical views proved quite popular, as their fine detail and uniqueness perfectly suited the burgeoning Victorian fascination with exotic places.

In light of this success, Frith quickly set off once more for the Near East in November 1857, persuaded by Negretti and Zambra to produce a new set of photographs concentrating on the biblical and historical sites of Palestine and Syria. On this second expedition Frith photographed the mosques, tombs and streets of Cairo, the important archeological sites of Jerusalem, Bethlehem, Damascus and Hebron, and the Roman ruins at Baalbek.

He returned to England in May 1858 with a second trove of photographs from the region. Once home Frith gave lectures on his travels while exhibitions of his photographic prints were held and projections of his transparency views drew large audiences. His photographs once again received wide circulation throughout England as stereo views, and were also combined with those from his first trip into a book titled *Egypt and Palestine Photographed and Described by Francis Frith.* This two-volume album, printed in an edition of 2,000 in 1858 and 1859 and distributed by subscription, proved immensely popular, its combination of remarkable photographic views with Frith's first-hand written account providing a surrogate tour of the Near East for Victorian tourists and would-be tourists alike.

Encouraged by the wide appeal and commercial success of his photographs from Egypt and Palestine, Frith embarked on a third and final trip to the Near East in 1859. On this last photographic expedition he re-photographed Cairo, the pyramids and monuments of Giza and Abu Simbel, and the Hall of Columns at Karnac. His team also traveled by camel up the Nile River, pressing on to a remote point almost 1000 miles south of the Nile Delta where only a handful of Europeans and no other photographer had ever ventured before. There, in the region of southern Egypt and northern Sudan then referred to as Nubia, Frith photographed the temple of Amenhotep III at Soleb.

Upon his return to England in 1859 Frith married Mary Anne Rosling—with whom he would go on to have eight children—and set about establishing his own photography printing and publishing firm in Reigate. The firm, F. Frith & Co., was largely devoted to the publication and dissemination of travel photography in a variety of formats. Frith continued to have books of his photographs from his three expeditions published, among them a series published in 1860–1861 concentrating on his final expedition titled *Cairo, Sinai, Jerusalem, and the Pyramids of Egypt, and Egypt, Nubia and Ethiopia (1862), a volume devoted to one hundred of Frith's stereographs to be experienced with a small viewer provided with each copy. Additionally, some fifty-six of Frith's views of the Holy Lands adorned a* two-volume edition of the *Queen's Bible* published in 1862–1863.

Soon after the founding of his company, Frith turned his attention to photographing and publishing views of the towns and countryside of Britain and Continental Europe, driven in part by his ambition to photograph every city, village, ruin and site of topographical interest in Britain. From his rapidly-expanding photographic archive Frith sold individual prints of his scenic views and later souvenir picture postcards, both of which proved popular among the growing throngs of Victorian tourists traveling across the British countryside by rail. As the demand for such souvenir views grew over the years the production of photographic cards became a large part of the Frith & Co. printing and publishing business.

In order to keep pace with this demand for photographic keepsakes and to expand his inventory of views, Frith employed a team of photographers. He and his photographers scoured Britain for worthy views and embarked on photographic tours of Italy, Switzerland, Scandinavia, and the Rhine valley in Germany. Frith also bought the rights to suitable photographs from other photographers and published them under his studio's name. Among the photographers who contributed to Frith & Co.'s image archive were such notables as Francis Bedford, Frank Mason Good, William Bell and Roger Fenton, whose collection of negatives Frith had bought in 1862. Thus, while Frith's earliest photographic prints often bore his own signature and date scratched onto the negative, as Frith & Co. grew most of the firm's images remained unsigned, often bearing

only an identifying imprint of the firm itself, typically "Frith & Co" or "F F & Co."

Before long Frith had amassed the largest archive of its kind, including images from all across Britain and beyond, and he continued to publish in a variety of formats. Indeed, twenty-four of Frith's views of the Rhine and Switzerland illustrated an 1865 edition of Henry Wadsworth Longfellow's *Hyperion.* He also supplied the text and images for both *The Gossiping Photographer at Hastings* and *The Gossiping Photographer on the Rhine*—two curious books published at his Reigate facilities in 1864, which he published in addition to such straightforward regional studies as his 1867 Book of the Thames. Above all, however, Frith increasingly sold his images as individual prints and as picture postcards through a network of more than two thousand shops and newsagents in cities and towns across Britain. By 1876 the firm's nearly 700-page catalogue listed over 4000 images including many from Asia, Canada and the United States, and by the 1890s the firm had tens of thousands of subjects on file relating to Britain alone. Indeed, in its production, commercial distribution and sheer variety and quantity of photographic images Frith & Co. was in Frith's lifetime without peer.

By the 1880s Frith, with his health deteriorating, had effectively handed over control of Frith & Co. to two of his sons, Eustace and Cyril. The elder Frith went on to write several books about his Quaker faith, take up oil painting, and penned his autobiography. He died at his winter residence in Cannes, France on January 25 1898 at the age of seventy-six. Frith & Co. continued on under Eustace and Cyril, who for a time sustained the firm's position as a leader in the postcard business around the turn of the century, when the Post Office's acceptance of a standardized format accounted for a new explosion in the postcard's popularity. Eventually, however, the company's prominence waned, and by World War I the family sold the business.

The company's image archive did continue to grow after Frith's death, as successive teams of photographers that met the strict standards and requirements of Frith & Co. continued to photograph for the collection. Indeed, by 1914 the company archives contained some 50,000 photographs, which increased to over 70,000 by 1939. And while the company managed to survive under new management well into the 20th century, the Reigate facility was soon sold and much of the original photographic archive languished as increased competition and rapid topographical change in urban and rural areas relegated Frith & Co. to the margins of the postcard business, their outmoded views of towns and countryside from bygone eras of little interest. By the time the company finally closed in 1971 the archive, which contained over 250,000 prints and 60,000 original glass plates, including views of 7,000 cities and towns from around the world, was in poor condition from years of neglect. Now restored and preserved as an important photographic record of the 19th century, a substantial collection of the company's glass negatives now resides in the Birmingham City Library.

FRITH, FRANCIS (1822–1898)

English photographer, publisher

Francis Frith dominated the photographic publication industry in England in the late nineteenth century. As a photographer, he is known for the hundreds of photographs he made in the Near East during the course of three separate journeys (1856/57, 1857/58, 1859/60) through Egypt, Syria, and Palestine. In execution and in published presentation, his photographs, accomplished on wet collodion glass plate negatives and printed in albumen, set the standard for the burgeoning market for travel photography.

Frith was born to a Quaker mercantile family in Derbyshire. Apprenticed in the cutlery trade, he ultimately settled in business as a wholesale grocer provisioning ships out of Liverpool. His business did well and he sold up and retired at age thirty-four to devote himself to personal interests which included photography. He appears to have learned photography in the early 1850s and in 1853 was one of the founding members of the Liverpool Photographic Society. In 1856, accompanied by a friend, Frances Wenham, Frith set out on a meticulously planned expedition to photograph Egypt. He had shown photographs prior to this; in January 1856 he exhibited at the Photographic Society of London. And he established a connection with the London firm Negretti and Zambra, which listed for sale stereo views of Wales by Frith. When he set out for Egypt in the fall of 1856 he had with him cameras in three formats—standard,

Frith, Francis. The Ramesseum of El-Kurneh, Thebes-First View. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Anonymous Gift, by exchange, 2005 (2005.100.633) Image © The Metropolitan Museum of Art.*

mammoth plate, and stereo. Frith's correspondence, as well as journal entries and reports by Wenham published later, provide detailed information on the logistics of travel photography.

Frith returned from this first trip in July 1857 and departed again that fall for Egypt with the intention of extending his photographic coverage into the Holy Land. While Frith was on this second tour, the publisher James Virtue announced *Egypt and Palestine Photographed and Described by Frances Frith* (1858-1860), available by subscription. The first numbers were released prior to Frith's return and received great acclaim. This was not the first publication of his photographs of Egypt. Negretti and Zambra had released an extensive set of stereo images, *Egypt and Nubia: Descriptive Catalogue of One Hundred Stereoscopic Views of the Pyramids, the Nile, Karnak, Thebes, Aboo-Simbel, and All the Most Interesting Objects of Egypt and Nubia* (1857) which met with wide success. Upon his return he exhibited photographs from the second journey, including an impressively large (8½ feet in length) panorama of Cairo. Inspired by the commercial success of stereo views and the subscription *Egypt and Palestine*, and perhaps to insure the quality of photographic printing, Frith formed a photographic printing firm, Frith and Hayward, with a London printerseller. He returned to Egypt and the Holy Lands for a third and final time in 1859, at which time he rephotographed Jerusalem and other biblical sites, and retraced and photographed the putative path of Moses and the Israelites across the Sinai Peninsula.

Frith's career as a publisher of photographic images began in earnest in 1860. Frith and Hayward's printing operation expanded and moved to Reigate. In 1862 Frith acquired sole ownership and continued printing as F. Frith and Company. Nickel estimates that to meet the demand for Frith's Near Eastern views, the Reigate operation printed more than 152,000 plates from Frith's negatives (Nickel 2004, 78). A second publication with Virtue followed; *Cairo, Sinai, Jerusalem, and the Pyramids of Egypt* (1860–1861), also offered by subscription, and based on photographs from Frith's third expedition. At the same time, twenty mammoth plate photographs were offered in a folio edition by Wm. Mackenzie, *Egypt, Sinai, and Jerusalem* (1860). In 1862 he brought out two editions of a photographically illustrated Bible—a version with twenty standard format photographs, and a lavish version with mammoth plates, dedicated to Victoria and titled *The Queen's Bible*. The definitive publication of photographs from all three expeditions, *Egypt, Palestine, and Nubia* (1862) was released in four volumes organized by region. Frith offered his Near Eastern views in a variety of formats for distinct audiences—stereo views and lantern slide programs appealed to both the popular taste for spectacle and the Victorian interest in self-improvement. Lavishly produced volumes of image and text, offered by subscription, were intended for a cultured, well-educated audience. "In both stereo and projected forms, Frith's imagery was, at the outset, directed at a mass market…it was conceived and offered as spectacle…" (Nickel 2004, 71).

Frith's next project offered photographs from less exotic locations: *The Gossiping Photographer at Hastings* (1864) and *The Gossiping Photographer on the Rhine* (1864). *The Gossiping Photographer* books coincided with the change in travel patterns of the middle class.

When Frith had left for Egypt in 1856, he was making a journey that few of the viewers of his photographs would ever physically make. The multiple publications from his three journeys provided a photographic simulacrum of travel, as well as offered instruction in the lands of the Bible and North Africa. By 1864, travel around England and the continent for pleasure was not unusual. Thomas Cooke was well established offering package tours to regions of England, France, and Germany. (Package tours of Egypt were not introduced until late 1869.) The photographs in *The Gossiping Photographer at Hastings* show the recently built seaside hotels and growing crowds of holiday visitors. Frith's photographs and his breezy text describe places and experiences which his audience expected to share. Frith had relinquished the role of educator to become the "gossiping" photographer one might meet along the way, sharing his views of the places his readers expected to experience.

Frith's photographic printing enterprise is a milestone in the industrialization of photographic printing and publishing in Great Britain. Newly married and after sustaining financial losses, Frith needed income and recognized the burgeoning commercial possibilities in photographic printing. Beginning with the short partnership with Hayward, quickly followed by F. Frith and Co. at Reigate, he initiated the rapid, centralized, factory-scale printing of glass plate negatives. Frith and Co. soon became the largest photographic printing firm in the United Kingdom with a particular specialization in travel photography. Frith acquired negatives from other photographers and commissioned operators to expand the catalogue. In 1876, the catalogue listed over 4000 images. Frith and Co. published a variety of materials—photographic instruction books, illustrated books, and sets of stereo cards. He provided and printed photographs for illustrated novels and travelogues, such as Longfellow's *Hyperion: A Romance* (1865), which was illustrated with photographs he made on his Rhine trip. After 1870, Frith devoted less time to the firm. Always a deeply religious man, he took up service as a Quaker Minister. In the 1880s, he turned control of Frith and Co. to his sons. He died in 1898 in Cannes, France.

FRIZSHE, JULIUS FEDOROVICH (Carl Julius) (1802–1871)

Chemist and biologist

Julius Frizshe was born in 1802 in Neustadt, Germany. He graduated from the Berlin University in 1833 and settled in Russia in 1834. Since 1838 he was an adjunct professor in the St. Petersburg Academy of Science and in 1844 was elected an academician.

The newly invented photographic process aroused great interest amongst the Academy's members and they sent their corresponding member Josef Hamel (1788–1862) to acquaint himself with it. Hamel first visited Henry Fox Talbot in London, and later sent a description of the process in May of 1839 to St. Petersburg along with several prints. The Academy Assembly instructed Frizshe to survey Talbot's method. The academician informed them of the results of his research on the 23rd of May of 1839 and demonstrated how he made two pictures of foliage through the use of photogenic drawing, which he improved in the course of his work. Frizshe found Talbot's method capable only of creating images of flat objects, and from this point of view, the process greatly limited images capability and usability for scientific purposes. This report was the first scientific work on photography in Russia.

In 1843, Frizshe became a member of a commission which studied the Caucasus's mineral waters. He took a daguerreotype camera with him and under his supervision, S. L. Levitsky made daguerrotypes showing Caucasus's views, which were later sent to the French optician Chevalier in 1844.

ALEXEI LOGINOV

FROND, VICTOR (1821–1881)

Born in Montfaucon, France, on November 1, 1821, Jean-Victor Frond learned photography in Lisbon. He arrived in Brazil in 1852 after fleeing a penal colony in Algiers, where he had been a political prisoner of

Napoleon III. In 1858 he opened a photographic studio in Rio de Janeiro and embarked on an ambitious project with the support of Pedro II—producing a photo documentary on the emperor's vast realm with essays by French author Charles Ribeyrolles titled *Brésil Pittoresque* (Picturesque Brazil). Due to Ribeyrolles' sudden death in 1860, the project was limited to Rio de Janeiro, Minas Gerais and Bahia. The book contains engravings from Frond's photos, produced by Lemercier in 1859, including the first portrayals of plantation slaves at work and rural life in Brazil. Frond set the standard for landscape photography in Rio, and popularized subjects such as Sugarloaf Peak and Outeiro da Glória Church. He died in Varredes, France on January 16, 1881. Until six originals were found in 1994, the only known examples of his work were the prints illustrating *Brésil Pittoresque.* In 2004, researchers found 16 more original Frond photos of Swiss settlements in Espírito Santo province, commissioned by Pedro II in 1860 to lure more European immigrants there.

SABRINA GLEDHILL

FRY, PETER WICKENS (D. 1860)

English photographer

Peter Wickens Fry qualified as a solicitor and, towards the end of his life, represented the London wet plate portrait photographer James Henderson in the 1854 court case *Talbot v. Henderson* brought by Talbot for alleged infringement of his calotype patent. Judgement on the case was postponed as a result of the celebrated *Talbot v Laroche* case, and Fry eventually gained damages and costs for his client amounting to £330.

Fry developed an interest in photography in the 1840s, and was one of the founder members of the Photographic Club (often now referred to as the Calotype Club), an informal grouping of enthusiastic users of Talbot's process. He later became a founder member of the Photographic Society of London in 1853.

He first collaborated with Archer shortly after Archer published his account of the wet collodion process, and at the Great Exhibition of 1851, Archer and Fry contributed a single collodion positive (ambrotype) to the photographic equipment exhibit staged by London dealers Horne & Thornthwaite.

Fry counted many early photographers amongst his friends, including photographers John Dillwyn Llewellyn and fellow lawyer Roger Fenton, and was the study of a well known caricature by the artist George Cruikshank.

Obituaries to him were carried by both the *British Journal of Photography* (October 1st 1860) and *Photographic Notes* four days later.

JOHN HANNAVY

FRY, SAMUEL (active 1870s–1880s, d. 1980)

"When great difficulties were looked for none were found," declared Samuel Fry in 1879, on progressing from collodion to dry plates. Fry lived in Surbiton, Surrey, England, but practised professionally throughout the Thames Valley because it was the "favourite place of residence for city merchants." Fry travelled in a horse-drawn van, which carried sufficient equipment to undertake views, groups and outdoor portraits, but including "some small-sized plates of a more rapid description, in case groups, portraits, or animals have to be photographed."

Eschewing the "stern necessity of keeping still for portraits," Fry explored the boundaries of "instantaneous photography" and developed techniques to record "in the twinkling of an eye." By 1881, he had established a company for manufacturing his own brand of plates, the Kingston Special, which "preserve their qualities indefinitely in any climate." Advertisements in *The Photographic Journal* emphasised that tests involved portraits and landscapes before despatch.

Warning readers that "we must remember that photography is still very young," Fry published papers on positive printing, printing on ivory, printing transparencies, lunar photography, the moon in the stereoscope, photography and its students, instantaneous photography, defects, and remedies for paper prints, and often lectured to South London Society.

RON CALLENDER

FRY, WILLIAM ELLERTON (1846–1930)

The book *The Occupation of Mashonaland* by William Ellerton Fry, privately published in 1891 offers a unique visual record of the Pioneer Column expedition into the area of Africa which is present day Zimbabwe, and the establishment of Fort Salisbury.

William Ellerton Fry had arrived in South Africa in 1872 and worked briefly as a farmer and a merchant, before taking on the post of Secretary of the Royal Observatory at Cape Town, a post he held for almost twenty years, eventually attaining the position of Assistant Astronomer Royal. Then in 1890, enrolled as a lieutenant in the Pioneer Corps, he accepted the role of official photographer to the Mashonaland expedition.

The expedition, amounting to several hundred soldiers, policemen and native bearers, trekked into areas where a camera had never before been seen. Arriving at the ruins of the city of Zimbabwe, Fry's equipment caused consternation. In a memoir written later, Henry Hoste noted that "Fry, who was our official photographer, got his camera going, to the great alarm of the

natives, who watched him in fear and trembling, expecting an explosion every moment."

Fry's published visual account of the journey comprised 150 145mm × 195mm carbon prints on pages 465mm x 300mm, of the places and the peoples the Pioneer Corps encountered along their arduous journey.

He is believed to have left Africa after the expedition, and traveled to Australia and New Zealand.

JOHN HANNAVY

FULHAME, ELIZABETH (active 1780s–1790s)

English chemist

Mrs Elizabeth Fulhame's scant personal details are known almost without exception by her own few comments, published in the preface of her 1794 chemical treatise, An Essay on Combustion with a view to a new art of Dying and Painting wherein the phlogistic and antiphlogistic hypotheses are proved erroneous (London: J. Cooper). The book became rapidly known in chemical circles, having been donated to the Royal Society Library in 1795 by the author, and translated into German in 1798, by August Gottfried Ludwig Lentin (1760–1823) a tutor in Chemistry at the Georg Augustus University, Göttingen. The book was later reprinted in an American edition of 1810. It is the practical part of her treatise that concerns photographic chemistry, although it was her theory on combustion that earned her praise and election as an honorary member of the Philadelphia Chemical Society. Fulhame precipitated silver and gold salts not only to dye patterns on cloth, but also to paint rivers on maps. In making these experiments, Fulhame was an important part of the 18th century movement to use metal salts and chemical reactions to make patterns visible. Her demonstration of the reduction of silver proved influential to many later experiments in photochemistry, embodying the principle of 'hypo,' as invented by J.F.W. Herschel.

KELLEY WILDER

FYFFE, ANDREW (1792–1861)

Scottish photographer

Andrew Fyffe was a minor, but briefly influential, figure in early Scottish photography. He was the eldest son of Andrew Fyffe, dissector in anatomy at Edinburgh University. The younger Fyffe graduated in medicine in 1814 but earned his living primarily as a teacher of chemistry. He became Vice-President of the Society of Arts in Edinburgh in 1839, the same year as the announcements of the first practicable photographic processes. Fyffe began investigations into the chemistry of the early processes and embarked on a series of popular and well-attended lectures where he described Talbot's photogenic drawing along with his own improvements. He recommended paper sensitised by silver phosphate as an alternative to silver chloride, outlined a procedure for making direct positives, showed how photography could be applied to lithography, and suggested replacing the lens of a camera with a mirror. By January 1840, Fyffe was able to give perceptive comments on daguerreotype practice to an enthusiastic Scottish public. Although the Society of Arts for Scotland awarded Fyffe a silver medal for his photographic work, he soon returned to teaching. He died in Edinburgh in 1861. A lithograph derived from photographic images by Fyffe survives in St Andrews University Library.

JOHN WARD

G

GAENSLY, WILHELM (GUILHERME) (1843–1928)

Swiss-born Brazilian photographer

One of Brazil's most renowned 19th-century landscape photographers, Wilhelm Gaensly was born in Switzerland on September 1, 1843, in the evangelical community of Felben-Wellhausen. In 1848, his mother, Anna Barbara Kym Gaensly, took young Wilhelm and his two brothers to join their father, Jacob Heinrich Gaensly, in Salvador, Bahia, in the Brazilian Northeast. Like other Swiss immigrants, they attended the British Church, the first Protestant church in Bahia, which Gaensly later photographed, providing a precious record of that historic building, which was demolished in 1975. Known professionally as Guilherme Gaensly, he started his career as a teenager, working as Albert Henschel's assistant at "Photographia Alemã" (German Photography). In 1871, he formed a partnership with Waldemar Lange and Joseph Schleier (1827–1903), a German national with a Swiss Protestant wife. The firm was originally called "Maison Gaensly & Lange," and its staff included the German photographer Karl Heinrich Gutzlaff, who had previously worked with Henschel and Schleier. From that time on, Gaensly enjoyed a steady rise to success and acclaim as a professional photographer. In 1877, the year he won three gold medals from the Imperial Liceu de Artes e Ofícios (a vocational school founded in 1872) and the Academia de Artes, Gaensly founded his own business at No. 1, Ladeira de São Bento, a prestigious address in the city center. Called "Photographia do Commercio" (Commercial District Photography), its advertisements declared that the studio owned "the biggest collection of views of Bahia, *carte-de-visites*, Imperial prints, convex prints and larger portraits." In 1881, he participated in the Brazilian National Library's "Exposição de História do Brasil" ("Brazilian History Exhibition") in Rio de Janeiro (his name appears next to Schleier's on some of the photographs shown there). He also expanded his business that year, opening a larger studio called "Photographia Premiada de Guilherme Gaensly" (Guilherme Gaensly's Award-Winning Photography) at No. 92, Largo do Theatro (now Praça Castro Alves). His gold medals are proudly illustrated on the backs of his cartes-de-visite, which also proclaim that his studio produced "Reproductions and Enlargements with Full Quality—Plates Kept for Reproductions." His services ranged from portraits to commissioned work, such as the "Álbum da Estrada de Ferro Central de Alagoas, Maceió e Vila Imperatriz" on the Central Railway in the province of Alagoas (1882–1884). All of his known works are albumen prints.

In 1882, Gaensly entered into a creatively productive and enduring partnership with his former assistant and future brother-in-law, Rudolf Friedrich Franz (Rodolpho Frederico Francisco) Lindemann, and the firm changed its name to "Gaensly & Lindemann." (Little is known about Lindemann. He was born in Germany ca. 1852 and in 1870 he contributed photographs to illustrate the entry on Brazil in Émile Levasseur's *La Grande Encyclopédie*.) In 1894, Gaensly moved to São Paulo and opened a branch on Rua XV de Novembro, a famous street in the city center, leaving Lindemann to run the Bahia studio. For over 20 years, Gaensly worked for the São Paulo Tramway Light and Power Company (now Eletropaulo) and government agencies, including the Department of Agriculture. His partnership with Lindemann ended in around 1900, when Gaensly changed his firm's name to "Photographia Gaensly," also advertised as "Photographia Guilherme Gaensly."

In Bahia, Gaensly photographed numerous views of the outskirts of Salvador that are remarkable for their beauty, including fishermen's huts and canoes in

Gaensly, Wilhelm (Guilherme). *Ladeira de S. Francisco de Paula, Agua de Meninos, Egreja de S. S. Trindade, Ancoradouro. Acervo da Fundação Biblioteca Nacional, Brasil.*

the Rio Vermelho district before it became part of the urban landscape. His photographs are valuable historical documents of the city's development between 1865 and the 1890s. The National Library of Brazil in Rio de Janeiro houses 64 photographs by Gaensly in the D. Thereza Cristina Maria Collection. Most are views of Salvador. In 1895, Gustavo Koenig Wald published photos by Gaensly in *São Paulo 1895.* Between 1900 and 1910, Gaensly's studio produced several series of postcards on the city of São Paulo, as well as the Port of Santos and coffee plantations. During his years in that coffee-growing region of Brazil, he had photographed numerous plantations in rural São Paulo, including Araraquara, Ribeirão Preto, and Campinas, for the Department of Agriculture. According to art historian Vânia Carneiro de Carvalho, "In his portrayals of plantations, Guilherme Gaensly seeks to make the geometrical lines of the countryside coincide with the dividing lines of photographic planes. Movement is replaced with a rigorously analytical treatment of the image in which nature is framed in an orderly universe and rationalized production…. [We] see in photography the intention of monumentalizing its motif, whether through extreme close-ups or the immoderate addition of formal value to the motif, as well as the attempt to show it as an integral part of its surroundings." Researcher and photographer Pedro Vasquez observes that Gaensly's work for the São Paulo Tramway Light and Power Company "gave him an opportunity to develop his tremendous talent for landscape photography, which is wonderfully expressed in his ample documentation of the city of São Paulo's modernization process." Like Marc Ferrez, Benjamin Mulock, and Auguste Stahl, Gaensly's railway photography transcended his commissions in documenting the natural surroundings and even human aspects of the works he portrayed, which accounts for his photographs' lasting appeal. His talents were recognized abroad during his lifetime. He won a silver medal at the 1889 Exposition Universelle de Paris, where photography was featured prominently in the Brazilian pavilion (Lindemann also won awards that year for his views of Salvador and Recife). Gaensly received another silver medal at the 1904 World's Fair in St. Louis, Missouri, where Brazil's pavilion was a remarkable building with an octagonal dome designed by St. Louis architect Charles H. Deitering. Gaensly worked until about 1915 and died in São Paulo in 1928, after a long and successful career. Since 1975 his works have been shown in New York, Zurich, Berlin, Madrid, Rotterdam, Paris, and major Brazilian cities, including São Paulo, Rio de Janeiro, Campinas, Belo Horizonte and Brasilia. In addition to the National Library collection, they can also be found at the Moreira Salles Institute, the Joaquim Nabuco Foundation and the Patrimônio Histórico da Energia de São Paulo (São Paulo Historic Heritage of Power) Foundation in Brazil.

Sabrina Gledhill

Biography

Wilhelm (Guilherme) Gaensly was born in Wellhausen, Thurgau Canton, Switzerland, in 1843, to Jacob Heinrich Gaensly and Anna Barbara Kym Gaensly. His father became a fabric merchant and cotton exporter in Salvador, Bahia, and the family—including the five-year-old Wilhelm and brothers Ferdinand and Frederick—joined him there in 1848. Gaensly's sisters Julia and Alaine and at least two other siblings, Albert and Alwina, were born in Salvador. His former assistant Rudolf (Rodolpho) Lindemann became his business partner in 1882 and his brother-in-law in 1888, when he married Alaine Gaensly. Guilherme Gaensly wed Ida Elisabeth Itschner

on May 5, 1888, in a Presbyterian ceremony witnessed by Lindemann. In 1894, Gaensly and his wife moved to São Paulo. He ran a branch of "Gaensly & Lindemann" until the partnership was dissolved in around 1900, and continued working there until about 1915. He died in São Paulo on June 20, 1928, survived by Ida Gaensly, who lived there until her death in 1933.

GALE, COLONEL JOSEPH (1830–1906)
English

Gale was a London architect and part-time soldier, serving with the 10th Surrey Rifle Volunteer Corps where he rose to the rank of Lieutenant Colonel.

Gale first took up photography in 1859 as an aid to his profession using a 10 × 8 inch Ottewill camera, later he used both stereo and panoramic cameras to make his studies. In 1866 Gale joined the Amateur Photographic Field Club whose 25 fellow members shared his interest in "mead and stream" subject matter, remaining a member until his death in 1906.

From 1879 he became a regular exhibitor at the Photographic Society's annual exhibitions, where he displayed examples of his favored pictorial subjects, which he largely took in the southern English counties of Berkshire, Surrey and Sussex, often in the company of fellow photographer and friend, George Davison.

Gale, who recorded the rapidly changing way of rural life at the end of the 19th Century, was noted for the quality of his work which he printed using albumen, gelatin-silver and platinum papers, he also produced lantern slides. Gale's best-known picture was the widely-published 1887 view "Sleepy Hollow," a classic naturalistic study of a pair of heavy-horses at a ford.

Gale was one of the first members of the Linked Ring, being elected in May 1892 and taking the pseudonym "Rambler."

IAN SUMNER

GALERIE CONTEMPORAINE

The cult of celebrity was fuelled, in France as elsewhere, by the ready availability of portraits of public figures. Essentially an urban phenomenon, the collection of visual representations of noteworthy persons pre-dates photography, and by the middle of the nineteenth century the commerce in engraved and lithographed portraits was widespread. The advent of photography, coupled with the growth in the popular press, led to further expansion in the phenomenon of celebrity portraiture, especially of stars of the Parisian operatic and theatre world. The public's taste for such imagery was catered for by serial publications such as *Paris-Théâtre*, founded in 1873, at 25 centimes per copy.

Another serial publication, *Galerie Contemporaine*, stands out due to its ambitious scope, as well as for the quality of photographic imagery it contained. Underpinned by a certain patriotic sentiment and a more sophisticated approach to celebrity, the subtitle *Littéraire Artistique* declares the work's focus of interest to be high art. In fact *Galerie Contemporaine* evolved into the most impressive set of celebrity portraits published in nineteenth-century France, forming a vital visual record of the leading figures who shaped public life, in science and politics as well as the arts, during the Second Empire and the emergent Third Republic.

Within its pages, some of the most emblematic portraits of the era appeared, such as Charles Baudelaire by Carjat, Alphonse Karr by Adam-Salomon and George Sand by Nadar. The usual claims to photography's superiority and importance for posterity are set out in the introduction to volume III: "Voilà pourquoi ce livre sera consulté plus tard, avec fruit; car le portrait dessiné, toujours suspect, même chez les peintres de génie, a été remplacé par la photographie, chose brutale, implacable, éminemment scientifique parce qu'elle est

indifférente" [This is why this book will be consulted later, with profit, because the drawn portrait, always suspect, even by painters of genius, has been replaced by photography, brutal, implacable, eminently scientific because it is neutral].

Galerie Contemporaine appeared weekly over a period of eight years from 1876 to 1884, under the imprint of Ludovic Baschet in Paris. Each issue comprised a biographical essay and accompanying portrait, reproduced in Woodburytype printed by Goupil (and the successor firm Boussod, Valadon & Cie for the final volume). The cover price per issue was a relatively high 1franc 25 centimes. Published in two concurrent sections or series—a first series "Littérateurs, Musiciens, Etc." and a second series "Peintres et Sculpteurs," probably appearing on alternate weeks, the work was subsequently bound up and re-issued in six monthly volumes comprising 26 issues, each volume containing separate title pages for the first and second series. Some biographies in the second series were spread over two or more issues, explaining the irregular number of portraits in some volumes. The full run amounted to a total of 241 portraits issued in 13 volumes. While the letterpress biography was essentially similar across both series, the illustrations differed, inasmuch as the subjects in the first series were each represented by a large format portrait hors texte, generally 24 × 18 cm, within an ornamental border, while the subjects in the second series were represented by a smaller portrait, on average 12 × 8 cm, mounted in with the text, as well an example of the artist's output, in a larger format print hors texte. Almost all these images of paintings and sculpture are reproduced directly from the original work, rather than after intermediate engravings or lithographs.

Since the letterpress matter was unpaginated, and the only table of contents was a cursory list of the celebrities featured on the title page to each series, collation is difficult and no standard bibliographical tool yet exists. Furthermore, individual part wrappers are undated. Much of the print run of the first edition must have remained unsold, since a second undated edition appeared as *Galerie contemporaine des illustrations françaises* under the imprint of Paul de Lacroix, in eight volumes containing between 126 and 141 portraits. Larger portraits from this edition can be identified as mounted on undecorated cardstock.

GALTON, SIR FRANCIS (1822–1911)

Francis Galton, one of the most prolific and controversial polymaths in an age that had more than its share, was born on February 16, 1822, in Sparkbrook, near Birmingham, England, the youngest child of a prosperous banker and his boldly intellectual wife. After a suitably pampered upbringing, Galton began his formal education in earnest in schools in France and in England where he demonstrated his precociousness with measurement by tabulating the number and intensity of floggings administered by dour schoolmasters to unruly pupils. Following a brief tour of the Continent, a period of medical study commenced, first in Birmingham and then in the far more dynamic center of London, a pursuit which brought him into the orbit of a cosmopolitan and innovative scientific community. Restless, Galton moved for a time to Cambridge, where he studied mathematics with great difficulty. On his father's death in 1844, Galton, always somewhat uneasy in the academic environment, was left a fortune that obviated the need for a professional career and which would facilitate a series of adventures and inquiries, culminating six years later in a journey to map the interior of the African continent. He proved to be adept enough a topographer to record with accuracy the features of a large swath of southwestern Africa, as well as the dimensions of a number of native women, whose voluptuous forms the fascinated European measured with precision.

Upon his return to London, Galton's achievements were lauded by the Royal Geographical Society, to whose fellowship he was enthusiastically elected. Increasingly immersed in the scientific milieu of the metropolis, Galton married Louisa Butler, the member of a distinguished academic family, in 1853. Situated as he was in the midst of scientific activity, Galton was deeply influenced by the publication in 1859 of *The Origin of Species*, written by his cousin Charles Darwin, with whom Galton renewed his youthful friendship. The impact of Darwin's account on both science and social thought can hardly be overstated, and Galton was so intrigued by the prominence accorded to heredity in the success or failure of creatures that he began to ponder an entirely new type of experimental inquiry. Extrapolating from the agricultural breeding Darwin had used to demonstrate the integral relationship between natural selection and the forms of organisms, Galton asserted that such rationalized mating might be usefully applied to another group. Furthermore, Galton claimed, if physical prowess was dictated by hereditary processes, then mental abilities must equally be inborn: "[i]f a twentieth part of the cost and pains were spent in measures for the improvement of the human race that is spent on the improvement of the breed of horses and cattle, what a galaxy of genius might we not create!" (Brookes, 2004, 144). These were not merely idle theoretical observations, but a concrete program by which Galton imagined his nation could expedite the glacial pace of evolution. Galton continued to refine what he termed "eugenics"

throughout the 1860s, and codified it most comprehensively in his 1869 book *Hereditary Genius*.

By 1873, Galton had begun to seek a way to apply his insights in a practical manner, and the necessary first step would be an accounting of the nation's entire pool of human resources. Galton attempted to accumulate data from schools of every rank throughout England, but when his efforts were received coolly by these institutions, he turned to an acquaintance, Sir Edward du Cane, Inspector of Prisons, for assistance. Galton was furnished with photographs of convicts, which he quickly sorted into classes based upon the type and severity of their transgressions. With this raw imagery at hand, Galton wondered how he could distill the essential physical attributes of each of these classes, soon arriving at a novel method. By successively photographing eight images onto a single plate, in the same position and with an equal fraction of the normal exposure time, Galton found that a superimposed composite of all eight faces could be produced. This composite portrait was of remarkable value to Galton's project, for it obliterated the individual idiosyncracies of the men, but emphasized those features which they shared. This photographic enterprise, while technically innovative, remained conceptually dubious, for it seemed to confirm the long-held position, to which Galton subscribed, that certain physical manifestations were exterior correlates of mental or even moral states. Yet, what was most important for Galton was the fact that the photographic breeding that occurred during the course of these experiments seemed to offer a predictive value for the kinds of policies that his eugenics sought to institute. In an article of 1882, Galton described the prospective use of these works: "The easiest direction in which a race can be improved is towards that central type...there can hardly be a more appropriate method of discovering the central physiognomical type of any race or group than of composite portraiture" (Galton, 1883, 10).

Galton's use of composite photography ultimately lead to a number of related projects, as when he used the measure of deviation from this photographically deduced "central type" as the basis for a system of indexing portraits, so that the likeness of an individual could be easily encoded and disseminated, for example, to law enforcement agencies via wireless. Other enterprises derived from this innovation included the creation of supposedly definitive likenesses of historical figures based upon a composite rendering of their representations on coins and medals, and a procedure for measuring the distance between two points through a series of photographs taken from distinct viewpoints.

For Galton, photography seemed to provide a reliable means for securing the scientific validity to which his eugenic theories aspired, and was imagined to be an objective medium through which the physiognomic manifestation of human qualities could be envisioned in pure pictorial fashion. His photographic experiments proceeded from his fundamental misunderstanding of the nature of this mode of representation, as well as his deeply flawed notions of heredity and evolution. It was in the service of this suspect program that Galton's technologically inventive photographic experiments were employed, and to which his ambivalent legacy can be attributed.

JORDON BEAR

Biography

Sir Francis Galton was born on February 16, 1822 in Sparkbrook, near Birmingham, England into the comfortable household of Samuel Tertius Galton and Violetta Darwin Galton. After schooling in medicine and in mathematics, he embarked on a cartographic voyage to Africa in 1850, returning to London to wed Louisa Butler in 1853. Deeply influenced by the 1857 publication of Charles Darwin's *Origin of Species*, he began a series of studies in heredity and proposed a program of breeding he called "eugenics," which aimed to accelerate the evolutionary process of sorting out what he deemed to be the inferior characteristics of humanity. In an effort to determine and demonstrate the nature of these unfavorable traits, Galton acquired in 1873 photographs of prison inmates and employed an innovative process of composite photography, in which several images were superimposed onto a single photographic plate. A great diversity of photographic pursuits based upon this technique followed in the 1870s and 1880s. Upon his death on January 17, 1911, the problematic program in which Galton's photographic ingenuity was employed had begun to overshadow his technical achievement.

GARDNER, ALEXANDER (1821–1882)

American photographer and philanthropist

Born on 17 October 1821 in Paisley, Scotland to James and Jean Gardner, Gardner was raised in Glasgow, Scotland by his mother after his father's death. Jean (Glenn) Gardner, was from an Ayshire family "of good standing" whose members included ministers, physicians, and farmers, and she single-handedly saw to the "training of the family." As a student, Gardner showed interest in astronomy, botany, and chemistry. At age fourteen, he apprenticed with a Glasgow jeweler, where he worked for the next seven years. During these early years of his life, he became concerned with the condition of the working classes and expressed his views on social issues, as well as on science in art, in the public press. After leaving the jewelry trade, he worked as the editor of *The Glasgow Sentinel*.

Inspired by Robert Owen, Gardner began planning his own utopia in 1848, writing out the colony's "schedule of duties with every minute particular." Established in Iowa by Gardner and his brother in 1850, the community prospered although Gardner returned to Scotland. In 1855, he finally emigrated to the United States, taking his mother, his wife, Margaret, and their two children with him, and they settled in New York. Mathew B. Brady paid for Gardner's fare to the United States though it is not clear why.

While there is a question of whether Gardner was trained in Scotland or America, his eulogy, printed in the *Philadelphia Photographer* in March 1883, suggests that Gardner's experiments in photography emerged from his interest in chemistry in Scotland. Already possessing knowledge of photography, Gardner was hired by Mathew B. Brady to manage his new Washington gallery as photographer and bookkeeper. Frequent portrait sitters at the studio included President Abraham Lincoln, whom Gardner admired, and Walt Whitman who called Gardner "mightily my friend" and "a real artist" who "saw further than his camera."

With expertise in the wet-plate collodian process (see wet collodian negative), Gardner became a member of Brady's corps of Civil War photographers, which also included Timothy Henry O'Sullivan and George N. Barnard. As a photographer for the Union army, Gardner took three-quarters of the pictures of the Army of the Potomac's advance, remaining with General George B. McClellan during the campaigns in Virginia. Gardner left Brady's group, however, in 1863 possibly over issues of authorship of photographs. Gardner then opened his own gallery in Washington and hired a group of photographers.

Civil War photographers relied on cumbersome equipment hauled by horse-draw wagons carrying glass collodian, silver nitrate, and developer; photographers used tents for development. In addition, images required a long exposure time. Thus, Gardner and others could not capture images of active battle but captured still landscapes and scenes of camp life. They made images in stereograph, cartes-de-visite, and large imperial formats.

Gardner's photographs also reached the public through a couple other venues, such as exhibitions and illustrated publications. Gardner's photographs of Antietam for Brady's studio, for instance, were exhibited within a month of the battle. A review in the *New York Times* on 20 October 1862 stated that Gardner's photographs brought the reality of the war to people's homes. Gardner also provided *Harper's Weekly* and *Leslie's Illustrated News* with photographs, which they copied and combined in illustrations for print.

In his two-volume publication, *Gardner's Photographic Sketch Book of the War* of 1866, Gardner had photographic albums in mind. Each volume contained fifty original Civil War photographs by Gardner, some of which were from his work for Brady. A caption supports each photograph, with text on the opposite page describing the scene and its significance. Concerned with accurate attribution of photographs, Gardner lists the name of the maker of the negative and the print below each image.

In introductory remarks, Gardner describes his *Sketch Book* photographs as "mementoes of the fearful struggle" and hopes for their "enduring interest" as war memorials. While many of the photographs show camp life and historic events, such as Lincoln's visit with McClellan at Antietam (1862) in Plate 23, the most memorable images depict the ravages of war. Among these images are Plate 36, "A Harvest of Death" (negative by T.H. O'Sullivan and positive by A. Gardner) and Plate 94, "A Burial Party on the Battle-Field of Cold Harbor" (negative by John Reek, positive by A. Gardner). Taken in Gettysburg, July 1863, "A Harvest of Death," shows the strewn bodies of soldiers on a field. Gardner's text places war within the natural environment:

> Slowly, over the misty field of Gettysburgh—as all reluctant to expose their ghastly horrors to the light—came the sunless morn, after the retreat by Lee's broken army. Through the shadowy vapors, it was, indeed a 'harvest of death' that was presented; hundreds and thousands of torn Union and rebel soldiers [. . .] strewed the now quiet fighting ground, soaked by the rain, which for two days had drenched the country with its fitful showers.

In "A Burial Party," taken on April 1865, Gardner shows us African Americans, probably soldiers, burying Union dead. In his text, one can hear Gardner's unequivocal support of the Union cause.

Because of the high cost of Gardner's *Sketch Book,* it failed commercially. Nonetheless, Gardner's career as a photographer continued to flourish with an expedition in the fall of 1867 to photograph the construction of the Kansas Pacific Railroad, Eastern Division, as it moved

westward to meet the Union Pacific. Gardner published these photographs in *Across the Continent on the Kansas Pacific Railroad* in Washington in 1868. From 1867 to 1880 Gardner photographed Indian delegates to Congress for the Office of Indian Affairs, and in 1873, he made a rogues' gallery for the Washington police.

Later in his life, Gardner devoted himself to philanthropic work for the Washington Beneficial Endowment Association and the Masonic Mutual Relief Organization (Washington, D.C.) for which he served as Secretary. Gardner died on 12 December 1882, but his work remains in collections at the National Archives, Library of Congress, the George Eastman House, and the New York Historical Society in the United States.

Francine Weiss

Biography

Alexander Gardner was born October 17, 1821, in Paisley, Scotland, but raised in Glasgow, where, as a teenager he apprenticed with a jeweler until he was in his early twenties. With knowledge of chemistry, Gardner experimented with photography and, after establishing an Owenite utopian community in Iowa in 1850, he settled in New York with his family in 1856 finding himself quickly hired by the photographer-entrepreneur Mathew Brady as the manager for Brady's Washington gallery. In the years before and during the Civil War, Gardner made his greatest contributions to photography with his many portraits of Lincoln, the last of which was taken in 1865 five days before Lincoln's assassination, and with his Civil War photographs, taken while working for Brady. In 1863, he left Brady to open his own gallery in Washington D.C., but his work as a Union photographer for Brady and as an independent photographer led to his publication in 1866 of a two-volume set of a hundred Civil War photographs, accompanied by text and captions, called *Gardner's Sketchbook of the War*. Containing images by Gardner and other Civil War photographers, these volumes documented

the aftermath of the war, as well as everyday scenes of camp life and other historic events. In September and October of 1867, Gardner photographed construction of the Kansas Pacific Railroad, Eastern Division publishing the photographs in *Across the Continent on the Kansas Pacific Railroad* in 1868. From 1867 to 1868, Gardner photographed Indian delegates to Congress for the Office of Indian Affairs, and in 1873 he made a rogues' gallery for the Washington D.C. police. As Gardner's interest in photography waned, he devoted himself to philanthropic causes through the Masonic Mutual Relief Organization in Washington D.C. and the Washington Beneficial Endowment Association until he died on 12 December 1882.

GAUMONT, LÉON ERNEST (1864–1946)

Born in Paris in 1864, from 1881 Léon Gaumont was employed in the workshops of Jules Carpentier, maker of precision instruments, who would later construct the Lumière Cinématographe. In 1894 Gaumont went to work for Felix Richard in his shop, the Comptoir General de Photographie, 57 rue Saint-Roch, Paris. (This had been founded in 1851 as the Maison Richard.) Gaumont bought the business in August 1895, in partnership with Gustave Eiffel, of tower fame, astronomer Joseph Vallot, and financier Alfred Besnier.

During the 1880s and early 90s several inventors and scientists around the world had become involved in sequence photography or 'chronophotography,' mostly for purposes of motion analysis. Some, fascinated by the possibilities of photographs that moved, had developed methods of re-synthesising motion from these sequences, leading to the development of cinematography. In 1895 Léon's company, named L. Gaumont and Co., started to manufacture and market the chronophotographic camera for unperforated rollfilm, and the Bioscope projector / viewer (previously the Phonoscope, now re-named) for sequence pictures mounted on a disc, both devised by Georges Demenÿ. Léon Gaumont obtained filmstock from Georges William deBedts, one of the earliest producers of cinematograph materials and equipment. However, these first Gaumont-Demenÿ machines were limited in their potential, and failed to find a market. Convinced of a future for the new moving image business, Gaumont was undeterred by this setback and was soon marketing new 60mm and then 35mm motion picture cameras and projectors—still based on the Demenÿ principle but now using perforated film—and these became very successful.

In the late 1890s Gaumont's young secretary Alice Guy directed films for the company, and Léon Gaumont experimented with Eiffel on "the new photography," X-rays. At the Paris Exposition of 1900, Gaumont displayed "prints, enlargements, and photographic processes." By now well known in the photographic business, Léon Gaumont was joint secretary of the second committee of the International Congress of Photography held during the Exposition, with responsibilities for the subject "Photographic Material." The Gaumont Company was at this time the principal agent for the Photo-Jumelles cameras of Jules Carpentier, and made and sold folding plate, vest pocket , detective, and stereoscopic cameras—with names including Block-Notes and Spido. Stereoscopic viewers were also produced and marketed by the company for many years, including the Gaumont Stereodrome; a salon stereoscopic viewer of superior optical and mechanical construction, for three standard sizes of glass stereoviews.

Every aspect of moving images engaged Léon Gaumont's fertile mind. In the late 1890s, long before the establishment of specially-built motion picture theaters, the manufacturers of motion picture machines and films were actively exploring the various possible outlets for the new medium. The domestic hobby market seemed ripe for potential if a simple-to-operate, relatively inexpensive, miniature system could be developed. The Gaumont Chrono de Poche launched in 1900 was an amateur cinematograph camera using a narrow-gauge (15mm) film with center-perforation; and was the first home movie camera to use a clockwork motor. The same 'beater' mechanism, which had served Gaumont so well, was also used for projection. At the close of the

century the company also manufactured and marketed various mutoscope flip-photo motion picture viewing machines, including the Lumière-Casler Kinora, a clockwork device for home entertainment.

From 1902 Gaumont gave demonstrations of mechanically synchronised motion pictures with sound. Léon Gaumont and his company continued to develop photographic inventions and devices, including sound and colour motion picture systems, throughout the early years of the 20th century. They maintained film production, distribution, and exhibition and Gaumont became, with Pathé, one of the top two companies in the cinema world. From 1905 to 1914 its studios at La Villette were among the largest anywhere. The name Gaumont survives in the twenty-first century motion picture business.

STEPHEN HERBERT

Biography

Léon Gaumont was born in Paris, France, on 10 May 1864. His father was Auguste Ferdinand Gaumont, his mother Marguerite Dupenloup. In 1888 he married Camille Maillard. A meticulous individual, Gaumont maintained a close involvement in all aspects of his business across the audio-visual field. He was evidently reluctant to delegate; a wide range of company letters of the period bear his signature. Léon Ernest Gaumont retired in 1930 and died at Saint-Maxime on 1 January 1946.

GELATINE SILVER PRINT

Gelatine silver papers evolved from a number of sources, including Richard Leach Maddox's work with silver bromide suspended in gelatine. These materials were also suitable for printing paper; the gelatine coating retained its permeability when dry, so that the paper could be prepared and sold ready-sensitized. The first commercial gelatine silver paper was silver bromide, predating gelatine silver chloride papers, which were produced in a variety of formulations in the early 1880s but not widely available until the next decade.

Variations in gelatine can affect photosensitivity; in the 1880s, inconsistent sensitivity slowed the acceptance of gelatine developing-out papers. In the late 1890s, Eastman and Company established special herds of cows fed on mustard plants to produce optimum photosensitivity in the gelatine made from their bones. By 1895, gelatine had replaced albumen as the standard colloidal binder for silver salts. As opposed to albumen, which contained residual sulphur compounds, gelatine was less likely to produce yellowing of the base highlights or sulphiding of the silver image.

Gelatine papers were made in both printing-out and developing-out formulas. An early silver chloride printing-out paper was introduced by William Abney in 1881. The addition of citric acid increased shelf life, and in 1884, Emil Obernetter began large-scale manufacture of pre-sensitized papers in Munich. Obernetter used baryta (barium sulphate in gelatine) as a subbing layer, providing a smooth surface to which the silver gelatine coating readily adhered. Printing-out paper had initial problems with the consistency of the emulsion, and its wider use only came in the 1890s with the development of continuous-roll coating machinery. Gelatino-chloride papers were often denoted as "aristo" papers; in 1891, Ilford called its version 'POP,' which has persisted as a generic nomenclature.

Developed-out silver chloride paper was proposed in 1881, when Guiseppe Pizzighelli published his work with Josef Maria Eder on the chemical development of silver chloride using new organic developers. In 1882, Dr. E. Just began limited production in Vienna, and subsequent improvements were introduced by Leon Warnerke, and Dr. Leo Baekland. In 1893, Baekland 's formula was used by the Nepera Chemical Company for 'Velox' paper (later popularized by Eastman Kodak). Such papers attracted the colloquial name 'gaslight' paper, as they could be handled under a red-shielded gas safelight and exposed by removing the shield and turning up the gas. Developed-out silver chloride could be contact-printed or exposed under an enlarger. Image quality was very good; a fine grain is typical of a silver chloride sensitizer. Gaslight paper was popular with amateurs and more generally used for commercial documentary and studio work.

In 1883, Eder reported a mixed emulsion developing-out paper of about 60% silver chloride and 40% silver bromide. It was one-twentieth the speed of silver bromide, but much faster than pure silver chloride and easier to control than pure silver bromide. In 1890, Ilford reintroduced 'Alpha' paper as chlorobromide gelatine. Mixed emulsion papers remain the standard for modern black-and-white photographic printing, marketed as variable contrast papers.

Printed-out silver chloride paper was typically glossy; a matt finish could be produced by squeegeeing the print face down on a sheet of ground glass and allowing it to dry *in situ*. This was common practice; platinotype and bromide papers had encouraged a preference for matt prints. In the early 1890s, matt developing-out papers were manufactured with rice starch and resin (shellac). In addition, the baryta substrate could be embossed to provide a textured finish. Chlorobromide paper usually had a matt and/or textured surface finish.

Printing-out papers show a warm brown colour (unless toned), because printed-out silver is deposited as small, spherical particles of metallic silver, which absorb blue light and reflect yellow light. Since brown is really a dark yellow, light reflected from spherical particles is perceived by the human eye as having a brown hue. 'POP' papers were usually gold-toned, giving a colder, purple-brown colour, and many 'self-toning' papers were manufactured with integral gold chloride. This was further moderated by a tinted blue-grey or lavender-grey baryta substrate, which suited the primary application of POP for commercial portraiture. The paper was also used for proofing negatives and printing early snapshot photographs.

Developing-out paper tends to a neutral-black image colour (unless toned), because developed-out silver is deposited as a tangle of filamentary silver whose light absorbing properties produce the appearance of a neutral-black hue. But platinum and bromide papers had established the taste for a colder image colour, which manufacturers produced in gaslight papers by modifying emulsion chemistry and developers. Gaslight paper responded well to a variety of developers; gallic acid gave a greenish-black to brown image colour, while hydroquinone and ammonium carbonate created a warm red. Additionally, decreasing the exposure time and increasing development affected the grain structure of the silver and shifted the hue towards black. Chlorobromide produced a warm-neutral black, but could be developed for brown tones, which were emphasized by an ivory or cream tinted paper base. These attributes suited portrait work, for which chlorobromide papers were typically used.

In the 1850s, platinic chloride was proposed for

toning silver chloride prints: gold toning was relatively expensive, and platinum was one-third of the price of gold. In 1889, Lyonel Clark improved the toner by substituting potassium chloroplatinite. Platinum gave rich black tones to manufactured papers and was employed from about 1895 until the early 1920s, sometimes combined with palladium (particularly for homemade chloride papers). In the 1890s, uranium nitrate toning was used for purple to red-brown colours, ferric ammonium citrate for browns, and traditional thiocyanogen or gold chloride for a violet-black hue. Other toning compounds included copper (for red), iron salts (Prussian blue), and vanadium (green). Sepia toning with sodium sulphide was not adopted until the early 1900s.

Silver gelatine papers show oxidative-reductive 'tarnishing' from acids (from handling or airborne pollutants), and staining and sulphiding from residual fixing chemicals. The gelatine can display moisture damage, evident in dull patches on the print surface, spots of mould, and delamination of the gelatin binder.

GENRE

As a category of subject matter in painting, genre refers to incidental scenes of everyday life. In photography, the term further suggests the artificial re-creation of such scenes for the camera (rather than the more direct recording of actual subject matter as in documentary or snapshot photography). Often associated with Victorian art photography, genre photography typically involves the staging of a narrative tableau, using paid or amateur models to enact familiar themes.

From the French for kind or variety, the word genre first designated the various kinds, or genres, of painting subordinate to grand manner history painting in the eighteenth-century academic hierarchy (such as landscape and still life), before acquiring its more restricted meaning in the 1790s (Stechow and Comer, 1975–6, 90). The terms high and low genre are sometimes used to distinguish between scenes of bourgeois life and peasant life. The initial popularity of such everyday themes in the art of the seventeenth-century Dutch Republic can be linked to the appearance of a moneyed merchant class, which in its painting preferred humble images of daily existence with subtle moral overtones to courtly or religious display.

In the decades prior to photography's invention, interest in genre painting surged internationally, spurred by the Enlightenment and industrialization. Reputations of Dutch seventeenth-century and French eighteenth-century painters previously deemed minor rose dramatically, and pictures of ordinary subject matter were collected widely, influencing trends in nineteenth-century painting up to and including impressionism. For example, the Scottish painter Sir David Wilkie modeled his work of the early nineteenth century on Dutch and Flemish seventeenth-century painters of peasant scenes such as Adriaen van Ostade and David Teniers the Younger. For early photographers, conventional genre subjects in painting similarly offered a source of recognizably "artistic" or "picturesque" images, while avoiding the pitfalls of more lofty subjects such as moral allegory, which, many critics argued, went beyond the proper scope of photography. Exemplified by the work of Henry Peach Robinson, who hired models to portray rustic farm workers, such scenes of everyday life in nineteenth-century photography could be elaborately constructed affairs. Made deliberately to achieve artistic effect, genre photographs were thus enmeshed in conflicting, and shifting, aesthetic debates about both painting and photography.

Though he did not use the term, William Henry Fox Talbot clearly referred to genre painting in his 1844 *Pencil of Nature* with his image entitled *The Open Door* (Plate VI). A self-consciously artistic study of light and texture, it shows a rustic cottage door with a bristle broom poised diagonally in the foreground. In the adjacent text, Talbot declared, "We have sufficient authority in the Dutch school of art, for taking as subjects of representation scenes of daily and familiar occurrence" (Talbot, 1969). Talbot here linked the incipient art of photography with contemporary esteem for Dutch painting while, visually, borrowing the motif of the broom, propped precariously at an angle, directly from seventeenth-century works by Pieter de Hooch and others (Chiarenza, 1975, 24).

Other early calotypists enacted scenes "from life" modeled on Dutch and other genre paintings. David Octavius Hill and Robert Adamson's *Edinburgh Ale* (1843–46), remarkable for the seemingly animated

Greene, John Beasley. Mariette's Excavations to the Left of the Sphinx. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Anne Tenenbaum and Thomas H. Lee Gift, 2005 (2005.100.276) Image © The Metropolitan Museum of Art.*

poses and expressions of its three drinking figures, was derived from scenes of jolly drinking companions in the work of a number of Dutch painters (Graham Smith, 1983). In France starting in 1841, Charles Nègre executed a well-received series of photographs of child chimney sweeps, a characteristically "low genre" theme found in painting. In such cases, photographic scenes that seemed to show a slice of life were in fact carefully posed, owing in part to long exposure times. As in genre paintings, the suggestion of everyday life in photographs was often achieved by highly deliberate means.

The Victorian art photographer Oscar Gustav Rejlander summed this up when he wrote that a photographer should look for his subject matter "in his daily life" at the social table, at a ball, an assembly, in the streets "and if he wishes to produce what he has seen, he can do so in the studio afterwards" (Spencer, 1985, 71). While Nègre and other calotypists had worked out of doors, Rejlander, along with his student Henry Peach Robinson, reenacted scenes of daily life in their studios. Throughout the 1860s, Rejlander produced photographs of street urchins in the studio; whether the child models in these urban genre scenes were actually from the street is unclear (Spencer, 1984, 18). Robinson, often making use of combination printing, specialized in rural scenes. Both photographers had much greater success with such subjects than with their more overtly contrived literary and allegorical pictures. With its perceived realism, photography was deemed by critics to be capable of rivaling the work of genre painters, even as those same critics condemned photographic attempts at High Art. "We may have a photographic Teniers," wrote one in 1856, referring to the Flemish painter of peasant scenes, "but not a photographic Raphael" (*The Journal of the Photographic Society*, 1856, 46). In addition to Rejlander and Robinson, many notable British photographers of the 1850s and 1860s, among them Roger Fenton, Lewis Carroll, and Viscountess Clementina Hawarden, staged narrative incidents of domestic life for the camera.

For the late nineteenth-century Pictorialist movement, artfully constructed "slice of life" scenes again constituted a central motif, as in the early work of Alfred Stieglitz. His *Paula* (1889) seems to capture a woman unawares as she writes a letter, light streaming in from a nearby window. The image, despite its naturalism, has been shown to correspond to similar themes in Dutch painting, and to show other signs of clear contrivance on the part of Stieglitz (Hulick, 1993).

With the advent in the late 1880s of snapshot photography, which offered the possibility of truly spontaneous images of daily life on a mass scale, genre remained a distinct approach, identified with the tradition of art photography. Writing in 1901, Frank Meadow Sutcliffe defined "Genre photography" broadly as the arrangement of figures to suggest an implied narrative. According to Sutcliffe, genre subjects might be drawn from imagination, literary or artistic sources, or from observation. In any case, they offered the photographer the challenge of composing an image that could convey a sense of momentary action. The photographer might at first have difficulty realizing his conception, he wrote, but "with a little practice he will soon learn the tricks of his trade and place his figures so naturally that his friends and critics will mistake his composition for a lucky snapshot" (Sutcliffe, 1980, 129). Despite superficial similarities, the carefully executed genre photograph was anything but a "lucky snapshot."

GENTHE, ARNOLD (1869–1942)

German photographer and studio owner

Arnold Genthe was born in Berlin, Germany in 1869. Upon completion of a degree in classical philosophy at the University of Jena, Genthe took a job as a tutor in San Francisco, California. While in San Francisco, Genthe became fascinated by its Chinatown neighborhood. He taught himself photography to accurately capture its residents. These early photographs are among his most well-known work. In 1897 he opened a studio and began to photograph celebrities, society people, and the changing face of the city, including photos taken in the immediate aftermath of the 1906 earthquake. In 1911 Genthe moved his studio to New York, where he focused mainly on portraits of the wealthy and well-known. He photographed modern dancers and film stars, including Isadora Duncan and Greta Garbo, and became well-known for those images. His portraits were unposed and artistic, mainly in the pictorialist, romantic style, and often used intricate lighting and soft-focus. Genthe was an early experimenter with color photography, and first exhibited color autochromes in 1911. Although primarily known for portrait work, Genthe documented his travels to Japan and Guatemala, and published a book of photographs of New Orleans. Arnold Genthe died on August 9, 1942 in New Milford, Connecticut.

JENNY GOTWALS

GEOFFRAY, STÉPHANE (1827–after 1895)

French lawyer, banker, and photographer

Born on 17 April 1827, in Roanne, France, Stéphane Geoffray was the son of Antoine Geoffray, a confectioner, and Claudine Julie Chavalland. Although he went by the name of Stéphane, his actual first name was Étienne.

Nothing is known about Geoffray's childhood. From 1852–1854, he apparently studied law in Rouen. By May 1855, he was established as a lawyer in Roanne, at 8, rue du Collège. He took up photography around 1850–1852, using the waxed-paper negative process of Gustave Le Gray from 1852–1854.

Most of Geoffray's renown as a photographer stems from 1854–1856, when the wet-collodion process was superseding the paper negative process. During this period, he wrote technical articles aimed at making paper a viable alternative to glass.

Geoffray's first procedure, published in 1854, was known as the cerolein process and was modified from Le Gray's original waxed-paper negative process. However, instead of saturating the fibers of the paper with melted beeswax prior to iodizing, as Le Gray had done, Geoffray first boiled the wax in alcohol, causing it to separate into three constituent components: cerotic acid (cerin), myricin, and cerolein. Upon cooling, only the cerotic acid remained in solution (which Geoffray consistently, but inexactly, called "*céroléine*") and the re-solidified myricin and cerolein were filtered off. Iodizing consisted of a second, alcohol-based iodizing solution being blended with the cerotic acid solution and sheets of paper being plunged into the bath, followed by drying. The sensitizing, developing, and fixing steps were similar to the waxed-paper negative process—with an additional final waxing step, utilizing the leftover myricin and cerolein.

This procedure had two advantages over Le Gray's: first, granularity and image definition were improved because the iodizing chemistry was directly dissolved in the cerotic acid solution; and second, the time required to iodize, sensitize, and develop the negative was greatly reduced.

Following the publication of Geoffray's procedure, a debate arose as to whether or not it was justifiably

different from Le Gray's. Acknowledging its benefits, Le Gray insisted that it was not a separate procedure but a simply a modification of his own. Maurice Lespiault criticized Geoffray's procedure for not being able to keep very long, but G. Roman and A. Cuvelier were pleased with it.

In early 1855, Geoffray published another cerolein procedure—primarily intended for glass, but also for paper. This consisted of collodion mixed with cerotic acid, the latter contributing to a thicker and more resistant coating. Geoffray also mentioned that the formula made collodion easier to spread on paper.

In his 1855 *Traité pratique pour l'emploi des papiers du commerce en photographie*, Geoffray lamented the contemporary state of paper production and discussed the steps needed to manufacture paper for photographic purposes. He also suggested methods for purifying paper for photographic purposes, alleviating stains caused by metal particles, and sizing.

In 1856, Geoffray published two more paper processes, stating his determination to find a paper process that would rival collodion on glass.

The first was a dry-paper process adapted from Jean-Marie Taupenot's 1855 collodio-albumen process. Here, a sheet of paper was sensitized twice: the first coating formed a lower layer of silver chloride in starch sizing; the second, an upper layer of silver iodide in albumen. According to Geoffray, after the exposure of the negative, the lower layer containing silver chloride would be more printed-out by the actinic action of light than the silver iodide layer; from this, he surmised that the silver chloride layer was less influenced by the subsequent process of development, isolating the upper silver iodide layer and contributing to a reduction in exposure time and an improvement in definition.

The second process required a preliminary step in which sheets of paper were soaked in a solution of gutta-percha dissolved in benzene and hung to dry. (The gutta-percha formed an impenetrable coating that kept the later formation of a light-sensitive surface entirely suspended above the paper—further augmenting light-sensitivity and precision of detail.) Next, a weak paste of glycerin was applied to a sheet of glass, and a sheet of the prepared paper was placed upon it. Iodized collodion was spread over the sheet of paper adhering to the glass, and the paper was removed and plunged, face-up, into a silver nitrate bath. The sensitive surface having been formed, the paper was briefly rinsed in water and replaced upon the glycerin-coated sheet of glass. Following exposure, development, and fixing—which were identical to the wet-collodion process—the paper was removed from the sheet of glass and washed, dried, and waxed like a typical paper negative. Geoffray claimed that photographs made using this process were indistinguishable from those made on glass.

In 1857, Geoffray complained of being too busy practicing law. From 1857–1873, he does not seem to have been very active as a photographer, remaining in Roanne and rarely travelling to Paris. In 1859, he married Marie Virotte, and that same year they had a son, Jacques Félix Geoffray. In 1864, he was listed as a banker in Roanne, in addition to being listed as a lawyer. In 1867, he exhibited prints in the *Exposition universelle*.

In 1874–1875, Geoffray returned to photography, making illustrations and writing articles for a short-lived archaeological journal entitled *Le Forez illustré*. This was the realization of a persistent goal in Geoffray's photography: documenting historical architecture in the environs of Roanne. Each cover featured a photograph made by Geoffray. The first issues consisted of albumen prints pasted on the covers, but by 1875, he had switched to making photographic prints on a press.

In the summer of 1875, Geoffray returned to Paris and established a photo-lithographic press at 40, rue d'Enfer. Apparently, he renounced the practice of law and banking, in order to devote himself to photography. In 1876, he and his family moved to 92, boulevard de Port Royal, where they lived until 1881.

From 1879–1881 Geoffray wrote and published a book on archaeological remains in the region of Roanne, *Iconographie des départements. Loire (Ancien Forez)*, illustrated by his photographs. His son made the prints on a typographic printing press. Therein, Geoffray expressed his photographic aesthetic: photography was a tool to document old artifacts *in situ*, before they were vandalized or removed from their original contexts

In the 1880s, Geoffray resumed writing technical articles and manuals. These addressed photomechanical reproduction, gelatin-bromide emulsions, and stripping negative emulsions from original supports. As late as 1880, he still voiced a preference for paper, writing, "Paper is for me, the support of predilection."

After 1895, there is no record of Geoffray. The last record bearing his name pertains to the death of his son on 14 November 1895.

Alan Greene

Biography

Stéphane Geoffray was born on 17 April 1827 in Roanne, France. A lawyer and banker, he took up photography in the early 1850s. In 1854, he published a variant procedure of Le Gray's waxed-paper negative process, inaccurately called the cerolein process. In 1855, he published a book on the manufacture of paper for photographic purposes; and in 1856, two negative procedures aimed at making paper a viable alternative to glass. From 1857–1873, Geoffray appears to have left photography for other pursuits; but in 1874, he returned to photography in order to start an archaeological journal

featuring his photographs of architectural ruins in the environs of Roanne. Just about all of his photography addressed the theme of the preservation of historical architecture. In the 1880s, he resumed writing articles and manuals, addressing the photo-technical concerns of the day and voicing a continued preference for working with paper negatives. Following a record dating to 1895, nothing is known about the remainder of his life.

GEOLOGY

Photography's function in the historiography of earth science is peculiarly complex. Geology as a modern discipline emerged in late eighteenth-century Europe from what had been a broad array of philosophical inquiries into nature. Conservative accounts of the earth's age came under particular scrutiny as the empirical evidence in the field indicated that millions and not merely thousands of years had past since the planet's beginnings. Theories of origin focused specifically on opposing arguments of the neptunists and plutonists, involving massive underwater and volcanic generations of earth forms, respectively, and whether cataclysmic events during relatively short intervals had contributed to the extremes of the terrestrial surface (*catastrophism*). By the middle of the nineteenth century most geologists had come to embrace variations of the notion that relatively uniform conditions over time were responsible for present-day appearances (*uniformitarianism*), though precisely what circumstances of movement had taken place were still under considerable debate.

Several kinds of delineation for the credible illustration of rock stratification, coastal formation, mountain building, and other forms of geological curiosity had been established during this period. Landscape painting and drawing, part of a growing interest in travel and topographical survey and aesthetic regard for the spectacle of nature, also served as background for the geological and geographical comprehension of the planet. Thus, by the time of photography's first decades, the ground had been broken for both symbolic and realist visual communication. The cultured society that recognized geology as an important scientific discipline also realized the importance of a medium that could record things in minute detail (e.g., Fox Talbot, Daguerre, Herschel, Arago). In 1841 Robert Hunt published his *A Popular Treatise on the Art of Photography*. A geologist himself, Hunt called his readers' attention to the possibilities of the camera as applied to nature. The art critic and amateur naturalist John Ruskin wrote passionately and often knowledgably about rocks, mountains, and glaciers. Although later unfavorably disposed toward photography as a form of artistic expression, Ruskin had practiced daguerreoptypy from the late 1840s to the mid 1850s, producing some of the earliest instances of Alpine scenery.

The photograph began to fulfill its promise as a mode of documentation when landscape photography and expeditionary work converged at mid-century, proving important not only for theoretical science, but also for reconnaissance, economic development, and territorial appropriation in the cause of nationalist and imperialist interests. By the 1850s Britain, continental Europe, and the United States each had scientific organizations that served to advance geological research. Studies of sediment and erosion, rock and fossil distribution, glacial action, valley and mountain formation were all subjects of domestic field work and theorization. Such subjects appear as intentionally selected in the work of both professionals and serious amateurs who explored the rocky coasts of Britain, the rugged terrain of Wales, and the great massifs of the Pyrenees and the Alps. John Dillwyn Llewelyn evinced his scientific background in his photographs of the Cornish peninsula. John Stewart, brother-in-law of Herschel, exhibited pictures of the Pyrenees in 1852 to the glowing acclaim of the photographic community, while the Alps occupied the attentions of William Bedford and William England. In France, Auguste-Rosalie Bisson, brother of fellow practitioner and partner Louis-Auguste, received attention for his photographs taken in 1862 on his second attempt to ascend Mont Blanc. In an effort to convey the spectacle and physical extent of the ranges beyond the capacity

Fennemore, James. Mukuntuweap Valley (Zion Canyon), Utah. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

of a single picture, operators like the Bissons devised ways to secure multiple views that, when assembled in total, comprised a panoramic vision evoking the original encounter. The French geologist Aimé Civiale provides an especially intriguing case of the use of panoramas with specific correlation between photography and geology. He produced hundreds of views in the Alps and Pyrenees between 1859 and 1866, including carefully calculated multi-plate panoramas designed to elicit a sense of spatial presence of the ranges from a full 360 degree scope.

The majority of wilderness and expeditionary photographers generally had multiple intentions for their exploits; undoubtedly many understood that photographs of geological phenomena might have importance for the support of theoretical discussion as well as visible authentication of regions of political and economic concern. Samuel Bourne, who had established himself as a commercial operator in Simla with partner Charles Shepherd in 1863, undertook his third photographic expedition into the Himalayas in 1866 with the British surgeon and amateur geologist George Rankin Playfair. Playfair directed Bourne to focus on specific "curious" and "singular" geological formations, some of which were directly linked with descriptions of the renowned geologist Charles Lyell. Robert Schlagintweit, one of several German brothers who traveled to India and the Himalayas and Central Asia lent his knowledge of photography to their scientific expeditions. The photographs from such projects became available to the scientific community and the interested public either through detailed reports, as in the case of the Schlagintweits, or through the acquisition of individual prints and albums of selected views, as in the case of Bourne.

The U.S. government sponsored a number of important surveys immediately following the Civil War, several of which were led by men with considerable knowledge of latest geological controversies. Clarence

King, who had trained with the renowned Swiss naturalist Louis Agassiz, clearly understood the desirability of having a photographic record of his expeditions along the 40th parallel (1867–69; 1872), since he recruited the experienced Timothy O'Sullivan for his campaigns into the Great Basin of the American West. King's catastrophist ideas were considered by the majority of the progressive scientific community as outmoded. Nonetheless, King's reports and O'Sullivan's startlingly austere photographs would appear to support the argument of relatively sudden traumatic upheaval of the earth's surface. Like his fellow geologist Ferdinand V. Hayden, who employed the photographer William Henry Jackson on his own surveys of the West (1870–78), including Yellowstone, King had to gain government support for his scientific activities by demonstrating the economic potential of mineral-rich areas of the wilderness. Photographers thus engaged in geographical exploration could serve both pragmatic and speculative roles in the gathering of evidence for specific geological study. Yet the photographic securing of imagery of the earth in its extreme forms also signaled artistic and emotionally evocative inclinations present in the nineteenth-century cultural imagination.

GERMANY

Until the year 1871, when the Second Emperorship was installed by the Prussian King, it was nearly impossible to name Germany as a political, economic, or social unit. Before this date one had to consider the German speaking countries, with the exception of the Swiss republic and the Austrian kingdom, as a loosely woven carpet consisting of dozens of minor kingdoms, dukeships, and counties. The two largest countries were the kingdoms of Prussia and Bavaria—and they, especially their capitals Berlin and Munich, played the most important roles in early German photography which is distinguished as such here only for reasons of linguistic practicability.

When the first announcements of photography arrived from Paris in German papers by January and February of 1839, there were lots of expectations among scientists and journalists which were widely discuseed in numerous articles and booklets. Academies began to discuss the science and art of depicting nature with light which had no name yet. The astronomer Johann Heinrich von Maedler was among the first to use 'photography' in the Berliner Zeitung of February 25, 1839, and a little later some entrepreneurs immediately started with their own experiments. Among those who could claim to have 'invented' a photographic method of their own were the Munich professors Carl August Steinheil and Franz von Kobell; another one was the inventor Johann Carl Enslen, then 80 years old.

An important role for the introduction of photography in Prussia was fulfilled by the scientist Alexander von Humboldt who had seen a number of daguerreotypes at a presentation on January 7, 1839, in Paris and had written several letters and articles about them. When William Henry Fox Talbot was about to claim the continental patent rights for his invention, Humboldt had already set the critical limits for looking at photographic images by insisting on the extreme sharpness in drawing details "that no painter would draw." Humboldt's words were so clear about photography's first and only quality in the depiction of detail that the calotype with its aesthetic roots in pictorial painting had no chance in German countries for nearly two decades.

Those who had heard of the stunning qualities of the daguerreotype had to wait until August 18, 1839, to see the new method presented to the public and the first equipment sold. Among the first to order a set of cameras, plates, and chemicals was the Berlin art dealer and entrepreneur Louis Ferdinand Sachse—but when his material arrived in Berlin everything was broken and inoperable. Thus the fame of having produced the

first German daguerreotypes was divided between Carl August von Steinheill who exhibited his daguerreotypes in early September 1839 and Johann Christian Gottlieb Noerrenberg, Professor of Astronomy at the University of Tuebingen whose oldest daguerreotype is said to have been developed in the same week and still exists today. Sachse's apparatus was repaired fairly quickly which allowed him to take part in the burgeoning photographic movement. In fact, from the end of September 1839 on, a number of amateur photographers successfully produced their first images in Berlin.

Except for the near total exclusion of the calotype, the early German photographic history reads like the ones of the neighbouring countries. One can draw a map of the wandering daguerreotypists; there is a certain emphasis on the south west and the far north areas where more portraitists seem to have rambled around than in the vicinity of larger cities like Munich, Leipzig, or Berlin. From 1845 on, the first studios were opened; by the early 1850s, each city address book listed large quantities of photographers offering portraits, corps pictures, and—with the success of the wet Collodion process from the mid 1850s onwards—scenic views of landscapes, famous buildings and mediaeval towns. The development of German industry followed the United Kingdom and France, and thus the subjects of German photographers participated in portraiture and landscape photography until the late 1850s.

Compared to other European countries and seen from the aesthetic side of the craft, Germany lacked fathering figures for the first two decades of photography. There was no William Henry Fox Talbot, no association like the one of David Octavius Hill and Robert Adamson, no Barbizon school. Nothing in Germany could be equalled to these geniusses. Among the better daguerreotypists are Carl Ferdinand Stelzner and Hermann Biow from Hamburg, Bertha Wehnert-Beckmann from Leipzig, Alois Loecherer and Antonia Correvont from Munich, and finally, Trudpert Schneider and his sons Heinrich and Wilhelm from Ehrenstetten near Freiburg. All of these photographers were far better than the average craftsman in their field but none of them could be called a world-wide first rate photographer. With their series on the damages caused by the Great Fire in Hamburg in May 1842, Carl Ferdinand Stelzner and Hermann Biow are certainly among the first men to use photography for journalistic purposes. Unfortunately, with the exception of a few singular images by Biow, this series is said to be lost as Hamburg's senate could not decide to buy them, as the records claim, due to "the possible lack of durabilty" of this new kind of imagery.

Even from the technological view of the matter, Germany had nothing more to offer than improvements of inventions made somewhere else. But from the 1850s onwards, these improvements were substantial both in optics and in the chemistry of photography. The German optical industry was initiated by Emil Busch's takeover of his uncle's firm at Rathenow near Berlin in 1848. By 1852 the business not only produced lenses with the help of steam engines but opened a department that manufactured camera bodies of all kinds. In 1852, Jakob Wothly from Aachen successfully licensed his own printing process. In 1854, Eduard Liesegang opened his first photographic studio in Elberfeld (today: Wuppertal) which subsequently became the first wholesale retailer for chemicals and apparatus. By 1857 the company started albumen paper production, and a year later started to manufacture cameras and lantern slide projectors and by 1863, the company moved to Duesseldorf where it still resides. The German photographic industrial concentration on mechanical engineering, optical specimen, and chemical production was developed from these earlier enterprises. Although larger parts of this industry were not installed before the late 1870s and early 1880s, these beginnings in the 1850s show all significant focal points for future developments.

The 1860s saw a formative disposition in German photography due to both the political developments and the growing tourism within German countries. Portrait photography centered around Munich, Berlin and Hamburg as there were the larger groups of very important people to be included in albums of contemporaries—a European fashion from the late 1850s onwards which helped to install a collective memory with the even larger success of the carte-de-visite and cabinet formats. The most important German contribution to this genre was formed by a long series of photographs portraying the members of the Frankfurt parliament of 1848, the first attempt of a democratic government ever within these states. Hermann Biow from Hamburg began the task of depicting the 831 elected parliamentarians; later he was followed by Jacob Seib from Frankfurt and Phillip Graff from Berlin. As all of them worked in the daguerreotype process their resulting images had to be transferred into drawn lithographs which were printed and sold in large quantities throughout all German countries. Seven years later the next series of its kind was released but the political landscape had changed considerably . And in 1856, Franz Hanfstaengl portrayed in his 'album of contemporaries' the royal suite of the Bavarian King Maximilian II, royalties and courtiers.

Additionally, photography began to merge with the growing interest in tourism from the 1850s onwards. Along the Rhine and the Elbe, in picturesque cities like Frankfurt on Main and Dresden, around important buildings like the Cologne cathedral and the Heidelberg castle, one could find entrepreneurs who not only produced images but sold them with their own publishing houses and printing presses. Hermann Emden in Mainz started this business successfully in 1856 as one of the

earliest of these entreprneurs, as did Carl Friedrich Mylius in Frankfurt on Main, Theodor Creifelds in Cologne, Hermann Krone in Dresden and Joseph Albert in Munich. Their fame spread far over the souvenir kiosks in their home towns which helped them pursue careers in photography. As Germany was still divided into many small countries, the photographers usually first dedicated an album of their photographs to their king, duke, or baron, and then hoped to sell even more of these precious specimen.

A secondary effect of these developments was the rise of the economic situation of photographers in general which helped them to establish their own professional groups and societies. Although primarily concerned with scientific and technical developments within photography like the 'Berliner Photographische Gesellschaft' founded in 1864 by Hermann Wilhem Vogel, these groups gave themselves the image of a guild and thus grounded the constitution of photography as a craft which finally was installed by law in 1902 and established as a profession until the 1980s. Although many of these pre-guild congregations did not live for longer than a few years and did not gain influence farther than their local district area, they formed the average image of photography in both the German language and the public opinion. Still today there is the legal division between a 'simple depiction' of reality and the 'work of art' in photography causing courts to investigate cases of copyright which stem from these formative years of photography.

The most important concern of these guild-like groups was a social notion: the institutionalisation of photography as a business, and respected like any other. Exhibitions were arranged, as were gatherings in upper-class hotels, and symposiums of all kinds where everybody could see that photographers were people to be taken as seriously as civil servants or dealers of antiquities. Carefully avoided in those circles was any reference to photography as a fine art which was given a pejorative notion—those who could not survive on their craftsmenship, whether they lacked technical quality, which was mostly suspected by the colleagues, or fortune in the profession, were nicknamed 'followers of art.' It was the time of voluptuous studio decorations, huge wooden frames around each portrait photograph, and money being made on quantity, not quality. But it was the time of science as well, and photography played an important role in many fields of human knowledge.

Photography became the most important instrument of description in positivistic approaches towards knowledge. Hermann Krone and Hermann Wilhelm Vogel within the 1860s established photography as a 'scientific aid' and accompanied dozens of excursions throughout the world for a large variety of reasons like solar eclipses in New Zealand and Egypt, and research for botanic and zoologic specimen in Asia and Africa. It may be seen as typically German that travel photography arose here not as business in the vicinity of literature and tourism but as a part of science and diplomacy. Wilhelm von Herford and Wilhelm Hammerschmidt travelled to the near East as diplomats whereas Fedor Jagor and Franz Stolze started their tours throughout the Middle East and Central Asia with an interest in anthropology and archaeology. From there it was only a small step for the scientists of the 1870s and 1880s to take up photography by themselves, as Heinrich Schliemann did when he excavated Troja. The ony exception to this rule may be described by the German expatriate Georg (later Giorgio) Sommer who fled his home town Frankfurt on Main after the bourgeois revolution in 1849 and became one of the most important travel photographers in Italy.

There is no science when it is not printed, and this fact stimulated a European-wide research for printing processes with results ready for use in the then rising publishing industry. Germany had four major contributions to make in this field throughout the 19th century, and all of these contribution came from Munich. In 1855, Edgar and his father Franz Hanfstaengl—then already well-known as photographers and lithographers—announced their charcoal printing process which they used in the business of art reproduction successfully for more than two decades. In 1868, the photographer Joseph Albert launched his 'Alberyype' process, a major development of the phototype process for producing large quantities of copies. His printing press sold images of Bavarian landscapes, the castles of King Ludwig II, and group portraits of all sorts of congregations with great economic success. The third contribution cannot be credited fully to a German inventor but to an Austrian as well: In 1883—at the same time as Karel Klietsch from Vienna, Georg Meisenbach published his autotype method of setting half-tone photographs through grids of glass, and in 1885, the first photographs were printed this way in a daily newspaper, the Illustrierte Zeitung from Leipzig. And in 1892, Hermann Wilhelm Vogel's son Ernst released the news that he and his companion William Kurtz had successfully installed a three-colour-printing process after photographs.

As the knowledge of Roger Fenton's participation in the Crimean war spread over Central Europe, photography became an integral part of early political propaganda in due course. In 1864, the war between Denmark and German troops under Prussian direction became an early symbol of the coming unification of all German states, and it might be for this reason that this rather unspectacular war with only one important battle received an enormous coverage by press and photographs. On the German side, the three photographers Christian Friedrich Brandt from Kiel—he produced large albums of medieval art afterwards, Heinrich Graf and Charles

Junod from Hamburg demonstrated their abilities by showing battlegrounds, artillery, and corpses but nearly no portrait of a general nor depictions of groups. As the photographs were commissioned by the army's leadership command, no one of the military officers seems to have understood the principles of effective propaganda as did their British colleagues.

Exactly the opposite practice was the result of Carl Friedrich Mylius' participation in the German-French war of 1870 and 1871. Mylius who had been specialised in architectural photography at his hometown of Frankfurt on Main before, concentrated on portraits of both the troops and the officers, and his business must have florished throughout the war. When the Prussian King Wilhelm was made Emperor of Germany in the castle of Versailles near Paris, the Berlin photographer Heinrich Schnaebeli was commissioned to produce an album of the military presence at this occasion—and his images are clearly to be viewed as photomontages. The invisibility of these important events had partially historical reasons—the crowning of the Prussian king in 1861 had been a quiet feast, the 1863 assembly of dukes and counts in Frankfurt on Main had failed in the unification of Germany, and Joseph Albert's photograph of this congress only showed a part of those invited—but there was a certain dislike in the medium due to old-fashioned ideas about art within the ruling class in Germany. Only at the very end of the 19th century, some members of the royal family began to spend an interest in photography which can be considered amateurish.

The military interest in photography grew with the technical developments: When Ottomar Anschuetz presented the first results of high-speed photographs with his patented focal-plane shutter to the General Staff in 1883, he immediately was made the official photographer of the Emperor's spring manœuvers, and the photographs of the 1884 manœuvers were the first ones to be printed in the autotype process in a German newspaper just a few days after the actual event. Anschuetz' close cooperation with the photographic industry bore many fruits, and the military use of the medium for technical purposes—like producing maps and area surveys—as well as for propagandistic use grew rapidly into the preparation of all kinds of applications of photography and cinematography as implemented in World War I. These developments coincided perfectly with the double use of another invention at least in larger parts stimulated by German scientists: photogrammetry. After seven years of investigation, the architect Albrecht Meydenbauer in 1865 presented a method of re-constructing buildings and sculptures by drawings in orthogonal projection made after stereo photographs under specific conditions. In 1885, the Berlin institute of photogrammetry (Messbildanstalt) was installed and became the most important source of architectural photographs of historical buildings for the next two decades. The military use of photogrammetry lifted considerably with balloon and aerial photography short before World War I.

In 1861, one of the most remarkable figures in German industrial history, Alfred Krupp, commissioned his far relative Hugo van Werden to learn photography in a studio in Hannover then well known for its qualities in depicting industrial products. After a short apprenticeship, van Werden set up the Krupp photographic and lithographic institute which from then on had to deliver all visual materials used for documentation, press releases, and public relation of Krupp's steel company. As early as in 1862 on the occasion of the London World Fair, Krupp was able to show and deliver larger quantities of photographs of all his products, and the company gained fame for the use of the new medium in advertising. Smaller companies of the fine-mechanical and optical industries immediately followed this example and created catalogues of their products by assembling series of photographs depicting each object as meticulously detailed as possible. But it must be admitted that the integration of photography into industrial advertisement and public relation was delayed in Germany if one compares the country with European or North American competitors on the world market, due to to two factors: a long period of economic recession throughout the 1870s and early 1880s, and above all, a comparatively low interest of German industrialists in the aesthetics of their products. This was only to change, with the help of photography, short after 1900.

On top of the Krupp stand at the World Fair in London in 1862 there was a large display of a panoramic photograph showing the Essen company site. Made of 12 images, it correlated to a recent fashion among manufacturers: showing a bird-like view of their establishment on top of all business papers. These were still etched in copper for the rest of the 19th century but each chief office had to have on the wall at least one panoramic view of the company's site. These photographs were either made by the company's own photographic department or by photographers specialized in landscape and architectural views. Parallel to the success of the travel photographers, a number of studios started to offer portfolios displayed specific types of architecture like villas, office buildings, town halls, and industrial sites. These portfolios were sold to architectural schools as well as to administrations in towns and countries, and some even caused interest among better-off citizens looking for the latest fashion in homes and gardens. Among the well known photographers working in this field one has to name Friedrich August Albert Schwartz, Hermann Rueckwardt, and Waldemar Titzenthaler from Berlin, Johannes Noehring from Luebeck, Julius Soehn from Duesseldorf, Anselm Schmitz and Johann Heinrich

Schoenscheidt from Cologne, Friedrich Georg and Hermann Friedrich Brandseph from Stuttgart, Carl Teufel and the company of Jaeger & Goergen from Munich, Bernhard Johannes from Partenkirchen. One should not under-estimate the visual training given to the public by these photographs which were as influential as the average portrait photography of the same days.

The last and—from an aesthetic view—most exciting chapter of German photography in the 19th century was opened with an exhibition in Berlin dedicated to the half-centennial of the medium's history. Installed by the Photographische Verein zu Berlin under the direction of Hermann Wilhelm Vogel, this exhibition comprised not only the newest developments of photographic science and the use of photography within science and practice; it did not only show the early pride of the rising photographic industry in Germany by displaying cameras, lenses, and all kinds of apparatus; this exhibition had a special department devoted to photographic art—and it saw the future of imagery in the works of amateurs like the young Berlin student Alfred Stieglitz. He was the actual star of both the exhibition and its juries, in all parts of the show he either received gold and silver medals or was an important member of the panel. Whether he crowned a lens for portraiture or honoured a print-out paper, Stieglitz was an integral part of the photographic establishment mentored by his teacher Vogel and other celebrities of German photography.

Stieglitz' astonishing success was accompanied by the distinction for several amateur photographers from all over Europe and defines the actual birth of a fine art Photography movement in Germany. When the art historian Alfred Lichtwark became director of the Kunsthalle in Hamburg in 1886 he delivered a number of speeches emphasizing the importance of amateurs' activities in the arts. Subsequently he supported the foundation of the first Hamburg society for the amelioration of photography which became the nucleus of the German Fine Art Movement in photography. Similar societies existed already in Berlin and Dresden, numerous others were founded within the 1890s, and at the turn of the century Germany had a lively scene of fine art photographers who were dedicated amateurs.

The social distinction of these amateur circles is obvious: There were well-to-do merchants like Heinrich Wilhelm Mueller, Georg Einbeck, and Gustav E.B. Trinks, physicians like Eduard Arning and Konrad Biesalski, military officers like A. Boehmer, Ludwig David, and Walter Heinrich von Ohlendorff, civil servants like the brothers Theodor and Oskar Hofmeister and Anton Christian Bruhn, school teachers like Otto Scharf, Rudolf Crell, and Heinrich Linde, and the women involved often enough had an aristocratic background, e.g. like Alma Lessing, Harriet Helene von Bronsat, or Anna von Krane. The collectors of these early fine art photographs either shared the interests of their friends or were busy with acknowledging photography as a true medium of art—among them one has to name Ernst Juhl and Fritz Matthies-Masuren who were not only private collectors of interest and quality but instigated several graphic departments of established museums to build up photographic collections of their own. These collections in Hamburg, Berlin, and Dresden today still rank among the finest in Germany.

Above all other implications, the fine art movement instigated a substantial rise of quality within professional photography. Be it the careers of Rudolph Duehrkoop from Hamburg, of Nicola Perscheid from Berlin, of Hugo Erfurth and Erwin Raupp from Dresden, of Albert Gottheil from Danzig, of the brothers Jacob and Theodor Hilsdorf from Bingen and Munich, and of Wilhelm Weimer from Darmstadt—neither of these were possible without their early acknowledgement of what happened in the fine art circles and their exhibitions. The life history of Hugo Erfurth may be seen as exemplary for most of his competitors: He participated in three major amateur photography exhibitions—including the famous 1893 show of the Hamburgian friends of photography—before he enrolled as an apprentice with the Dresden photographer Wilhelm Hoeffert. Only one year later he already owned his first studio, and within the last five years of the 19th century, Erfurth managed to become one of the five most celebrated photographers in Germany.

The 'professional fine art photographers' balanced economic success and aesthetic interest by combining all important developments of their century. The subjects were chosen in accordance to classical genres: portraiture, nude, landscape—with a general exclusion of heroic scenes and an equally general inclusion of symbolic settings. The method of making allotted to a personal style—chosing gum printing in one, two or more specific colours or sticking to carbon or platinum printing, furnishing reception from the public by brushing the negative or painting on the positive. All of these manipulations formed a stylistic approach that had secured the amateurs of fine art photography in their creative autonomy but worked out as a valuable set of distinctions between professional competitors. At the end of the 19th century, photography in Germany finally was a renowned practice of design if not fine art—modernism, already visible in other forms of art, just had to come.

GERNSHEIM, ALISON (1911–1969) AND HELMUT ERICH ROBERT (1913–1995)

Helmut Gernsheim was born in Munich, Germany, on March 1, 1913, of mixed background, his mother coming from Catholic stock and his father being a Protestant convert with a long Jewish heritage in the Bavarian city of Worms. His family was comfortably middle-class, his father being a literary historian employed by the Munich University Library, and growing up in the progressive European city of Munich afforded the youth both an excellent education and a strong cultural upbringing. Fascinated by materiality he became an inveterate collector of objects and upon graduation in 1933 resolved to study art history like his eldest brother, Walter—first under the art historian, William Pinder, and then at the Bavarian State School of Photography.

He graduated *summa cum laude* in 1937, worked as a practical photographer for a year, and then fled the rising tide of Nazism in Germany. He moved to London in July of that year, first working for Walter who owned an art gallery there, and then establishing himself as a commercial photographer. Nonetheless, the critical and scholarly aspects of photography were never far from his mind and—rejecting such schools as pictorialism, photojournalism and experimental abstract art—he became an early advocate for the principles of the German photographer Albert Renger-Patzsch and his *Neue Sachlichkeit* school of modern art, while actively participating in the British photographic societies and exhibitions of the era.

Alison Eames was born in London on February 10, 1911, receiving a middle class education at Brikbeck College and a finishing school in Paris. Back in London and while pursuing a clerical career, she married an accountant, Blen Williams. The couple met Helmut at a London nudist park in 1938 where all were members. Within a year Alison separated from her husband and began her relationship with Helmut. Like so many others at the time, their lives were dramatically interrupted by World War II.

Helmut was interned in Australia as a "friendly enemy alien" in July of 1940 and, following a long bureaucratic struggle, finally made it back to embattled London in November of 1941. There he and Alison were able to establish a home in 1942 after she won an amicable divorce from her husband, maintaining a *de facto* marriage until they could legally wed after the war. While enduring the bombing of London, Alison pursued her secretarial career and Helmut won a coveted position with the Warburg Institute as the chief photographer for the London area, documenting British buildings and statuary for the National Buildings Record from 1942 to 1945. While engaged in making a permanent photographic record of the art and architecture endangered by the war, Helmut also produced a major body of work which sought to "instill life and action in the stone."

He also became a published author in 1942 with his *New Photo Vision*, a small but important critical treatise which condemned the staid practices of pictorialism, advocated the principles of modern European photography, pointed out the vibrant historical roots of the medium, and argued for the active role of the photographer in making the world see things anew. The book would provide him with the initial fame and advocacy he craved and marked his emergence as a dynamic and critical voice for the new art.

At the end of 1944 the Gernsheims were visited in London by Beaumont Newhall, the dean of American photohistorians. They discovered a kindred spirit and Newhall for his part encouraged them to begin collecting historical British photography as the war was winding down and a new era was beginning. The suggestion ignited Helmut's old collecting urges and on January 6, 1945, he headed off into the antique shops and fairs of London to begin building a collection. The man and the timing proved to be more than correct and Helmut quickly amassed some important and discriminating pieces of art and apparatus from the nineteenth and early twentieth centuries. Supported by Alison's encouragement, scholarship and writing talents, they began to build an important body of art and artifacts in their London flat.

In 1947 they elected to make the brave decision to abandon their careers—his as a photographer and hers as secretary to a Member of Parliament—and devote themselves full-time to the building and marketing of the already famous Gernsheim Collection and the support activities of writing, editing, lecturing and the creation of exhibitions. They would do so actively, carefully and passionately for a total of eighteen years, until 1963. In the course of their efforts they discovered and acquired whole bodies of art by such important figures

as D.O. Hill, Robert Adamson, Julia Margaret Cameron, Roger Fenton, Lewis Carroll, Henry Peach Robinson, Peter Henry Emerson, Paul Martin and Alvin Langdon Coburn—not to mention the rediscovery of Joseph Nicéphore Niépce's first photograph in 1952.

Their labors and careers did not just begin and end with the process of acquisitions. The Gernsheims backed up their collection-building with scrupulous and massive original research, careful scholarship, public lectures and teaching, and a variety of advocacy and enterprises that eventually became international in scope. Not content to merely discover works and artists and to add them to their holdings, they also began to actively publish their findings. In the course of their eighteen years of productivity they authored more than 200 articles and nearly two dozen books from their collection. The publications ranged from picture books of Helmut's photographs to important scholarly monographs on such individuals as Carroll, Cameron and Fenton. In order to help their own finances and make the collection self-sustaining they also authored and edited general picture books on such figures as Queen Victoria, King Edward & Queen Alexandra, and Winston Churchill, as well as providing illustrations from their collection for a large number of magazine and book publishers of the time. Their classic *History of Photography,* first published in 1955, grew out of their passion for historical British photography but became more massive and international in scope with each newer edition and in tandem with the expanding parameters of their own collection's growth.

Besides utilizing publications, they also based their advocacy for expanding the word about photography's significance as a major art form through a variety of traveling exhibitions. Beginning with their newsmaking exhibition, *Masterpieces of Victorian Photography*, at the Festival of Britain in 1951, they learned the value of bringing the original art to the public. This was followed in 1952 with their expanded show, *A Century of Photography*, held at the World Exhibition of Photography in Lucerne, which also first revealed the international and modernist expansions that the Gernsheim Collection had begun to undertake. Between 1956 and 1961 the collection would be featured in eight massive European venues (each with its own catalogue as well) that served to spread the word about the artistic and cultural heritage of photography and its history.

Throughout the 1950s and early 1960s the Gernsheims also struggled to find an institutional home for themselves and their collection. Building up the collection while making a living through publications, print sales and exhibitions was an exhaustive process, and the couple tried in vain to find an organization or museum that would help them share the burden while also allowing them the independence to continue adding to their world-renowned holdings. At least three dozen groups—ranging from UNESCO to the cities of Cologne and Gothenburg—were approached and abandoned. In 1963 a private investment scheme brought the Gernsheims and their collection to Detroit, Michigan, USA, but the plan fell apart. In the summer of 1963 the Gernsheims accepted an offer from The University of Texas at Austin and sold the collection, together with their research library, correspondence, research files and archives, for $300,000. (They also sold a much smaller selection of all their duplicate prints to the Moderna Museet in Stockholm.) Rather than accompanying the archive, however, they elected to receive the funds over a period of six years and retired to Lugano,Switzerland, in 1965.

In "retirement" the Gernsheims continued to update and edit their publications and travel the world. Alison was injured in a fall on a South American trip in 1969 and died as a result of surgical complications afterwards. Helmut remarried in 1970 and began to take a renewed interest once more in photohistorical advocacy, education and scholarship. In the remaining twenty-five years of his life he began building another collection—this time of contemporary photography with an international range—as well as writing more books and starting to rewrite and enlarge his massive *History* once more. He maintained a large volume of correspondence and, throughout the 1970s and 1980s taught at a number of universities and workshops in Switzerland, Britain, France and most especially the United States. In 1984 he arranged a traveling retrospective exhibition of his own photography—his first in nearly 40 years—so that a new generation could rediscover his own artistry. Finally, in 1995 after completing an exhibition from his new collection, he died of a heart attack in Lugano.

His widow sold his new library, collection of contemporary photographs and remaining papers to the Reiss-Engelhorn Museum in Mannheim, Germany. Between this final deposit and the two existing collections in Austin, Texas, and Stockholm, Sweden, the Gernsheims remain the only photohistorians who are represented by having collections/archives in three major institutions around the world.

ROY FLUKINGER

Biography

Helmut Gernsheim was born in Munich, Germany, on March 1, 1913. An inveterate collector in his youth, he studied art history and graduated from the Bavarian State School of Photography in 1937. He fled Nazism that year and immigrated to London, England where he became a commercial photographer. He met Alison Eames, a native Londoner, who was born on February 10, 1911 and, following a middle-class British upbringing, was pursuing a clerical career. Separated by Helmut's alien

internship in Australia at the start of World War II, the Gernsheims were reunited in London in 1942 where Helmut went to work for the Warburg Institute until 1945. A meeting and continuing friendship with Beaumont Newhall led to their beginning to collect original photographic art and apparatus in that year. By 1947 their Gernsheim Collection was growing to such an extent that they abandoned their previous careers and became full-time collectors, historians, researchers, advocates, lecturers, teachers and authors. In the course of 18 years, from 1945 to 1963, they built one of the greatest photohistorical collections in history, specializing in nineteenth century British photography. During this extremely creative interval they also authored some 200 scholarly and popular articles and nearly two dozen books on the subject, as well as instituting a series of major international traveling exhibitions from the collection. In 1963 they sold their collection and archive to The University of Texas at Austin and retired to Lugano, Switzerland. They continued to write, edit and travel until Alison's death on March 27, 1969. Remarrying in the following year, Helmut continued to research, write, teach and lecture for another quarter century. He also began collecting contemporary photographs up until the time of his death on July 20, 1995. His later collection and archive are now housed at the Reiss-Engelhorn Museum in Mannheim, Germany.

GHÉMAR, LOUIS (1819–1873)

Belgian photographer, lithographer, and painter

Louis Joseph Ghémar was born in Lannoy, northern France, on 8 January 1819, the first child of aspirational parents of modest means. His father, Ange Ghémar, was an *instituteur* [primary school teacher] and his mother, Catherine Horlait, the daughter of a brewer of Belgian origin. After the death of her husband in 1830, Catherine moved back to Belgium and remarried Toussaint Ouverleaux, *professeur* [high school teacher] and future principal of the Collège royal d'Ath. Ghémar studied there and had lessons at the art academy in Ath.

Ghémar moved to Brussels aged 17 in order to train and earn his living as a draughtsman. He became a pupil of the painter Paul Lauters (1806–1875). Ghémar initially came to prominence as a caricaturist, his portraits appearing in the Belgian edition of the French satirical magazine *Charivari* from April 1839 onwards. In the 1840s, Ghémar gained a reputation as a prolific lithographer, supplying views in the Romantic tradition for

series such as the *Album pittoresque de Bruges* (1840) and *La Belgique monumentale, historique et pittoresque* (1844), as well as undertaking copy work, notably the *Album du Salon de 1845*.

Ghémar moved to Edinburgh in 1849 to form a partnership with the lithographer Frederick (Friedrich) Schenck. The partners, operating from their establishment at 9 Greenside Place, communicated an innovation to the Royal Scottish Society of Arts in August 1849, enabling lithographs to be "drawn, lithographed, and cast off in three hours." They published *Portraits of the Leading Reformers* in the new process.

When exactly Ghémar came to photography is unrecorded, but his career move parallels that of another caricaturist and lithographer, Ghémar's lifelong friend Nadar. For both men, photography, making inroads into the classic graphic processes, would principally be used for portraiture. Ghémar did not practice commercially in Edinburgh, but he may well have learned photography there, since, very soon after his return to Belgium in August 1854, he advertised himself as a photographer. He opened a studio in Antwerp, at Rue Houblonnière 1474, in partnership with Robert Severin (1839–after 1883), son of Ghémar's friend, the leading Düsseldorf photographer and lithographer Wilhelm Severin (1809–1888). A visiting journalist described the studio as "…un atelier modeste de dimensions, mais littéralement encombré d'œuvres très distinguées et de portraits exquis" [a studio of modest dimensions, but literally crammed full of very fine works and exquisite portraits] (*Le Précurseur*, 23 February 1855). Ghémar and Severin organised a well received exhibition at the Cercle artistique et littéraire in August 1855, where they showed the full range of their output, townscapes and reproductions of artworks as well as portraiture.

Ghémar used his foothold on the Belgian market to secure his new reputation as a photographic portraitist and to prepare his return to the capital. The partners sold the Antwerp studio to Auguste De Bedts in February 1856 and moved into premises in Brussels at rue de l'Ecuyer 27. Using Ghémar's contacts in artistic circles and high society, Ghémar and Severin's studio enjoyed immediate success. On the occasion of Leopold I's silver jubilee in 1856, the king sat for them. One of the resulting portraits, showing the king in general's uniform, was published as a lithograph by Simonau and Toovey and became the most popular graphic representation of the Belgian monarch. The portrait also featured prominently in the partnership's submission to the photography exhibition held in Brussels in August 1856, where Ernest Lacan noted Ghémar's characteristic techniques of retouching in pastel and overpainting and concluded: "En s'associant, MM. Ghémar et Severin ne pouvaient produire que des œuvres de mérite. En effet, l'un est peintre de talent, l'autre photographe habile." [By forming a partnership, Messrs Ghémar and Severin could not but produce works of merit. One is a painter of talent, the other a skilled photographer.] (Lacan, Ernest, "Exposition photographique de Bruxelles," *La Lumière*, 27 September 1856: 149)

By 1860, the partnership had been dissolved and Severin moved to The Hague. Ghémar initially ran the studio alone, then formed a partnership with his younger half-brother Léon Louis Auverleaux (1832–1869) under the denomination *Ghémar frères*. The new partnership coincided with the introduction of the carte-de-visite, and the studio would prosper riding the wave of popularity enjoyed by this format in the early to mid 1860s. Ghémar continued to receive royal patronage and in 1864 published a set of 37 portraits of the Belgian royal family. He created another significant series when the took the portraits of all eighty guests at the dinner held in honour of the exiled Victor Hugo by his publishers Lacroix, Verboeckhoven in Brussels on 16 September 1862. This event, which has gone down in history as the "*banquet des Misérables*," shows the raffish and witty Ghémar's talents at their best, as he passes each one of the literary and artistic devotees and friends of the French novelist in front of his lens, not as a hired hand, but as an equal.

In June 1863 Auverleaux set up his own studio in Brussels, but Louis Ghémar retained the company name of *Ghémar frères*, instantly recognisable to the public at large. Ghémar formed a liaison with the younger Marie Catherine Jadoul (1844–1882) who bore him four children between 1864 and 1871; they married on 15 July 1871. During his career as a photographer, Ghémar maintained some output as an artist, and also traded in paintings and objets d'art, at the *Galerie Ghémar*, at Rue du Persil 4, open by 1865, and where he was also domiciled from 12 December 1868. A highpoint of sorts was constituted by his exhibition, the *Musée Ghémar*, a satirical but affectionate side-swipe at the art world held in 1870, and made up of 100 pastiches in oils of contemporary artists, all painted by Ghémar himself.

Ghémar exhibited infrequently and only at prestigious venues, at the universal exhibitions in London in 1862 and Paris in 1867. The reputation of his studio was secure in any case. An atypical commission for urban views of Brussels constituted his final important series. The Belgian Public Works Company, charged with redeveloping the centre of Brussels and bricking over the pestilential river Senne, entrusted Ghémar with recording the picturesque corners of the capital doomed to demolition. Ghémar produced a series of twelve full-plate views entitled *Assainissement de la Senne. Bruxelles en 1867. Vues photographiques prises à l'emplacement du nouveau boulevard…* [Sanitising the Senne. Brussels in 1867. Photographic views taken on the site of the new boulevard…].

Louis Ghémar died in Brussels on 11 May 1873 and is buried in Laeken cemetery, in a mausoleum designed by the French sculptor Ernest Carrier-Belleuse (1824–1873). The inscription refers to Ghémar as an "*artiste dessinateur*" [artist draughtsman] rather than photographer. The studio continued trading as *Ghémar frères*, much reduced in reputation and quality, until 1894, when its negatives were acquired by the neighbouring firm of *Géruzet frères*.

There are substantial holdings of Ghémar's work at the Archives de la Ville de Bruxelles, Archives du Palais du Roi, Brussels, Bibliothèque royale Albert Ier—Cabinet des estampes, Brussels, Provinciaal Museum voor Fotografie, Antwerp, and Musée de la photographie, Charleroi. The recently restored mausoleum is accessible to the public.

STEVEN F. JOSEPH

Biography

Louis Joseph Ghémar was born in Lannoy, northern France, on 8 January 1819, the first child of aspirational parents. Ghémar moved to Brussels aged 17 in order to train as a draughtsman. He initially came to prominence as a caricaturist. Ghémar worked in Edinburgh from 1849 as a lithographer. On his return to Belgium in 1854, he opened a studio in Antwerp in partnership with Robert Severin. The partners sold the studio in 1856 and moved to Brussels. Using Ghémar's contacts in artistic circles and high society, Ghémar and Severin's studio enjoyed immediate success. Following dissolution of this partnership by 1860, Ghémar formed a partnership with his younger half-brother under the denomination "Ghémar frères." During his career as a photographer, Ghémar maintained some output as an artist, and also traded in paintings and objets d'art. Ghémar formed a liaison with the younger Marie Catherine Jadoul (1844–1882) who bore him four children between 1864 and 1871; they married on 15 July 1871. Ghémar died on 11 May 1873 and is buried in Laeken cemetery.

GIROUX, ANDRÉ (1801–1879)

André Giroux was born in Paris on April 30, 1801. Coming from a middle-class family familiar with the artistic medium, he was directed early on towards a career as a painter. Studying initially with his father, he entered the workshop of the neo-classic landscape designer Thibault. He exhibited his first paintings at the Salon of 1819, then integrated two years later in 1821 into the prestigious School of Art, Paris. Consequently, for him the prospect opened for a traditional career devoted to painting, which was crowned by the award of du Grand Prix de Rome de Paysage historique in 1825. During his stay in Rome, André Giroux met Camille Corot, Leon Fleury, Edouard Bertin and even Theodore Caruelle d'Aligny with whom he established a long friendship. The emulation produced by these meetings strongly influenced his practice and his renderings of Italy undoubtedly count among his most accomplished pictures. On his return to Paris in 1830, Giroux continued his painting career and continued to exhibit, every quarter, at the Salon until 1846.

The first traces of his photographic activity go back to the early 1850s. Well-informed of his career as a painter, we are missing documentation of the important years that were devoted to photography. His father Alphonse Giroux celebrated commercial art and had a shop with his wife Zoé Colin on the 7 rue du Coq Saint-Honoré in Paris, which had been open since 1799. In this shop, which was to become famous, they sold objects of curiosities, marquetry, and paper but also drawings, pictures, and engravings. In 1834, on the first floor of the shop of his parents, André Giroux undertook with his elder brother, Alphonse-Gustave, the marketing of objects of curiosities and imagination. Four years later, on May 19, 1938, the two brothers repurchased with their parents the assets of Giroux et Cie of which they became sole owner. Alphonse-Gustave headed the commercial endeavors, while André simply played the part of silent partner. The following year, in the weeks

that followed the advertisement of the discovery of photography, Jacques Louis Mandé Daguerre, the inventor, signed on June 22, 1839 a franchise agreement with company, "Giroux and Co" for the construction and marketing of his photographic systems, including cameras, plates, chemicals and ancillary equipment. At the same time, André and Alphonse Giroux published on August 20 the first descriptive instructions of the daguerreotype process.

This agreement created great interest in photography for André Giroux; however nothing indicated that he tried out the technique of the daguerreotype, and if he did, none of those attempts have survived. It is not certain if André Giroux's artistic reflections found in the use of this new technique were prolonged and developed throughout his career. He waited more than ten years for the introduction of the negative-positive process on paper in France, when his taste for photography became apparent.

Compared with the production of his contemporaries who, like him, practised photography as "amateurs"—such as Olympe Aguado, Louis Robert, or Humbert de Molard—the photographic oeuvre of André Giroux can be regarded as modest. Hardly more than sixty prints have been found, spread throughout many public and private collections. This choice of paper negatives and salted paper prints determined the character of André Giroux's photographs. This choice of negative paper and the use of the positive prints on salted paper determined the esthetics of the photographs of André Giroux. During the four years of his activity—one can indeed reasonably think that he ceased his production around 1857—he used alternatively two formats of negative (22 × 28 cm and 28 × 38 cm).

With two exceptions, André Giroux took landscape and architectural pictures exclusively. Landscapes of edges of rivers, interiors of courts, views of agrarian buildings or ancient monuments constitute the main portion of his images. In contrast to the photographers who drew their inspiration from the forests in the neighborhoods of Paris, in particular that of Fontainebleau, André Giroux showed a clear predilection for more remote places. One can, however, only partially reconstitute his various voyages taken in various areas of France. In the same way their chronology remains speculative. Thanks to the titles of the works provided by the catalogues of expositions in which he took part, as well as with the indications reproduced on some of his photographs, one is able to establish that André Giroux returned to areas of Arles like the valley of the Rhone. But it is in Auvergne that he carried out, it seems, a majority portion of his captured images.

André Giroux had already experienced the tradition of the Grand Tour during his years training as a painter in Italy and later, while working in certain areas of France and Europe. He followed in the vogue of the landscape naturalist introduced in France at the beginning of the century by the theories of Pierre-Henri Valencian and relayed in 1817 by the publication *Les nouveaux voyages pittoresques en France*. There is consequently nothing astonishing to find in the photographic work of Andre Giroux in this evocation of the picturesque landscape that one frequently finds in his paintings. Some of his photographs, like *Hangar au bout du chemin*, testify to this art of the setting in scenes of the picturesque and whose audacity of composition, in particular the marked presence of the foreground, announces the style characteristic of the photographic work of Andre Giroux.

In what is known of this work, the images of Auvergne are first rate, by their number as well as by their formal diversity. The geographical situation of the regions that he crossed—Lozere, Aveyron, and to combine them at the border of Auvergne—offered to him varieties of semi-mountainous landscapes with many villages crossed by rivers. The edges of the gorges of Jonte, between Peyreleau and Meyrueis, at the border of Aveyron and Lozere, particularly seem to have held his attention. The damaged character of the landscape gave him the opportunity to emphasize the picturesque aspects of the places that he photographe: a path bordered with houses with thatched roofs, a stone bridge spanning water, a hut on the wooded and precipitous slopes of the mountains, a line of houses on side of river. The quasi-systematic reference to the painting that one can read in criticisms from the time concerning the photographic oeuvre of Andre Giroux does not show anything surprising. One finds indeed marked stylistic similarities between some of his paintings and some of his photographs.

If these landscapes were largely admired, some not hesitating to compare them with those of Gustave le Gray, no criticisms, however, failed to stress the importance of the final improvement in the photographic work of Andre Giroux. This artifice so violently attacked by Eugene Durieu, president of the Société française de photographie in 1855, for which "... to invite the brush with the help of photography under pretext of introducing art there, it is precisely to exclude the photographic art" (*Bulletin of the Société française de photographie*, 1855, t.1, p. 301). In spite of criticisms and like majority of the photographers of his time, André Giroux frequently improved his negatives. A detailed examination of each one of his prints indeed makes it possible to detect the subtle interventions to which it proceeded in a systematic way, thus giving to each one of these prints a particular character. This technique then enabled him to approach the effects that he could obtain in his paintings while creating artificially, by the means of the gouache and the scraping directly applied to negative, an effect of cloud as in *Obtevoz, Rhône* (J.Paul Getty Museum), or the transparency of water in his many photos of edges

of rivers, *Cascade dans le Massif central* (Philadelphia Museum of Art). If in some of this photography, as in *Rivière avec effet de lune* (Musee d'Orsay), the artifice seems to have been pushed to its extreme, conferring on these images the characteristic forerunners of the impressionist current, they do not remain less learnedly composed. In the same way, one finds in the images of architecture of the area of Arles, this consumed art of the final improvement giving to the vestiges a romantic atmosphere, contrary to the topographic sights of the same place of an Edouard Baldus or a Domenica Roman. This taste of the effect and formal research so present in André Giroux gives to the whole of hhis sound oeuvre a singularity not found elsewhere.

Undoubtedly, André Giroux was a painter much more than photographer, even if his technical ability in this field did not have anything to rival that of his famous contemporaries. To take again the beautiful expression the photographer Edouard Baldus used to define him, one could qualify André Giroux as *peintre photographe*. But contrary to many photographers such as Edouard Baldus, Gustave le Gray, Henri le Secq, Charles Nègre or Roger Fenton, all former painters who gave up painting for the profit of photography, André Giroux was the only one not to disavow his artistic origin. Concerned with his independence, he never hoped to be among the members of prestigious Société française de photographie, however important it was to the supporters of photographic art. In the custom of the annual Salon des beaux arts, he exhibited some of his photographs however with the exposition organized by French Société of photography in 1857 and 1870, like in Brussels in 1857, thus showing his will to subject his work to criticism. His last exposition was held with the Salon of 1874, during which three of his paintings were presented. He died a few years later in Paris, in 1879.

GLAISHER, JAMES (1809–1903)

Victorian meteorologist and aerial physicist

James Glaisher was born on April 7th, 1809, at Rotherhithe, England, and christened at St Mary's, Rotherhithe, on April 30th. By 1816 his father, also named James, and mother, Mary (believed born Middleton), moved to Greenwich. It is not known to what extent Glaisher received a formal education. He was introduced to the work of the Royal Observatory, Greenwich, by William Richardson, a family friend, and assistant observer there.

Appointed as an assistant to the Ordnance Survey of Ireland, Glaisher made meteorological measurements and observations in 1830–1831 on Bencorr Mountain in Galway, and at the summit of Keeper Mountain (now Hill) in Tipperary. His obituary in *The Aeronautical Journal* of April 1903 quotes him as saying, "In the performance of my duty I was often compelled to remain sometimes for long periods above or enveloped in cloud. I was thus led to study the colors of the sky, the delicate tints of the clouds, the motion of opaque masses, the forms of the crystals of snow." His interest in atmospheric phenomena may be traced from this time.

Between 1833 and 1836 Glaisher worked as an astronomical assistant at the Cambridge Observatory in England, under the direction of George Biddell Airy (1801–1892), Professor of Astronomy at Cambridge University. In February 1836 he moved to the Royal Observatory, Greenwich, where in 1835 Airy had become the 7th Astronomer Royal.

At Airy's suggestion a separate Magnetic Observatory was built in 1838, and in 1840 Glaisher became Superintendent of the Meteorological and Magnetic Department, where recordings of variations in the direction and intensity of the Earth's magnetism were measured in order to improve compass navigation, and readings from thermometers, barometers, and other meteorological instruments were taken every two hours, day and night. In 1848 a system of photographic self-registration for the instruments, devised by Charles Brooke FRS (1804–1879), was introduced. Glaisher described these activities in "The Application of Photography to investigations in Terrestrial Magnetism and Meteorology as practiced at the Royal Observatory, Greenwich" (Glaisher, 1859).

On December 31st, 1843, James Glaisher married

Cecilia Louisa Belville (1828–1892). Her father, John Henry Belville (1795–1856), was an assistant observer at Greenwich, and author of *A Manual Of The Barometer* (London: R. & J.E. Taylor, 1849) and *A Manual Of The Thermometer* (London: R. & J.E. Taylor, 1850).

Glaisher's career is representative of the transition in science in mid-nineteenth century Britain, when the study of natural phenomena became a regulated and professionalized field. He helped to establish and organize a network of people around the country, and promoted the use of accurate, standardized instruments to record the meteorological observations they supplied him with. He correlated the data into reports, which were published in *The Times* by the Registrar-General.

He was elected a Fellow of the Royal Astronomical Society in 1841, and a Fellow of the Royal Society in 1849. From the early 1850s his rise in the scientific community began. On April 3rd, 1850, he helped to found the British Meteorological Society at Hartwell House in Buckinghamshire, the home of Dr John Lee (1783–1866).

Glaisher wrote the report for the jury of "Class 10," the category in which photography was placed at the 1851 Great Exhibition. On February 4th, 1852, he gave a lecture on "Philosophical Instruments and Processes, as represented in the Great Exhibition," one of the series of lectures given at the Society of Arts, reviewing the Great Exhibition. Between December 22nd, 1852, and the end of January 1853, a large exhibition of photographs was held there to coincide with the formation of the Photographic Society on January 20th, 1853 (see Taylor, 2002, 16–20). On January 26th, 1853, Glaisher read a paper, "On the Chief Points of Excellence in the different Processes of Photography, as illustrated by the present Exhibition." The Photographic Society held its first Ordinary Meeting at the Society of Arts on February 3rd, 1853. Glaisher was elected on March 2nd, 1854.

There are references in contemporary journals to James Glaisher having made photographs of architectural and landscape views. Whilst it appears uncertain whether any of these may survive, work that does remain from this period are photogenic drawings of ferns made by Cecilia Louisa Glaisher between approximately 1854 and 1856. A project in collaboration with the fern expert and publisher Edward Newman (1801–1876), *The British Ferns—Photographed from Nature by Mrs Glaisher* was planned to be issued in a series. Newman presented a portfolio of ten positive salt paper prints to the Linnean Society in London, along with a flyer in which he explained the intention of the work. Twelve prints were shown at the photography exhibition held in conjunction with the British Association for the Advancement of Science's meeting in Glasgow in September 1855. Although the project appears to have been abandoned, two albumen prints of ferns were entered by James Glaisher in the 1885 International Inventions Exhibition held in South Kensington, as examples of "Nature-printing, taken over 30 years ago" (*The Photographic Journal*, 9:9 1885, 168). Prints from this exhibition became part of the historical collection of the Photographic Society, now at the National Museum of Photography Film and Television in Bradford.

Glaisher helped to found and was President of the Blackheath Photographic Society in 1857. He oversaw the chemical side of the production by A.J. Melhuish (1829–1895) of albumen prints for Charles Piazzi Smyth's *Teneriffe: An Astronomer's experiment*: *or, Specialities of a Residence Above the Clouds*, which was illustrated with tipped-in photo-stereographs, and published by Lovell Reeve in 1858. A member and referee of the Amateur Photographic Association, Glaisher sorted and examined the photographs submitted to the Association by its members, producing detailed annual reports on the numbers, sizes, and merits of the processes and pictures.

In 1862, on behalf of the British Association for the Advancement of Science, he began a series of experiments during high-altitude balloon ascents with the aeronaut Henry Coxwell (1819–1900). The experiments included measuring how temperature varied with altitude, examining the humidity and electrical condition of the atmosphere at different heights, recording the sun's spectrum and taking measurements of the intensity of light.

He appears to have twice attempted to photograph during balloon ascents. Describing one ascent from Wolverhampton on September 5th, 1862, he wrote: "On emerging from the cloud at 1 hr. 17m. we came into a flood of light, with a beautiful blue sky without a cloud above us, and a magnificent sea of cloud below, its surface being varied with endless hills, hillocks, mountain chains, and many snow-white masses rising from it. I here tried to take a view with the camera, but we were rising too rapidly and revolving too rapidly for me to do so; the flood of light, however, was so great, that all I should have needed would have been a momentary exposure, as Dr Hill Norris had kindly furnished me with extremely sensitive dry plates for the purpose" (*The Photographic News,* 6:210, 444, 1862). On the second occasion, his eleventh ascent, made from Wolverton in June 1863, he attempted to photograph with a camera provided by Melhuish, but was unable to do so due to strange weather conditions (see *The Times*, July 2, 1863).

Glaisher was elected President of the Photographic Society in 1869, following Sir Frederick Pollock. It's longest serving President, he held office until 1892, except for an interval in 1874–5 when he resigned and the Presidency was offered to William Henry Fox

Talbot (see *The Correspondence of William Henry Fox Talbot*, document number 03448), an offer Talbot declined. When Glaisher stood down in 1892, William de Wiveleslie Abney FRS was elected. (For comments on Glaisher's presidency, see Gernsheim, 1955, 256, and Harker, 1979, 64).

Having left the Meteorological and Magnetic Observatory at Greenwich in 1874, aged 65, Glaisher continued to be involved with, write reports for, and give lectures at many learned societies and other institutions. He was on the Executive Committee of the Palestine Exploration Fund, its Chairman in 1880–1900, and wrote reports on the meteorology of Jerusalem which were published in the Fund's *Quarterly Statement*. He was a member of the Council of the Aeronautical Society from its foundation in 1866 until his death, which occurred on February 7th, 1903, two months before his 94th birthday. His funeral took place on February 11th at St John's Parish Church in Shirley, Croydon. A report in *The Times* the following day described the arrangements as having been of the simplest nature.

CAROLINE MARTEN

Biography

James Glaisher (1809–1903), Superintendent of the Meteorological and Magnetic Department at the Royal Observatory, Greenwich, studied meteorology and atmospheric phenomena by ground-based observations and in a series of scientific experiments during high-altitude balloon ascents in the 1860s. A member of the British Association for the Advancement of Science, Glaisher was elected a fellow of the Royal Astronomical Society in 1841, and a fellow of the Royal Society in 1849. He helped to initiate the founding of the British Meteorological Society in 1850, serving as a Secretary until 1873, and President in 1867-68. He worked to organize meteorology into an exact science, promoting the use of accurate, standardized instruments. He was a fellow of the Microscopical Society, and its President in 1865–8. Elected a member of the Photographic Society in 1854, he was President from 1869–1874 and 1875–1892, interested mainly in the practical, technical, and scientific applications of photography. In 1843 he married Cecilia Louisa Belville (1828–1892), who collaborated with him on a paper about the formation of snow crystals. A snow crystal drawn by Cecilia Louisa Glaisher forms the basis of the emblem of the Royal Microscopical Society. The Glaishers had three children, Cecilia Appelina (1845–1932), James Whitbread Lee (1848–1928), and Ernest Henry (1858–1885).

GLAISTER, THOMAS SKELTON (1824–1904)

Thomas Glaister was born 12 June 1824 in Holme Cultram, Cumberland, England. His father was a mariner who worked out of Maryport. Thomas trained as a carpenter but later became a druggist. In 1849 he married Elizabeth Gates, the widow of another mariner Joseph Metcalfe. Thomas worked as a druggist in Chicago and Woodstock, Illnois, then Burlington, Iowa before taking up photography, joining the studio of the Meade Brothers of New York. In November 1852 he landed in Melbourne and established a branch studio for the brothers in Melbourne. In 1855 after being joined by

his family Glaister moved to Sydney where he opened his own prestige daguerreotype facility in Pitt St. He photographed many eminent men and various places in Sydney and specialized in producing stereo images mounted in Mascher cases. In August 1855 John Watson opened a branch studio for Glaister in Brisbane. Daniel Metcalfe, Glaister's stepson trained in the Sydney studio and in 1864 he joined Robert Millington, the pair working as traveling photographers. In 1868 Metcalfe set up in Brisbane with his half brother Thomas Skelton Middleton Glaister. Their father operated his high class studio for 14 years but after it was destroyed by fire in 1870 he migrated to Sonoma County in California purchasing a vineyard and foregoing photography. He died there in 1904. His son "Middleton" succumbed to accidental cyanide poisoning in 1877.

MARCEL SAFIER

GODDARD, JOHN FREDERICK (1797–1866)

British photographer and popular scientific lecturer

Although little is known of his early years, Goddard developed an interest in science and became what today might be called a physicist. In 1838, he received a Society of Arts Silver Medal for his polariscope (an apparatus for experiments on polarizing light). He was a member of the British Association for the Advancement of Science in the early 1840s, by which time he was associated with two popular scientific establishments—the Royal Gallery of Practical Science, Adelaide Street (Royal Adelaide Gallery) and the (Royal) Polytechnic Institution in Regent Street—primarily as a lecturer on optics.

In 1840 Goddard became involved with photography. Richard Beard, who by that time owned the (English) daguerreotype patent, had also secured the right to use a reflecting camera invented by an American, Alexander Simon Wolcott. This did not work as well in Britain as it had in America, owing to the different climate, and exposure times were too long for successful portraiture, the main commercial application. To this end Beard sought advice from the Polytechnic Institution, and was recommended to employ Goddard, then engaged as lecturer on optics and natural philosophy at the Adelaide Gallery, who carried out the necessary scientific research at hired premises in Holborn. Goddard made good progress, though of a chemical rather than an optical nature. By September 1840, exposure times had been reduced from four minutes to one minute, but this was still too long.

He made further advances, announced in December, a day or two after Beard had completed his patent specification (incorporating Wolcott's work). Referring to his search for a way of making the daguerreotype plates more sensitive, Goddard claimed a valuable discovery; namely that when the bromide of iodine is used instead of simple iodine (as specified by Daguerre), this objective is achieved. But he did not give too much away, and the experiments continued. At the beginning of March 1841, Goddard deposited a sealed package containing laboratory notes made during January and February with the Royal Society. No doubt he did so in order to establish a priority claim for his work, should this become necessary. Other documents in the Royal Society's archives give additional practical details of his discoveries.

After assisting Beard at his London studio in 1841, Goddard took to the provinces. He was certainly in charge of Southampton's Photographic Institution by September 1842, holder of an exclusive licence for Hampshire and the Isle of Wight. What, if anything, had he paid for this? His (1847) advertisements in a little-known Southampton newspaper say: "Having for his important discoveries received of the Patentee a License for practising the science in Hampshire ...", it seems possible that he was rewarded by Beard, at least in part, by the grant of the Hampshire licence.

Goddard temporarily abandoned Southampton around July 1843. Perhaps the Photographic Institution did not support him adequately, or maybe he wanted to resume his career as a popular lecturer in London. However, he had not lost interest in photography. Although still in London at the beginning of February 1844, he was soon to be found at a new studio in Chester, where he remained for a couple of months. Goddard returned to London before the end of April, lecturing at the Royal Adelaide Gallery. However on 3 August 1844, the *Hampshire Advertiser* announced that Messrs Goddard and Mullins, from the Royal Polytechnic Institution, were taking portraits daily at No. 43, Pier Street, Ryde. Apart from an almost identical advertisement in the *Hampshire Telegraph*, this is the only evidence of what must have been another short-lived venture.

In May 1846, the *Hampshire Chronicle* announced the opening of Photographic Portrait Rooms in Winchester, conducted by Goddard and Alfred Barber, who had been the first professional photographer in Nottingham. In January 1847, Goddard was back in Southampton, though he seems to have departed by June of the following year.

There can be no doubt that Goddard fell on hard times. If he had not, probably much less would be known about him. The 1861 census finds the unmarried John F. Goddard, formerly Lecturer of Experimental Philosophy, in St. Joseph Alms Houses, Brook Green, Hammersmith. This deterioration in his circumstances was noticed by several well-established professional

photographers, including Cornelius Jabez Hughes, who drew attention to Goddard's plight in the photographic press.

The Goddard appeal launched by Hughes at the end of 1863 was not limited to the UK. One American periodical reprinted his article, sparking controversy over who had invented what, where and when. It must be remembered that, in the early, days several photographers working independently may have discovered much the same things at more or less the same time. In Goddard's case secrecy was paramount, on account of the English patent. Controversy grew to such an extent that Jabez Hughes felt obliged to address the matter again. He published articles, each in two parts, entitled "The Bromine Question and Mr. J. F. Goddard. Being two chapters connected with the early history of photography" in several journals. In the first part, Hughes reveals the existence of Goddard's sealed packet deposited with the Royal Society, printing its contents together with the latter's recent correspondence with the Society.

Goddard was not destined to benefit from his Testimonial Fund for long. Soon after his death in December 1866, controversy arose over what should become of the money raised on his behalf. Goddard had made a will in 1864, when the fund stood at not far short of £400, and his executor wished to dispose of the remaining money in accordance therewith. However the Committee administering the fund took the view that the balance should be returned to the original subscribers, and this view prevailed.

The intention had been to provide Goddard with an annuity, there being insufficient confidence in his judgment and prudence for him to be entrusted with the capital. Goddard resisted the annuity, although he did receive a small income from the fund (previously, a few well-wishers had supported him to the extent of each subscribing a guinea a year). As one commentator put it: "Whatever ability he may have possessed as a teacher of science, it is certain that he was weak in commercial matters."

RAYMOND TURLEY

Biography

According to the Parish Register of St. George, Bloomsbury, John Frederick, son of Thomas and Ann Goddard, was born on 8 December 1797, and baptized on 28 January 1798. His mother is probably the Ann Goddard who died at Chatham, Kent, on 16 November 1828. His father, Thomas (who died in 1842), was for many years Postmaster there, and had at least three other sons. John Frederick Goddard died on 28 December 1866, at the Middlesex Hospital, suffering from acute bronchitis.

GODDARD, PAUL BECK (1811–1866)

American physician and photographer

Credited with being the first to introduce bromide in the sensitizing of daguerreotype plates, Goddard's improvement greatly reduced exposure times and enabled the use of daguerreotypy for portraiture. While working as an assistant in the chemistry department of the medical college at the University of Pennsylvania, Goddard collaborated with Robert Cornelius, a metallurgist and lamp manufacturer, in conducting daguerreotype experiments in the fall of 1839, and by early December of 1839 the two were producing portraits using bromide as an accelerator. Goddard was Cornelius's silent partner in first commercial portrait studio in Philadelphia which opened in May of 1840, and continued in operation until 1842. Born in Baltimore on January 26, 1811, Goddard graduated from Washington College (1828) and the medical college of the University of Pennsylvania (1832). He practiced in Philadelphia as a physician and surgeon in addition to serving as professor of anatomy at Franklin Medical College 1847–1852. He is best known as an editor of numerous medical books. Goddard was a member of the American Philosophical Society and the Academy of Natural Sciences, as well as medical societies at the local, state and national level. He served on the Philadelphia Board of Health 1859–1863, and as a surgeon in the Civil War 1863–1865. He died at his home in Philadelphia on July 3, 1866.

JENNY AMBROSE

GOERZ, CARL PAUL (1854–1923)

His name stood for some of the most advanced technologies in photographic trade at the end of the 19th century, and yet he was neither an inventor nor a scientist. Carl Paul Goerz, born in 1854 in Brandenburg,

two hours north of Berlin, was seen as a typical German enterpriser of the late 19th century. He installed financial framework, erected production lines, secured transport and trading facilities, and finally, found the right products to sell. Accoriding to him, anything else was a matter of expertise for which one could hire specialists. However, Goerz had the touch of King Midas, and nearly any optical or photographic good his eye fell upon often became, under his influence, a necessity for the industry.

Carl Paul Goerz was born in the small town of Brandenburg north of Berlin where he grew up. Around 1870, after middle school, he became an apprentice in merchandising with the optical company of Emil Busch in Rathenow, then one of the best known companies in this field. During the four years of his apprenticeship in Rathenow, Goerz learned everything he needed for setting up his own business. From the mid 1870s to the mid 1880s Carl Paul Goerz worked throughout Europe, mainly in Paris, as a sales agent for a number of German companies including Busch. The latter part of this time, he held shares of Eugen Kraus' agency, then well known for its distribution of optical instruments in astronomy and industrial use. In 1886 he returned to Berlin and opened up his first wholesale venue for optical instruments, presumably mostly selling Busch's products. When Emil Busch passed away in 1888, Goerz saw his chance for establishing his own ventures of production and assembly of pre-fabricated goods.

From the beginning his partnerhsip was with a friend, the photographer and inventor Ottomar Anschuetz, who not only provided Goerz with the economic use of his patent for a focal-plane shutter but with numerous advices as well for building easy-to-handle and simple-to-use cameras. In September 1888, Goerz worked with the Swiss theoretical optician Carl Moser who calculated the famous 'Lynkeioskop' lens shortly before his untimely death in 1891. He was followed bei Emil von Höegh, the inventor of the even more successful 'Dagor' lens and 'Hypergon' mentioned above. Anschuetz and Moser / Höegh each were the first of a long line of inventors, engineers, and physicists to work for Goerz; some of the best renowned theoretical opticians in Germany had at least been involved with this company as an important part of their career.

Goerz's cameras and lenses were part of every major development in photography between the 1890s and World War I. The miniaturisation of plate and film formats, from 9 × 12 cm in 1890 to 4.5 × 6 cm in 1908, was accompanied with both acclaim from photographic amateurs and fierce rejection by the critics in the papers. Easily transportable and designed for hand-held use, folding cameras were a special item of the Goerz company, and in 1910 it released the first type of camera with a lens pre-focused on it. Similar developments were encouraged by Goerz in the construction of lenses; from 1890 onwards a-planatic lense like the 'Lynkeioskop' were severe competitors to Voigtlaender's, Dallmeyer's, and Busch's similar products. The Daguerreotype lens was introduced in 1893 and became an instant success: 30,000 units sold in three years, and by 1911 the output increased to 300.000 pieces. In 1900, the Goerz company brought out the Hypergon lens which is sometimes remembered as one of the most remarkable constructions in photographic history consisting of an a-planatic lens with a wide angle of 110°, without any distortion or spherical aberration. At the same time, Goerz found world-wide acclaim and success for its large scale reflectors, projection devices, and panoramic binoculars which were mainly used for military purposes.

The company was open to any invention dealing with photography. From its earliest days in 1888, it produced exposure meters. From 1890 onwards, it was the first supplier of the Anschuetz type focal-plane shutter and, of course, there was a full production line of cameras furnished with this device; its brand name was Ango, made of Anschuetz and Goerz. In 1905 the first colour slide projector after Adolf Miethe's three plate system was built and sold, succeeded by a long line of similar devices. In 1907, Goerz launched the first industrially produced yellow glass plate as filter for landscape photography. By 1908 and the start of the company's partnership with Joseph Arthur Berson, a long line of balloon cameras started to be produced, to be followed by a number of air survey cameras after 1913. And in 1910, Goerz built one of the earliest so-called 'night cameras' with especially designed lenses and shutters for journalistic uses. Considering all of these successes and novelties in one company history, it is remarkable to note that its founder and all-time leader was neither a chemist nor a physicist, and by no means a scientist but instead an entrepreneur par excellence.

Goerz knew what he owed to his workers and employees, and he gained a certain fame with the early introduction of social benefits for them. In 1894, the company inaugurated the average working week of 48 hours; and in 1897, all of his company men received two weeks of fully paid holidays each year. The company later moved to new buildings in 1898, which had a statue five meters height in front of the building, honoring photography. By this time, the name Goerz incorporated glass and film production as well as cameras, lenses, and binoculars. With the launch of several products for military use after 1905, the necessity arose for opening a number of branches in Europe, the United Kingdom, and the United States which included production lines as well as distribution offices. In 1917, the company was at its largest size with more than 10.000 employees, and it even survived both the German revolution of 1918 and the depression of the early 1920s.

Carl Paul Goerz passed away in January 1923. Three years later, his company was one of four to form Zeiss-Ikon. In the year of Goerz' death a cheap box camera was launched under the brand name Tengor which was the first one to be completely transferred into the new company's name—and produced until the late 1950s. Other Goerz products are more difficult to trace but still earn a high reputation for both the company and its founder for being at the very top of industrial quality and technical innovation for their time.

ROLF SACHSSE

Biography

Carl Paul Goerz, born in Brandenburg, Havel, July 21, 1854. Apprentice as merchant in Emil Busch's Company of Optical Instruments at Rathenow, Berlin, 1870–74. Sales agent for German optical and mechanical instruments companies in Europe, mainly in Paris; several years as participant in the company of Eugen Kraus, Paris, 1875–86. Return to Germany and opening of a wholesale agency for optical instruments and drawing aids in Berlin-Friedenau, 1886-88. Producer of cameras and lenses in his own company from 1888. Opening of subsidiary companies in the United States, the United Kingdom, France, and Italy, 1905-09. Died in Berlin, January 14, 1923. The company was one of four to form the Zeiss-Ikon Company in 1926. Since then the brand name Goerz has been used for several venues of minor importance.

GOLDENSKY, ELIAS (1867–1943)
American photographer

Elias Goldensky built his reputation as one of America's eminent portrait photographers by producing artistic prints that were as individualized as his sitters, many of whom were celebrities. Born on September 9, 1867 in Ukraine to a Russified Jewish family, his father was an oculist and photographer. Immigrating to Philadelphia, Pennsylvania in 1891, Goldensky opened his first portrait studio in 1895. He briefly associated with fellow Pictorialists Alfred Stieglitz and F. Holland Day after exhibiting work at the National Academy of Design in New York and the Pennsylvania Academy of the Fine Arts in Philadelphia in 1898. An early practitioner of color photography, Goldensky used the gum bichromate process and different papers to lend color and texture to his personalized prints, characterized by soft tones and intimately depicted sitters. Recognized as both a commercial and artistic photographer, he received numerous international awards and widely demonstrated and lectured on his techniques. Goldensky served on the board of directors of the American Museum of Photography and was a member of the Photographic Society of Philadelphia, the Camera Club of New York, and the Salon Club of America. He died in Philadelphia on March 10, 1943. The George Eastman House holds the largest collection of his work.

CHARLENE PEACOCK

GONNET, ESTEBAN (1830–1868)
French surveyor and photographer

This French man appeared in Argentina by 1858, receiving a license of surveyor by 1859. In 1864 he announced at the newspapers his photographic activity from a studio in downtown Buenos Aires.

During the rest of his short life he worked both as photographer and surveyor.

His studio Fotografía de Mayo was located at 25 de Mayo street, where he make portraits. He also produced very early albums of views from Buenos Aires urban and rural views, titled "Recuerdos de Buenos Aires" and "Recuerdos de la campaña de Buenos Aires."

His activity as surveyor gave him the opportunity to visit estancias, being an early the recorder of rural scenes. He traveled along a large part of province of Buenos Aires, working in many small cities.

He passed away very young, in 1868.

All known production is in albumen prints, never signing them, except by his rubber stamp "Fotografía de Mayo."

Many of his early photo historical studies attributed wrongly to Benito Panunzi.

ROBERTO FERRARI

GOOD, FRANK MASON (1839–1928)
English photographer

Good was a professional photographer who lived at Hartley Wintney in Hampshire. He joined the Photographic Society of London in 1864 and showed several landscape studies at that year's annual exhibition. Most of the works exhibited were made in the southern English counties of Hampshire, Surrey, Dorset and Devon. Along with his landscapes he also produced flower

and tree studies. Many of his views were published in early photographically illustrated books and as stereo cards.

He made up to four trips to the Near and Middle East in the 1860's and 1870's, producing whole-plate prints and stereo views, many of the images being signed Good or monogrammed FMG in the negative. His Middle Eastern views were published by both Francis Frith and W.A. Mansell & Co. Frith commissioned Good's first trip to the Near East and later published his views of Malta, taken during his return from Constantinople and Egypt in the winter of 1871/2.He may have been Frith's assistant at one time.

Good's output, particularly his Middle Eastern work, is distinctive and of high technical and artistic merit, especially when the difficulties of working with wet-collodion in remote areas is taken into consideration. He has been generally overlooked as a photographer.

IAN SUMNER

GOODWIN, HANNIBAL (1822–1900)

American photographer and inventor

"His experiments culminated in 1887 in the invention of the photographic film. As a memorial to the inventor of the device that has proved so potent for the instruction and entertainment of mankind this tablet is erected." So reads the memorial tablet to Hannibal Goodwin, the inventor of celluloid rollfilm.

The Reverend Hannibal Goodwin, born in Tompkins Country, New York, and an Episcopal rector in Newark, New Jersey from the mid 1860s, turned to photography as a means of illustrating the talks he gave to children and local organisations. From 1867, until he retired from church life in 1887, his illustrated talks were a regular part of his Sunday Schools.

Using gelatin dry plates, he became interested in the idea of reducing the weight of materials he had to carry with him on location. His experiments led him to the creation of a celluloid film "especially in connection with roller cameras" and he applied for a patent for it in May 1887. For unexplained reasons—although some writers hint at a sustained campaign of obstruction by George Eastman—final patent protection was not given until 1898, by which time Eastman had already introduced his own flexible celluloid rollfilm.

Goodwin was almost ready to go into production with his roll film when he was killed in a traffic accident. His business interests were sold to Anthony & Scovil (Ansco), and courts eventually ruled that Eastman had infringed his (rather loosely specified) patents, resulting in a multi-million dollar payout.

JOHN HANNAVY

GOUIN, ALEXIS-LOUIS-CHARLES-ARTHUR (d. 1855)

French photographer

Gouin was supposedly born in New York at the end of the 18th century. His exact birth date remains unknown like the details about his parents and childhood. After his arrival in Paris, he studied painting at the Fine Arts Academy where he received the teaching of Jean-Baptiste Regnault, admirer of Raphaël and creator of many important historical paintings. Next, he worked in Anne-Louis Girodet's (1767–1824) studio, a pupil of David, both neoclassical and romantic painter, who excelled in lighting effects and in disrupting contemporary norms of sexuality. The production choices and fine colourings of Gouin's negatives ilustrate this pictural legacy without being a strict imitation.

Gouin assessed the value of this new medium, so, such as attests the obituary published in the *Humphrey's Journal*, he was one of the first to engage in photography after the daguerreotype process became public knowledge. However, his name only appeared in the Bottin, the Parisian Business register in 1849 (at rue Basse-du-rempart, 50). Working with his wife and his daugther, Laure (the dates of his wedding and daughter's birth are unknown), who hand-coloured his photographs, he met Bruno Braquehais, who was previously a litographer in Caen, around 1851. Gouin moved to rue Louis-le-Grand, 37, and invited Braquehais to join his studio (until 1852). The same year, he created a machine for polishing daguerreotype plates—the photographer Bertrand affirmed at its subject that if he could do 150 plates per day, it was only thanks to the Alexis Gouin's remarkably fast machine—and a photometer, which was a precision instrument that measured luminous flux and intensity. He received a medal of honourable mention for his coloured daguerreotypes at the London Exhibition. Nevertheless, his inventions were never mentioned. In September however, his name appeared among the souscriptors list to erect a memorial in remembrance of the heliography inventors, Niepce and Daguerre.

Then he began producing stereoscopic daguerreotypes of female nudes. Other photographers such as Belloc, Derussy, D'Olivier, Duboscq-Soleil, Moulin and of course Braquehais, also used this process to create women Académies and erotic studies. These images were often anonymous or secretly diffused because of the "good taste" and the censorship that judged them too "natural" or too "real," the hand-coloured stereo nudes particularly. But with this process, Gouin signed as well quite famous portraits of several personalities of the period. Among them, those of Camille Saint-Saëns, that Gouin presented with some bright hair, a lively and inspired eye, a quill in the right hand, and in the left, the Berlioz score "Lélio" for which the french composer made the piano reduction.

He also portrayed the sculptor James Pradier, his sister, and the *Trois Mousquetaires* author, Alexandre Dumas, who seemed to be young and laughing.

Alexis Gouin produced a major part of his known images from this time until his death in 1855. According to an obituary column written by Lacan in *La Lumière*, Gouin succumbed to death "after one of those cerebral affections that struck like lightening." Gouin's widow, and daughter Laure, who became Braquehais' wife, all inherited the studio.

Afterwards, Mrs Gouin maintained her miniaturist skills and put Gouin colours up for sale and placed an advertisement, which was frequently published on the last page of *La Lumière* from 1856 onwards: "Gouin colours. Colour of such great reputation that Mrs. Gouin has decided to put them on the market. 75c for each tube, 1fr for carmine. Box of colours with compartments and drawers, consisting of an assortment of 12 tubes of colour, a gold and a silver receptacle, and 6 brushes, all for the price of 15fr. A special depot has been set up with Alexis Gaudin & Bros. At rue de la Perle, 9."

The "Gouin's firm" continued creating images during the decade and the pictures produced were quite similar so much so that Lacan underlined Laure and her mother's talent which didn't keep him from wondering about Alexis Gouin's real part in the work. Mrs Gouin died in 1863 and the studio was transferred at Boulevard des Italiens, 11, where the Braquehais couple worked for several years.

Gouin's negatives were recognized for their quality and poetry, and several contemporaries' statements proved it, particularly the discussion of a meeting at Lacan's, 15 days before Gouin died, which was published in *La Lumière*: "…. It is inconceivable to come closer to perfection. His bodies are alive, their flesh throbs before our eyes. Nature has been captured on the spot and translated into poetry through the talent of a painter." He was praised too with the descriptive phrase "The French Claudet" or "The Claudet of Paris" and according to E. Lacan, "this comparison is very natural." Indeed, as well as Antoine Claudet, Gouin was commonly considered a master of the stereoscopic images. But their works differienciate themselves, especially in the field of colour use. While Claudet's portraits contain very few colors (some plates are even uncolored) which the major part is not modified, Gouin's show the use of a large number of colours often mixed with white and neutrals. In her book, Janet E. Buerger affirms for that matter even a black pigment was found on one Gouin's plate, extremely unusual thing on daguerreotype where the polished surface of the plate naturally produced deep black effects. Therefore Gouin is above all received as a fine colourist caring on effects and composition and Claudet as a technician with a classical making, nearer from the Victorian style.

Gouin's photographs reside at the Musée d'Orsay (Paris), George Eastman House International Museum of Photography and Film (New York), Agfa Foto-Historama (Cologne) and in several private collections like Derville (Paris) Nazarieff (Geneva), Van Keulen (Amsterdam), Auer,(Geneva) or Briechle (Munich).

At present, although he was absent from most of the great books on the subject, his work is shown in texts and in daguerreotypes and photography exhibitions. The last exhibition where appeared his pictures took place at the Metropolitan Museum of Art in New York from September 23, 2003 to January, 4, 2004.

FRÉDÉRIQUE TAUBENHAUS

Biography

Gouin was born in New York at the end of the 18th century. Pupil of Regnault and Girodet, he was one of the first photographers to use the daguerreotype process. Working with his wife and daugther, who hand-colored his negatives, from 1849 (date of his inscription in the parisian business register), he met Bruno Braquehais towards 1851 and invited him to join his studio (until 1852). From this time to his death in 1855, Gouin devised a photometer and a machine polishing daguerreotype plates. He get a honourable mention at the London Exhibition and portrayed, among others, Alexandre Dumas, Camille Saint-Saens and James Pradier. With the stereoscopic daguerreotype process, he made series of female nudes. His contemporaries praised his photographs for their subtility and quality so that he was called "The French Claudet." His daughter married Braquehais in 1856 and the Braquehais-Gouin's firm produced colours and images during a decade.

GOUPIL & CIE (active 1850–1884)

French art publishers and art dealers

Henry Rittner (1802–1840), a young German immigrant with experience in the London print trade, opened a print establishment in Paris in 1827. This was the beginning of what was to become the most powerful art-publishing company of the nineteenth century. Two years later, Rittner formed a partnership with Adolphe Goupil (1806–1893), second son of a pharmacist and, through his mother, a collateral descendant of the rococo painter, François-Hubert Drouais. The Maison Goupil—Rittner & Goupil and its successors—remained in business for almost a century, until the ultimate successor, Manzi, Joyant & Cie, ceased active operation in 1917. In 1921, a print dealer from Bordeaux, Vincent Imberti, acquired all of the remaining stock: hundreds of thousands of prints, photographs, engraved copper plates, glass-plate negatives, illustrated books, and archival documents (although in this last category there were many gaps). In 1987 and 1990, Guy and Gabrielle Imberti ceded what remained from this ensemble to the City of Bordeaux, which placed it in a new museum, the Musée Goupil.

From 1829, Rittner & Goupil published as well as sold prints from their premises in the Boulevard Montmartre and distributed them through correspondents in Europe and the United States. After Rittner's death, Adolphe Goupil admitted two new partners, Théodore Vibert and Alfred Mainguet. During the 1840s the three partners built a vertically integrated business with its own printing facilities and, as of 1846, an art gallery. After buying original artworks (including copyrights), the firm commissioned every kind of relevant reproduction, finally selling both the original work (usually retaining the copyright) and its various reproductions at a substantial profit. To expand distribution, they opened branches abroad, beginning with New York in 1848, then London, Berlin, The Hague, and Brussels. By the 1860's, a multinational empire was in place. Goupil & Cie was at the very heart of an informal, international network of art dealers and publishers, all of whom distributed one another's merchandise—paintings, prints and photographs. Apart from Goupil, this network, constituent parts of which remain in existence today, included Colnaghi, Agnew, and Gambart in England, Sachsé in Berlin, Van Gogh in The Hague, and Knoedler in New York. Michael Knoedler had been Goupil's New York manager, arriving in the city in 1852, and although he purchased the branch for his own account in 1857, his house remained intimately allied with the parent firm until the end of the century.

Because they made it possible to generate multiple prints from a single negative, William Henry Fox Talbot's discoveries were highly applicable to publishing. The Maison Goupil first showed interest in photography when they co-published the groundbreaking *Excursions daguerriennes*, completed 1842. In May 1853, the company released the first installments of major photographic publication: Félix Teynard's *Voyage en Égypte et en Nubie* (160 plates in total), Benjamin Delessert's *Notice sur la vie de Marc-Antoine Raimondi* (67 photographs mounted on 59 plates in total), and, as a single plate, Gustave Le Gray's *Portrait of Napoléon III*. Though not attributed in Goupil's catalogue, the series

Paris photographié (30 plates) was due to François-Auguste Renard. This initial releases also included a series of views, monuments, landscapes, seascapes, and gothic architecture entitled *Excursions photographiques* (30 plates, and "more each day") by Le Gray, Henry Le Secq, and others referred to as "the most distinguished photographers." In October 1853, Edouard Baldus' eleven plates reproducing the stained-glass windows for Sainte Clotilde church in Paris appeared. Goupil's catalogue of that date advertised that: "One can find at Messrs. Goupil & Cie all of the most remarkable achievements that were obtained in photography of all genres; views from Italy, Switzerland, Spain, studies of landscape, architecture, and figure, etc., by the most distinguished artists. Each photographic plate can be sold separately, price range is from 2 to 25 francs, according to the size and importance of the subject." The next catalogue (June 1854) featured Baldus (*Monuments, vues générales et tableaux*, 25 plates), the Bisson brothers (*L'œuvre d'Albert Dürer*, 104 plates, and *Vues de Paris*, 16 plates), Giroux, (*Vues d'Auvergne*, 32 plates), Grillet (*Vues de Pompéi*, 17 plates), Kier, (*Vues de Venise*, 32 plates), Le Secq (*La Cathédrale de Reims*, and *Études de paysage*, 32 plates each), Le Gray (*Études diverses*, 40 plates), Friedrich Martens (*Vues de Suisse*, 36 plates), and Joseph Vigier (*Vues des Pyrénées*, 38 plates).

The catalogues hardly mention photography again until 1858 but the June 1854 stated: "Our collection of photographs contains everything remarkable which has been made until now in France and abroad. It is impossible to list in our catalogue all the sheets from this collection, hence we will only quote some of the most important." Some of Goupil's important publications (such as Charles Nègre's *Midi de la France*, 1854, 10 plates) are not listed, which makes analysis difficult. However, this first incursion in the realm of photography showed the extent to which Goupil considered the new medium merely a tool applied to a general publishing policy. Photographs had their own section in the catalogues, beside "Engravings," "Lithographs," "Collections," and "Studies." Names of the photographers usually appeared, and prices were comparable to those for prints—less than for engravings, but more than for lithographs, on average. The format itself mimicked the formulas used in the print trade, with carefully designed and printed letters, bearing all the customary information and the publisher's address. Appropriating the tradition of printmaking was not specific to Goupil but was a general trend in photo-publishing's early years. Martens' *Vues de Suisse* epitomized these intricate relationships between photography and printmaking. Not only was Martens a successful engraver, published by Goupil since the 1840's, but his Swiss photographs were interpreted as color lithographs by Eugène Cicéri, in two sizes, both published by Goupil (1859–1864). Though representing the same subjects, the photographs and lithographs were not aimed at the same market. Goupil's marketing talent was to identify various distinct clienteles and to tailor publications to their specific needs.

The subjects of Goupil's early photo publications were consistent with their print publications. The only portrait, Le Gray's *Napoleon III* ("in civil costume") fitted into the long sequence of official or more casual portraits of the emperor that Goupil published in every possible size and technique, and with a wide range of prices. The emphasis on topographical and picturesque views, architecture and travels echoed the numerous views published by the Maison, especially as lithographs. Reproduction of works of art formed the other important category, with Delessert's celebrated reproduction of Raimondi's prints, and Baldus' photographs of stained-glass windows. Goupil would eventually specialize in fine-art photographic reproductions capitalizing on his experience as a print publisher.

After the first wave, photographs re-appeared in 1858, when Goupil created the *Galerie photographique*, the first of his extensive series of reproductions of works of art. The *Galerie photographique* grew to 1,779 items by 1894. Five other series would follow: *Musée Goupil & Cie* (1860), *Cartes de visite* (c. 1863), and *Cartes album* (Cabinet cards, 1872) amounted to more than 1,100 items each by the end of the century. Less important, *Photographies d'après les grands maîtres* and *Album de photographies* appeared in 1860 and c1863, respectively. For the most part, the six major Goupil photographic series were devoted to contemporary art (almost exclusively painting), carefully selected at each Salon. Though Goupil installed a semi-clandestine photographic studio in the Louvre in the 1880's (*État des lieux* 2, 1999, 129), reproductions of old masters were the province of other firms, such as Braun. From the constant flow of Goupil art reproductions would only emerge few "direct" photographs, such as Louis Rousselet's *Voyage dans l'Inde* (c. 1870, 160 plates) or Auguste-Rosalie Bisson's *Vues d'Italie* (c. 1870, 56 plates).

In the beginning, Goupil had no photographic facility but commissioned the printer, H. de Fonteny (responsible for printing Teynard and Nègre portfolios), and professional photographers, chiefly Robert Bingham, but also C. Michelez and Henri Voland, all specialists in art reproduction. An in-house photographic studio opened in 1860, directed by Henri Rousselon (1822–1902), an engineer. Initially limited to the production of albumen prints, this facility soon made the wet collodion negatives itself, and by 1862, Goupil's flourishing photo-publishing activity was autonomous. In 1869, the firm opened a large factory in Asnières, thereby gathering under one roof all its technical and

manufacturing activities, be they related to photo or print publishing. Driven by steam and electricity, the Asnières plant embodied modernity—but not from a social viewpoint: in 1880, of the 107 persons working there, nine were children.

In the most logical way, considering its experience in print publishing, the firm's interest in photomechanical processes began early. In 1853, it was part of the photolithography venture and co-published the *Premier Cahier de Lithophotographie* (6 stunning plates obtained with the Lemercier, Lerebours, Barreswil and Davanne process, from negatives by Le Secq). In 1867, Goupil bought from Walter Woodbury an exclusive license for the exploitation in France of the Woodburytype process. In 1870, he sold back secondary licenses to Lemercier and Braun. Meanwhile, the Asnières factory produced Woodburytypes on an industrial level. A single worker could print 500 copies of the same image in one day. Surprisingly, Goupil did not advertise the process in his catalogues, whereas he could have promoted its permanency, which was a major issue at the time. For Goupil, Woodburytype was more a step forward industrialization than a victory over the self-degradation of albumen silver prints. Both processes always co-existed, and the same reference in the *Carte de visite* or *Galerie photographique* series may often be found both as albumen prints and Woodburytypes. The selection of the process probably depended upon the quantity of prints needed at a given time. The excellent quality achieved at Asnières led other publishers to commission Goupil for their own productions—as was the case for Baschet's famous *Galerie contemporaine* (1876–1884).

Goupil stopped producing Woodburytypes at the beginning of the 1880's. Meanwhile, Rousselon had perfected another photomechanical process, the photogravure. This was another demonstration of Goupil's modernity: constant experimentation and refinement of technologies, developed in-house. Rousselon was encouraged to work on a photomechanical process compatible with intaglio printing. Capitalizing on Woodbury discoveries, he found a way to obtain a special grain on the dichromate gelatin, suitable for retaining ink. This grain appeared on the subsequent lead mold, which was itself copied on a copper plate by electrotyping. Rousselon presented his process at the Société Française de Photographie in 1872 (seven years before Karel Klič's process), and Goupil released his first photogravures in 1873. The results were superb; no other firm ever achieved such quality and accuracy, neither in Europe nor in the United States. The process earned many awards in international exhibitions throughout the decade. Thousands of photogravures reproducing artworks were mass-produced, along with a few topographical photographs, such as those illustrating Auguste Mariette's *Voyage dans la Haute Égypte* (1878). Other publishers, especially Americans (Gebbie & Barrie, and Appleton), commissioned photogravure printing from Goupil; in the United States, the process was often called "Goupilgravure." As with any intaglio plate, these could be printed with several colors (up to 20), offering dramatic results. This was the case for the luxury portfolio *Les Dessins de Auguste Rodin* (1897, 125 copies).

Rousselon retired in 1884, to be replaced by a young Italian engineer, Michel Manzi (1849–1915), who, from 1897 to his death, co-directed the company with Maurice Joyant (1864–1930). Manzi introduced a photomechanical process of his own: *typogravure*. Based upon block printing, similar to half-tone processes, it allowed simultaneous printing of photograph and text. Thenceforward, the Maison Goupil published photographically illustrated books and magazines: *Le Figaro Illustré* (1890), *Les Sports Modernes* (1898), *Le Théâtre* (1898), *Les Modes* (1901), *Les Arts* (1902), and *L'Hygiène* (1909). However, in spite of this shift in its publishing policy, the firm slowly declined and failed to survive World War I and Manzi's death. Both the academic art they promoted and the very products they manufactured were out of fashion. After forming the most significant part of the media explosion of the 19th century, reproductive prints and photographs, sold either as individual plates, or in series or portfolios, had virtually disappeared, a circumstance fraught with consequences for the dissemination of art, as well as for its production.

GOVERNMENT PRINTERS

The 19th century saw the rapid growth in the establishment of government printers required to supply public documents. A number of these printing offices were also centres of technological experimentation and played a significant role in developing and exploiting photographic and photomechanical processes.

The most influential Government printer during the majority of the 19th century was in Austria. The Kaiserlich-königliche Hof- und Staatsdruckerei (Imperial and Royal Court and State Printers) was founded in 1804. By the end of the 1840s it had a photographic department founded by its Director, Alois Auer (1813–1869) who placed Paul Pretsch (1808–1873) as a manager of the department. This state printer also heavily influenced the Russian State Printing Office.

As Director-General of the British Ordnance Survey, Colonel Sir Henry James (1803–1877) successfully exploited photozincography to save thousands of pounds a year in the reproduction of maps. James used photozincography to reproduced important national manuscripts, particularly the 11th century Domesday Book published from 1861–1863. In 1867 James used the Albumen print process to create illustrations to *Plans and Photographs of Stonehenge, and of Turusachan in the Island of Lewis.*

The königlich-preußischen Staatsdruckerei (Royal Prussian State Printer) was founded in 1852 and was incorporated into the Reichsdruckerie in 1879. In 1883–4 a new 'Chalcographic Department' was established for the photomechanical reproduction of works of art, using photography, heliography, collotype, lithography, chemography, copper engraving and electroforming.

ANTHONY HAMBER

GRAF, HEINRICH (active 1860s–1870s)

Little is known about Heinrich Graf, to the degree that sometimes his name also appears as Graff. There is evidence that he came from Berlin, worked in several German countries, most prominently in Altona near Hamburg where his photographs are collected now. Besides being a portraitist of some fame and good quality, he covered the Prussian-Danish war in 1864-65 alongside to the Swiss Charles Junod and Friedrich Christian Brandt. His war photographs concentrate on portraits of staff officers in ambient settings. What has survived of his work are albumen prints made after the wet collodion process.

The spelling Graff came from some etchings made after his photographs in German newspapers. These photographs show members of the Prussian Royal Court in Berlin throughout the 1870s, mostly at military parades

and official occasions. There is no record of Graf/Graff after these years.

ROLF SACHSSE

GRAFF, PHILIPP (1814–1851)
Berlin daguerreotypist

Philipp Graff, born 1814 in Berlin, was like his father Philipp Graff senior, an optician. Early on, he was engaged in the construction of photographic apparatus, and in 1840, he began daguerreotyping opening a portrait studio, in which he also received commissions from the Prussian royal family, in 1843. Graff was famous for his painted city views, which he used as a backdrop and was one of the first daguerreotypists to advertise by putting photographs in his shop window instead of, in the usual way, by advertising in the papers. He trained many photographers, of whom the best known was Richard Scholz. Graff is well known for his *Graffsche Mischung* [Graff's mixture]—a method to heighten the sensitivity of the plates which was very popular. After Graffs death on 7 March 1851 his widow continued the business until it was taken over by August Beer in 1854 who then employed Leopold Ahrendts. Most of his daguerreotypes are kept in the *Kupferstichkabinett* Dresden, the *Stiftung Stadtmuseum* Berlin and the *Museum Ludwig/Agfa Photo-Historama* Cologne.

STEFANIE KLAMM

GRAHAM, JAMES (1806–1869)
Scottish itinerant photographer

James Graham's photography provides a more accurate account of the personal journey of the traveller of that time than any of the bought 19th Century albumen prints, purchased as souvenirs, because they are unhindered by notions of commercial, and possibly even artistic success. They can be contrasted with the new commercial travel photograph, the albumen print, which depicted known stage sets for a knowing public; rather, Graham's images are often private and personal. Yet while they provide a unique document of precise moments, even to the extent of tracing a walk through the landscape on a particular day, they intriguingly do not reflect the life and harrowing times that Graham lived through and took part in, especially in Jerusalem. They are, instead, desired realities. He was to ignore the remarkable detail embedded in his waxed paper negatives in favour of tone, characterised by a deep, rich yellow or brown which produced a brooding melancholy, as befitted this argumentative and principled Scot. They included some of the earliest photographs of Jerusalem and the Holy Land

James Graham (1806–1869) was the sixth and youngest son of Alexander Graham of Lymekilns and Fereneze in Scotland and Margaret, daughter of John Cochrane, banker. He was the younger brother of Elizabeth and Agnes, and he succeeded to part of the family estate near Barrhead, Renfrewshire, after the death of his eldest brother Patrick Graham Barns (1793–1867). Graham remained a bachelor and none of the family appears to have had any issue. After the failure and loss of his money as a banker, perhaps associated with the notorious and long running collapse of the Western Bank of Glasgow which finally closed in 1857, Graham took up a new career as a lay missionary. He became the Lay Secretary of the London Society for the Promotion of Christianity amongst the Jews (The London Jews Society) and joined the Mission in Jerusalem in 1853, aged 47. He stayed 5 years and departed in 1857.

Elizabeth Finn (1825–1921) and her husband James Finn (1806–1872), British Consul in Jerusalem (1846–1863), founded the Jerusalem Literary Society in 1849 where the 'only subject excluded was religious controversy.' This Society no doubt helped to bring about the foundation in London of the Palestine Exploration Fund in 1865 with the support of the Archbishop of York and the Dean of Westminster, 'for the purpose of investigating the archaeology, geography, geology and natural history of the Holy Land.' The aim was to 'illustrate the Bible,' that is, obtain documentary evidences of the scriptures. Elizabeth Finn contributed frequently to the Palestine Exploration Fund's publications between 1869 and 1892 and later donated to them her collection of photographs, which included a substantial collection by James Graham. She had been shown the use of the calotype by the Rev. George W. Bridges (1788–1863) on his visit to the Holy Land in 1850 and thought it would be a useful addition to fund-raising by selling photographs to itinerant Christian travellers in the Holy Land and also sending them back to Britain. Graham took up calotype photography just before his arrival in Jerusalem in order to aid this mission work. A Jewish convert from the American Baptist Church, Mendel John Diness (1827–1900), became his helper and pupil, and Graham subsequently sold Mrs Finn's unused camera equipment to him. Thus James Graham reputedly became the first resident photographer in Jerusalem and Mendel Diness became the first indigenous Jewish photographer in Palestine, although he may have also helped in that capacity the Rev. James Turner Barclay, physician and also photographer, who founded the American Christian Mission in Jerusalem in 1851 and employed the converted Diness as his translator. Barclay had an 'excellent French photographic apparatus' and could have been photography before Graham's arrival. Diness was to practice photography after Graham left,

eventually emigrating to the United States in 1861, firstly as a photographer, then he became a lecturer and finally an evangelical minister.

James Graham became a travelling companion to British and American visitors and entered the world of art in 1854 and 1855 when he chaperoned, accommodated and befriended two Pre-Raphaelite painters: Thomas Seddon (1821–56), the first Pre-Raphaelite painter to enter a national collection with '*Jerusalem and the Valley of Jehoshaphat from the Hill of Evil Counsel'* (1854, bought by the National Gallery, London 1857), which much resembled a Graham photograph of the same view, together with Holman Hunt (1827–1910). Both Seddon and Hunt used Graham's photographs, including Graham photographing the goat for Hunt's famous painting '*The Scapegoat*' (1855). In his diaries Hunt described Graham as 'a churchman with a strong tendency of Presbyterianism' and that he was 'prosy and an incorrigible procrastinator.' He was a man of rigid principles but also outspoken against injustice. Hunt was to join Graham in his growing criticism of the treatment of the Jewish Christian converts and their appalling conditions under the bishopric of Bishop Samuel Gobat (1799–1879); both were to issue protest pamphlets in Britain. Jewish converts were totally economically dependent on the Christian community for work or charity as the Turkish rulers had as much contempt for them as the Jews. Like the Finns, Graham befriended the Christian Jews and became increasingly criticised by the church for 'indulging too much in the society of worldly people.' Such complaints to the British establishment resulted in his dismissal in 1856 and later brought down the Finns who were recalled. Throughout, Graham had a peculiar access to those of importance but little is known of his activities after leaving Jerusalem: he is known to have travelled to Syria, Rhodes, Egypt, and frequently to Naples, where he photographed extensively, at least for seven years between 1857-1864, but probably until c.1868. He died in Paris in 1869 on his way from Scotland to winter in Naples. He made an extensive tour round the Gulf of Naples using waxed paper negatives and produced a remarkable set of photographs which included probably the earliest calotypes of Capri, Ravello and Scala, and some of the finest of Pompei. In Naples he assisted the Anglican community with the building of Christ Church (1865), the first Anglican church allowed in Southern Italy. This including negotiating with the Italian government over the site for the church promised by Garibaldi to the Anglican community in 1860 when he 'liberated' Naples.

Although Graham began to copyright his images from 1862 onwards, his photographs are extremely rare as he never became a commercial photographer, although, in later life, some of his prints were used for reproductions, particularly Biblical texts; rather he appears to have used them to put into albums for presentation to family and friends. Throughout he remained with the 'out of date' paper negative. Not particularly known in the annals of photography, he nevertheless exhibited in exhibitions at Crystal Palace (1855 and 1864) and in 1859 in Paris (where he had an address) where his *'Voyage à Jerusalem'* of some 50 images found much favour.

GREAT BRITAIN

Composing a national survey is a difficult task; it requires attention to a wide range of practices and can induce an excessive focus on canonical pictures and 'inventions.' More significantly, it is hard to avoid the ideological assumptions embedded in a 'national tradition.' During the nineteenth century the British nation was in the making and there were plenty of Brits abroad whose images count among the highpoints of 'British photography,' while quite a few photographers working in the British Isles were emigrants or passage migrants without whom 'British photography' would be very different. The story is further complicated, because at the time Britain was the foremost Imperial power. The photographs produced in parts of the globe coloured pink, appear in some accounts as British images, but they also figure in the history of other social formations—'Indian photography' or 'photography in Burma.'

Accounts of origin are also notoriously problematic and photography provides no exception. One place to start is with the fact that some people were looking for a cheap and reliable copying technique in the later eighteenth century. In 1802 Thomas Wedgwood and Humphrey Davy published a paper in the *Journal of the Royal Institution* giving details of how to copy existing images on paper, or pale leather, treated with silver nitrate. The veracity of these early experiments is open to dispute, but Wedgwood and Davy probably produced images that they were unable to 'fix.' Following Arago's announcement of Daguerre's process in 1839, William Henry Fox Talbot came forward to contest priority of invention, having independently discovered 'light drawn pictures.' Talbot, a landed gentleman with interests in mathematics, ancient languages and other things, wrote in the introduction to *The Pencil of Nature*, that in:

> …1833, I was amusing myself on the lovely shores of the Lake Como, in Italy, taking sketches with Wollaston's Camera Lucida, or rather I should say, attempting to take them: but with the smallest possible amount of success.

Dismayed by the transitory nature of the 'natural images' he saw with the aid of the camera lucida and the camera obscura, he claims to have considered ways of rendering permanent the fleeting scenes. On returning to Lacock Abbey he began experimenting with pictures made with light sensitive chemicals. In this account, photography emerged from the gentlemanly aesthetic of the picturesque (a proviso is that the landed class was not somehow outside capitalist social relations). However, there is a contradiction here because his first public showing of his photogenic drawings at the 1839 British Association for the Advancement of Science meeting in Birmingham was dominated by copies of lace, prints and textiles. From the beginning, Talbot may have imagined photography as a reproductive technology.

Talbot called the images he made from 1833 'photogenic drawings.' In 1835, he realised that the process could be repeated, using this first image as a "negative" for generating a "positive" print. (The terms 'negative' and 'positive' where suggested by Sir John Herschel, who is also usually credited with the term 'photography'). At this stage, Talbot's negatives were insufficiently dense to produce strong positives. In 1840 he discovered a second process, which he called the calotype (from the Greek word *kalos* for beautiful and useful). Also sometimes called 'Talbotypes' in honour of their creator, calotypes gave a latent image after a few seconds exposure, creating a negative strong enough to print from.

Photography in the 1840s was slow and required good light. However, the main restrictions on its development were legal rather than technical. In exchange for a pension from the French state, Daguerre allowed free use of his process—except in the lucrative British market. He sold the right to licence his process in England, Wales and the colonies to the coal merchant Richard Beard, who opened the first commercial photographic portrait establishment in Britain. Beard is sometimes represented as a pioneer photographer, but he was a proprietor and employed Jabez Hogg as his 'operator.' Professional licenses were expensive and Beard sold very few. Antoine Claudet, a Frenchman based in London, obtained a separate licence from Daguerre and also opened a commercial studio. In 1841 Talbot sought and was granted a patent on the calotype process, which he further extended in 1843. The result was that licences were required for paper photography too.

Nevertheless, during the 1840s the first tentative employments of photography began. Talbot had an eye on the mass image market**.** In 1843 he founded an establishment in Reading, run by his manservant Nicholas Henneman, to print negatives and produce books as well as teach photography. In 1844 Talbot issued the first part of *The Pencil of Nature*; printed at Reading it was arguably the first photographically-illustrated book. Produced in six parts, between 1844 and 1846, the twenty-four calotypes are a mix of picturesque views, botanical specimens, facsimiles of documents, reproductions of art works, and records of possessions. *The Pencil of Nature* was probably a demonstration album anticipating uses for the new process. In 1847, he opened the Sun Picture Rooms in Regent Street, London to make portraits and topographic and picturesque views. Talbot also entered a venture to establish the French *Société Calotype* for the commercial production of paper photographs; later, in 1852, he patented photoglyphic engraving, a method for producing photographic engravings on steel plates (he had intended to establish a factory to manufacture these images, until ill health intervened).

In the early years three groups were concerned with photography. Firstly, there were a small number of licensed commercial portraitists including Claudet.. Henry Collen obtained a licence from Talbot in 1841 to make calotype portraits, but had little commercial success and folded in 1844; Claudet then took over (he also proved unsuccessful). At Talbot's instigation, Henneman briefly established a calotype studio in London, before running the Sun Picture Rooms. Despite its fragile character and the single image that resulted, the daguerreotype was favoured for commercial portraiture, partly because it proved practicable before Talbot's process, partly for its incredible detail. Portrait work rapidly assumed a routine appearance, drawing on stock poses and settings from conventional painting. There were some exceptions to this rule, notably the partnership of David Octavius Hill and Robert Adamson, active in Edinburgh between 1843 and 1848. Hill was commissioned to create a large painting commemorating the founding of the Free Church of Scotland in 1843 and employed Adamson to make photographic studies of the churchmen. The resulting photographs are less formal than most contemporary portraits and the grain of calotype adds to the chiaroscuro effects. Hill and Adamson also made picturesque portraits of masons working on the Walter Scott memorial, soldiers and Newhaven fishing workers. Hill intended to market albums of pictures, but this came to little.

The second group were the men of science who were interested in photography as a chemical phenomenon and as a means to document nature. Talbot's account of photography posited images generated "without the aid of the artist's pencil." This 'objective' vision supposedly allowed things or phenomena to be recorded without the subjective intervention of artists. In this way, photography was significant in bolstering the emerging ideologies of science. This conception was extended by Sir David Brewster and Robert Hunt, who developed

the idea of the photographic record or document. Hunt made "nature prints" at this time, as did the amateur botanist Anna Atkins.

Thirdly, there were wealthy amateurs engaged in photography for their own amusement, though some also attempted to market pictures. Talbot's own circle was prominent in the early exploration of photography: Christopher Rice Mansell Talbot (a cousin), John Dillwyn Llewelyn (who married another cousin), Nevil Story-Maskelyne (Llewelyn's son-in-law), and their friend Reverend Calvert Richard Jones, all made picturesque calotypes. Particularly interested in the maritime scenes provided by the Welsh ports, Jones and Llwelyn intended to contribute 'Marine Talbotypes' to *The Pencil of Nature*. Jones sympathised with Talbot's attempts to exploit his invention commercially, and between 1845 and 1846 made calotype's in Italy and Malta marketed through the Sun Rooms. Work for Talbot's venture subsequently passed to the Reverend George Bridges who produced about 1,700 negatives in seven years, working in Italy, Greece, Egypt and the 'Holy Land.' Talbot lost interest and Bridges produced a prototype album: *Illustrations of the Acropolis of Athens*; and in 1858 published *Palestine as It Is*. In 1845, Talbot issued *Sun Pictures of Scotland*, comprising of twenty-three calotypes from subjects drawn from the life and writings of Scott. Photography in the 1840s was by no means restricted to this circle. Horation Ross, one time MP for Aberdeen, worked with both the daguerreotype and calotype, producing family portraits and sporting pictures. In 1847 a small group of interested photographers (including, Hunt, Frederick Scott Archer and Dr Diamond) established the Calotype Club; renamed the Photographic Club in 1848. This group provided the nucleus for the next phase of photography in Britain.

Photography received a significant boost from Archer's wet-collodion process, introduced in 1851. Glass-plate negatives where already in use, but collodion plates, exposed and processed while wet, were faster and gave quite fine detail. This process effectively killed the daguerreotype. Archer's process was represented by only one picture at the Great Exhibition of 1851. Ten years on, at the International Exhibition of 1862, photographs *not* made with collodion were singled out.

In the early 1850s Talbot engaged in a series of legal defences of his patent. In 1852 he obtained an injunction to restrain Richard Colls from trading without a licence and in 1854 the court upheld Talbot's claim against John Henderson who was "restrained under penalty of five thousand pounds" from selling calotype portraits. The same year he was also involved in the celebrated lawsuit of Talbot v. Laroche. This case was so significant because it tested Talbot's claim that Archer's process was covered by his patents. The court reasserted Talbot's calotype patent, but rejected any claim over Archer's process. Effectively, this ended Talbot's legal restriction and he subsequently allowed his patents to lapse. It has been estimated that Talbot recovered less than half of the £5,000 he spent on photography, but at a time when opposition to patents was central to liberal political economy, his reputation suffered considerably. In contrast, Archer did not patent his process and was acclaimed for his decision.

In response to photographic display at the Great Exhibition some suggested that English photographers had slipped behind the French. This argument gave impetus to the development of photographic societies and specialist journals. The first society appeared in Leeds in 1852, whereas the Photographic Society came into being in London in 1853. Initiated by Fenton and Claudet, it held regular meetings, discussed papers; from 1854 an annual exhibition was mounted. The society's periodical—*Journal of the Photographic Society of London* (subsequently the *Photographic Journal*)—appeared in 1853. Also in 1853 Queen Victoria and Prince Albert became the patrons (the title of Royal Photographic Society being adopted in 1894).

Societies spread rapidly throughout mainland cities and further a field. The Liverpool Photographic Society was established in 1853; Dublin in 1854, Manchester in 1855 and the Photographic Society of Scotland founded in Edinburgh in 1856. In the mid-1850s there were three societies in India. Many of these societies published proceedings and occasional papers in the *Journal of the Photographic Society*; some of them also organised exhibitions. In 1874 the Photographic Society was renamed the Photographic Society of Great Britain in recognition of its umbrella role. Two other journals of note emerged during this period: *The British Journal of Photography* was launched in 1860, but had existed under various names since 1854; and *The Photographic News* was founded in 1858, running until 1908. From the 1860s these groupings and their publications provided the armature for professional photography, however, they initially represented mixed interests. The early years of the Society saw tensions between amateurs, who favoured a gentlemanly organisation unsullied by trade, and those engaged in commercial photography. Fenton was in the later camp. Grace Seiberling argues that this wrangle dragged on until 1858 (Sieberling, 73).

The exchange clubs in the Society—the "Photographic Society Club" (established 1856), and the "Exchange Club of the Photographic Society" (sometimes called the "Photographic Club")—were probably vehicles for amateur hegemony. According to Seiberling, no more than forty people were involved in these clubs and the related the Photographic Exchange Club (9–10). The work produced was shaped by antiquarian-amateur interests with picturesque landscapes featuring dilapi-

dated rural buildings or ancient ruins occupying pride of place. Benjamin Brecknell Turner produced picturesque calotypes of English scenes throughout the 1850s; Llewelyn continued making picturesque views of Wales; Diamond, Edward Kater, George Shadboldt and others worked in this mode. Not all picturesque photography was conducted by amateurs: Edward Fox—"Landscape and Architectural Photographer"—worked in Brighton and Sussex; James Mudd, a portrait and industrial photographer, had a sideline in picturesque scenes of the Lake District. In the late 1850s Francis Bedford made an extensive record of picturesque Britain; Fenton was also particularly active in producing picturesque and topographical photographs throughout the mainland. Even during this period the hegemony of amateurs was incomplete. Commercial portraitists were involved in the Society and Fenton's Crimean war pictures of 1855, or Frith's tours of Egypt and the Holy Land, from 1856, were commercial speculations. In 1853 prominent early 'amateurs' founded the Photographic Institution, trading in photographic equipment, selling photographs and charging for lessons; Fenton and others temporarily left the Society to found the (unsuccessful) commercial Photographic Institution in 1856. Robert Howlett, one of the Institution's partners, documented the making of the Great Eastern steam ship in 1857. Unusual in capturing the industrial transformation of Britain, nine engravings from this series of pictures were published in *The Illustrated Times* in 1858. Philip Delamotte was one who made the successful transition from amateur to professional photographer, producing among other things, pictures of the rebuilding of the Crystal Place in Sydenham. By the later 1850s the trade in views—British and foreign—had become a viable business. In 1859 Frith opened an establishment to produce albumen prints, which expanded to become an extensive photographic emporium (in 1862 he purchased Fenton's archive). George Washington Wilson also ran a significant studio trading in Scottish scenes, producing an estimated 400 prints a day. While he continued to issue picturesque Scottish subjects, his business developed into a merchant house distributing views.

However, during this period the predominant accounts of photographic pictures did not come from professional photographers. Sir William J. Newton, Elizabeth Eastlake and William Lake Price who all tried to account for the new image were artists or, in Eastlake's case, closely associated with Fine Art; they rejected the idea of "art-photography." In the first issue of the *Journal of the Photographic Society* Newton argued that photographs were more 'artistic' when taken a little out of focus, he had in mind studies for artists, not independent photographic pictures. Subsequently, a debate raged on this subject with the men of science advocating optical sharpness while artists supported Newton: neither side imagined they were addressing artworks. In her much cited 1857 review of photography and political economy, Eastlake championed, what she called Newton's "heresy." She insisted that photography was not a fine art, but a "new medium" that could serve artists. Price's essays "On Composition and Chiaroscuro," which appeared in 1860, were among the most significant assessments of photography during this period. His account drew on the ideas of Academic artists like Reynolds, while refusing to sanction the photograph as independent artwork. The Academic tradition stressed idealisation and the importance of following artistic rules, rather than imitating nature's particularities. While he was certainly not alone, Price played an important role in introducing the antimonies of the Academic tradition into photographic discourse: hands and minds, mechanical and liberal, workers/slaves/servants and gentlemen, details and broad effects and low and high genres. Copies and copyists were 'base,' 'servile,' and 'mechanical.' He believed photographers must impose their intellect on the subject, rather than imitate it. This account cast a long shadow over the medium.

Photography really developed as a significant profession when the *carte-de-visite* arrived from France. Cartes probably appeared during the mid-1850s, but the carte craze dates from 1859. There were a mere 66 photographic firms in London in 1855; by 1864 this number had shot up to 284. Proportional increases are seen in most major cities. Estimates vary, but one suggests that between 1861 and 1867 some 300 to 400 million cartes were sold in Britain (Darrah, 4). Carte portraits usually sold at half a crown a dozen, and while the format resulted in virtually interchangeable images they extended portraits to the middle class. The carte trade operated in very different 'economies.' Camille Silvy, Oliver Sarony, J.J.E. Mayall and Williams catered to the luxury trade. Operating from lavish studies, they employed a range of assistants: receptionists, printers, colourists, even an operator who took the photograph. It was a mark of Silvy's distinction that he arranged poses and operated the camera. Nevertheless, his establishment was a portrait factory employing 50 people; Andrew Wynter suggested that by 1862 Silvy had produced 700,000 carte portraits (Wynter, 173). However, the main body of photographers were petit-bourgeois traders who owned some capital, but worked in the business, sometimes alongside family members and perhaps an assistant. Then there were the "cheap workers" who scandalised the champions of photography. The photographic press was full of stories of "photographic dens" employing "touts" in Bermondsey, Cheapside, the New-Cut, and Whitechapel. The pictures made in these studios could be rudimentary.

In addition, celebrity cartes featuring Royalty, clergymen, politicians and actresses became a lucrative

business. George Bishop, manager of the carte wholesale-company Marion & Co., claimed by 1862 they were monthly printing 50,000 cartes ('Mason v. Heath,'116). These merchant houses, and large companies like the London Stereoscopic Company, were not universally applauded. Stephen Thompson complained of "tradesmen or capitalists" who "hold much the same position in the trade with regard to their *employees* as what are termed 'sweating houses' do in the slop-trade. Everyone is under-paid and over-worked on the one hand, and the public over-charged on the other, and thus profits are made at both ends." (Thompson, 'The Commercial Aspects of Photography,'407). The large concerns increasingly drew smaller studios under their control. The corollary of success with celebrity portraits was the growth of 'photographic piracy'—the illegal copying of pictures. One report recorded wholesalers possessing between 500 and 700 illegal images: it claimed one dealer held a stock of 100,000 (Anon., 'Photographic Piracy,'566–7). Although this issue was not clearly resolved, the Copyright Act was extended to photography in 1862, largely to protect producers of celebrity cartes.

The rise of professional photography was important for the aesthetics of the medium that developed in the 1860s. The central event in this transformation was the International Exhibition of 1862. In 1861 commissioners for the exhibition announced their plan, categorising photography with machinery. In a long running dispute, the Photographic Society mounted a campaign to see their worked reclassified as Fine Art. Eventually, a compromise was struck and photography appeared in a "separate apartment" within the Machinery Court. This was a pivotal moment because for the first time a significant number of photographers began to view their work as a Fine Art.

The development of professional photography provides the context for the aesthetics of photography. This was an aesthetic of distinction designed to assert the respectability of photographers. During this period important figures like Alfred H. Wall and Henry Peach Robinson built on Price's ideas, but claimed that photography now constituted a Fine Art. These men retained central categories from Academic theory, but in line with wider trends in English art, they suggested that photography was best suited to pictures in the lower genres: portraiture, picturesque landscapes and moralised genre scenes in the tradition of Wilkie and Hogarth; they also emphasised the importance of nature. The pictures that resulted took three forms, all typified by a distance from the copy or document. Firstly, there were genre scenes, sometimes made with allegorical intent, sometimes depictions of "everyday life." Price, Robinson, Rejlander and Cameron all worked in this vein; which could take the form of posed tableaux or 'combination prints' (pictures assembled from multiple negatives): examples of the latter include Rejlander's *The Two Ways of Life* (1857) and Robinson's *Bringing Home the May* (1862). The extensive labour involved and the reliance on accepted subjects and compositional arrangements emphasised the role of the photographer. Combination prints met with a mixed reception and the tableau gradually assumed precedence. Secondly, the picturesque landscape tradition provided a great deal of scope for photographers, because it combined attention to nature with formal rules. The trick was to demonstrate taste in finding suitable arrangements. Robinson's *Pictorial Photography* is an important statement of this trend and he, along with Mudd and many others, worked in this tradition. Thirdly, there were tasteful portraits, often made by the elite studios, which placed a premium on poses, arrangements and backgrounds derived from painting. To some extent, Cameron broke with the established consensus by employing a "soft" focus equally across the picture.

While British colonial photography was not restricted to India, the 'jewel in the crown' occupied a central place in the Imperial imagination. Many photographers working in the sub-continent from the 1850s were army officers or employees of the British East India Company, or both. From 1853, John Murray, a Scottish army doctor and employee of the Company, focused on exotic and picturesque subjects; his pictures were distributed by the Dehli School of Industrial Art and *Picturesque Views in the Northwestern Provinces of India* appeared in 1858. Linnaeus Tripe, an army captain, published 300 views of Burma and under commission for the Company recorded objects of interest to antiquarians and architects as well as documenting the 'races' in the southern provinces of India. In 1862 Samuel Bourne visited the 'Holy Land' and was allowed to photograph previously restricted sites. In 1863 he travelled to India to work as a professional photographer producing 800–900 negatives; in the mid-1860s he made three tours of the Himalayas, resulting in images, which Haworth-Booth characterised as 'imperial picturesque' (104). The Bombay government employed a number of army officers to photographic ancient sculptures and inscriptions. Among the most ambitious colonial photographic projects was *The People of India*, edited by Dr. John Forbes Watson and Sir John William Kaye, which appeared between 1868 and 1875. This government-authorised pseudo-scientific study of "the Races and Tribes of Hindustan" contained 468 albumen prints by fifteen photographers. From about 1870 a booming trade developed in Indian views, to which some indigenous Indian photographers such as Lala Deen Dayal contributed. After a British military invasion in 1840, China surrendered Hong Kong and subsequently opened coastal cities to colonial adventurers: photographers followed in their wake. Felice Beato worked for the army

producing images of military positions, temples and palaces. He also worked in Japan and issued the albums *Photographic Views of Japan* and *Native Types of Japan* in 1868; John Thompson photographed in Malaysia and Indochina, Cambodia, Hong Kong and China from the mid-1860s. His *The Antiquities of Cambodia* appeared in 1867 and *Illustrations of China and its People* was published in 1877/78.

The carte trade was hit by a crisis of profitability in 1863/64 and never regained its previous giddy heights. While the portrait business was precarious, some studios thrived and expanded. During the 1870s W. & D. Downey and A. & G. Taylor developed businesses with multiple branches selling through a club system on credit, causing further anxiety to the smaller 'respectable' proprietors. Cameron, Robinson and others continued to make exhibition pictures, but on the whole the 1870s saw a lull in art activity. The development of the gelatine bromide dry plate by Dr Richard Leach Madox in 1871 facilitated outdoor work and photography in difficult spaces. Dry plates could be prepared in advance and developed much later; they were also more sensitive than collodion negatives. By the end of the decade their use was widespread. In 1873 Walter B. Woodbury introduced a form of photographic engraving—the Woodburytype—which contributed to the wider dissemination of images.

The key change during this decade was the increased role photography played in state and private institutions of social investigation and regulation. In the early 1870s experiments were conducted with penal photography; photography also came to play an important role in anthropology and colonial administration. During the later 1860s and 1870s photographers also turned their cameras on the poor and the working class. Along with other social investigators—journalists, urban missionaries and social reformers—they voyaged into 'unexplored' urban slums, often drawing on colonial imagery. Thomas Annan was hired by Glasgow City Improvement Trust to document slum conditions in some of the city's courtyards and alleyways, prior to their demolition. He produced thirty-one albums for the City Council. In 1878-9 a small edition of these prints appeared as *Photographs of Old Closes, Streets, Etc*. Perhaps the best known of all these projects was John Thompson's *Street Life in London*, which appeared in twelve parts between 1877 and 1878 and was subsequently issued as a book. Thompson's work was distinctive because each of the thirty-seven Woodburytypes focused on one individual engaged in some aspect of the metropolitan street economy. Each plate was accompanied by a commentary written by Adolphe Smith. This individuation amplified the evidential mode of investigators like Henry Mayhew and provided a central feature of subsequent documentary. "Street life" was often depicted through the filter of the urban picturesque, rendering dilapidation and ruinous dwelling conditions fascinating yet safe for middle-class viewers. The Society for Photographing Relics of Old London was founded 1875 to combat the proposed demolition of a sixteenth-century coaching inn. Henry Dixon and Alfred and John Bool were commissioned to record this building and many others. In 1868 Archibald Burns published fifteen albumen prints in his *Picturesque Bits of Old Edinburgh*.

We have a good picture of the top end of the trade during the first half of the 1880s due to H. Baden Pritchard's surveys. In this period photography became a large, concentrated industry. The Autotype printing works employed 80 people and daily processed 1,000s of feet of carbon tissue; A & G Taylor employed between 500 and 600 workers (their Forest Hill establishment printed for scores of regional branches). In the early 1880s, in addition to their Liverpool base, Brown, Barnes & Bell conducted two London studios and twelve regional ones. The provincial branches sent their work to Liverpool for printing: Pritchard reports that every day 2,000 impressions ran through the toning bath. The Woodbury Permanent Printing Company produced extensive runs of pictures for parliamentary candidates and Royal weddings. Allegedly, anything with a print run of less than 100,000 was not worthwhile. James Valentine and Son of Dundee, the largest Scottish studio, employed forty workers and made 3,000 prints a day. Alexander Bassano, Valentine Blanchard, William England, Hughes, Mayall, Robinson and Sarony all conducted grand studios in London and fashionable towns. Of course, there were still plenty of studios trading in cheap work.

By this point photography was embedded in a wide range of social institutions. It was, for instance, an important plank in the penal system. Prisons increasingly included studios on the premises; the practice was regulated by formal rules and an archive was established at Pentonville Prison, centralising photographs of all British prisoners. Francis Galton also developed his pseudo-scientific composite portraits which claimed to reveal the underlying characteristics of the 'criminal type.' According to Pritchard, by the mid-1880s photography was employed by astronomers, meteorologists, surgeons, physicians, geologists, chemists, physicists and botanists. (Pritchard, *Photography and Photographers*, 83) By the middle of the 1880s, the half-tone printing process was capable of reproducing photographs and combining them with type, although it was not until the 20th century that publications routinely featured photographs.

The last twenty years of the century saw a range of technical innovations that lead to capturing motion and more casual compositions: these included faster lenses and shutters and materials tolerant to flash powder. However, the most fundamental change occurred when

George Eastman introduced the Kodak camera in 1888. Rather than a technical innovation, Eastman's revolution turned on a marketing and business reorganisation typical of monopoly capitalism. The Kodak was a small box camera without a viewfinder, which came pre-loaded with celluloid roll film. When the roll was finished the camera was sent to Eastman's company, who processed the film and returned the prints complete with a newly loaded Kodak. As *The Kodak Primer* made clear the effect was to: "furnish anybody, man, woman or child, who has sufficient intelligence to point a box straight and press a button" the means of making photographs without "exceptional facilities or, in fact, any special knowledge of the art" (Coe, *George Eastman and the Early Photographers*, 67). Professional studios lingered on, but Eastman's system decisively shifted photography onto the terrain of the new mass amateur. This new amateur photography took off because it dovetailed with wider social changes, including, for some, increased leisure time and an improved standard of living. In the early years of photography amateurs had been wealthy gentleman, but the new amateur was a lower middle-class hobbyist with a little free time and some spare cash. Small folding cameras also became increasingly popular during 1890s. The result was a wider range of subjects and an increasing casualness in framing and composition. The people who made these images were primarily interested in recording rights of passage and fun moments and were largely unconcerned with the 'rules of art.' Paul Martin's pictures of high days and holidays, made after 1892 with a hand-held camera, are probably the best know.

The rise of the mass amateur and the preoccupation of the Photographic Society with representing a range of interests lead to a number of photographers committed to art increasingly taking a separate path. In 1885 P.H. Emerson, with Captain Abney, George Davison and others, founded the Camera Club of London as a forum for 'serious' amateur photography (in the earlier sense of 'amateur'). After meeting the painter Thomas Frank Goodall, Emerson became committed to 'Naturalism,' a supposedly truthful depiction of nature that emphasised rural labour. He also employed a selective focus, which he believed was closer to actual perception. Emerson's photographs typically consist of formally composed genre subjects from rural Norfolk; important examples appeared as platinum prints in *Life and Landscape of the Norfolk Broads* (1885). His influential manifesto *Naturalistic Photography for Students of the Art*, was published in 1889. Frank Meadow Sutcliffe worked in a less self-consciously artistic mode photographing Whitby, but related concerns are visible in his pictures.

In the middle of the 1880s W. Jerome Harrison established a number of photographic surveys of rural Warwickshire with the aim of recording old buildings as well as declining folk traditions. The photographic survey movement rapidly spread and Harrison, in collaboration with the industrialist Benjamin Stone, attempted to establish a national organization. However, Harrison's strident challenge to the photographic establishment proved his undoing, and Stone—who had become Tory M.P. for Birmingham—set up the National Photographic Record Association in 1897, which generated thousands of images of rural Britain. The international movement known as Pictorialism, which developed in the final decade of the century was, in the main, equally anti-urban in orientation, though it followed a different aesthetic path to either Emerson or the surveyists. In the wake of the Vienna Camera Club exhibition of 1891, a number of photo-associations split from the established societies. The Linked Ring Brotherhood broke from the Photographic Society in 1892, conducting a single-minded campaign for Pictorialist or artistic photography. This organisation restricted numbers, members, who had to be elected, never exceeding seventy five. Key figures include: Robinson, James Craig Annan, George Davison, Frederick H. Evans and two Americans domiciled in England—F. Holland Day and Alvin Langdon Coburn.

Pictorialism developed existing aesthetic concerns, but these photographers chose to pursue art-photography with vitality. Adopting conventional subjects and compositional modes from the existing pictorial arts, Pictorialists often gravitated to specialist photographing printing techniques that gave their images the appearance of drawings in ink or chalk and etchings. They tended to do extensive work on negative and print, giving the final image a unique and handcrafted appearance; they adopted a soft-focus approach and worked to suppress detail. Some were wealthy amateurs; others were professionals with a sideline in exhibition pictures; yet others still occupied a specialist niche in the amateur leisure market for photographic commodities, but their work entailed a common strategy of distinction, separating its proponents from 'mere' hobbyists. *Amateur Photographer,* a journal promoting a softer version of this Symbolist aesthetic, appeared between 1884 and 1918. The ethos of Pictorialism dominated photography until the rise of photo-journalism and modernism after WWI, but it survived much longer as a camera-club aesthetic; arguably, it still does.

GREAT EXHIBITION OF THE WORKS OF INDUSTRY OF ALL NATIONS, CRYSTAL PALACE, HYDE PARK (1851)

The Great Exhibition of the works of Industry of All Nations (the Great Exhibition) continued the series of the exhibitions of the products of the industry introduced in France to the end of the eighteenth century; those presented in Paris in 1844 and 1849 were the first great official demonstrations where one could see specimens of the new medium (daguerreotypes and photographs on paper). The first World Fair, organized by Prince Albert, opened in London from May 1 to October 11, 1851; it accommodated 17,000 exhibitors and 94 nations. This demonstration began a period of prosperity and economic stability after the political and social turbulences of the 1840s. If the previous decade had seen the birth and the rise of photography, the 1850s saw the processes diversify then and industrialize themselves. The new medium was used as much to emphasize the richness of two powers in full colonial expansion, the Victorian reign in England and the Second Empire in

France, as to restore the effigies of the newly triumphing middle-class.

The exhibition was presented in the 'Crystal Palace' built by Joseph Paxton, a palace of glass and cast iron, which was noted in the history of architecture for its vast metal structure which made it comparable to a greenhouse. Large workshops were built in the following years in the centers of London or Paris, the light entered in abundance; it made it possible to capture interior scenes, as a very beautiful daguerreotype of the Baron Gros (Paris, BNF) attests, which showed a part of the exhibition and made it possible to have an idea of the interior space and the arrangement of the objects and decoration. The effect of transparency and space was not the only contribution to the idea of the erasure of hierarchy among the exhibited products.

The Great Exhibition excluded painting; sculpture, engraving, and architecture were allowed there because of the roles they had in industrial creation. Photography did not constitute a section in itself: it was included in class X (instruments, clock making, surgical, musical, philosophical), and in the department of the "machines and instruments," in a relatively narrow space. One could also see photographs from various sections of the country. Three photographers had the honor of the court of the fine arts: Thomas Craddock, David Octavius Hill, and Samuel Buckle. It was the first great exhibition of photography on the international scale, opened in a fertile period in inventions (collodion by Scott Archer, stereoscopy by Brewster, on the English side) and in photographic foundations of all kinds (société heliographique, Blanquart-Evrard printing works, Missions heliographique, newspaper *La Lumière*, on the French side); *La Lumière* published two reports on the Great exhibition, one of which was signed Jules Ziegler, painter, photographer, and critic of art.

Approximately 770 photographic images were presented by six countries. Those shown might have seemed weak compared to what was then being produced in the rest of the photographic world, but only major studios, manufacturers, or photographers could take part because of the very high cost of transportation and insurance and of the risks of losses or accident during the voyage; moreover, the foreign participants needed an agent on the spot. In fact, three nations provided most of the exhibited works: England, the United States, and France. The three others were Germany, represented by William Albert and Frederic Strauch, both of Frankfort am Main (the first exposed reproductions of objets d'art); Austria was represented by Paul Pretsch, with views of Vienna, of Schoenbrunn, and reproductions of sculptures; Italy was represented by F and G Vogel, of Milan, with portraits based on paper negative.

All the techniques practiced since 1839 were shown; the two dominant processes were the daguerreotype and the paper negative, for which it was necessary to add negative glass to albumen. Wet collodion negative, developed at that point by Scott Archer in 1849, was introduced in 1851, the year of the exhibition; for this reason, it was hardly present (whereas in 1855, in Paris, collodion dominated the whole of the exhibited works). The daguerreotype was still well represented, especially by the Americans, who were honored by the panel: portraits by Brady, portraits by Meade, a Sight of the moon by Whipple, a Panorama of Cincinnati by Fontayne and Porter. Jules Ziegler criticized the presentation of the American daguerreotypes, which were placed under a platform that darkened the room considerably and accentuated the mirror effect of the plates, which made viewing difficult. The English Martin Laroche and John Mayall showed, on daguerreotypes, reproductions of sculptures. The French daguerreotypists included Amédée Thierry, of Lyon (self-portrait, scene of Lyon), Vaillat, Sabatier, Victor Plumier. Others who exhibited little afterwards are less known today: the manufacturer Christofle (a daguerreotype), A. Gouin (ten portraits with the daguerreotype including eight colored), Maucomble, present in Paris in 1844 (five portraits with the daguerreotype). The Schiertz manufacturer sent apparatuses. The technique of the stereoscopy, published a few months earlier by David Brewster, its inventor, constituted one of the innovations of the exhibition; Queen Victoria was fascinated by the stereoscope and Brewster sent one to her only a few days later, built in Paris by Duboscq. The photographers Claudet and Mayall showed stereoscopic daguerreotypes. French photography included work by several leading pioneers in early paper photography: Hippolyte Bayard (three frames containing 17 prints if the monuments of Paris and Rouen, of the reproductions of low-reliefs and statuettes, as well as "Gothic portraits" mentioned by Ziegler), Flacheron-Hayard, of the circle of photographers established in Rome (seven great sights of Rome), the Blanquart-Evrard printer (tallies of nine prints), Cousin (landscapes and portrait of woman), Gustave Le Gray (eighteen prints without precise details), Henri Le Secq (twelve shots of the cathedrals of Amiens, Chartres, Rheims). Frederic Martens exhibited a panoramic sight of a tower of Notre-Dame captured with the mégascope, a panoramic apparatus of his invention, and other prints obtained with the apparatus of Lerebours and Secrétan. Among the English, Antoine Claudet, a Frenchman located in London, who had appeared in the Parisian exhibition of 1844 with daguerreotypes and works on paper, showed portraits of the daguerreotype and various processes of his invention. The Scots David Octavius Hill and Robert Adamson were present with several frames containing of the scenes obtained on paper negative (Fishermen of the village of Newhaven, close to Edinburgh) as well as portraits. Hugh Owen of Bristol should be mentioned,

who photographed trees, Voigtlander with portraits, Ross and Thompson.

Photography also played an important part as a means of documenting the exhibition. In addition to individual initiatives like that of the baron Gros already mentioned, a report was made of the whole demonstration, and the photographs were used to illustrate the Reports of the Juries (each set of four volumes illustrated with 155 salt prints from calotype negatives). On the whole, 20,000 prints were made and mounted; it was the most important illustrated publication of photographs ever created, but not without difficulties. The photographers Nicolaas Hennemann, assistant of Talbot; Frederic Martens; and Claude-Marie Ferrier were in charge of the negatives, Hennemann specifically for salted prints and the two others for glass with albumen; Hennemann also made photographic prints based on paper negative of Owen (objets d'art applied). Jules Ziegler evoked the campaign sights made by Ferrier in London (seen external and interior of the exposure) in company of a Mulhousian patron of photography (undoubtedly Dollfuss-Hausset, Mulhousian industrialist and collector of photographs). Certain sights of the exposure per Antoine Claudet and John Mayall were sold to the visitors as souvenirs. Guides of the exhibition were also illustrated with engravings created based on photographs. Robert Hunt, man of science, member of the Royal Society, author of the first paper on photography in England (1841), and a member of the grouping usually referred to as the Calotype Club, published a summary review of the exhibited products of industry; he noticed the many collections of daguerreotypes there; calotypes of a remarkable beauty, in particular the pictures of forests; works on negative glass, and in particular portraits. The panel, anxious to encourage the development of the "applied arts to industry," in accordance with the general orientation of the exhibition, deplored the small number of scientific applications (archaeological copies of inscriptions, plants, animals, etc.) compared to the traditional kinds of the portrait and landscape.

In the context of economic and industrial emulation between the two principal nations of Europe, which had been also translated into the field of photography (simultaneous research on paper negative by Talbot and Bayard, then on negative glass), this demonstration offered an assessment of the work carried out since 1839. For the scientific community of the photographers, England had to acknowledge itself overcome in its own territory: technical subtleties and the obstacles imposed by Talbot on the distribution of his process (an obligation for any person using it to pay a royalty) limited the spread of the English calotype; whereas on the French side, the system of patents and the support of the government allowed the practice of photography to be much freer. Because of the small number of calotypes presented, English inferiority on the artistic level was all the more glaring. To rectify this situation, in October 1851, Roger Fenton went to Paris where he met Henri Le Secq, Gustave Le Gray, Charles Nègre, his former fellow-members of the studio, and Paul Delaroche at l'Ecole des beaux-arts; on his return, he wrote a report on his stay, in which he underlined the unifying role of the société heliographique and the newspaper *La Lumière*, the importance attached to printing works of quality, as well as the involvement of the French government. From this point of view, the exhibition of 1851 stirred the community of English photographers, who constituted themselves thereafter in companies. After a first exhibition entirely devoted to photography, accommodated by Society of Arts, during the winter 1852–1853, the Photographic Society of London, founded in January 1853, become the Royal Photographic Society, and organized an exhibition every year.

The exhibition of the Crystal Palace was a great public and economic success (six million visitors). Prince Albert decided to donate the profits created to the creation of an academy of arts and trades, an establishment intended to record the level of quality of industry connected with new aesthetic orientations. A plot was acquired in the district of South-Kensington, the museum of South-Kensington was established, and opened in 1856. At the end of the century it became the Victoria and Albert Museum; this museum, reserved for the applied arts, preserved photographs from the beginning and developed a photographic department of reproduction with the service of arts. Other measures were taken in the following years by the British government: creation of exhibitions, educational establishments of design, in order to familiarize the industrial class with the objets d'art. After the closing of the exhibition, the building was repurchased by the Crystal Palace Company, and was dismantled and reassembled in Sydenham, in the south of London, between August 1852 and 1854. The photographer Philip Henry Delamotte chronicled the construction through photography (a hundred pictures) on the rebuilding of the building (London, British Library); in 1855, he published it under the title *Photographic Views of the progress of the Crystal Palace, Sydenham*, and showed some of them at the Exposition Universelle, in Paris. Reopened in 1854, the Crystal Palace was destroyed in 1936 in a fire.

GREAT EXHIBITION, NEW YORK (1853–1854)

The Exhibition of the Industry of All Nations took place in New York City from 14 July 1853 to 1 November 1854. It was the first international exhibition (or, loosely speaking, "world's fair") to take place in the United States. The exhibition has ever since been popularly known as the Crystal Palace Exhibition. The New York exhibition was directly modeled on the London Great Exhibition that took place in the Crystal Palace, Sir Joseph Paxton's monumental greenhouse-like edifice of glass and cast iron, in Hyde Park in 1851. In New York, the architects Georg Carstensen and Charles Gildemeister designed a variant on the Paxton building. (Exhibitions at this time typically took place within a single building. Later in the century Paris would pioneer the use of a campus of several buildings to house an exhibition.) The New York Crystal Palace comprised 1,800 tons of iron and 15,000 panes of glass, and its 123-foot-high dome was the highest that had been built in the United States. The exhibition building was located in what is now known as "midtown" Manhattan, but which in the 1850s was the northernmost settled area on Manhattan island. The precise location was Reservoir Square (now known as Bryant Park), to the immediate west of the Croton Distributing Reservoir in the block bounded by Fifth Avenue, 42nd Street, Sixth Avenue, and 40th Street. There were 4,390 exhibitors at the Crystal Palace, exhibiting industrial products, consumer goods, artworks, machines, carriages, scientific instruments, recent inventions, agricultural equipment, guns, fire engines, clocks, telegraph machines, ships and boats, minerals and metals, dry goods, and, not least, photographs and photographic equipment. With the opening in 1825 of the Erie Canal, New York had solidified its standing as the most important port city of the United States, as well as the country's most important financial, mercantile, commercial, and industrial center. Europeans had begun to say that New York was, or was destined to be, the "London of the New World." Seeking to show the city off to the world, New York businessmen, chiefly allied with the Chamber of Commerce of the State of New York, and other civic leaders organized the exhibition with the backing of the municipality.

The exhibition brought many visitors to New York City, and most New Yorkers attended the exhibition at least once. Both Mark Twain and Walt Whitman visited it, and both were suitably impressed; Whitman visited on many occasions. The tourist boom occasioned by the exhibition led to the construction of numerous hotels, several of them on an unprecedentedly grand scale. The national importance of the exhibition was underscored by the fact that President Franklin Pierce delivered a speech at the Crystal Palace on its opening day.

The exhibition coincided with the immense and sudden popularity of photography, especially daguerreotypy, in New York. The *New York Daily Times* of 29 March 1853 wrote of one exhibit that it was "arranged...in such a manner as to be a daguerreotype of the resources of every State in the Union." The metaphorical use of "daguerreotype" is a clear indication that photography had very rapidly worked its way into the collective consciousness of New Yorkers. Also, by 1853 popular New York magazine illustrations often were lithographs from daguerreotypes. The distinguished Putnam's magazine in that year presented a series called "New York Daguerreotyped," showing among other things images, destined to become iconic, of the Crystal Palace, a building that may have been among the first in America to be designed to be photogenic, and certainly one of the most extensively photographed new buildings in America to be constructed during the first two decades following the New York painter and inventor Samuel F.B. Morse's introduction of daguerreotypy to the United States.

The common usage of the new word "daguerreotype" underscores how in the fourteen years separating the exhbition from the introduction of daguerreotypy to America the medium had become so widely and wildly popular in the United States that historians have been hard pressed to explain the phenomenon. Morse introduced the daguerreotype to New York approximately one month after Louis Daguerre had first demonstrated his invention in Paris. From that point on, the United States took the lead in daguerreotype production and in the refinement of daguerreotype technique. This was amply evidenced in the New York Crystal Palace exhibition. Indeed, two years before the New York exhibition, Americans had won the majority of awards for daguerreotypy presented at the London Crystal Palace exhibition.

In discussing the Great Exhibition, *Scientific American* (20 August 1853) noted, "It is generally understood that the best daguerreotypes are produced in the United States: The fame of our operators is world-wide." About forty deguerreotypists exhibited at the New York Crystal Palace, and it appears they were all Americans. "Probably the best daguerreotypes in the world may be found here....There are good pictures by all the exhibitors, but the palm will be borne away by our New York artists."

In the number of the *Photographic Art-Journal* (June 1853) coinciding with the exhibition's opening, it was noted of New York that "The daguerrean galleries of this city are among the primary objects of interest to visitors,

and the collections here presented are incomparably superior to any to be found in a European metropolis, without exception." Whether this was true or not, it was generally understood by New Yorkers to be so, and the exhibition provided an outstanding venue for the city's and the country's self-celebration as a world center of photography.

Among the daguerreotypists exhibiting at the Crystal Palace were such well-known practitioners as Mathew B. Brady, Jeremiah Gurney, Alexander Hesler, Marcus Aurelius Root, and Gabriel Harrison, with lesser-known figures such as William C. North, Enoch Long, Anthony K. Zuky, John Adams Whipple (inventor of the "crayon daguerreotype"), and Samuel L. M. Meacham.

The Crystal Palace building was used for a variety of purposes following the closing of the exhibition. The building burned down in a spectacular blaze, itself the subject of many well-known photographs, on 5 October 1858.

GREECE

Interest in traveling to Greece has a long history and, to judge from the ever-increasing number of visitors, the desire to see the country remained unaffected by the constant political social changes within Greece. Due to its geographical location the country served both as a place of transit for voyagers to the Holy Land and as a destination in itself. The country was photographed for the first time in October 1839, only two months after the official announcement of Daguerre's method at the French Académie des Sciences in Paris. The first daguerreotypes were taken by the Canadian Pierre Gustave Joly de Lotbinière (1798–1865) who was travelling across the Mediterranean on behalf of Noel Marie Paymal Lerebours. According to Lotbinière's diary he made a total of eleven daguerreotypes in Athens, but only three of these images—the Parthenon, the Propylea and the Temple of the Olympian Zeus—were included, as aquatints, in Lerebours's album entitled *Les Excursions Daguerriennes: Vues et Monuments les plus remarkables du globe.*

The oldest existing daguerreotypes of Greece belong to the French artist and historian of Islamic architecture Joseph-Philibert Girault de Prangey (1804–1892). Prangey visited the Greek capital during his travels in the Mediterranean and the Near East in 1842. He spent approximately five to six weeks photographing not only the classical monuments but also examples of early Byzantine architecture.

Photography was introduced to the Greek population by travellers visiting the country. Its was in 1846 when the French photographer Philibert Perraud taught the secrets of the new medium to the Greek painter Philippos Margaritis. The eleven daguerreotypes that survive testify that the two men worked together for a short period of time. In 1853, Margaritis opened the first professional photographic studio in Athens where members of the Royal Family and celebrities were photographed, earning him the title of the 'first Greek professional photographer.'

The non existence of talbotypes in Greece verifies the assumption that Greek photographers did not practice the calotype process. The pioneer calotypist to visit Greece was Reverend George Wilson Bridges who was travelling in the Mediterranean between the years 1846 and 1852. During his travels, Bridges made a total of 1700 negatives, sixty-six of which pictured Grecian antiquities. On his return to England in 1852, he had made plans for the publication of an illustrated folio entitled *The Illustrations of the Acropolis of Athens* and a supplement to it, containing 36 and 30 calotypes respectively. It appears that the album was never published.

The early 1850s was a period of further transition in terms of photographic technology. The calotype was replaced by the wet collodion process making photography more resistant to elements such as hot climates. Additionally, travellers became increasingly intrigued by the 'new discovery,' and the profession of photographer began to appear more attractive in commercial terms. Thus began a dynasty of photographers whose photographic views of the Grecian antiquities would

invade Europe in the form of souvenirs brought home by tourists. Prominent among them are James Robertson (1813–1888), Francis Frith (1822–1898) and Francis Bedford (1816–1894).

The serious economic and social problems that Greece faced during the 1850s did not restrict the practice of photography to the richer classes. However the number of professional Greek photographers remained relatively small. At the same time a new type of photographic production aroused. 19th Century photographic portraiture in Greece has often been characterised for its lack of artistic or aesthetic value. Individuality of any kind seems to be abolished by the expressionless faces of the sitters and the characteristic uniformity of their costumes. Among the few practitioners, the work of Dimitrios Constantinou, Athanasios Kalfas and Petros Moraites is distinguished.

Petros Moraites was born on the island of Tinos in the Aegean Sea. He studied painting in Athens but very soon, fascinated by the new medium, he became involved in photography. In 1859, in collaboration with the Greek photographer Athanasios Kalfas, he opened a studio in Athens. The very same year, the two partners presented photographs at the 1st Olympiad (held in Athens) winning a silver medal for their photographic reproductions of landscapes. Many important personalities of the Greek society: politicians, intellectuals, ambassadors, actors including members of the royal family, as well as ordinary people, posed before his camera. It is assumed that around 1868, he was appointed 'photographer to H.M. the King,' a title bestowed for the first time on a Greek photographer.

By 1875 photography in Greece was not restricted within the boundaries of the country's capital. Photographic studios were also found on islands such as Syros and Crete and in other cities such as Corinth and Patra. The Rhomaides Brothers (Konstantinos and Aristotelis) originally from Bucharest, opened a studio in Ioannina and subsequently settled in Patras. In 1875 they undertook the photographing of the excavations at Olympia carried out by the German Archaeological Institute. This collaboration led to their specialising in archaeological photography, which is why they were employed almost exclusively by most of the archaeological schools operating in Greece at that time. They established themselves in Athens in 1876 while retaining, at the same time, their studio in Patras. The Rhomaides Brothers also won fame as portrait photographers, recording for posterity many of the prominent people of their time. Well-known photographers, such as Ioannis Xanthakis and Antonis Milionis, received their training in their studio.

By 1891, there existed 27 photographic studios in Greece. Among them, the photographic work of Anastasios Gaziadis is of great interest since he was one of the very few Greek photographers of this period to photograph factories, buildings and products for industrial and advertising purposes.

Towards the end of the nineteenth century, and as photography became mass-produced, the iconographic interest began to change. 'Traditional' depictions of the antiquities were now dull and new ideas were explored. An interest in Greece's social environment and political life began to emerge; indeed, despite all the difficulties still involved in the photographing of moving subjects, photographers were now to be found at events of every kind. In addition, the Greek countryside and scenes of everyday life are also documented, thus demonstrating how photography can overcome its static and silent nature and befriend reality.

GREENE, JOHN BEASLY (1832–1856)

J.B. Greene (as he signed his work) was the first photographer active in the Middle East who was also a trained Egyptologist, and despite the handicaps of his youth and nationality, he achieved some recognition both fields during his lifetime. However, his early death resulted in almost immediate obscurity and Greene remained largely forgotten until the late 1970s, after his photographs were included in exhibitions for the first time since 1856 and vintage prints began to appear on the market. John Beasly Greene is now recognized as one of great masters of 19th century photography, admired for his distinctive and unique proto-modernist vision. Prime examples of Greene's work are rare and are avidly sought by museums and private collectors.

John Beasly Greene was born in Le Havre but was an American national by virtue of his father's citizenship. John Bulkley Greene (1780–1850), a native of Concord, New Hampshire, had been a resident of France since around 1814; at the time of his death he was the head of Greene & Co., the major American bank on the Continent, and a leading figure in American expatriate community in Paris. John Beasly Greene, his only son, inherited the status and the financial independence to devote himself to his joint avocations of photography and Egyptology. His teachers were preeminent in their fields: Gustave Le Gray taught him photography and the waxed paper process; Emmanuel, Vicomte de Rougé, Champollion's successor as head of the Egyptian Department of the Louvre, taught him hieroglyphics. No dilettante, Greene was inducted (as a foreign member) into the prestigious Société asiatique, the French archaeological society, in 1853, at the age of twenty-one; in 1854, he became one of the founding members of the Société française de photographie.

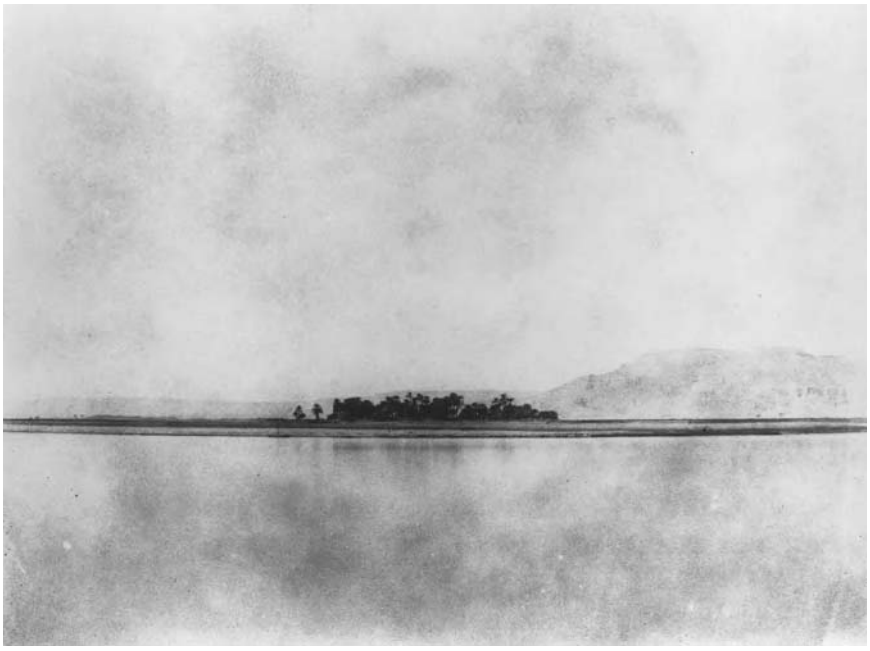
Greene completed two extended trips to Egypt in the course of his brief career. On the first, made during the winter season of 1853/54, he traveled up the Nile as far as the Second Cataract in Nubia, photographing the landscape, notable landmarks, and ancient Egyptian monuments along the route. Greene returned the following winter season (1854/55) with a *firman* (permit) to excavate at the Mortuary Temple of Ramses III at Medinet Habou at Thebes. Greene systematically photographed the progress of his excavation of the second courtyard of the Temple, the hieroglyphs that covered the walls of the courtyard, as well as architecture and details of the temple complex itself. The images of Medinet Habou include a remarkable series of views of the site taken from different points of the compass and at decreasing distances, in which the massive structures are so diminished by the vast scale of the empty landscape surrounding them that they look like miniatures .

Greene also made two trips to Algeria. In December 1855, he joined an official French expedition as official photographer for a two-part exploratory excavation of "Le Tombeau de la Chrétienne" (the Tomb of the Christian Woman), a 1st century BC burial mound near Tipasa, about 85 miles west of Algiers. He returned to France when the first phase of the excavation ended in early January 1856, but was back in Algeria in mid-February, six weeks prior to resumption of the excavations. It is probable that Greene used those six weeks to visit Constantine, an ancient city 200 miles northeast of Algiers, perched dramatically on a high plateau above—and half-encircled by—the deep gorge of the Rhumel River. The photographs he made of Constantine and the landscape surrounding it are among Greene's finest, most compelling images: tight, almost abstract compositions that seem charged with emotion and portent. When the excavations at the Tomb of the Christian Woman ended in early April, Greene sailed to France from the port city of Cherchelle, where he took his last photographs.

Greene made a third trip to Egypt in early November 1856. Already seriously ill when he arrived in Cairo, he died a few days later, the victim of an unidentified "cruel disease" (probably *not* tuberculosis). His death was announced at a meeting of the Société française de Photographie, and in the French, British, and American press. He was just 24 years old.

Greene's photographs are metaphors for his emotional response to Egypt rather than the more descriptive records produced by contemporaries such as Maxime du Camp or Leavitt Hunt. His Egyptian photographs are characterized by their emphasis on the emptiness and vastness of the Egyptian sky and landscape, which dominate most of the compositions and overwhelm the scale of even the most massive of the ancient monuments in most of Greene's images. His images reveal an extraordinary, proto-modernist eye, interested in the impact of graphic form, which distinguishes Greene from his contemporaries: his signature image, "Bank of the Nile, Thebes," consists of three simple elements—the dark straight line of the west bank of the Nile supporting the darker silhouette of a small oasis centered against the faint outline of the Theban Hills behind it—suspended between an area of slight tone at the bottom (the Nile) and blankness that fills the upper half of the frame (the sky)—is a composition unparalled in 19th century photography. Greene organized his Egyptian photographs into three series: "P" *(Paysages*, landscapes), "M" (*Monuments*, architectural monuments), and "I" (*Inscriptions*, hierogylphic inscriptions). The images in each series are numbered in geographical sequence, south to north, with the series number inscribed in the negative, usually in the lower left-hand corner. The images were also often signed "J.B. Greene" in the negative, usually in the lower right of the print. The highest recorded numbers for each series are M-42, I-108, and P-56, and each series includes photographs taken on both his trips to Egypt, in 1853–54 and 1854–55. There are also numerous Egyptian images that were not assigned a series number. The total body of Greene's Egyptian photographs numbers approximately 300 images.

Greene made no effort to organize his Algerian work, which consists of only about 40 images (including those documenting the excavation of Le Tombeau de la Chrétienne), all of which seem more personal and more purely pictorial than his Egyptian photographs. The photographs he made at Constantine, and particularly those taken in the Gorge of the Rhumel, seem so brooding and filled with portent that it is tempting to believe they are expressions of a premonition on Greene's part of his impending death, and what he intended to do with



Greene, John Beasley. The Nile. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 (2005.100.63) Image © The Metropolitan Museum of Art.*

them is not known. None of the existing Constantine photographs were ever mounted, none were given to any of the French institutions to which Greene had given his Egyptian photographs, and although four of these photographs are known to have been posthumously exhibited in Brussels in 1856, where they won an honorable mention, there is no other reference to them in contemporary literature.

Greene was clearly concerned from the beginning of his career with ensuring the preservation of his legacy. He donated important collections of his prints to the Institute de France, the Bibliothèque nationale, and the Société française de Photographie. He also announced that Goupil would publish a 60 print album of his Egyptian photographs and commissioned Blanquart-Evrard to make the prints, although album never materialized. (The album *Le Nil, Monuments, Paysages. Explorations Photographique par John B. Greene,* in the collection of the Société française de Photographie, which is *credited* to the "Imprimerie photographique de Blanquart-Evrard, a Lille, 1854" on its letterpress title page may be the dummy for the proposed Goupil publication.) Greene published a two part report on his excavations at Medinet Habou, *Fouilles exécutées à Thèbes dans l'année 1855,* illustrated with lithographs of hieroglyphic inscriptions copied from his photographs. An article in the *Bulletin Archéologique de l'Athenaeum Française* on a fragment of Egyptian sculpture he found and photographed in the museum at Cherchelle, Algeria, was his final professional effort.

The major holdings of John Beasly Greene's photographs are in the French institutions collections to which he gave the work, as well in as the Musée d'Orsay, which holds the definitive archive of Greene's Egyptian photographs, the comprehensive set of prints and negatives that had been deposited with Egyptian Department of the Louvre sometime after Greene's death by Théodule Devéria, the son of the lithographer who made the illustrations for *Fouilles exécutées à Thebes*, Greene's contemporary and probably a friend, and like Greene, a trained Egyptologist. Interestingly, apart from complete set photographs from the excavations at the Le Tombeau de la Chrétienne, none of Greene's Algerian photographs are in the French collections; the National Gallery of Canada owns the most extensive institutional collection of this material. The other important collections of Greene's photographs (both Egyptian and Algerian) are held by the Metropolitan Museum of Art and by the Museum of Modern Art, in New York; and in the J.Paul Getty Museum in Los Angeles.

The spelling "Beasley" that appears in almost every current reference is incorrect. The correct spelling is as given here, without the second "e." The authority for this is the family tomb in Père-Lachaise cemetery in Paris, which is the only place I have ever seen Greene's full name spelled out. (He usually signed his name as "J.B. Greene," sometimes as "John B. Greene.") The spelling with two "e"s originated, unfortunately, in a confused phone conversation I had with a prominent dealer in the earlym 1980s, shortly after I located the Greene tomb. The Greenes usually used either the mother's maiden name or a deceased first wife's maiden name as the middle names for a son. I have never been able to determine the name of John Bulkley Greene's wife (or wives), however, it is worth noting that one Reuben Beasley (also spelled Beasly in the records) was the American consul in LeHavre when J.B. Green was born there in 1832. John Bulkley Greene and Reuben

Beasley certainly knew one another; they may even have been close friends, and it is even possible that they were related by marriage (I would guess Greene to Beasley's daughter)—although that remains to be established. In any event, it seems very likely (if not probable) that John Beasly Greene was named after Reuben Beasley—though if this is indeed the case, the reason for the different spellings needs to be clarified.

GREENLAW, COLONEL ALEXANDER (1818–1870)

English photographer

Alexander Greenlaw was born in London and, at the age of seventeen, joined the Madras Infantry as a cadet and was posted to Trichinopoly in Madras.

His interest in photography dates from before 1855, when he first exhibited photographs at an exhibition of art and industry in Madras.

He used both paper and glass negative processes, having exhibited images on both at exhibitions organised by the Photographic Society of Bombay, of which he was a 'corresponding member.'

In 1856 he produced an extensive series of large format, 16 × 18 and 16 × 20 inch, images on paper negative, many of which are still extant, depicting the ruins of the city of Vijayanagar in south-western India.

Despite his experience with collodion, Greenlaw's preferred method—which he used into the 1870s—was his own simplification of the calotype, which became known as 'Greenlaw's Process.' While collodion had long been the process of choice throughout most of the world, Greenlaw believed that a simple paper negative process was the most ideally suited to the Indian climate and conditions.

The earliest account of Greenlaw's Process was carried in *Photographic News* in January 1869, and extensive accounts of it were carried in the 8th edition of John Towler's book *The Silver Sunbeam* in 1873, and in the 7th edition of Abney's *Instruction in Photography* in 1886.

JOHN HANNAVY

GROLL, ANDREAS (1812–1872)

Austrian photographer

Andreas Groll was born on 30 November 1812 in Vienna as a son of a man servant. He might have come into close contact with photography as a consequence of his employment and as a lab assistant at the polytechnic institute (today the technical university) in Vienna from 1845 to 1853. At that time, the polytechnic institute was the most important place of early photography in Austria because of the employment of different professors (Johann Joseph of Prechtl, Anton of Schroetter, who promoted Groll personally) and particularly the activity of Anton George Martin. Groll busied himself at that time with the daguerreotype and salt paper and albumen, moving from paper to glass negatives. In addition, predominantly concerned with portraits and architecture photographs (Viennese step Hans cathedral) he developed, particularly interesting pictoral documents of monuments. In co-operation with Eduard von Sacken, Groll's first large special photographic work was to photograph historical weapons and arms in the imperial collections. Groll photographed locomotives of the K.K. and at about the same time was granted privilege to the Austrian state railway company (StEG) for the Exposition Universelle in Paris 1855. Comissioned by the StEG, between 1860 and 1865 he produced another *Album der Banater Besitzungen*, most originally in the combination of landscape and industrial photographs as well as images of employees and native groups of peoples at this oldest railroad line in what is Romania today. Groll's speciality remained photography of architecture. Subject matters were historical buildings in Vienna, Prague, Krakau, Kuttenberg and other places of the Austrian Kronlande. New churches and stations came into Vienna, which stood in connection with the large urban extension after 1857. Groll's photographs often appear remarkably careless and nearly roughly arranged.

MAREN GROENING

Biography

Andreas Groll was born on November 30, 1821 in Vienna as a son of servants Anna and Joseph Paul Groll. In 1845 he married Josepha Brenner and found in the same year (until 1853) a job as a lab assistant at the Viennese polytechnic institute where he had worked since 1844 with professor von Schroetter as an assistant. In 1857 he opened his first studio in Vienna. He had already seen success as a special photographer, awarded in 1855 at the Paris world exhibition. He also documented important architectural projects of the Viennese urban extension (Votivkirche, arsenal). In 1861 he became a member of the photographic society in Vienna, where in 1864 he showed an extensive spectrum of his past work in a large exhibition (including nine Daguerreotypes from 1843). In 1865 he appeared in a publisher's catalogue with 788 numbers. Groll died on 12 October 1872 of typhoid fever in Vienna.

GROS, BARON JEAN BAPTISTE-LOUIS (1793–1870)

Baron Jean Baptiste-Louis Gros was born in Ivry-sur-Seine on February 9, 1793. His father was an employee of the Duchess of Bourbon. Little is known of his training, except that he traveled and practiced drawing and painting as an amateur. In 1823, he entered the diplomatic service as a free attache with the Legation of Lisbon. In 1828, he was sent to Egypt and received the title of baron the same year. A diplomatic missions then brought him to Mexico City, where in 1831 he was at the head of a diplomatic mission, then in Bogota, as chargé d' affaires, in 1838.

It is there that he took note of the invention of Daguerre and where he created his first daguerreotypes, probably, at the beginning of the 1840s. To do this he used the Chevalier lens, applied the bromine according to the technique recommended by Foucault, and resorted to the iodide box developed at that point by the baron Séguier. In 1841, he presented to the Academy of Science of Paris a way to reproduce colors but appeared unable to bring the least proof of its invention. Two daguerreotypes of Bogota created during this period are known today.

Shortly after, he returned to France, sometime between 1844 and 1847. His photographic activity continued in various fields: about 1845, he created astronomical pictures with Eugene Durieu, while making many architectural daguerreotypes of French monuments, many in Paris (the Pantheon, Our-injury, quays of the Seine) and in the province (Ste Croix of Orleans, Amboise, Chambord). In 1847, he published the first of his two works devoted to photography " Recueil de mémoires et de procédés nouveaux concernant la photographie». In 1850 he wrote his second treaty "Quelques notes sur la photographie."

At the end of 1840, diplomatic missions were carried out it in Argentina (Plata), then in England, and in London in particular. In May 1850 he was sent to Athens to settle the Anglo-Greek disagreements, in particular those relating to the transfer of the marble of the Parthenon. There he created approximately eighty daguerreotypes, views of monuments, architectural details, general scenes, and several views showing, according to statements from his contemporaries, the waves moving.

From 1851 to 1856, while living in Paris, he devoted most of his time to photography, and judging by the exceptional quality of the plates he produced during that time, Gros fully masters his technique. In this period he connected with the photographic medium that seemed closest: he then enjoyed a great reputation as a technician, an appropriate title if one judges by the exceptional quality of the preserved plates. In 1851, he was one of the founding members of the Société heliographique of which he was the inaugural president, and wrote several of the articles in the first issue of *La Lumière*. In the autumn of 1851, he was again in London, where he is known to have photographed the interior of the Crystal Palace. A little later *La Lumière* tells us that he created five daguerreotypes from the Fête des Aigles sur le Champ de Mars, which formed a panorama of five plates. In 1853, he made prints using negative paper coated with collodion.

In 1854, he was one of the founding members of the Société française de photographie, which replaced the Société heliographique, and exhibited at its first exposition in 1855 his "memories of Athens." Ernest Lacan saw at his place, rue Saint Lazare, the daguerreotypes of Athens and the images of Egypt, now disappeared, and of South America.

In the second half of the 1850s, his diplomatic activity took him abroad again and away from the photographic medium. He was sent as plenipotentiary to Bayonne to determine the exact layout of the Franco-Spanish border, then to China in 1857. From this date the honors flow: he was made a grand Officer of the Legion of Honour, then Grand Cross of Isabelle the Catholic. In 1858, he was named ambassador extraordinaire and then received

full powers to sign the treaty of Tien-Tsin and a trade pact with Japan. In 1859 he was made Senator; then in 1861, Grand Cross of the Legion of Honor. In 1862–63, he became ambassador to Great Britain. His retirement taken, he died in Ivry sur Seine in 1870.

It is not known whether he practiced photography beyond 1857, the date of the last mention of his name in the Bulletin of the Société française de photographie. His production known now consists only of daguerreotypes, as a large majority of the views of architecture, generally full plates, of Colombia, London, Athens, and Paris, but also some reproductions of precision and chemistry, and works of art (engravings, paintings) out of the common run. His work is in the following institutions: National library of France, museum of Orsay, Centers Canadian of Architecture, George Eastman house, Musée Getty, Tokyo Metropolitan Museum of Photography.

GRUNDY, WILLIAM MORRIS (D. 1859)
English commercial photographer

William Morris Grundy worked in Sutton Coldfield, Birmingham and specialized in stereoscopic views of picturesque rural scenes. The London Stereoscopic Company bought about 200 of his negatives, and individual stereographs still exist. However, Grundy's work is best known for the twenty original albumen prints pasted into the anthology *Sunshine in the Country, A Book of Rural Poetry Embellished with Photographs from Nature (*London: Richard Griffin and Company, 1861).

The book was published two years after Grundy's death. Although it is impossible to be sure, it seems likely that the photographic vignettes were not specially commissioned but that the publisher matched them to suitable poems. Each photograph appears to depict the subject of a particular poem, such as 'The Fowler' or 'The Squirrel-Hunt,' though some illustrate less specific subjects such as 'Rural Pleasures' or 'An Autumn Landscape.' Each plate is one-half only of the original stereoscopic view, some keeping the characteristic rounded top corners. However, many pictures have been cut into roundels or cut squarely at the corners, which removes them from Grundy's own intentions as stereographs. Yet most images retain the structure of stereographs, with bold features in the foreground, middle distance and background.

JOHN TAYLOR

GSELL, EMILE (1838–1879)
French photographer

Born in Sainte-Marie-aux-Mines (Alsace, France) on December 31, 1838, E. Gsell was, like J. Thomson, one of the first ever to photograph the temple of Angkor Vat in June 1866. He was then following the exploration mission of the Mekong, under the commandment of E. Doudart de Lagrée.

In September or October 1886, he established a studio in Saigon. Afterwards he participated to two other official missions; one in Hue, April 1875, under navy lieutenant Brossart de Corbigny, the other upstream the Red River, with de Kergaradec, French consul in Hanoi, from November 1876 to January 1877.

The utmost quality of his photographic production owed him a medal of merit during the World's fair of 1873 in Vienna. He was on of the first professional photographers to settle in Saigon and probably the only one to remain in practice there such a long time, until his demise on October 16th, 1879. The collection of his works was then exploited first by O. Wegener in the early 1880s, then by Vidal, under his name or under Salin-Vidal, until the end of 1883. His works comprises hundreds of photographs, portraits, landscapes, most of which may be found in the photo archives of Guimet museum, Paris.

JÉRÔME GHESQUIÈRE

THE GUM PRINT

"Gum printing" should really be called colloid printing or the pigment process**.** The *colloid* is any liquid which, when combined with an appropriate sensitizer, becomes capable of hardening when exposed to light; in the case of 'gum printing,' the colloid can be made from a combination of: gelatin, or egg white, fish glue, or the more commonly used gum arabic, together with potassium or ammonium bichromate (the sensitizer), together with the pigment as colouring material (you can also use gouache, watercolour etc.) This *combination,* colloid + sensitizer + colouring, is called a *mucilage* or, in more common usage, an *emulsion.*

Thus the term 'gum print' covers a variety of different processes which came into their own during the heyday of nineteenth century "Pictorialist" photography with its advocacy of photography as a form of self expression on a par with other art forms, principally painting and printmaking. In order to become a similar 'art' Pictorialist photographers, influenced principally by the British

Gsell, Emile. Angle d' Une Cour Interieure de la Grande Pagode. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 [2005.100.501 (34)] Image © The Metropolitan Museum of Art.*

photographers Oscar Rejlander (1813–1875) and H. P. Robinson (1830–1901), believed that the photograph must therefore be capable of similar *manipulation* of materials as that enjoyed by the painter or printmaker. Manipulated photography became the rage which spread to Europe and the United States. Many felt that the image became art the more it did not look like a photograph. The processes allowed for coloured images with soft, textured surfaces, similar to the mezzotint, etching, watercolour, chalk, pencil, and crayon drawing, and even to the extent of mirroring oil painting. Thus their photographs took on more and more the visual characteristics of artists' prints and drawings. As a result the characteristic sharpness of the camera's negative dissolved and 'out of focus' became the prevailing style. The justification, both theoretically and stylistically, was derived from the American painter James Abbot McNeill Whistler (1834–1903) with his "out of focus" paintings and etchings and his advocacy of "art for art's sake"; that a picture should be nothing but a picture. Whistler had no particular interest in photography and thus it demonstrates the closeness of those who wished photography to be an art to that of painting and printmaking. It was his translations from nature that was most copied, along with some of the compositional and visual devices of the painter Edgar Degas (1834–1917). The process was published by the main French exponent Robert Demachy (1859–1937) and Linked Ring member Alfred Maskell in *Photo-Aquatint, or the Gum Bichromate Process* (London, 1897), and by Demachy in 'The gum bichromate process,' *The Photographic Journal* (28.04.1898). The Pictorialist High Art Movement was not without its critics who viciously labelled them "paperstainers," with their "precious daubs" signifying only "meretricious effort." They were all swept away after the turn of the century with the emergence in the USA, led by Alfred Steiglitz, one time fellow Pictorialist, by "Straight" photography with its backlash to "truth to materials" using "unmanipulated" negatives, derived from the earlier idea that photography was fundamentally different

from painting, drawing and printmaking and thus had different attributes. With today's sophisticated methods of photo-manipulation, available by computer (now used even in journalism!), to create once again fictions that pretend to be real, contemporary photographers *et al* no longer need to despise those who worked in the same tradition in the 19th century.

In 1855 Alphonse Poitvin, regarded by many as the father of gum printing, in an attempt to make more permanent images than silver prints, published his results of using various colloids, but it was not until 40 years later that the pigment process came into its own when photographers wished to make images in a certain way. The knowledge of the colloid process went much further back than Poitvin: in 1798 Vauquelin, French, knew the effect of bichromate as a sensitizer; Mungo Ponton, Scottish, patented this in 1839; the French physicist Edmond Bequerel had found that the size in paper, when combined with a chromic salt, caused the paper to become sensitive to light.

A sheet of paper is thus coated with gelatin or gum arabic, mixed with pigment and sensitized with gum bichromate. This emulsion hardens when exposed to light and becomes insoluble in proportion to the densities of the negative; called a gum bichromate or photo-aquatint**.** Because the sensitizer is too slow for an enlarger, negatives have to be the actual size of the print and processed by contact printing. After exposure any excess of unhardened emulsion is washed out and the whole hardened further with sodium or potassium bisulphate. All sorts of combinations are possible; using several negatives, including drawn and painted ones, and parts of cut negatives (to build a composition, as in painting), various colours of pigment, together, or one layer on top of the other, will produce the multiple gum print**.** All can be fixed to a variety of watercolour and drawing papers. Because the process is restricted to the translation of a few simple tones (whatever kind of negative is used) and that the colour source is contained within the emulsion, and has to be physically coated onto the paper (usually by brush), the end result can provide an equivalent texture and mark, including brush stroke, pencil line, to that obtained by hand in drawing and printmaking. It allowed therefore for a similar method of working *towards a final image* as draughtsmen and printmakers enjoyed; parts could be removed, added to, printed over, the tonal values altered, so that, under a glass frame, it is often difficult to tell if you are looking at a drawing, print or photograph. It was thus also favoured by many who could not draw or paint *but wanted to*. The main technical problem was that of registration and often the result was that "out of focus"—now called soft tone impressionism, became merely a multi focus blur.

Because of the thickness of the dried emulsion the colloid process lent itself to other adaptations. A gum print could be formed on top of an initial platinum print to produce the gum platinum (1902). Glycerine together with various strengths of oxalate solution can be painted on to deepen tones. The carbon print sat along side the gum print and was also patented by Poitevin in 1855, and perfected by Joseph Swan in 1864 by introducing image transfer. Manufactured colloid papers using carbon came in a variety of colours from red chalk to dense green but could not be manipulated. They produced, however, the finest tonal range, accuracy and most permanent images of all the colloid processes and were seen as a more accurate and controllable form in preference to the instability and difficulty of obtaining sufficient control over tone than the gum print. Thus the gum print had many similarities with other processes that used a similar colloid system, such as the oil print (or oil pigment process), also patented by Poitvin 1855, and the oil transfer print**,** revived by G. E. H. Rawlins in 1904 and also popularised by Robert Demachy. The next developments included the bromoil print, bromoil transfer and dye transfer.

In the end, whatever artists, photographers, thought of the value of the results of the gum printing process—it has to be said mostly disparaging then and now, the simple *gum print*, the practical applications of a *sensitized colloid,* became a vital part of the development of the printing industry.

GURNEY, JEREMIAH (1812–1886)

Originally a jeweller in Saratoga, Gurney was one of the first to study photography under Professor Morse. In 1840 he moved to New York, where he opened a gallery, sold daguerreotypes and offered portrait sittings. His photographic gallery was the first to open in America. At his premises he taught numerous people, including his more famous rival, Matthew B. Brady. He achieved success in photographing society people, exhibited internationally and attended the Great Exhibition in 1851 at the Crystal Palace, London. He also won the coveted Anthony Pitcher prize in 1883. In the 1850's he broke new ground by using mammoth daguerreotype plates, and he constantly experimented with new photographic methods, such as mezzo graphs. He worked with a number of people; for example, John Bishop Hall on the Hal-

lotype, and he was in partnership with C.D. Fredericks at one point in his career, and then with his son, Benjamin. As well as photographing celebrities, such as Dickens, Gurney undertook theatre photography. Gurney had no problems with working in what had been seen as a morally dubious part of society. He also frequented a well known medium and psychic artist based in New York. This may be why he was the first to photograph a dead president. He photographed Abraham Lincoln, in his open coffin, on April 24th 1865. This photograph was hidden in the Illinois State Historical Society, until its discovery in 1952 by a fifteen year old Ronald Rietveld, where it was promptly confiscated, until its later rediscovery, again by Rietveld.

JO HALLINGTON

GUTCH, JOHN WHEELEY GOUGH (1808–1862)

English photographer and editor

John Wheeley Gough Gutch was born at Kingsdown, Bristol, in south-west England on 23 December 1808. He left Britain for Italy in 1831 and in December 1832 married Elizabeth Frances Nicholson and a year later a son was born.Gutch worked as a medical practitioner in Florence and, before the invention of photography, made many pencil drawings of Florence and the Italian Lakes, probably with the aid of a camera obscura (or camera lucida). Interestingly, William Henry Fox Talbot was attempting to sketch in Italy in the early 1830's and it was his failure to satisfactorily record scenes with a similar instrument that led to his idea of photography.Gutch and his family left Italy in 1835 and returned to Britain where he appears to have been practising medicine at Swansea in South Wales, where, in March 1838, his young son, John Frederick Lavender Gutch, sadly died.

Gutch was interested in a wide variety of scientific pursuits—he was a member of the Meteorological Society of Great Britain and a fellow of the Linnean Society. He maintained a tide gauge at Swansea and corresponded with astronomer royal Sir George Biddell Airy (1801–1892).He was also interested in geological phenomena and later made many photographic studies of quarries and rock outcrops.Insects were another fascination, having a particular interest in Coleoptera (winged beetles), which he collected on his travels.

Around 1851 he abandoned medicine and became a Queen's messenger, a government post which involved taking diplomatic dispatches to European cities.It was on a mission to Constantinople that he became ill and suffered the partial paralysis which forced his retirement from diplomatic service and later prompted his photographic quests "...in Search of Health and the Picturesque."

Gutch was experimenting with photography as early as 1841 (no early work is known) and was in contact with the photographic chemist Robert Hunt.Hunt passed on a letter from Gutch to Talbot which asked Talbot's advice on preparing paper negatives.Talbot replied, sending Gutch a "specimen of good iodised paper" and "a few specimens as requested." (Schaaf.The Correspondence of WHF Talbot. 14 Sept 1841, document no: 04333).

Gutch was born and lived in the south west of England, which became the birthplace of early British photography; Talbot was at Lacock in Wiltshire and many well-known early photographers worked and lived in and around Bristol and nearby South Wales. These included: Nevil Story-Maskelyne, John Dillwyn Llewelyn, Hugh Owen, the Reverend Calvert Richard Jones and the Rev. Francis Lockey along with photographer friends of Gutch: John Morgan and John Bevan Hazard. Gutch knew and photographed the early photographer, the Reverend George W. Bridges, who also lived in Gloucestershire. He was also in contact with the photographic printer and editor of *Photographic Notes*, Thomas Sutton, who was at St. Brelade's Bay on the island of Jersey.

Between 1856 and 1859 Gutch supplied several articles for Sutton's *Photographic Notes* including: "Recollections and Jottings of a Photographic Tour, Undertaken during the Years 1856–7 [&1858]" and "Positive Pictures Taken From the Camera of a Peripatetic Photographer in Search of Health and the Picturesque 1859." These essays provide some insight into his work and methods, including his preferred camera (from 1856 he used an Archer's wet-plate camera, designed by photographer and inventor Frederick Scott Archer). This allowed the operator to prepare and develop the glass negatives within the camera itself, doing away with the need for a separate darktent. Archer's camera was, however, bulky and with Gutch's infirmity it would of required an assistant to help. Many of his landscapes show Gutch in the image, indicating third-party assistance. Gutch appears to have travelled to his photographic destinations mostly by train,often hiring carriages from railway stations to his chosen location.

Gutch's preferred subjects were influenced largely by the cult of "The Picturesque." (At the end of eighteenth century artist and author William Gilpin (1724-1804) invented the term "Picturesque Beauty" which he defined as: "that which would look well in a picture"). Gutch avoided photographing industrial, urban Britain and concentrated rather on recording picturesque scenes: ruined ancient buildings,geological formations,rocky streams and trees, particularly old elms and oaks, were all favorite subjects.

In 1856 Gutch visited the English spa town of Malvern to attempt a cure for his illness. He attended James

Manby Gully's Hydropathic Establishment where Gutch hoped that the controversial Dr. Gully's water treatment would help his paralysis. He also thought that the discipline of photography would beneficial to his health. He spent two months photographing Malvern and the surrounding areas, recording old houses, lanes and ancient trees along with a few small portrait studies. Later the same year he spent several weeks in Devon, where he made studies of streams as well as street and beach scenes (including a few three-part panoramas).

Gutch mainly worked with whole-plate wet-collodion glass negatives and printed his photographs on salted paper.He mounted his work into slim,soft-cover albums where he initialled, titled and dated the images, often decorating the title page to each album with a photographic collage. The collages were made by placing leaves, flowers and feathers in printing frames (in contact with salted paper) to produce negative images (photograms) which were then cut up, made into patterns and pasted onto the page, Gutch often writing an epigraph or dedication in the centre, using quotes from a wide range of authors and poets, reflecting his literary background.Gutch was from a well-read middle-class background (he edited the annual Literary and Scientific Register for many years) and was at one time prospective editor of *The British Journal of Photography*.

In 1857 Gutch travelled further afield, taking his cumbersome camera to the English Lake District, Scotland and North Wales. In "Recollections ...1856–7" *Photographic Notes* part 4, vol. 3, no. 60, 1 October 1858, 230. Gutch wrote that he considered his camera couldn't do justice to the Lakeland landscape, it being more suited to the "brush and the painter." In consequence he took few images of the lakes themselves and concentrated on intimate rustic scenes and architecture,spending three days photographing the ruins of Furness Abbey. In Scotland he again avoided the natural landscape and concentrated on ruined castles and abbeys (*Photographic illustrations of Scotland 1857 Album*, George Eastman House collection). His visit to North Wales provided a chance to record a larger variety of his usual subjects such as quarries, coastal landscapes,cliffs and bridges.

By the Spring of 1858 he was at work recording local architecture in and around Bristol. In August he headed further west,spending three months in the Land's End area of Cornwall where he photographed rock formations, quarries, coastal scenes, ancient tombs, local fishermen and boats.

By 1859 Gutch had set himself the daunting task of photographing every church in Gloucestershire (over 500). Even though the Bishop of Bristol and Gloucester, The Hon. Charles Baring, had promised to order a copy of each church photographed, this must of been a difficult and expensive undertaking.Gutch even purchased a new Ross Petzval wide-angle lens to aid his task. Even today it would be a daunting task to record every church, Gutch, however, managed the remarkable feat of photographing at least 200 of them in five months but the church series seems to have been his last major photographic project;the summer of 1859 had been hot and perhaps the exhausting task of recording so many country churches had taken its toll on Gutch's already frail health.

Gutch died, less than three years later, on 30 April 1862 at 38, Bloomsbury Square, London, aged 53.

Ian Sumner

Biography

Gutch was born on 23 December 1808 in Bristol, England, where his father, John Mathew Gutch (1776–1861), was a journalist, publisher and bookcollector.John Gutch senior was a former schoolfriend and member of the literary and scientific circle that surrounded the writer and poet Samuel Taylor Coleridge (1772–1834). Also in this circle were the early photography experimenters Thomas Wedgwood and Humphrey Davy.

JWG Gutch trained as a surgeon in Bristol and practised medicine in Italy and later Swansea, South Wales. Later he quit medicine and became a Queen's messenger. He also edited the annual Literary and Scientific Register. He was experimenting with photography as early as 1841, but did not pursue it seriously until the mid 1850's. His busiest years were from 1856–1859 when he travelled around the south west of England, Wales and Scotland recording architecture and "wayside scenes." He showed his work at several Edinburgh and London Photographic Society exhibitions between 1856–61.

GUTEKUNST, FREDERICK (1831–1917)

American photographer

Known as the "dean of American photographers," Frederick Gutekunst was born in Philadelphia, Pennsylvania on September 25, 1831. A prominent portraitist and professional photographer whose work was prolifically published, Gutekunst, the son of a German cabinetmaker, served apprenticeships with a lawyer and a druggist before opening his first studio in 1856 with his brother, Louis. He photographed celebrity authors, artists, scientists, foreign dignitaries, Civil War generals, and presidents, as well as ordinary citizens, and kept detailed ledgers of his sitters, one of which survives at the Library Company of Philadelphia. A member of the Photographic Society of Philadelphia 1862–1900, Gutekunst gained recognition for his set of Gettysburg battlefield views, and for printing in 1876, what was then the world's largest photographic mural, a 10 foot wide by 18 inch high panoramic view of the Centennial Exposition made from seven negatives. As official photographer for the Pennsylvania Railroad, he documented structures and scenery of three of its divisions in 1875. In 1878 he purchased the rights to the phototype process, a photomechanical process allowing mass production of high-quality reproductions of photographs, which proved to be an additional boon to his business. Gutekunst worked until eight weeks before his death at his Philadelphia home on April 27, 1917.

GYOKUSEN, UKAI; See UKAI GYOKUSEN

H

HAAS, PHILIP (ACTIVE 1840s–1860s)
German daguerreotypist

Born in Germany around 1808, Philip Haas emigrated to the United States in 1834 and established himself as a lithographer and print publisher in Washington, D.C.

When the invention of the daguerreotype was announced in 1839, Haas possibly went directly to Paris to learn the art. Although his earliest documented daguerreotype is dated March 1843, Haas was still among the first resident daguerreians in the nation's capital.

With his image of John Quincy Adams in 1843, Haas became the first to produce a lithograph directly from a daguerreotype. In 1844, he moved to New York City and established a daguerreian gallery on Broadway. Between 1844 and 1860, he moved up Broadway at least four times.

In 1861, at age 53, Haas lied about his age to enlist with the First New York Engineers, which was sent to South Carolina. Here, he was detailed with Washington Peale to shoot photographs. Their most distinctive image shows the USS *New Ironsides* in action in Charleston Harbor as the smoke from its broadsides trails into the southern sky.

Haas apparently was weakened by ill health in 1862. He resigned from the army on May 25, 1863 and from here the trail of his life is lost.

BOB ZELLER

HAES, FRANK (1833–1916)
English photographer

Frank Haes was born on 3 January 1833 in the Hambro Synagogue, London and died in 1916 in the same city.

He first exhibited his photography in 1858 at the age of 25, by which time he had emigrated to Australia and married London-born Adele Valentine in Sydney. The 1858 exhibition of the Photographic Society of London included five of his views of his adopted city.

By the early 1860s, the family was back in London, and Haes was earning a reputation as a photographer of stereoscopic views of zoo animals—including what is acclaimed as the first photograph of a living elephant, and rare photographs of a *quagga*! These stereocards were published by McLean & Haes of 26 Haymarket, London. McLean & Haes also produced cartes de visite, even designing and manufacturing their own four-shot camera specifically for the purpose. A rear-focussing half plate studio camera was designed and marketed by the enlarged partnership of McLean, Melhuish & Haes in the later 1860s.

At the International Exhibition of 1862, McLean & Haes achieved awards for their 'coloured photographs,' and two years later they wrote to W.H.F Talbot to arrange to photograph Talbot as part of a series they were creating of Fellows of the Royal Society.

When the 1901 Jewish Encyclopedia was published, Haes was acknowledged as one of those who had provided illustrations.

JOHN HANNAVY

HALE, LUTHER HOLMAN (1823–1885)
American daguerreotypist

Luther Holman Hale, one of Boston's better known daguerreian artists, was listed with a gallery there from 1845 to 1862. He was born September 21, 1823, in Milbury, Massachusetts, and apparently first went into business with his brother, C. E., on Milk Street in Boston before opening his own gallery.

From 1846 to 1850, with Benjamin French as a partner, Hale did business at the L. H. Hale & Co. Daguerreotype Miniature Rooms at 109 Washington Street, advertising: "Miniatures taken in any weather,

with or without colors, in a superior style, and neatly set in Lockets, Pins, Rings, Bracelets, or Cases." The firm also sold daguerreian materials.

From 1850 to 1857, Hale continued at the same address alone before listing G. A. Ayling as a partner in 1858 and 1859. Hale also taught the daguerreotype process and perhaps his best-known student was William Herman Rulofson, one of the first great American western photographers. He continued to be listed in Boston through 1862.

Hale died in 1885 and his personal collection of family daguerreotypes is preserved today at the American Antiquarian Society in Worchester, Mass.

Bob Zeller

HALF-TONE PRINTING

Half-tone is a widely used photomechanical printing process where a photographic image is translated onto the printed page as a fine pattern of dots. The dot pattern is so fine that the individual dots cannot be seen by the naked eye. Rather the naked eye blurs the dot pattern into an image that appears to have the quality of a photograph. The dot pattern can be seen under magnification. Half-tone was an important invention as it provided an effective process for commercial printers to mass print photographically realistic images. Invented in the 19th century it still commonly used today in commercial printing. It is often referred to as the *screen process* or *dot process*.

Before the half-tone process, the pages of newspapers and magazines did not contain the photographically realistic images that we take for granted today. The most common type of picture in a newspaper was a woodcut or wood-engraving. These prints, made from hand carved blocks of wood, could not produce the minute details and subtle tones of a photograph. While often attractive, these prints more resemble hand drawn sketches.

Since the invention of photography, commercial printers wanted a practical way to realistically reproduce photographs onto the printed page. The essential problem lay in the fact that the most common mechanical printing processes can only print areas of ink or leave blank areas on the paper. They could print different tones. A newspaper press could only print black or nothing. Photographs, on the other hand, have a range of tone, meaning there are various shades of gray between black and white. This is what gives photographs realistic images. While there were earlier mechanical printing processes that could imitate the tone and subtle details of a photograph, most notably the Woodburytype, these processes were expensive, difficult to make, and not practical for mass commercial printing that used relief printing.

The half-tone process overcame these limitations, offering a practical process that could create near photographically realistic images. The half-tone process translates the tones and detail of a photographic image into a printed pattern of tiny dots or similar marks. With a magnifying glass these dots can be seen. Examination of a photographically realistic picture in a modern newspaper or magazine reveals the half-tone dots. Though it was later applied to a variety of printing processes, its initial triumph was that it could be applied to relief printing, which was the staple of the book, newspaper and other periodical industry.

The traditional half-tone process in relief is as follows: First, a negative is made by taking a picture of the desired item through a special screen. Sometimes a glass with crossed lines is used instead of a screen. The screen breaks up the illuminated image into a pattern of dots on the negative. The lightest areas of the object create large dots close to each other. The darkest areas of the object create smaller dots further part. The negative is then used to expose the printing plate that has a photographically sensitive coating. The dots sizes are reversed on the printing plate. This means that the largest dots on the negative become the smallest on the printing plate, and vise versa. The printing plate is developed, the unexposed areas are washed away, and the plate is etched. The finished printing plate has the dot pattern in relief (raised from the rest of the plate). During printing, ink is placed on the raised dots, which is translated into a pattern of dots on the printed page. Depending on the fineness of the screen used, there will be more or fewer dots per inch in the print. The more dots per inch, the higher the quality of the image. On rough paper, such as newspaper, fewer dots per inch are necessary. On fine paper, more dots per inch are best.

The first half-tone print in a newspaper appeared in 1880. By the 1890s, many newspapers and magazines had half-tone images.

Half-tone applied to intaglio printing is called photogravure. Photogravure has a similar dot pattern, but the ink is deposited in different amounts. In the dark areas of the image, where the ink is the heaviest, the ink is physically raised from the paper. This quality is observed under a microscope. Photogravure could create quality images, but not lettering. Half-tone could be applied to lithography in the 19th century, but was not widely used in commercial printing until the 20th century. Today, most newspapers, magazines and other commercial prints use lithography.

Color Half-tone. Half-tone printing is often tinted or colored by printing solid colors onto the black half-tone print. Sometimes, a black and white half-tone print is hand tinted (2 additional colors) or hand colored (3 or more colors). To make a true color half-tone, printing plates are made, each for a different color. In the 19th

and early 20th century, the colors were red, blue, yellow and often black. Today, the common colors are cyan (light blue), magenta (darkish-purple), yellow and black. To make the negative, the object is photographed four times through a half-tone screen and through filters that eliminate all colors from each negative except for the desired color. When printed successively on top of each other, the resulting has the realistic color. If you examine a color picture in a magazine with a magnifying glass or microscope, you will see that the image is made of a made dots of different color. True color half-tone relief printing was introduced in the 1890s, though it did not produce quality color pictures until the turn of the century. In this printing, black ink was not used until the 20th century. Instead, the red, blue and yellow were printed on top of each other to achieve black. Color half-tone lithography was not commercially successful until the 20th century.

HAMMERSCHMIDT, WILHELM (active 1858–1870)

Wilhelm Hammerschmidt seemed to have been born in Berlin around 1830. Between 1858 and 1870, he resided in both Cairo and Berlin and operated photographic studios. Besides an extraordinary quality in technical respects, his images resemble the light of the southern parts of the Mediterranean Sea with a hitherto unknown character. In the early years of his Egyptian travels, he worked up and down the Nile River into the Sudan, and covered the Lybian desert as well. He apparently worked for Hermann Wilhelm Vogel. His panoramic views of Egyptian cities and the desert countryside belong to the pantheon of the best material produced of the second generation of travel photographers. Their vision was not only dedicated to the ruins of antique origins alone, but to the integration of everyday life and modernisation as well.

In 1865 Hammerschmidt was offered membership in the Société française de la photographie, in 1867 he showed his photographs at the Paris World Fair. In 1869, Wilhelm Hammerschmidt took photographs of the opening of the Suez canal which were widely published. After this event, he fell into total obscurity. There is no record of his later life.

ROLF SACHSSE

HANSEN, GEORG E. (1833–1891).

Danish photographer by appointment to the king

Georg Emil Hansen was born in Næstved, Denmark, on May 12, 1833. He was out of a family of photographers. His father, Carl Christian Hansen, became a photographer in 1849, initially using the daguerreotype, his father's brother, Just Hansen, also became a daguerreotypist, and his brother, Niels Christian Hansen, became a painter and photographer. In 1854, G.E. Hansen's father opened a studio in Copenhagen. Two years later, G.E. Hansen opened his own studio, also in Copenhagen.

Hansen became one of the most respected and well-paid photographers of his day. Among his regular customers were the Danish Royal Family, not least Princess Alexandra, the later Queen of England. In 1864, he was appointed Photographer to the King. His most famous portraits are, however, of the fairytale writer Hans Christian Andersen, whose large profile he immortalized in innumerable versions.

G.E. Hansen was one of the leading Danish photographers with regards to photographic technique. He was the first to open a studio with paper prints, the first to use prepared gelatine plates, and the first to make full body size enlargements. He exhibited internationally and received medals for his work in London (1862) and Berlin (1865).

JANNIE UHRE EJSTRUD

HARE, GEORGE (1825–1913)

American born photographer and inventor

George Hare was born in 1825 and served an apprenticeship as a joiner before moving to London. He joined the firm of Ottewill, Collis & Co. where he began making cameras and photographic equipment. He stayed with the firm for one or two years before establishing his own business *circa* 1857. Hare's business was last recorded in 1911.

Hare's portable binocular, or stereoscopic, camera was exhibited in 1860 and his 1864 design for a studio camera was popular throughout the century. The New Universal camera was based on W. J. Stillman's patent of 1871.

British patent number 3035 of 27 June 1882 was Hare's main contribution to camera design. He described a camera where the baseboard was hinged to the body of the camera and held in position by brass bars which could be secured in any position by retaining knobs

running in slots on each side of the camera. The lens panel, in common with many Hare cameras was held in position by two vertical rods running in slots on the baseboard. As the *British Journal of Photography* remarked 'it forms the model upon which nearly all others in the market are based.' Hare's only other patent was granted on 7 May 1875 for a photographic changing box which held twelve plates that could be changed within the box without the need for a darkroom. He also made cameras for other camera makers, notably J H Dallmeyer, to sell under their own names.

George Hare was 'regarded as *the* maker of a field or studio camera of the very highest class' whose name 'was a household word among photographers.' Mechanisation in camera manufacture from the later 1880s gradually made Hare's cameras expensive and his designs which had not altered significantly since the 1860s were increasingly seen as being dated and less practical compared to more portable models.

Hare retired around 1911. His son, James 'Jimmy' Henry Hare (1856–1946) had emigrated to America in 1889 where he had a successful career as a photographer and war correspondent. A Quaker, Hare was described as 'an upright, honest, hard-working temperate citizen.' He died in York on 21 November 1913 aged 89 years.

MICHAEL PRITCHARD

HARRISON, CHARLES C. (D. 1864)

American photographer

Sometimes referred to as C.C. Harrison, Charles C. Harrison was an American daguerreotypist and lens maker who was active in New York in the late 1840s and 1850s. In 1846 Harrison began to made daguerreotypes in New York, where he continued to operate until his death in 1864. Little is known about his photographs, but he exhibited, either photographs or apparatus, at the Crystal Palace exhibition in 1853–54, and in other exhibitions in New York through the 1850s.

Harrison is best known for his innovations in camera lenses. In 1849, Harrison began to manufacture high quality lenses and in 1851 was awarded a silver medal at the American Institute for Daguerreian apparatus. He continued to manufacture lenses for daguerreotype cameras, in joint partnership with Edward Anthony and later James L. Scovill. In 1858, Harrison was awarded a patent for a lens diaphragm in 1858. In 1860, he began to work with the German lens designer J. Schnitzer on the "Globe" lens. Patented in 1862 and used primarily for stereo photography, this was the first true wide angle lens that reduced distortion and provided a large, flat viewing field. By that time, Harrison's operation, which he continued to supervise, was jointly owned by Anthony and Scovill, subsequently sold it to Nelson Wright. Harrison died in New York on November 23, 1864.

SARAH KENNEL

HARRISON, GABRIEL (1818–1902)

Born March, 1818, in Philadelphia. Father was an artist and engraver who moved the family to New York in 1820. Harrison made his professional acting debut in 1838, then married, and fathered son George Washington Harrison.

He began daguerreotyping in Plumbe's New York gallery, about 1844. Won first gold medals in 1845, becoming known for daguerreotypes of "religious, patriotic, & poetical subjects." Worked in the M. M. Lawrence gallery from 1847–51, yet remained active in acting & politics.

In 1852, opened the magnificent Harrison & Hill Gallery, in Brooklyn. Continued in various photographic mediums—plus acting—until political life set-backs ended his photographic career in the early 1860's. He remained active in painting, music, & acting in Brooklyn, dying there in 1902, at 83.

He is well-known for promoting high aesthetic & operating standards for photographers. Harrison's famous

Harrison, Gabriel. California News.

daguerreotypes include *The Infant Saviour Bearing the Cross, Young America*, and an 1847 plate of his friend, Poe. Romer suggests he won more awards than any photographer of the period.

The definitive analysis of Harrison is in *IMAGE: Gabriel Harrison: The Poetic Daguerreian*, by Grant B. Romer. The George Eastman House has the Harrison family records and images. A self portrait of him as an actor is in the West Archives.

LARRY WEST

HARRISON, WILLIAM JEROME (1845–1908)

English amateur photographer

Founder of the Photographic Record and Survey Movement, William Jerome Harrison was a remarkable example of the archetypal Victorian polymath. He was an original thinker, a geologist of national repute, an innovative educationalist and a leading figure in the amateur photographic world of the late-nineteenth century.

Harrison did not begin practical 'work in the art-science' until 1881 at the age of 44 years. He had gained an encyclopaedic knowledge of the subject from meticulous studies of the history, chemistry and various applications of photography. Harrison undertook these investigations in his early career as a writer, museum curator and science teacher, as his awareness of the role that photography could play in the illustration of educational material developed. The publication of Harrison's account *A Sketch of the Geology of Leicester and Rutland* in 1877, 'the first geological book… illustrated by photographs' was an early demonstration of the reciprocal relationship that Harrison perceived between science, photography and education. 'Let nature be thy teacher' was reflected on his personal bookplate and became a personal credo throughout his life.

Harrison's photographic self-education was prompted by his belief that 'it is the man who takes as his starting point a knowledge of what others have done and are doing, who will best be able to advance photography in the future.' In 1885 he made another contribution to the advancement of photography with the first of a large number of essays on all aspects of the subject. From the prolific manner in which Harrison contributed to the literature of photography in British and American photographic journals, it might be reasonable to conclude that he had decided to undertake this task single-handedly. By 1887 he had compiled the first complete bibliography of photography, the results of which were published in *The Photographic News*. On completion he had listed and often annotated 328 titles of books of photography. His accounts of the 'bibliography' of the subject were unmatched in his own day and remain important reference works for all modern photographic historians.

Another important project for Harrison was *A History of Photography, written as a practical guide and an introduction to its latest developments… with a biographical sketch of the author, and an appendix by Dr. Maddox on the discovery of the gelatino-bromide process*. This was published in New York by the Scovill Manufacturing Company in 1887 and by various publishers in Britain the following year. Harrison also wrote instructional articles and textbooks with *Photography for All: an elementary textbook and introduction to the art of taking photographs* published in 1888.

In the two decades on either side of the turn of the century, a documentary photographic movement evolved amongst amateur photographic societies that shared the notion of the photograph as evidence. The initiation of this Record and Survey Movement has been ascribed to Sir Benjamin Stone, through his work with the Warwickshire Photographic Survey (WPS), the National Photographic Record Association (NPRA) and the Federation of Photographic Record Societies (FPRS). Although Stone may be credited with aiding the establishment and promotion of Record and Survey photography, it was Harrison who was the visionary and guiding force and truly responsible for the creation, momentum and dissemination of interest in this work.

Shortly after the re-formation of the Birmingham Photographic Society (BPS) in 1885, Harrison as the society's new Vice-President replied to enquiries made to him concerning the goals of an amateur photographic society. As part of the work that Harrison proposed members undertake, he suggested that:

> … by securing accurate representations of old buildings we can furnish a record for posterity whose accuracy cannot be disputed, and whose interest in the future would be great. But I would not only photograph the old buildings, I would secure, on rapid plates, impressions of our streets, of the principal lines of thoroughfare, and of the busy crowds by which they are traversed.

At a 'Special Meeting' called on 11th December 1889, Harrison presented his paper 'Some Notes on a Proposed Photographic Survey of Warwickshire.' In this he points out that only now had such a scheme become possible with the publication of the government map on a six-inch to a mile scale showing the outline of every field and the position of every tree. Warwickshire comprised two hundred sheets of this map. Harrison proposed to allot one sheet of this map to every pair of photographers who were willing to share the enterprise and obtain good negatives of every point of interest within the area allotted to them. He suggested illustrating the state of things 'as they exist today' to be printed on sensitive dry plates and printed in platinum. The size

of picture recommended is whole plate (8½ × 6½ inches) while pictures of other sizes could be bound in special albums, and complete sets of views could be produced for the public reference libraries.

While this proposal was local in nature, Harrison saw it as having a general application and this was reflected in the fact that a dozen or more photographic societies copied this example initiating local surveys. Encouraged by this activity in response to his paper, Harrison developed his ideas on the scale and scope of Survey Photography. In 1892 he read his proposal 'A Photographic Record and Survey' to the Royal Photographic Society (RPS), and in 1893 he presented his paper 'On the desirability of an International Bureau: established to record and exchange photographic negatives and prints' at the World's Congress in Chicago. Although the scheme for a National Survey was thought to be 'impracticable, unwieldy, [and] of doubtful utility' with 'problematical longevity in its execution,' his 1893 paper led to the appointment of an International Committee which considered how his ideas might best be carried out.

Harrison occasionally contributed articles under the pseudonym 'Talbot Archer' and it was the radical Talbot Archer that feared the RPS 'is in too fossilised a state to furnish the men, the energy, and the funds that are needed to inaugurate this great movement.' In 1893 Harrison resigned from the BPS and WPS and retired from mainstream photographic life, after his identity was revealed following the RPS's rejection of a National Survey. The National Photographic Record Association (NPRA) was formally established in September 1897 when Stone was elected as its first, and only president.

Harrison was involved in contributing to the first Geological Photographic Survey of Great Britain and the National Collection of Geological Photographs, initiated by the British Association for the Advancement of Science in 1899, contains hundreds of examples of his work.

There was no lack of support for record and survey photography at a local level and picking up on these trends in 1906 Harrison presented a paper on 'The desirability of Promoting County Photographic Surveys' at the Annual Meeting of the British Association of the Advancement of Science. This paper, which may be seen as one of the definitive texts on Survey Photography, traced the evolution of the movement and acknowledged the work done by the NPRA. Harrison declared the 'three great objects' of Surveys were to benefit 'the individual photographer, the Scientific and Photographic Societies and the nation generally' maintaining that survey work was 'a liberal education for any man' for it was impossible to 'photograph without learning much about the objects photographed.' He appended an encyclopaedic set of 'Suggestions and Memoranda' and proposed the establishment of a Committee to collect, disseminate and coordinate the work of these surveys. Both he and Stone were subsequently nominated as members of a provisional committee, but Harrison never lived to see the fruits of its labours.

MICHAEL HALLETT AND PETER JAMES

Biography

William Jerome Harrison was born at Hemsworth, Yorkshire on the 16th March 1845 and died in Birmingham on the 6th June 1908. While still a child he accompanied his parents to Australia in the hope of improving his father's health, to no avail as his father died shortly after the family's arrival. On his return to England Harrison was educated for seven years at the Westminster Training College and afterwards for two years at Cheltenham College. A brilliant pupil, he graduated as Senior Prizeman and holder of the highest obtainable Government Certificate. He was appointed as Headmaster of a large boys' school in Leicester in 1870. His scientific education may be said to have commenced in 1868 when he began to study for the examinations of the Science and Art department. Within the next ten years he carried off the highest distinctions in chemistry, physics, geology and physical geography, being a gold medallist in the last two subjects in 1872. During these years he spent much time in the laboratories of the Government Science Schools at South Kensington. In 1872 he was appointed Chief Curator of the Leicester Municipal Museum where he established very large and successful science classes. He was elected a Fellow of the Geological Society (FGS) in 1876. In 1880 he was appointed Science Demonstrator to the Birmingham School Board. With a large staff of assistants, well appointed laboratories and a Technical School, he directed the scientific studies of about six thousand elder children and some hundreds of younger teachers. For continuing work in geology he received the Darwin Medal in 1884. Harrison became a widely read journalist, contributing articles on a broad range of subjects to respected publications.

HARROLD, SERGEANT JOHN (ACTIVE 1860s–1890s)

A member of the Royal Engineers, Harrold was in charge of the photographic section (10th Company), during the Abyssinian Campaign of 1867–68, in which British forces invaded Ethiopia to free European hostages taken prisoner by King Theodore. The resulting photographs represent the first occasion in which the work of the Royal Engineers' photographic school was put into practice in the course of a military campaign. This documentary record of the progress of the campaign produced a series of some 60 images, from which albums were later produced, and for which Harrold received the commendation from the *The Photographic Journal* (May 16, 1868) as 'the right man in the right place, as combining within himself the qualities of a skilful photographer and the power of accommodating himself to any circumstances.' These 'pictorial views,' however, were considered of lesser importance from a military point of view than the more than 15,000 prints of maps produced during the campaign by Harrold and his five assistants. Harrold's subsequent career was spent in India. In 1873 he joined the Survey of India in Calcutta as a photographer and in the following year assisted James Waterhouse in the taking of a series of 100 photographs at Roorki of the Transit of Venus. He remained with the survey department until his retirement in 1898.

JOHN FALCONER

HARTMANN, SADAKICHI (1867–1944)

Critic, poet, and lecturer

As a perceptive observer, and talented writer and critic, Sadakichi Hartmann contributed much to an emerging Modernism in the United States at the end of the nineteenth century and early twentieth century. In particular, Hartmann played an important role in the history of photography.

Carl Sadakichi Hartmann was born on the island of Deshima in Nagasaki Harbor, Japan in 1867 to a Japanese woman, Osada, and a German government official, Carl Herman Oscar Hartmann. His mother died several months later.

Motherless, Sadakichi and his brother Tanu were sent to be raised by his paternal grandmother and uncle in the upper middle class society of Hamburg, Germany. At age fifteen young Sadakichi was sent off to the naval academy, but quickly ran away, and was subsequently sent to live with relatives in the United States in Philadelphia.

Two years later Hartmann left his puritanical relatives, and obtained work at a lithographer's shop designing tombstones, while reading avidly at the Mercantile Library in Philadelphia in his free time. By 1884 Hartmann was devoting full time to his studies supported by an allowance from his grandmother.

In that same year, Hartmann met Walt Whitman, who was to become a major influence on Hartmann's writing. The older poet and sensitive young man initially admired each other. Whitman saw Hartmann's mixed heritage and experience in Europe as an advantage in presenting new perspectives on American culture. Hartmann recorded his visits with Walt Whitman in a small book, *Conversations with Walt Whitman"* (1895).

Following eight months of apprenticeship at the Royal Theater in Munich, Germany, in 1885 and visits to various German artists' studios, Harmann returned to the United States once again. By the late 1880s he began writing art criticism in Boston. Continuing to travel abroad, his articles from Europe were published in Boston papers.

In Boston, Hartmann attempted to produce an Ibsen play, which failed, sending Hartmann to New York, spending several unsuccessful years there during which he became increasingly depressed. In 1889 he wrote his controversial erotic play, *Christ*, which was burned in Boston when copies were distributed. The young author spent Christmas of 1893 in the Boston Charles Street jail for having published obscene literature.

In 1891 he attempted suicide. His hospital nurse, Elizabeth Blanche Walsh, was to become his wife.

Recovering enough to write again, Hartmann met S.S. McClure, who sent him to Paris on assignment for the McClure Syndicate. There Hartmann met the Symbolist poet, Stéphane Mallarmé, and other Symbolists. Hartmann's own writing was to become informed by the Symbolist aesthetic with its poetic capacity to suggest another reality, a world that prized dreams, mystery, intuition, and innuendo.

In 1893 Hartmann launched his own magazine the *Art Critic* visiting over seven hundred and fifty studios in New York, Boston, and Philadelphia to get subscriptions. But the magazine failed after three issues. By the late

1890s Hartmann was trying his hand at various types of journalism, from sketches of New York life ranging from studies of the poor to the upper class for the *New York Staats-Zeitung* to articles on pictorial photography for *The Critierion*; to critiques of dance performances.

Hartmann himself was an avid dancer, and had skills as a visual artist. He painted and did pastel work as an amateur much of his life. Exhibitions of his work were held in 1894, and in 1900 at the Allen Gallery.

Hartmann met Alfred Stieglitz in 1898, a meeting that was to become important for both men's lives—Stieglitz recognized Hartmann's writing talents and hired him to write for his publication "*Camera Notes*" and subsequently for the well-known *Camera Work*.

Hartmann's articles for Stieglitz's publications helped elevate photography to the realm of fine art. Articulate, poetic, and direct, Hartmann's vision and voice were strong and persuasive. As example, Hartmann wrote in 1898, "Whenever I have spoke of the possibilities of photography becoming so independent and artistic that it can claim to be ranked as one of the expressions of pictorial art, the work of men like Robert De Machy, and Alfred Stieglitz has formed the basis and starting point for my speculations. Alfred Stieglitz is to me indisputably the foremost photographer of America…"

Or in 1902, Hartman wrote, "I had seen them depart on their great mission, those valiant Knights of Daguerre [Stieglitz, Keiley, Steichen, Coburn]. I had seen them depart on their perilous journey over the Allegheny Mountains to open the Secession Shrine in Pittsburgh…Imagine my ecstatic joy when I received a telegram…money enclosed. We cannot do without you…So I sharpened my pencil, took my dress-suit out of pawn, bade farewell to my wife and offspring, and set forth on my nocturnal pilgrimage." (Above quotations from Sadakichi Hartmann, *The Valiant Knights of Daguerre,* Harry Lawton and George Knox eds., Berkeley: University of California Press, 1978, 159, frontispiece.)

Hartmanns profles of various photographic pioneers such as Stieglitz, Edward Steichen, Clarence White, Gertrude Käsebier, F. Holland Day, Frank Eugene, etc., helped bring the new work of these photographers to the public eye.

By 1901, Hartmann had published his *Shakespeare in Art*, his first book in art, and in 1902 he published the first *History of American Art* (Boston: L.C. Page & Co.), as well as a portfolio edition of *Modern American Sculpture*. The *History* was used for many years as a standard textbook, and revised in 1938. In 1903 he published a book on *Japanese Art.* Two other books, *The Whistler Book* and *Landscape and Figure a Composition* were published in 1910.

Hartmann's critical writings tended to be less analytic, more poetic, than much criticism, often becoming works of art in themselves in response to the beauty of a visual art piece. As he noted in his prose poem, *White Chrysanthemums*,"'…to learn to look at pictures…we look at the flush of the evening sky, at a passing cloud, at the vision of a beautiful woman, or at a white chrysanthemum" (*Camera Work,* No. 5, January 1904, 119–120).

In 1902 Hartmann also began using the pen-name of "Sydney Allan" for a number of articles. From 1904 to approximately 1907–08, Stieglitz and Hartmann become distanced from one another and Hartmann wrote primarily about the Salon Club photographers rather than Stieglitz and the Photo-Secessionists. In that interim period Hartmann also lectured to the National Center of Photographers and began a lecture tour throughout the United States, these tours lasting until 1910.

In 1906 Hartmann was also commissioned to assist John Beatty, Director of the Carnegie Institute, to acquire American Drawings.

Hartmann's health began to deteriorate by 1911, and he decided to leave New York City and the art world, moving to East Aurora, New York, where he met Lillian Bonham, whom he subsequently moved west with, while continuing to give lectures and write for numerous American photography journals from 1912–1918.

Moving to Los Angeles in 1923, Hartmann tried to cultivate the "Hollywood Scene." For a number of years he was the Hollywood columnist for the London publication, *"The Curtain."* He even appeared in a small part as the court magician in Douglas Fairbanks' *The Thief of Baghdad.* In general, though, Hartmann's years in Hollywood were the beginning of a slow slide into obscurity, even though he was often at parties with W.C. Fields, John Barrymore, and a literary group that gathered at Margery Winter's home, all liking to hear and see Hartmann's sharp wit, recitations, and dance routines.

In the last years of his life, beginning in 1938, Hartmann retreated from Hollywood, and built a shack in the California desert near the home of his daughter Wistaria Linton, on the Morongo Indian Reservation in Banning, California. There he sporadically wrote and painted pastels, and corresponded with other writers such as Ezra Pound and George Santayana.

World War II brought nightmarish treatment to Hartmann as the FBI interrogated him due to his Japanese-German background, and threatened to intern him. Many of Hartmann's friends, questioned by the FBI as well, stopped seeing or calling him. The harassment never completely ended. On November 21, 1944, Hartmann died at the home of his eldest daughter, Atma, in St. Petersburg, Florida, where he had gone to gather material for an unfinished autobiography.

Hartmann's contribution to American culture and the history of photography was unique, given his Japanese-

German heritage. His poetic insight and sense of purpose were significant in examining the rise of American Modernism and in helping transport photography to the realm of Fine Art.

KATHERINE HOFFMAN

Biography

Carl Sadakichi Hartmann was born in 1867 in Japan to a Japanese woman, Osada, and Carl Herman Oscar Hartmann, a German government and business official. Since his mother died a few months later, the young Hartmann was sent to Hamburg, Germany, with his brother Tanu, to be raised by his paternal grandmother and uncle. He came to the United States in 1882. In 1884 he met Walt Whitman, and in 1898 he met Alfred Stieglitz, two major influences on his life and work. Writing also under the name of Sydney Allen, beginning in 1902, Hartmann was prolific as a critic, poet, and dramatist. Many of his signficiant pieces appeared in Stieglitz's *Camera Notes* and *Camera Work.* In 1902 his well known two volume, *A History of American Art* was published. In 1923 Hartmann moved to Los Angeles and attempted to become part of the Hollywood crowd. In 1938-1939 he built himself a small place near his daughter, Wistaria, in the California desert. He died on November 21, 1944, on a visit to his eldest daughter, Atma, in St. Petersburg, Florida.

HAUTMANN, ANTON (1821–1862)

Painter, sculpter, photographer, and studio owner

Anton Hautmann was born into a Bavarian dynasty of sculptors and painters and trained in Munich before travelling to Italy to complete his education as a sculptor. He settled in Florence in 1849 and established a modest reputation as a sculptor of classical subjects and portrait busts. A decade later, in 1858 or shortly before, he opened a photographic studio specialising in portraits and stereographic views. Hautmann's photographic career was brief, for he died four years later. In the short period that he practised photography Hautmann made more than a hundred stereographic views of Florence and its environs. These portray the city as it appeared in the last months of the Grand Duchy and in the months following the plebiscite of 1861. Most of Hautmann's photographs focus upon subjects identified by Baedeker and by John Murray in his *Handbook for Travellers in Northern Italy* as "*most* worthy of the traveller's attention." Many of Hautmann's photographs teem with activity, recording the bustling, untidy character of daily life in Florence ca 1860; this distinguishes them from the formal, large-format plates produced contemporaneously by the Fratelli Alinari and other major commercial firms.

GRAHAM SMITH

HAWAII

Shipping routes in the north Pacific were established in the 19th century by whaling ships, imperial interests, and the development of trade. Photography followed these oceanic paths to port towns in the Hawaiian Islands. The first successful daguerreotype portraits were made by an itinerant daguerreian from Peru in the winter of 1846–1847. Fernando LeBleu (known in Hawaii as Senor Lebleu), a laundryman and some time daguerreotypist from Lima, arrived in Honolulu in December 1846. He charged residents, eager to have their portraits made, twice as much as the going rate in Lima. Local newspapers reported that LeBleu was the cause of a "daguerreotype mania" that swept through the community.

The Hawaiian Islands (annexed by United States in 1898) are 2500 miles west of California. In 1849, gold brought the frontier of the United States to California

and to the shore of the Hawaiian Islands. By 1850, many men who had gone to California to seek their fortunes, disappointed they turned to other opportunities to earn their living, including apprenticeships in San Francisco daguerreotype studios. Adventurous young men were also drawn across the Pacific by the discovery of gold in Australia in 1851. The more pragmatic adventurers made the voyage with equipment, and a stock of supplies to make daguerreotypes.

Hugo Stangenwald (1829–1899) and Stephen Goodfellow were on their way to Australia when they stopped in the town of Hilo in 1853. They unloaded their daguerreotype equipment and made portraits of American missionary families stationed in Hilo. Receiving recommendations as talented artists and sober minded gentlemen, Stangenwald elected to remain and operated a studio in Honolulu from 1853–1858. Goodfellow continued on to Australia.

In the 19th century photographic studios were primarily located in Honolulu. Photographers traveled to the other islands in the Hawaiian Island chain and set up temporary studios to make portraits and scenic views. Throughout the 19th century, photographers continued to migrate from California to establish studios in the islands. Charles Leander Weed (1824–1903), a well-known California photographer, arrived from San Francisco in March 1865. He set up a studio in Honolulu with his brothers and began making portraits. Like many newly established photographers, he knew it was good business to attract the Hawaiian royal family as clientele. His large studio portraits (17 × 22 inches) of King Kamehameha V and other chiefs, attracted local residents to the Weed Brothers studio to sit for carte-de-visite portraits.

Before coming to the islands, Weed had made mammoth views with wet-collodion plates of Yosemite Valley, California. He was the first experienced landscape photographer to practice in the islands. He traveled around Oahu and to the island of Maui with his mammoth camera and a stereo camera. His photographs document the absorption of traditional Hawaiian communities by the development of sugar plantations. Weed focused on the newly built sugar mills, with tall smoke stacks that dominated the island landscape, pushing aside native houses made from *pili* grass, and taking over traditional taro cultivation. He found it too difficult to photograph the island landscape. Heat, humidity and dust added to the existing challenges of preparing wet-collodion plates. He departed for Hong Kong in December 1865.

Island photographers imported supplies and recruited photographers from the better known San Francisco galleries. James J. Williams (1853–1926), founder of the longest established family photo business in Honolulu, arrived from Sydney in 1880. He had passed through the islands in 1879 from San Francisco where he worked for photographers I.W. Taber and Jacob Shew. In Honolulu, he worked in the studio of Menzies Dickson (ca. 1840–1891), buying this business in 1882.

Williams not only had a thriving portrait business, he was also actively involved in promoting the islands through a variety of publications and exhibitions. Visitor promotion provided a larger market for his images. He prepared photo displays and albums for expositions and displays in hotels, steamship and railway stations throughout the American west and in Australia. He published *Tourists' Guide* (1882), and in 1888 he established a monthly magazine, *Paradise of the Pacific*. Williams felt strongly that visitors "want to… view something of the native life [with]… a cocoanut tree somewhere in the landscape."

Eighty-six photographers operated Honolulu studios in the 19th century. Most of these studios were owned by American citizens. Horace Crabbe and John Meek, Jr. were the only Native Hawaiians to operate a photo studio (1867–1869). In the 1890s, there was an increase in the number of photo studios operated by Japanese and Chinese residents, reflecting the changes in the island population due to imported labor for sugar plantations. Japanese photographers would often apprentice in a Honolulu studio and then establish studios near rural communities with large sugar plantations.

European and American government interests, dominating global trade routes, led to sponsored scientific expeditions to chart navigational routes and document Pacific island countries. Germany, Britain and the United States maintained a regular circuit of touring naval ships to support their interests in the north Pacific. In 1874–1875 two British scientific expeditions that visited the islands were accompanied by photographers. Edwin Myers and astronomer J.W. Nichols spent three months in the islands making observations and photographing the transit of Venus in December 1874. Although their photographs of the transit were not successful Myers made some of the earliest known photographs of hula performers. Due to the influence of the American missionaries, hula was seldom performed publicly. Princess Ruth Keeliokalani, a high ranking chief, brought the hula group to honor the visiting scientists. The following year in July 1875, the British oceanographic survey ship, *Challenger*, arrived in Honolulu from Japan. An official photographer was part of the crew, and special dry-collodion plates were prepared in London for the voyage.

For Native Hawaiians, making fun at the expense of foreigners' ignorance and arrogance was at times difficult to resist. When another group of British scientists came through the Hawaiian Islands in 1882 on their return from observing the transit of Venus in the north Pacific, they went sightseeing in Hilo: "We found a party of ladies at the top of the cliff dressed in Hawai-

ian costume, and one of our party asked permission to photograph them as they made a picturesque group. They replied in the native language, and as it was supposed they could not speak English we were rather free with our remarks." Upon returning to Hilo they met the King, Kalakaua, who had just arrived from Honolulu. Having heard of their photographic outing, he asked for a copy of the picture as his sister-in-law was part of the group. "To our horror we learnt that these ladies had understood our conversation."

Images of the islands increased with the availability of commercially prepared dry plate negatives. The local amateur photography society, the Hawaiian Camera Club (1889–1893), was open to photographers throughout the islands, as well as to visitors. Danish sugar mill engineer, Christian J. Hedemann (1852–1932), was instrumental in founding the organization. A photograph of the club members, made with the aid of magnesium flash, was taken in 1889 with the assistance of a British naval officer, Lieutenant Pears. Pears also photographed a musical gathering with Robert Louis Stevenson, his family and friends at Waikiki.

The reigning monarch, Liliuokalani, was overthrown by American business interests in 1893 and an interim government was established. The U.S. annexed the Hawaiian Islands in1898. Earlier that year, U.S. military recruits came through Honolulu on their way to fight the Spanish-American war in the Philippines. The military build up in the islands provided a significant market for picture postcards. Images of Hawaiian women posed as "scantily dressed hula girls," and men casting fishing nets became a commodity in expanding the islands' tourist economy.

HAWARDEN, VISCOUNTESS CLEMENTINA ELPHINSTONE (1822–1865)

British photographer

Viscountess Clementina Elphinstone Hawarden (nee Fleeming) was born at Cumbernauld, her family's estate near Glasgow, Scotland on June 1, 1822. Her father Charles Elphinstone Fleeming was an Admiral in the Royal British Navy who met and married Hawarden's mother Catalina Paulina Alessandro, originally of Cádiz, Spain, while stationed in Spain and Portugal in 1816. Her mother's Spanish, Roman Catholic identity has caused some scholars to forge links between the photographer's work and that of religiously themed Spanish Old Master paintings.

Educated at home with her sisters, Hawarden studied the primarily "feminine" subjects of languages, music, the visual arts, needlework and literature until the fall of 1841, when she and her mother and sisters, in the company of her uncle Mountstuart Elphinstone, traveled to Rome after Admiral Fleeming's death. Before settling in Rome, the party sojourned in Florence, where Hawarden was particularly taken with the Renaissance painting collections at the Pitti Palace. Little is known of her daily excursions in Rome, but it is likely that she visited the major art and architectural attractions and experienced the lively masquerading of the carnival season while in residence. This respite in Italy perhaps colored Hawarden's later photographic choices. Careful study of Renaissance painting compositions and the theatricality of carnival may have inspired the harmonious figural relationships and creative role playing characteristic of her mature work.

The Fleemings moved to London in 1842, where Hawarden married Cornwallis Maude in 1845, much to the displeasure of the Hawarden family who were aristocratic Protestant landlords in Ireland and believed their son to be marrying below his social rank. The couple lived in upper-class circumstances in London for the first twelve years of their marriage, during which time Hawarden was often pregnant. She gave birth to ten children, many of them her future photographic models, in her lifetime and was survived by eight of them, seven daughters and one son.

Hawarden, Lady Clementia.
Photographic Study.

Life changed dramatically for the family after the death of Maude's father in 1856, at which time he inherited the large family estate Dundrum in County Tipperary, Ireland and ascended to the rank of 4th Viscount Hawarden. Now secure in the ranks of the Britain's wealthiest landowners, the family moved to Dundrum in 1857 where the time, money and space afforded by their new position in society relieved Hawarden from many of her domestic duties and allowed her to begin taking photographs.

Hawarden's earliest photographs were landscape views of the grounds at Dundrum, portraits of the estate's laborers and costume pieces of family members posed as laborers taken with a stereoscopic camera. For the most part, these early pieces are artistically derivative and were not exhibited during her lifetime, yet they demonstrate Hawarden's knowledge of both art history and modes of art photography. The depictions of laborers at Dundrum, posing with their gardening and farm implements recall earthy Dutch baroque genre paintings and the costume pieces that artificially echo these more naturalistic photographs are reminiscent of Thomas Gainsborough's eighteenth-century fancy pictures as well as contemporary Henry Peach Robinson's ambitiously contrived narrative tableaux. From the beginning, then, Hawarden positioned herself within the second generation of amateur art photographers including such figures as Lewis Carroll (Charles Lutwidge Dodgson) and Julia Margaret Cameron.

In 1859 the family took up residence at 5 Princes Garden in the South Kensington section of London. It is in this house that Hawarden spent the remainder of her short life and developed her mature photographic style, converting the second floor of the house, with

its distinctive architectural details and grey wallpaper with gold stars, into a suite of photographic studios and using her children as models. Isabella Grace, Clementina and Florence Elizabeth appear most frequently in Hawarden's "Photographic Studies" and "Studies from Life," which she produced between 1859 and 1864 and exhibited at the Photographic Society of London beginning in 1863. It may have been one of these daughters, or Hawarden herself, who painstakingly pasted almost 800 of these photographs into the albums from which they were torn when bequeathed to the Victoria and Albert Museum by a member of the family in 1939, accounting for their irregular shapes, curled edges and scarred surfaces. Although the Victoria and Albert Museum is the primary repository for Hawarden's photographs, the National Museum of Photography, Film and Television, the J. Paul Getty Museum, and the Musee d'Orsay in Paris also own pieces.

Despite their physical state, which has been greatly ameliorated by conservation efforts, the romantic photographs made at 5 Princes Gate maintain their aesthetic and psychological power due to their well-balanced compositions, suggestive coming of age narratives and imaginative variations on a single theme. In the "Studies from Life," Hawarden's daughters are depicted in a variety of repeated tableaux often dressed in costume, interacting with such evocative props as mirrors and orientalist cabinets and playing theatricalized feminine roles. The figures are often pushed into corners and draped over one another creating a close, claustrophobic and intimate atmosphere that offers the viewer a rare glimpse into the inner lives of upper class Victorian girls and women confined to the domestic sphere by their gender and class.

Hawarden exhibited a selection of "Studies from Life" at the Photographic Society of London in 1863, where she was awarded a silver medal for the best contribution by an amateur and was elected to be a member of the society, with Oscar Rejlander perhaps serving as her sponsor, the same year. She showed her work at this venue again in 1864 and won another silver medal for composition. The only arena in which she sold her work was for charity at the Grand Fete and Bazaar. . . in Aid of the Building Fund of the Female School of Art which was held between June 23 and 25, 1864. Lewis Carroll bought five of Hawarden's photographs at this time.

Hawarden died suddenly of pneumonia early in 1865 and was eulogized by Rejlander in the *British Journal of Photography*, who believed that in her work "she aimed at elegant and, if possible, idealized truth." Her work was shown posthumously at the Dublin International Exhibition in 1865 and not only influenced such contemporaries as Lewis Carroll, but such celebrated contemporary photographers as Sally Mann.

KIMBERLY RHODES

Biography

Viscountess Clementina Elphinstone Hawarden (nee Fleeming) was born at Cumbernauld, her family's estate near Glasgow, Scotland on June 1, 1822. Her father Charles Elphinstone Fleeming was an Admiral in the Royal British Navy who married Hawarden's mother Catalina Paulina Alessandro, originally of Cádiz, Spain in 1816. After Admiral Fleeming's death in 1841 the family traveled to Italy and in 1842 settled in London. Hawarden married Cornwallis Maude, later 4th Viscount Hawarden, in 1845 and had ten children with him. Her photographic career began in 1857 at the Hawarden's Irish estate and continued until her untimely death in London in 1865. Her work was shown and won awards in 1863 and 1864 at the Photographic Society of London and exhibited posthumously at the 1865 Dublin International Exhibition.

HAYNES, FRANK JAY (1853–1921)

American photographer

Frank Jay Haynes was born on October 28, 1853 in Saline, Michigan. He learned photography between 1874–1876 from two Wisconsin photographers, S.C. Graham (Beaver Dam) and "Doctor" William H. Lockwood (Ripon). Haynes was a prolific, visionary photographer who documented the settlement of the American West by railroad development and displacement of the Native population. He photographed over vast distances as the Northern Pacific Railroad's (NPRR) photographer (1876–1905), traveling as far as Alaska

in 1891 to help boost its fledgling tourist industry. In 1881 the Canadian Pacific Railway Company hired him to photograph construction of its line. While still engaged as the NPRR's photographer, he also obtained a photographic concession in Yellowstone National Park (1884–1916). Between 1885–1905 Haynes had the use of a special Pullman Palace Car, equipped as a mobile photo studio. His wife, Lily V. Snyder (m. 1878), managed the darkroom and business in Fargo, North Dakota, between 1879–1889. Haynes relocated from Fargo in 1889 to St. Paul, Minnesota, where he remained until his death on March 10, 1921. Haynes worked in both stereograph and single-lens formats up to at least 8 × 10 inch glass negatives. His negatives, business and personal records are jointly preserved by the Montana Historical Society and Montana State University.

David Mattison

HEADINGLEY, ADOLPHE SMITH (1846–1924)

English photographer

The bringing together of the photographer John Thomson and the left-wing political writer and activist Adolphe Smith Headingley to work on the project which resulted in *Street Life in London* (1877–78), was a logical progression from the collaboration between Richard Beard and Henry Mayhew more than two decades earlier on Mayhew's study of *London Labour and the London Poor.*

Headingley, who wrote under the name of Adolphe Smith, was relatively unknown when he and Thomson collaborated on *Street Life* and the pairing was an inspired one. Both men had sympathy towards the living and working conditions of their subjects. Smith wrote twenty-four of the essays, to Thomson's twelve, and his texts are generally more socially contextualised and fact-filled than Thomson's.

Smith would later make a name for himself as a political writer with an evangelical reforming zeal. To Smith is also credited the marrying of the words of Irish journalist Jim Connell's 1889 song *The Red Flag*, official anthem of the British Labour Party, with the traditional tune *Tannenbaum*, or *Maryland* instead of *The White Cockade*, the old Jacobite tune to which Connell had originally set the words.

From 1886 until 1905, he served as an interpreter at successive International Trades Union Congresses.

John Hannavy

HEID, HERMANN (1834–1891)

Austrian photographer, manufacturer, and publisher

Hermann Heid was born on 17 December 1834 in Darmstadt (Germany, at that time the residence of the Grand Duchy of Hessen darmstadt). He was a chemist and had already attained a doctorate when he started his career in photography, which led to the creation of the private technical school of Julius Schnauss I in Jena by 1855, then in 1861 to the studios of Emil of the Rabending in Vienna. Consequently he developed into one of the most versatile photographers in Austria. In 1864 at the first exhibition of the photographic society in Vienna, he still predominantly showed as a coworker of Rabending Portraets. However, from today's view his architectural and industrial photographs (plants of the Semmeringbahn, quarries of the Viennese building firm, Danube bridges, large-scale building sites of the Viennese struggle race) are impressive. Heid published the majority of its photographs in his own publishing house. Its painter studies appeared successfully also, with Adolphe Giraudon in Paris (frequently wrongly attributed at Louis Igout). Since the mid-1860s owner of studios in Vienna and Budapest, in 1875 he entered additionally into the production of photographic materials, first the production of collodio-wool (starting from 1875), then from gel drying plates (starting from 1880).

Maren Groening

Biography

Hermann Heid was born on 17 December 1834 in Darmstadt (Germany). He studied chemistry in Gießen and Heidelberg. After graduation he studied photography at the technical school of Julius Schnauss in Jena, then moved to Austria and worked in Vienna as a technical manager with Emil Rabending. A few years later he created a company, which opened an additional local branch in Pest (today a quarter of Budapest) around 1865/1866 with Ferdinand Ronninger. Their line was taken over in 1867 by Gyoergy Kloesz, previously coworker of the Viennese of principal firm. The enterprise had traded since 1874 under "Dr. Heid, photographic-artistic institute." Since 1875 Heid had in addition his own production of collodio-wool, and since 1880 of gel drying plates. In 1861 he was among the first members of the photographic society, and in 1882 promoted the establishment of the association of photographic coworkers to Vienna. Heid took part in many larger national and international exhibitions (1864, 1875, 1881 exhibitions of the photographic society in Vienna; 1865–7. Exhibition of the Société française de photography; 1868 exhibition Hamburg photographic association; 1871 opening exhibition in the new building of the Austrian museum for art and industry; 1873 Viennese world exhibition; 1878 Paris world exhibition; 1891 international exhibition of artistic photographs in the Austrian museum for art and industry).

Collections that possess copies of his photography include: in Vienna, Vienna museum; Technical museum Vienna; Photo collection of the Albertina (continuous loans of the higher graphic federal bundes-Lehr and laboratory); Museum for applied art. In Berlin, University of the arts Berlin, university archives. In Budapest, Historical photo archives of the Hungarian national museum. In Paris, Bibliothèque national de France, Estampes.

HELIOGRAVURE

Name given by Nicéphore Niépce (1765–1833), in France, to the first photomechanical process by which reproductions of drawings and engravings could be made. Beginning in 1822, he succeeded in making copies of images by contact printing documents on thin layers of asphalt coated on glass, stone and later on copper and pewter.

In 1822, Niépce made a successful reproduction—a portrait of Pope Pius VII—on glass. No acid etching was used at the time. The following year he experimented on stone, with the help of a lithographer in Dijon. In 1825 he succeeded in exposing and engraving a copper plate. This was the forerunner of photogravure as we know it today.

Niépce has long been recognized as the inventor of the first photographic process capable of producing a permanent photographic image. His oldest extant *camera made* photograph was made in the summer of 1827 (Marignier, 1999) and is now in the Harry Ransom Center at the University of Texas, U.S.A. This photograph, however, is not the oldest extant *photographically produced* image.

Some years ago the well-known Paris collector and historian André Jammes had the opportunity to acquire an unassuming reproduction of a 17th century Flemish print together with an extensive series of autograph manuscript letters by Joseph Nicéphore Niépce and his son Isidore (1795–1868). The correspondence included a detailed description of the processes with which Niépce eventually achieved his historic discovery. The date of this heliogravure was 1825. On March 21st, 2002, this photomechanical reproduction was sold to an anonymous telephone bidder at a Sotheby's auction in Paris for nearly half a million euros. The price was relatively low because the French government had made it clear that the print was considered a National Treasure and would never be allowed to leave France. After the sale the French National Library used its right of preemption and acquired the print for the cost of the highest bid.

The term *heliogravure* referred originally to the *asphalt* or *bitumen* process. For a brief period after 1839 several experimenters tried to obtain printing plates from etched daguerreotypes but this never proved viable. Niepce de Saint-Victor (1805–1870), the cousin of Nicéphone Niépce, resumed the latter's experiments in 1853 but could only succeed in reproducing line illustrations. Many years later, in 1883, he presented to the public heliogravures with a full scale of tones, made from photographic negatives and printed on steel plates with the help of an intaglio press.

The secret to reproducing the tonal elements came from the old aquatint etching process invented in the

1760s by J.B. Le Prince (1734–1784). With this printmaking process a full scale of tone is obtained by etching a multitude of extremely small pockmarks in a random manner on the printing plate. This is achieved by sprinkling the metal plate with resin particles in a specially designed dustbox. When the plate is heated the particles adhere to it and create minute areas of grain. The plate is then placed into an acid bath that eats into the exposed areas of metal. The design on the plate is developed and the gradations of tone are achieved by repeated bitings of the plate. In the first rebiting, all the areas intended to be in the lightest tone, are "stopped out" or covered with an acid resisting varnish, and the plate is again immersed in the acid bath. The process is repeated until a full scale of tone is obtained, the darkest tone being those that are etched the longest and deepest.

Niepce de Saint-Victor had documented the use of the aquatint grain in his *Traité Pratique de Gravure Héliographique* (Paris 1856, 44). The idea was also exploited by Paul Pretsch and Karl Klic, in their work on photogalvanography and photogravure, among others.

Among the most successful héliograveurs we must mention the work of Charles Nègre (1820–1880) who was considered by his contemporaries to be the first to obtain truly remarkable results with his version of the asphalt process. He used the process to produce intaglio steel plates for a monograph on Chartres' Cathedral, with which he won the highest rewards offered at the Exposition Universelle of 1855. Although Nègre used "officially" the bitumen process with an aquatint grain, he probably utilized dichromated gelatin as in the photogravure process for his later work. Nègre always worked alone and never accepted students, so his techniques were never fully understood. Nègre also experimented along the lines of Pretsch's photogalvanography process.

According to Louis-Philippe Clerc, Edouard Baldus (1813–1889), Garnier & Salmon and Charles Nègre used a variant of the aquatint technique where the printing plate was etched in multiple stages, a process used in some Paris printing plants up until the 1920s.

HELMHOLTZ, HERMANN LUDWIG FERDINAND VON (1821–1894)

German scientist

Hermann von Helmholtz was born on 31 August in Potsdam, Germany. His father, Ferdinand Julius Helmholtz, had served in the Prussian army fighting against Napoleon then, having a good university education, he taught philology and philosophy at Potsdam Gymnasium. It was a poorly paid job and Hermann, the eldest of four children, was brought up in financially difficult circumstances. Ferdinand was artistic and his influence meant that Hermann grew up having a passion for music and painting. Hermann's mother Caroline Helmholtz, the daughter of an artillery officer, was a calm person who also strongly influenced his character.

Hermann attended Potsdam Gymnasium where his father taught. He was interested in physics and would have liked to have studied that subject at university but the family's financial position meant that was only possible with a scholarship. Hermann's father persuaded him to study medicine which was supported with government scholarships. In 1838 Helmholtz entered the Royal Friedrich-Wilhelm Institute of Medicine and Surgery in Berlin. The scholarship he received had strings attached, however, committing him to ten years as a doctor in the Prussian army after graduating. During the medical course he also attended courses in chemis-

try and physiology at the University of Berlin and read many mathematics and philosophy books. His began work on his dissertation in 1841. He rejected the direction which physiology had been taking, based on vital forces which were not physical in nature, and argued for founding physiology completely on the principles of physics and chemistry.

After graduated from the Medical Institute in 1843 Helmholtz was assigned to a military regiment at Potsdam, but spent all his spare time doing research. He still concentrated on showing that muscle force was derived from chemical and physical principles. In 1847 he published his ideas in an important paper *Über die Erhaltung der Kraft* arguing in favour of the conservation of energy with both philosophical and physical arguments. That philosophical arguments came right up front in this work was typical of all of Helmholtz's contributions. He argued that physical scientists had to conduct experiments to find general laws. The paper is an important contribution and it played a large role in Helmholtz's career for the following year he was released from his obligation to serve as an army doctor so that he could accept the vacant chair of physiology at Königsberg. He married Olga von Velten on 26 August 1849 and settled down to an academic career.

On one hand his career progressed rapidly in Königsberg. He published important work on physiological optics and physiological acoustics. He received great acclaim for his invention of the ophthalmoscope in 1851 and rapidly gained a strong international reputation. In 1852 he published important work on physiological optics with his theory of colour vision. However, experiments which he carried out at this time led him to reject Newton's theory of colour. The paper was rightly criticised by Grassmann and Maxwell. Helmholtz was always prepared to admit his mistakes and indeed he did just this three years later when he published new experimental results showing those of his 1852 paper to be incorrect. Helmholtz's theory of colour vision led to Maxwell projecting the first colour photograph.

A visit to Britain in 1853 saw him form an important friendship with William Thomson. However there were problems in Königsberg. Franz Neumann, the professor of physics, was involved in disputes concerning priority with Helmholtz. Also the cold weather in Königsberg had a bad effect on his wife's delicate health. He requested a move and, in 1855, was appointed to the vacant chair of anatomy and physiology in Bonn. In 1856 he published the first volume of his *Handbook of physiological optics*, then in 1858 he published an important paper in *Crelle's Journal* on the motion of a perfect fluid. However Helmholtz had become unhappy with his new position in Bonn. Part of the problem was that complaints had been made to the Minister of Education that his lectures on anatomy were incompetent. Helmholtz reacted strongly to these criticisms which, he felt, were made by traditionalists who did not understand his new mechanical approach to the subject. It was a somewhat strange position for Helmholtz to be in, for he had the reputation of a leading world scientist. Offered the chair in Heidelberg in 1857, he did not accept it at once however. When further sweeteners were put forward in 1858 to entice him to accept, such as the promise of setting up a new Physiology Institute, Helmholtz agreed.

Helmholtz suffered some personal problems. His father died in 1858, then at the end of 1859 his wife, whose health had never been good, died. He was left to bring up two young children and within eighteen months he married Anna von Mohl, the daughter of another professor at Heidelberg, on 16 May 1861. Some of his most important work was carried out while he held this post in Heidelberg. He studied mathematical physics and acoustics producing a major treatise in 1862 which looked at musical theory and the perception of sound. From around 1866 Helmholtz began to move away from physiology and towards physics. When the chair of physics in Berlin became vacant in 1870 he indicated his interest in the position but Kirchhoff was offered the post since he was considered a superior teacher to Helmholtz. However, when Kirchhoff decided not to accept, Helmholtz was in a strong position. He was able to negotiate a high salary as well as having Prussia agree to build a new physics institute under his control in Berlin. In 1871 he took up this post.

A major topic which occupied Helmholtz after his appointment to Berlin was electrodynamics. He discussed with Weber the compatibility of Weber's electrodynamics with the principle of the conservation of energy. In fact the argument was heated and lasted throughout the 1870s. It was an argument which neither really won and the 1880s saw Maxwell's theory accepted. During this period he taught Alfred Stieglitz, who was a major contributor to the history of photography, and Gabriel Lippmann who developed the theory of photographic reproduction of colour. Helmholtz died on 8 September 1894 in Berlin.

HENDERSON, ALEXANDER (1831–1913)

Canadian photographer

Alexander Henderson was born in 1831, possibly in Press Castle, near Edinburgh, Scotland. He started photographing as an amateur a few years after emigrating to Montreal, Quebec, in October 1855. Although he opened a portrait studio in Montreal in 1866 or 1867, Henderson's portrait work was not exceptional, and he abandoned portraiture to concentrate on landscape studies in stereo and large-format negatives. He excelled at exquisitely rendered landscapes, particularly winter scenes, which he also self-published beginning in 1865. Henderson received numerous exhibition awards in the 1860s and 1870s. Like his contemporary William Notman, he was widely known outside Canada. The Canadian Pacific Railway Company hired him around 1885 to document construction of its line through British Columbia, and by the early 1890s he was managing its photographic activities. Retired from photography in the late 1890s, Henderson died in Montreal on April 4, 1913. In the early 1950s his grandson disposed of the glass negatives, stored in the basement of his home, as garbage. Only several hundred individual prints and albums survive in the Notman Photographic Archives (McCord Museum, McGill University), the Library and Archives Canada, and other Canadian and British institutions. Henderson was one of four 19th-century Canadian photographers commemorated with a 1989 postage stamp.

David Mattison

HENNEMAN, NICOLAAS (1813–1898)

Dutch photographer in England, assistant to W.H. Fox Talbot

It is unlikely that Nicolaas Henneman would have become a photographer if he had remained in the Netherlands. Before entering the service of William Henry Fox Talbot (1800–1877) at the age of 26, he had shown little creative energy or obvious artistic talent. He did, however, possess an adventurous spirit that took him, via Paris, to England, where he first became Fox Talbot's servant. Fairly soon after, he became Fox Talbot's assistant in the latter's experiments with photography. Talbot taught Henneman to make photogenic drawings and later calotypes and salted paper prints. Henneman also accompanied Fox Talbot on his (photographic) travels through Germany (1842), France (1843) and Scotland (1844).

Fox Talbot showed great faith in Henneman's capacities. In 1844, he made him head of the photographic printing business in Reading that later scholars would call the Reading Establishment. It was one of Fox Talbot's first attempts at making the calotype a commercial success. The intention was for Henneman to produce large quantities of photographs that could be used as book illustration or sold separately. One of the most famous publications for which Henneman's Reading Establishment produced the photographic prints was Talbot's *Pencil of Nature*, which was published in six instalments with a total of 24 plates between 1844 and 1846. Talbot selected these photographs with immense care from his collection of negatives and provided each with accompanying texts that covered the technical, historical and aesthetic aspects of photography. While at Reading, Henneman also produced the prints for Talbot's homage to Sir Walter Scott, *Sun Pictures in Scotland*.

Henneman did not just work for Fox Talbot in Reading, however. John Walter, the editor of *The Times*, for instance, published a small book in 1844 in memory of his daughter Mary Catherine that included a photograph of a marble bust of her taken by Henneman. He also produced a photographic supplement for Sir William Stirling's *Annals of the Artists of Spain* in 1847 and made prints from the negatives of other photographers such as Calvert Richard Jones and George Bridges. Jones and Bridges mostly worked in countries around the Mediterranean and Henneman distributed their photographs to book and print dealers throughout England.

Henneman also toured Reading and its environs with his camera. His photographs give a good impression of what Reading looked like at the time. The printing establishment itself can be seen on two unique photographs from 1846. Taken in the back garden, they fit together to form a panorama. The left-hand photograph, probably taken by Henneman, shows Talbot taking a photograph and an assistant making a reproduction of an engraving. The right-hand photograph, probably taken by Talbot, shows Henneman standing behind the camera in front of a sculpture, with various assistants busy with two racks of the printing frames that were used for printing.

The printing establishment was not a financial success and Talbot decided to close it in 1847. The intended market—print collectors and photographers—turned out to be much too small. Moreover, buyers complained that the photographs faded too quickly.

In 1847, Henneman moved to London, opening a portrait studio on the upper floors of 122 Regent Street, above the instrument makers Newman & Co., which Talbot rented. In his letters to Talbot, Henneman had more than once pointed out that making portraits might prove to be a very lucrative business. While at Reading, Henneman had made portraits of local stationer George Lovejoy and of the author Mary Mitford and her dog Flush (collection of the National Media Museum).

In 1848, Henneman took over control of the studio together with the chemist Thomas Agostine Malone, whom he had met in Reading. While Henneman ran the

studio, Malone spent most of his time experimenting. Unfortunately, very few of the photographs taken by Henneman and Malone remain. The only portrait that can definitely be attributed to them by means of the stamp on the back is one of the painter William Henry Hunt (collection of the *Museum of the History of Science*). The fine pencil screen on the photograph may indicate that Hunt used it to make a self-portrait. It would have pleased Talbot that the photograph has not been retouched. He often complained at the way in which the miniaturists employed by Henneman and Malone ruined the photographs with their heavy retouching. Malone left the studio in 1851 to take up a teaching post at the Royal College of Chemistry, leaving Henneman to carry on alone, under the name of Henneman & Co.

Henneman and Malone took part in the Great Exhibition of 1851. With Talbot's help, Henneman almost landed a significant order from the Royal Commissioners to make the photographs for the jury reports. However, the Commissioners were so disappointed at the quality of the first photographs that Henneman made for them, especially considering the price, that they cancelled the deal. Talbot's intervention failed to prevent the order going to Hugh Owen, Claude-Marie Ferrier, Friedrich von Martens and Robert Bingham.

Henneman enjoyed greater success following the invention by Scott Archer of the wet collodion glass negative in 1851. In 1852, he was one of the first professional photographers to make negatives using this technique. And not without success: the portraits that Henneman made using this technique garnered considerable praise, including a report by Ernest Lacan in the French photography journal *La Lumière* (24 December 1853):

> Ce qui les distingue surtout, c'est une grande finesse de détails, qu'on les croirait obtenues sur ivoire ou sur glace ... Ce qu'il y a de certain, c'est qu'il sait donner à son modèle une expression naturelle, et qu'il éclaire de façon à produire un effet de relief saisissant. (Ernest Lacan, "Revue Photographique. Artistes Anglais. M. Henneman," in *La Lumière*, 3/52 (24 December 1853), 207–208)

The portrait of an old man in a cape, for example, is reminiscent of the portraits that the French photographer Nadar began to make around this time. Because of his grandeur, the man in the portrait was long thought to be the Hungarian freedom fighter Lajos Kosuth, who had previously posed for Henneman in 1851. Another photograph of the same man in profile, however, is labelled as being of a certain Signor Senture. In any case, the daguerreotypes that the American photographers Southworth & Hawes took of Kosuth a year later show an entirely different man.

1853 was a highly successful year for Henneman, with 833 portraits made. That year, a writer for Charles Dickens' magazine *Household Words* described Henneman's studio, in which he witnessed the photographer expertly preparing a glass negative. The English-based Swede Oscar Gustav Rejlander also found his way to 122 Regent Street when he was looking for a good photographer to teach him the art. According to Lacan's description, Henneman had a talent for putting his subjects at ease. As a result, his portraits never seem contrived. This is immediately apparent in his series of photographs of Zulus and earthmen that was exhibited in London in 1853. Despite the frightening situation in which they found themselves, Henneman was nevertheless able to make them adopt a fairly natural pose. A number of these photographs is now in the collection of the *Royal Archives* at Windsor.

After 1853, the number of professional photographers in London grew rapidly. Henneman proved unable to hold his own among competition that was extremely fierce and not always equally fair. In 1858, Talbot secretly paid off many of Henneman's debts. Their ways finally parted when Henneman left with his family for Birmingham to try his luck as an operator. As his last letter to Talbot in 1866 shows, it was not a success:

> I am here in a situation till July. I was obliged to take it as London is overwashed with photographers. They advertise themselves as first rate artists at 30 shilling a week. I do get four pounds here but I am sorry to say it does not suit my health. I am pretty well shut up for 8 hours in a room by stretching my arms out I can touch the walls both ways so I can't call it a room but a closet" (Letter of 30 March 1866, NMeM 1937-5439).

Not long after, Henneman began a second career, as a lodging house keeper in London.

Photographs by Nicolaas Henneman have been preserved in the collections of, among others, Lacock Abbey, the National Media Museum in Bradford, and the Rijksmuseum in Amsterdam.

Saskia Asser

Biography

Nicolaas Henneman was born in Heemskerk in the Netherlands on 8 December 1813. After various adventures he came to England in 1838, entering the service of William Henry Fox Talbot as valet and soon assisting him with his experiments with photography. When Talbot set up a photographic printing establishment in Reading in 1844, he appointed Henneman to run it. At the Reading Establishment, as it later came to be called, Henneman made photographic prints for various clients and publications, including Talbot's *Pencil of Nature* and *Sun Pictures of Scotland* and Sir William Stirling's *Annals of the Artists of Spain.* After the printing establishment was closed in 1847, Talbot helped Henneman set up a portrait studio at 122 Regent Street in London. Later that year, Henneman was appointed "Photographer in Ordinary to

Her Majesty." Until 1851, he worked together with the chemist Thomas Malone, continuing independently under the name of Henneman & Co. until 1858. During the 1860's, Henneman worked as an operator in the studios of photographers such as Napoleon Sarony and Robert White Thrupp in Birmingham. Henneman died on 18 January 1898 at 18 Half Moon Street, London, where he had run a lodging house since around 1872.

HENRY, PAUL (1848–1905) AND PROSPER (1849–1903)

The two brothers, Paul Pierre Henry (1848–1905) and Prosper Mathieu Henry (1849–1903), were born in Nancy a year apart. Paul Pierre was born on August 21, 1848 and his younger brother Prosper Mathieu on December 10, 1849. Coming from a modest family, little is known of their training other than that they completed their elementary studies within the framework of a catholic school. When they finished schooling, each 16 years old, they became employees of the Service Météorologique des Prévisions, which had been recently created at the Observatory of Paris. Quickly, they learned the skills of their astronomical vocation and were passionate about the construction of optics intended for telescopes. While they performed their daily tasks at the Observatory, they developed their research on optics in a workshop that they arranged in their house in Neuilly and later at Montrouge.

In 1871, Charles-Eugene Delaunay, then director of the Observatory, having learned of their work on optics, transferred them from the service of Meteorology to the department of Astronomy in order to continue unfinished work left by the death of the astronomer Jean Chacornac. From 1852, at the Paris Observatory, they were engaged in the production of astronomical charts which, it was hoped, would help in the search for asteroids and small comets. The establishment of such charts involved a genuine tour de force. The observer had to measure the positioning of each star and transfer it by drawing on sheets which were then engraved. In the areas close to the Milky Way, there are 18,000 stars in a portion of five degrees of the celestial vault. With such a concentration of stars, the limits of the ordinary processes of observations were quickly reached. In 1884, the idea came to Paul and Prosper to substitute observations by the naked eye with a method of photographic recording based on that of the American astronomer Pickering who obtained in 1882 a perfectly readable image of the nebula of Orion.

The first results achieved by the Henry brothers were surprising. On certain negatives, one could count 1500 stars that were invisible to the naked eye. The advantages that the delicate plate represented in the development of the celestial charts did not escape those in charge of the observatory for Paris, in particular its new director, the admiral Ernest Mouchez. The utility of the process was not in any doubt: " Using photography, one will be able, to obtain in one hour a Sky chart of the same quality as the ecliptic Chart, which would require several months of an assiduous work by the ordinary processes."

Other observatories considered at the same time the possibility of a photographic chart of the sky. In order to prevent all isolated approaches, Mouchez considered it necessary to found an international scientific collaboration. In 1886, he submitted the photographic chart of the sky for the approval of the Academy of Science, an international Congress. The following year, 15 directors of the selected observatories found themselves in Paris to agree on the methods of its execution. The inaugural speech that Mouchez gave summarized for them the posted ambitions of the project: "It will be a glorious and unforgettable date, as will be unforgettable in the history of Astronomy the imposing work which we want to bequeath to the future generation's work, one which will be able to define as the Inventory exact and as complete as possible of the perceptible universe in the end of the 19th century."

It was however necessary to await the meetings of 1889 and 1891 to reach an agreement among all the observatories. Eighteen of them ultimately held out, those of Greenwich, the Vatican, Catane, Helsingfors, Potsdam, of Oxford, of Paris, Bordeaux, Toulouse,

Algiers, of San Fernando, Tacubaya, of Santiago, of Plata, Rio de Janeiro, of the Cape, of Sydney and finally Melbourne. With these three congresses, several provisions were adopted. They agreed on certain points among which were the dimensions of the objectives, focal distances, sizes of the plates, the maximum size of stars to be recorded, the reproduction of stereotypes intended to fight against the accidental damage, their conservation, as well as the measuring apparatus allowing the examination *a posteriori*.

Despite everything, these provisions and the schedule of conditions of the recommendations discussed was interminable, obliging the majority of the observatories to defer the project. The exorbitant cost of the operation also slowed down the enthusiasm of some of them. On the eve before of the First World War, only the observatories of Paris, Toulouse, and Algiers had partly completed work. At the same time, other astronomical fields of research appeared, relegating the sky chart to the secondary row of concern. Three quarters of a century after its launching, at the General meeting of the International Astronomical Union held in Brighton in 1970, the project of photographic chart of the sky was definitively abandoned. In spite of this failure, never had the affirmation of an official and systematic use of photography been so strong.

The reputation of the Henry brothers, which is not due to any spectacular discovery as it is to scientific logic, finds legitimacy in the decisive part that they played in the establishment of this photographic chart of the Sky and more largely in the history of French astronomical photography.

On July 25, 1903, Prosper, younger of the two brothers, died in a climbing accident that occurred in the climbing station of Pralognan in Savoie. Two years later, January 4, 1905, Paul died in Montrouge on the outskirts of Paris.

HENSCHEL, ALBERT (1827–1882)
German-born, Brazilian photographer

Albert (Alberto) Henschel was born in Germany on June 13, 1827, to Helene Henschel and Moritz Henschel, a successful engraver based in Berlin. By the time Albert arrived in Recife, Pernambuco, Brazil, in 1866 together with business partner Karl Heinrich Gutzlaff, he was an experienced photographer. Henschel later opened studios in Bahia, Rio and São Paulo. Wilhelm (Guilherme) Gaensly worked as his assistant at the "Photographia Allemã" studio in Salvador, Bahia. In the early 1870s, Henschel formed a partnership with fellow German Francisco Benque and on December 7, 1874, Henschel & Benque became Photographers to the Imperial House in Rio. Henschel is best known for his cartes-de visite and landscapes taken in Rio de Janeiro Province. Noted for their respectful portrayals of their subjects, his portraits of African and Creole slaves and freedpersons belonged to a series of about 40 taken in Recife, Salvador and Rio. Henschel participated in several Brazilian exhibitions and won a medal of merit at the Vienna Universal Exhibition of 1873. He died in Rio on June 30, 1882. His works are housed at the Leibniz-Institut Für Länderkunde, Leipzig (Germany) and the Emanoel Araújo Collection, the Moreira Salles Institute and the Joaquim Nabuco Foundation (Brazil).

SABRINA GLEDHILL

HENTSCHEL, CARL (1864–1930)
English photographer

Carl Hentschel founded his firm of photo-engravers, designers, electrotypers and stereotypers in 1887 and there were premises in London, Manchester and Liverpool. The firm advertised that it was the largest firm of photo-engravers in the world.

Hentschel was born in Lodz, in Poland on 27th March, 1864 and emigrated to England with his parents at the age of five. He served his apprenticeship with his father and initially worked using the 'photo-on-wood' process.

Hentschel's reputation lies in his invention of the first photomechanical process block to bring about a revolution in half-tone newspaper illustration. However, Hentschel was also involved in book illustration such as the photomechanical reproduction of Aubrey Beardsley's compositions for Oscar Wilde's *Salome* (1894) and those he created of photo-micrographs for Lennox Browne's *Diphtheria and its associates* published in 1895.

Carl Hentschel Colortype Company formed in 1899 and exploited a three-colour printing process based on colour-separation onto monochromatic plates. Beatrix Potter's first book, *Peter Rabbit,* published in 1902, was, at the author's suggestion, printed using this process.

Hentschel was closely linked to the London theatrical world and was founder of the O.P. Club. The character

of William Harris in Jerome K. Jerome's *Three Men in a Boat* (1889) was based on Hentschel.

Hentschel died on Thursday 9th January, 1930.

ANTHONY J. HAMBER

HEPWORTH, THOMAS CRADOCK (1835–1905)

English lecturer and writer, specialist in the optical slide lantern

Fellow of the Chemical Society. Lectured at the Royal Polytechnic, London in the 1870s. Later, as an itinerant lantern lecturer, his subjects included "A Trap to Catch a Sunbeam" (photography) and "The Rontgen Rays." He promoted electric illuminants for slide projection. His articles included 'The Evolution of the Magic Lantern,' in Chambers's Journal, 1897–8. T.C. Hepworth's books included: *Photography for Amateurs: a non-technical manual for the use of all* (1884); *Evening Work for Amateur Photographers* (1890), and two manuals on projection: The Magic Lantern and its Management (1885), and The Book of the Lantern (1888). The latter contained instructions for photographic lantern slide making with both wet and dry plates, coloring photographic transparencies for projection, and "The Hand Camera as an Aid to Lantern Work." T.C. Hepworth's son Cecil Milton Hepworth, also a lanternist, started in the motion picture business in the 1890s and became an important early film producer.

STEPHEN HERBERT

HERING, HENRY & CO. (1814–1893)

Henry Hering was born in St Marylebone, London in 1814, and at an early age was apprenticed to his family's bookselling, publishing and bookbinding business in St Marylebone. He was admitted as a partner in1836, after the retirement of James Hering, and in 1843 went into partnership with Henry Remington as booksellers and print sellers at 153 Regent Street, Westminster, moving to 137 Regent Street in 1844. The partnership was dissolved in 1856, when Hering decided to switch the business wholly to photography.

An advertisement in the Athenaeum at the time of the studio opening, July 12 1856, notes Portraits taken by the collodion process, of all dimensions, from the brooch size to 12 in by 10 in ... Paintings and drawings copied ... out-door photography. Engineers' and builders' works in progress "Impressions taken from photographers' own negatives, either on albumenized or plain paper, or by the Ammonia Nitrate or Sel d'Or process ... Coloured photographs by the best artists ... Extensive variety of photographs—Views of Sebastopol and the Crimea, by Robertson." Landscapes in France ... Views of the churches and colleges of Oxford and Cambridge, Isle of Wight ... Photographs by the most eminent English artists.

Hering's confidence and success in the studio is evident in a further Athenaeum advertisement January 8 1859.

From its long-existing artistic pre-eminence, this establishment offers unique advantages to the nobility and gentry who are desirous of having portraits taken, or oil or water-coloured paintings and drawings copied.

By the early 1860s, Hering was acting as London agent for several prestigious foreign studios, including Alinari, Beato and Bisson Freres.

Hering exhibited at the International Exhibition of 1862 in London, and received an honorary award for artistic excellence in Class XIV (No. 3094). In 1856, he issued part 1 of Henry Taylor' "Photographic memoranda," which was favorably reviewed in the Art Journal December 1856 but which did not progress further. In June 1864, Hering started publication of a serial entitled "The Studio," in monthly parts at 1 guinea each. It ran to 5 parts, each part featuring 4 photographs of eminent contemporary painters in the style of Old Masters. Part 1 included Phillip, Calderon, Faed and Watson. The series was apparently unsuccessful, and ended abruptly; at the same time, Hering disposed of his print business.

In 1863, Hering was involved in a copyright law suit, over photographs of Lord & Lady Canning, taken by an Indian photographer and illegally copyrighted by Hering without permission. In his defense, Hering claimed that he was the official agent for Beato, but that over 400 views in India & China had been pirated and sold illegally.

It is a considerable irony that Hering's main claim to lasting fame in the annals of photographic history derives from photographs not even attributed to him during his lifetime. In the early 1850s, a series of photographic studies of mental patients at the Bethlem Hospital, then situated in South London, were taken at the instance of Dr Hugh Welch Diamond (q.v), himself resident superintendent of the Female Department of the Surrey County Lunatic Asylum. Over fifty of these whole-plate images were made, probably for the private collection of the Medical Superintendent at Bethlem, Sir Charles Hood. There were no case notes, but a series of wood engravings from the photographs were issued in 1858 to accompany articles by Dr John Connolly in the Medical Times & Gazette. These engravings were credited as "from photographs by Dr Diamond," and were still so listed in references almost down to the present day. In the 1970s, when the whole history of early medical photography was being re-examined, it was noticed that most of the mounts from the surviving photographs in the Bethlem archives were in fact credited as "Hering

photo." In their book on the "Diamond photographs, Burrows and Schumacher (see infra) noted 'The series looked like the work of one photographer. Had Hering simply supplied a set of prints from Diamond's originals?" Connolly's articles make no mention of Hering, Diamond being the only named photographer. The English translation of Burrows & Schumacher (1990) includes an extra preface noting that these photographs are now considered to be the work of Hering, in view of the fact that more than half of the mounts are so inscribed. This is considered to outweigh the attribution to Diamond in the Medical Times & Gazette, which must therefore be seen as an error.

Hering's photographs of Bethlem patients can now be classified with those of his French contemporary, G-B Duchenne de Boulogne, whose detailed studies of treatment have an immediacy impossible to obtain from Hering's carefully posed quasi-studio portraits. This is most obviously exhibited in the well-known portrait of Bethlem inmate the painter Richard

Dadd, working on his fairy painting "Contradiction. Oberon and Titania" (c 1856). It is worth

noting that all of Hering's subjects had been confined to Bethlem for violent crimes, which makes it all the more remarkable that he was able to photograph the patients in "before& after" poses.

Hering closed his London studio in 1873, and retired to a mansion on the outskirts of Redhill in Surrey. His business had made him a wealthy man, and he must have been devastated when his wife Eliza died in 1879. Hering caused a considerable local scandal in 1884 when, at the age of 70 he married his 22 year old housekeeper, Louisa. She duly inherited the bulk of his £17432 fortune (more than £¾ million today) on his death at Redhill April 231893; she had run through £13500 of it by the time of her own death in 1909.

The major holding of Hering's mental patient photographs is still held by Bethlem Archives, with smaller collections at the Royal Society of Medicine and the National Media Museum. The National Portrait Gallery has a good collection of his studio work.

HERSCHEL, SIR JOHN FREDERICK WILLIAM, BARONET (1792–1871)

English astronomer and mathematician, photographic inventor, photochemist

J. F. W. Herschel was born on 7 March 1792 at Observatory House in Slough, the only child of the musician and Royal Astronomer Sir William Herschel and Mary Pitt, née Baldwin. Herschel's father, who was born in Germany as Friedrich Wilhelm, had carved himself a niche in the history of astronomy for his discovery of the planet Uranus and for his construction of unprecedentedly large telescopes. As a result, Observatory House was a scientific landmark and it was visited throughout John Herschel's childhood by royalty, gentry and scientists from all parts of the world. Growing up in such a household and under the influence of his renowned father and aunt, the astronomer Caroline Lucretia Herschel, it is hardly surprising that John Herschel acquired his own fame in astronomical and mathematical subjects. But, as he wrote to his wife Margaret in 1841, "Light was my first love!," and it was through this lifelong interest in the properties and vagaries of light that he came to photography.

Herschel's university years at St John's College, Cambridge (1809–1813), were devoted primarily to mathematics. Not only did he carry away the top academic prizes during this time, he was also elected a Fellow of the Royal Society, and co-founded the Analytical Society with Charles Babbage and George Peacock. The Analytical Society succeeded in revolutionizing the teaching of calculus in British universities, adopting Continental notation in place of Sir Isaac Newton's fluxions. Even at this early stage of his career, Herschel's zeal to "leave the world wiser than [he] found it," was already fully formed, and this clearly motivated his approach to photography when that too appeared on his horizon. His brief forays into legal studies and then into an academic career at Cambridge, ended abruptly at the close of 1816 when he settled finally on learning the trade of astronomer as his father's assistant. Herschel's life as a scientist of independent means, in a time when such a profession hardly existed, allowed him the freedom to pursue his personal interests, among them the study of light.

In 1819 and 1820, Herschel published several articles on the action of hyposulphurous acids. His observations would later form the basis of the 'hypo' used commonly

to fix silver-based photographs. At the time, he recorded that among the novelties of these compounds was the singular characteristic of the hyposulphites to dissolve "muriate of silver," that is, silver chloride. This ability would allow a photographer to wash the unexposed silver from the emulsion of the photograph, rendering it insensible to further exposure. When it became clear early in 1839 that this "washing out" method differed from Talbot's "stabilizing," he tested both, finding Talbot's simpler, but his own more dependable.

Like many active scientists of the early 19th century, Herschel was intent on discovering what light really was, and whether it moved in waves or in particles. Although noone of his generation, or indeed the following generation, would formulate an answer this question, Herschel believed light travelled in waves, that is, he believed in undulatory theory and not particle theory. He also believed, and would use photography to prove, that the visible part of the spectrum was a small portion of the actual spectrum. In 1819 Herschel began an exhaustive study of the nature of polarized light. Not only did he intend to correctly categorize the various phenomena, he also intended to clarify the terminology used by British scientists who studied light. He was joined in this endeavor by Sir David Brewster. Herschel's contributions to the language of photography, which are discussed below, can be seen as a part of this much larger endeavor.

The late 1820s were a busy time for Herschel, who was rapidly attaining a level of fame that would surpass his father's. In 1827 he wrote his essay on Light for the Encyclopaedia Metropolitana. The essay, which was published along with one on Chemistry in 1830, quickly attained the status of a classic and set out many of the principles on which he would conduct his photographic investigations. In 1828 he married Margaret Brodie Stewart, beginning a long and happy domestic, artistic and intellectual partnership that was, by all accounts, one of the great joys of his life. And finally, to complete the decade, he published his A Preliminary Discourse on the Study of Natural Philosophy, in which he prescribed methods for the successful prosecution of experimental science. In this treatise, which influenced Charles Darwin and John Stuart Mill among many others, Herschel put forward a system for organizing scientific enquiry, in this way furthering it. The organizing principles he formulated would govern his behavior towards photography, which he viewed as a most fascinating branch of science. One of the most striking peculiarities of the book is the prominent place given to scientific nomenclature as a crucial componant for molding a particular field of study into an organized science. Herschel applied these standards to photography as well.

A series of chemical experiments in the Spring of 1831 on the light sensitivity of certain salts of platinum had Herschel most of the way to inventing a photographic process. Like Johann Heinrich Shulze, Herschel cut masks and allowed the action of light to pattern the platina solution through the masks. He shared these pretty experiments with his friends David Brewster, Charles Babbage, and William Henry Fox Talbot. Although nothing in the way of photography came directly from this demonstration, Herschel recalled it immediately in 1839.

Photography was announced to the public at the very height of Herschel's career. He had just returned from four years in South Africa, having completed an examination of the skies of the Southern Hemisphere, and had been reluctantly raised to a baronetcy. Herschel learned of the announcement of the Daguerreotype on 22 January, and of Talbot's competing process within the space of a few days. By the 30th, needing no help from either inventor, he had made and fixed his own photographs on paper, envisioning even the necessary steps to reverse the tones of the original, converting the negative image into a positive.

Herschel did not coin the name 'photography' for the new art. Both Charles Wheatstone (in a letter to Talbot, 2 February 1839) and Johann von Mädler (25 February, Vossische Zeitung) had already suggested its use. It is possible that several early experimenters also thought the term appropriate. There is some evidence that Hercules Florence, in Brazil had called his own experiments of the 1830s by name photographie. What Herschel did was to endorse this name, and encourage its adoption within the scientific community. Herschel employed 'photography' in a paper titled 'Note on the Art of Photography' presented before the Royal Society on 14 March 1839, but he withdrew the paper from publication. In 1979, Larry J. Schaaf rediscovered this paper, enabling us to understand that Herschel's motives were not only to define the realm of what 'photography' would be, but to exhibit a photograph produced in experiment. This use of photography as a piece of demonstrative scientific evidence encouraged his scientific audience to do the same. He went on in 1840 to introduce the titles "positive" and "negative,"' without which we would still speak of "originals" and "transfers," or "impressions" and "re-reversals." In 1860 he also appropriated 'snap-shot' from its hunting roots, to designate an "instant" picture.

It has often been noted that Herschel appeared quite indifferent to making photographs in camera. Many reasons could be given for this tendency, but the two principal ones are his facility with the camera lucida in taking sketches, and also his concentration on making photochemical experiments, many of which required more exposure than a camera of the time could conveniently supply. Nonetheless he did success in making a camera image of his father's 40-foot reflecting telescope. This was no ordinary camera image, either. It was cir-

cular glass negative 10 centimeters in diameter, made by percipitating muriate of silver directly onto the glass, and then washing it with a further wash of silver nitrate. Herschel marvelled at the clarity and sharpness of the image, calling the result a "glass daguerreotype." The image could be blackened or varnished to enable it to be viewed as a positive, or "if the varnish be omitted there seems to be no reason why impressions should not be taken from it ad infinitum."

Although Herschel's time was increasingly monopolized by the completion of his astronomical catalogues, he continued to follow up his photochemical experiments for the next three years. A great part of these experiments were made with organic compounds, usually the juice distilled from the petals of flowers. This particular vein of research was motivated by his firm belief that the complete spectrum, color for color, could be reproduced photochemically. Although Herschel ultimately failed to achieve a workable full- or even multi-colored process, he saw that photography's future quite clearly lay in this direction. In the midst of these color trials, however, he began a much more fruitful line of enquiry.

Early in 1842, the electro-chemist Alfred Smee sent Herschel a quantity of the bright red compound now called potassium ferricyanide. While testing the sensitivity of this substance under the light of the spectrum, Herschel noted that it acted with much the same sensitivity as guaiacum, and when thrown into water, it became a deep prussian blue. Smee suggested two further compounds, Ammonio Citrate and Ammonio Tartrate of Iron, and by June of 1842, Herschel had developed both the Chrysotype, named for its use of gold "to bring about the dormant picture…," and the Cyanotype, his most practical and enduring process. ("On the Action of the Rays of the Solar Spectrum on Vegetable Colours, and on Some New Photographic Processes" in *Philosophical Transactions of the Royal Society of London*, vol. 132, 1842, 181–214.)

Herschel's 16 June 1842 paper presented his experiments not as independant inventions of processes, but as a series of observations on the basic principles of photographic chemical action. Although he describes his many experiments, both organic and metallic, he refrains from naming them or presenting wholly functional working processes. It would only be in November of 1842 that he would systematically describe the working details of his processes. ("On Certain Improvements on Photographic Processes Described in a Former Communication, and on the Parathermic Rays of the Solar Spectrum" in *Philosophical Transactions of the Royal Society of London*, vol. 133, 1843, 1–6.)

Having contributed, thus, in tens of small ways to the progress of photography, Herschel's experiments on photographic subjects came to a halt in 1843, victims of his astronomical writing and public duties. But his interest in photography never ceased. Anna Atkins, a close friend of the Herschel family, immediately took up the cyanotype in her self-publishing effort in Botony. Julia Margaret Cameron declared that Sir John was 'her first teacher,' and immortalized him in a series of portraits. In 1845 Herschel published his final contribution to photographic research, an observation of what he called 'epipolic dispersion.' George Gabrielle Stokes would later rename this phenomenon 'flourescence,' the study of which led directly to radiation photography of all types. When Sir John Herschel died in 1871, he was mourned by a nation, who buried him near Sir Isaac Newton in Westminster Abbey.

KELLEY WILDER

Biography

John Frederick William Herschel was born 7 March 1792 at Observatory House in Slough, near London. At the age of 24, having already been elected Member of the Royal Society (1813), he became assistant to his father, the astronomer Sir William Herschel, and dedicated his life to finishing the monumental Herschel star catalogues. Not only was he respected as an astonomer and mathematician, he contributed papers on geology, meterology, chemistry, botony, photography, and educational reform. He was a talented musician, linguist and draughtsman, leaving hundreds of camera lucida drawings. Herschel married Margaret Brodie née Stewart in 1828, and they had twelve children. In 1821 and 1847 he was awarded the Copley Medal of the Royal Society (RS). Herschel was a founding member, and served as President of the Royal Astronomical Society. He was, from 1824–1827 Secretary of the RS, and from 1827–1829; 1838–1840; 1847–1848; 1851–1852 Vice President of the RS. In 1831 he was knighted, and in 1838 made a baronet. He served as Master of the Mint (1850–1855), as Sir Isaac Newton had before him. Herschel was the first to publicly utilize photography's potential as a scientific tool in the study of light, and he invented numerous photographic processes, among them the cyanotype and chrysotype in 1842. Herschel died on 11 May 1871 at his house Collingwood, in the village of Hawkhurst, Kent, where he had moved in 1840.

HESLER, ALEXANDER (1823–1895)
American photographer

Alexander Hesler is best known for the photographs he took of Abraham Lincoln before Lincoln became president of the United States. Born in Canada in July, 1823, Hesler learned the daguerreotype process in 1847, and eventually settled in Galena, Ill., and opened a gallery in 1850.

He moved to Dubuque, Iowa, in November 1850, but returned to Galena five months later and soon established himself among the national fraternity of daguerreian artists, receiving several mentions in the trade journals of the time.

In August, 1851, Hesler took daguerreotypes of Minnehaha Falls that inspired Longfellow's poem, *Hiawatha*. In 1853, Hesler exhibited a daguerreian panorama of Galena and three views of St. Anthony Falls at the Crystal Palace exhibition in New York City and received a medal.

In 1855, he moved to Chicago, and remained there until after the Great Fire of 1871, when he moved to Evanston. He moved back to Chicago in 1880.

Hesler's photograph of Lincoln with tousled hair, taken in Chicago on Feb. 28, 1857, is the second earliest known image of the future president. Hesler also made four images of Lincoln in Springfield, Ill, on June 3, 1860 after he had become the Republican nominee for president.

BOB ZELLER

HETZER, WILLIAM (active 1850s–1860s)
German photographer

Hetzer was a German photographer who arrived in Sydney with his wife Thekla aboard the *Balmoral* in 1850, not long after setting up a studio at 15 Hunter St. He worked initially with calotypes, one of the few professional photographers in Australia to do so and he produced finely hand coloured portraits of Sir Thomas Mitchell and one of his sons. In 1858 Hetzer published by subscription a set of 36 stereo views of Sydney and environs. More were released the following year including aborigines at Camden Park and several panoramas of Sydney bringing to total number of views to 100.

He exhibited at the 1861 Sydney Exhibition and at the 1862 London International Exhibition, gaining an honourable mention at the latter. Hetzer excelled in producing quality cartes de visite portraiture from his studio "W. Hetzer's Photographic Gallery" situated at 287 George St, Sydney. His wife Thekla worked as his able assistant. Hetzer was engaged by the New South Wales commissioners to photograph various landmarks in Sydney, Newcastle, Singleton, Picton and Menangle for the 1867 Paris Universal Exhibition. In March 1867 an auction of the studio equipment was announced and that Hetzer and his wife were to leave for England. The studio and negatives were sold to fellow German John Degotardi.

MARCEL SAFIER

Holdings: Mitchell Library, Sydney; Macleay Museum, University of Sydney; National Library of Australia, Canberra.

HIGHLEY, SAMUEL (1825–1900)
English photographer, author, and studio owner

Samuel Highley was born into the book trade business. His father ran John Murray's bookselling business after Murray's death in 1793, and from 1795 in formal partnership with Murray's son, until 1803 when the partnership was dissolved. Highley was later joined by his son, Samuel junior, and the business moved to 32 Fleet Street.

Highley junior was a bookseller, publisher and dealer in scientific and medical instruments and specimens and he was an agent for the Royal College of Surgeons. His interests ranged from photography, to microscopy, mineralogy and chemistry and he wrote extensively on all these subjects, corresponding, for example, with Henry Fox Talbot on microscopy in 1853. He was Secretary of the Photographic Society in 1857 and was an assistant editor of the *British Journal of Photography* for nearly

forty years. He edited the Journal's *Photographic Almanac* for 1861 and 1862. He became a Fellow of the Chemical Society in 1854.

Optical projection was a particular interest of Highley and he is credited as amongst the first to design a biunial, or double lantern with two projecting lenses mounted vertically above one another, with a dissolving tap for the exhibition of dissolving views and he was an accomplished maker of photographic lantern slides. He designed a lantern for the projection of photo-micrographs with a paper on the subject being read before the Society of Arts in January 1863. He manufactured optical lanterns as part of his business as a manufacturing optician.

Highley wrote on photography from the early 1850s to the late 1870s after which he seems to have had no further public involvement photography and his obituary in the 1902 *Almanac* stated he had: 'long since passed out of the sight and mind of the photographic world.' He died in Stutton's Hospital, Charterhouse, London.

MICHAEL PRITCHARD

HIKOMA, UENO; See UENO HIKOMA

HILDITCH, GEORGE (1803–1857)
English painter and photographer

An early user of the collodion process and a calotypist, George Hilditich, came to photography after establishing himself as a painter.

He was born in 1803 in the City of London to Mildred and George Hilditch, a city silk mercer. As a boy, Hilditch spent the summers in the rural surroundings of Richmond-upon-Thames, London. It was here that he became a pupil of the painter Thomas Christopher Hofland (1778–1843) of Twickenham. Later he attended the Royal Academy schools and in 1823 had his first painting selected for the Royal Academy summer exhibition. He was awarded a gold medal for an original landscape in oils by the Society of Arts, Manufactures and Commerce, which actively encouraged fine arts skills in young people. It inspired the first of many summer painting tours to picturesque destinations in Britain and later to France, Germany and Italy and he established himself as a regular exhibitor at the Royal Academy, the Royal Society of British Artists and the British Institution.

Hilditch's love of painting was made possible by the family silk business, with which he had a high level of involvement, especially after the death of his father in 1832. Marriage to Mary Bracebridge and the birth of their two sons limited travel abroad and he turned his attention to the landscape of the south coast. The subject of these paintings in Sussex and Kent were later to be reflected in his photographs. He also returned to the riverside at Richmond.

At the Society of Arts exhibition of 1852, Hilditch exhibited both photographic landscapes (calotype) and portraits (collodion). Thirteen photographs were landscapes or townscapes. Some of his earliest photographs record scenes in Richmond, conveniently near to the riverside house of his brother, and several revisit viewpoints of his paintings. In comparison to his well-populated riverside oil paintings, his photographs of the same scenes are eerily empty with an occasional blur of figures in motion.

Photography took over from painting during the latter years of Hilditch's life. From1853, there is a notable decline in the numbers of painting he exhibited. He was one of the early members of the newly established Photographic Society of London and his photographs were shown at the 1854, 1855, 1856 and 1857 exhibitions. The subject matter echoes that of his paintings near the Thames at Richmond and Twickenham, in the city of London and in Sussex and Kent. Hilditch died in Islington, London in 1857. His photographs form the final phase of his artistic career.

HILL, DAVID OCTAVIUS (1802–1870) AND ADAMSON, ROBERT (1821–1848)
British photographers

The professional and creative partnership between David Octavius Hill and Robert Adamson is one of the most important artistic collaborations in the history of photography. In the span of only four years (1843–1847), the Scottish pair created a large and varied body of work that includes several enduring masterpieces. Best known for dramatically moody portraits and group scenes that

cut across Victorian class lines, the contemporary critic Lady Elizabeth Eastlake claimed their work "first cast the glamour of photography upon us."

The astounding aesthetic and technical sophistication of Hill and Adamson's photographs so soon after the medium's advent was a considerable feat, lending valuable credence to photography's artistic viability. Their broad use of light and innovative printing techniques would later influence the Pictorialists**,** while 20th-century modernists would admire the pair's unequivocal handling of the camera towards aesthetic ends.

As with many great partnerships, Hill and Adamson made an unlikely pair. Hill was born in Perth, Scotland on 20 May 1802, the eighth of 12 children to Thomas Hill, a bookseller and publisher, and Emilia Murray. Adamson, nearly 20 years his junior, was born in Burnside, Scotland on 26 April 1821, one of 10 children to farm proprietors Alexander Adamson and Rachel Melville.

Hill studied drawing at Perth Academy under David Junor and was admitted to the School of Design in Edinburgh in 1818, where he studied painting under Andrew Wilson. In 1821 he produced some of the first lithographs in Scotland in *Sketches of Scenery in Perthshire,* an album published under his father's imprint. Principally a landscape painter, Hill exhibited at the Royal Institution several times in the 1820s. From 1831 to 1840 he secured a reputation as a book illustrator, producing sketches and paintings of Scottish scenes to accompany the works of the country's most famous authors, including Sir Walter Scott and Robert Burns. He achieved considerable success in 1840 with the immensely popular *The Land of Burns,* for which he painted 61 landscapes, and his status as secretary of the Royal Scottish Academy (1830–1869) helped secure his place in the Scottish art world.

Adamson, on the other hand, was sickly and introverted as a youth and cultivated an aptitude for science and mechanics. He enjoyed building models and instruments and in his adolescence apprenticed for a millwright for one or two years, but his uncertain health prevented him from continuing in that field. His older brother Robert**,** a doctor and professor at St. Andrews University, learned William Henry Fox Talbot's calotype photography process from his colleague Sir David Brewster in 1841, and he taught Adamson the process the following year. The brothers embarked on an intense period of photographic experimentation and by early 1843 Adamson decided to become a professional photographer in Edinburgh.

Hill and Adamson's partnership arose from a fortuitous confluence of events in May 1843. On 10 May, Adamson opened his studio in Rock House, on Calton Hill Stairs in Edinburgh and a week later, beginning 18 May, the Church of Scotland held its general assembly in the city, an acrimonious event that resulted in the breakaway Free Church of Scotland. Hill attended the assembly and saw an opportunity to commemorate an important episode in Scottish history and further his own career by creating a large-scale painting depicting the momentous signing of the Deed of Demission, then selling engravings of the work by subscription. As the task would require hundreds of sketches of assembly delegates, by early June Brewster had suggested photography to Hill and introduced him to Adamson.

Adamson eagerly joined the project, hastily photographing church leaders, and soon both men apprehended the greater potential of their collaboration. By July they were advertising and exhibiting their work as a team and planned photographs "representing diff[eren]t bodies & classes of individuals." At year's end the Free Church series was nearly complete, after additional sittings at a second assembly in Glasgow, and the partners broadened their scope to make views around Edinburgh as well as commence a pioneering series of labor portraits from the nearby Newhaven fishing community.

Despite contrasting personalities and talents, Hill and Adamson easily established a productive relationship, suggesting that each had an almost intuitive understanding of the other. Hill's charisma and artistic background combined with Adamson's perfectionism and previous photographic experience allowed each partner his own strengths as well as a healthy sense of dependence on the other. Although photo-historians occasionally have credited Hill as the artistic force behind the collaboration, with Adamson acting only as assistant (since he handled all camera and printing operations), the relationship appears far more complex, and neither man's outside work rivals the pair's collaborative results.

Relying on their connections to the British publishing, art and academic worlds, they assembled a prestigious and willing pool of sitters that included painters, sculptors, writers, scientists, statesmen and scholars. Their portraits convey these individuals as engaging, dynamic and thoughtful, exhibiting a remarkable consistency in tonal range matched with compositional schemes inspired in part by the Scottish portraiture tradition, particularly the work of Sir Henry Raeburn.

Hill and Adamson blended sophisticated posing with modulated, reflected light that intensified forms and enhanced interplay with the surrounding space. Their work was frequently compared to Rembrandt's in its bold use of light, not merely to accentuate details but to create strong massings of light and dark that brought an emotional depth to the sitter. They turned the limitations of the camera and the calotype to their advantage, benefiting from the paper's rough grain and the lens' slight peripheral distortion to create areas of sharpness and softness. "The calotype failing in details," Adamson explained, "is the very life of it" (Ford and Strong 1974, 37).

In their portrait of "Miss Justine Munro," Hill and Ad-

Hill, David Octavius; Robert Adamson. Officer of the 92nd Gordon Highlanders Reading to the Troops, Edinburgh Castle. *The Metropolitan Museum of Art, The Rubel Collection, Purchase, Lila Acheson Wallace, Ann Tenenbaum and Thomas Lee, and Harriette and Noe.*

amson combine deep shadows with the paper's texture to soften the transitions from the sitter's patterned dress to her long, curly hair and smooth face. A curl dangling over her hand brings complexity and spontaneity to the pose, while the shadowy area below the face directs attention to her musing expression.

Hill and Adamson were unrivaled in their depictions of groups and children, despite the challenge of preparing interesting compositions that could withstand long exposure times. Their adult groupings, like "Dumbarton Presbytery" (1845), mimic animated discussions and other moments of camaraderie, as exchanged gazes suggest a secret shared or an evolving debate among participants. Their photographs of children tend to reflect moments of play or reverie, as in "The Gowan," where a girl tickles her sleeping sister, or "The Minnow Pool," where children peer expectantly down their fishing pole into murky waters.

Perhaps Hill and Adamson's greatest achievement, however, remains their series on the fishing families of Newhaven, a coastal village just outside Edinburgh. The project ran the length of their partnership and even may have had its roots in similar subjects taken by Adamson and his brother in 1842. An early attempt at social documentary photography, it was a comprehensive effort to convey the living conditions and social relationships of a community. To give authenticity to the endeavor, the photographers descended on the village to depict fishermen tending their boats and lines along the shore and women selling the catch in the streets.

In "Willie Liston Redding the Line" (c. 1845) a young fisherman leans as though ready for action, while the taut fishing line clenched in his hands indicates his potential energy. Photographs like "Bringing in the Catch" (c. 1845) or "Mrs Barbara (Johnstone) Flucker Opening Oysters" (c. 1845) sought to capture moments of everyday labor, despite the impossibility of instantaneous exposures.

Newhaven's inhabitants perfectly suited Hill and Adamson's interest in quintessentially Scottish subjects, offering a glimpse of an enterprising and fiercely independent traditional lifestyle in the face of rapid social and economic change. Accompanied by scenic views of Newhaven and its neighboring harbors on the Firth of Forth, the series produced a study of community on a scale that was rarely repeated before the 20th century. While the project reinforced existing class distinctions as much as it sought to reach beyond them, it is significant that the photographers often identified specific sitters in the titles, placing these people on the same level as the studio's more celebrated sitters, rather than treating them as genre study subjects.

Hill and Adamson sold these and other photographs through the Edinburgh gallery of Hill's brother, Alexander, and also accepted outside commissions on various themes. Their romantically-suffused images from Greyfriars Churchyard, for example, were originally undertaken as a study for the painter George Harvey. They also traveled to York, England, in September 1844, to make portraits and architectural studies during the meetings of the British Association for the Advancement of Science. While these projects kept the studio busy

enough to hire a photography assistant, a "Miss Mann," it still was not enough to satisfy their aspirations.

Having interrupted a promising career as an illustrator, Hill convinced Adamson early on that they ought to publish their work. In 1844 they acquired a custom-made, large-format camera capable of producing images up to 16 × 13 inches (41 × 33 centimeters) that could better compete with engravings. That August they announced plans to produce albums "in a style of great elegance" and available by subscription, advertising a half dozen titles: *The Fishermen and Women of the Firth of Forth, Highland Character and Costume, The Architectural Structures of Edinburgh, The Architectural Structures of Glasgow &c, Old Castles, Abbeys &c. in Scotland,* and *Portraits of Distinguished Scotchmen.*

Each album was expected to contain 20 to 25 prints, but none was ever realized. While the price likely dissuaded many, continued public uncertainty over the photograph's quality and durability perhaps proved an even greater impediment. The larger photographic formats turned out to be harder to prepare and manipulate, yet Hill employed them in his attempts to enter the more lucrative English market, sending sets of images to London art dealer Dominic Colnaghi in 1845 and London publisher John Murray a year later. Neither man was interested, however, especially given that Talbot maintained an exclusive patent on calotype printing in England. As a result, the only publication to appear during the studio's lifetime was the more modest *A Series of Calotype Views of St. Andrews,* printed in a small run at Rock House by the photographers themselves in 1846.

"My ambition is to leave my name on a great and noble work worthy of England," (Stevenson, 1991, 13) Hill confessed to a friend in 1845. In his discouragement over their limited success despite enormous critical praise, he considered giving up photography more than once. By 1846, as the pair made some of their most lyrical work in landscape photographs like "The Fairy Tree at Colinton" (c. 1846), Hill returned to painting to accept an ambitious commission for a scene of Edinburgh Castle, which he based in part on photographs of its architecture and Gordon Highlander guards. In the meantime, Adamson's failing health slowed the studio's photographic output, bringing it to a halt by mid-1847. Despite returning to his family in St. Andrews to recuperate, he died on 14 January 1848.

Adamson's death brought an end not only to the partnership but to the studio. Although Hill and Adamson's unmatched reputation would have made it easy for Hill to recruit another partner, only Adamson's brother Robert seemed an adequate replacement, but his medical practice prohibited the move.

Instead, Hill pursued his work as secretary of the Royal Scottish Academy and continued painting, making only brief returns to photography, the most significant of which was a partnership with the Glasgow engraver and photographer, Alexander McGlashan, from 1861 to 1862. While his glass negative wet collodion portraits with McGlashan bear some resemblance to his previous work, Hill's style was unsuited to changes in the medium. No longer able to rely on Adamson's subtle printing techniques, the uniform sharpness of the images diluted any overall impact in distracting details.

In 1866 Hill finally completed his painting "The Signing of the Deed of Demission," over two decades after the fact. Heavily dependent on the Free Church portraits, the curious composition resembles a photomontage of long, narrow rows of crowded faces. Hill's inclusion of Adamson pointing a camera makes the work as much a testament to photography as a depiction of the event it ostensibly sought to commemorate.

Hill sold the entire contents of Rock House—including all remaining photographs and negatives—to the photographer Thomas Annan in 1869 and died in Newington on 17 May the following year. It was Annan's son, James Craig Annan**,** who finally got the photographs exhibited in England and abroad at the close of the 19th century and published them as photogravures in Alfred Stieglitz's *Camera Work* from 1905 to 1912. The resulting renewal of interest in Hill and Adamson's achievement secured their place in the history of the medium as well as their significance to future photographers.

STEPHEN MONTEIRO

Biography

David Octavius Hill was born 20 May 1802 in Perth, Perthshire, Scotland, the eighth of 12 children to bookseller Thomas Hill and Emilia Murray. He studied drawing at Perth Academy under David Junor and painting under Andrew Wilson at the School of Design in Edinburgh (1818–c. 1821). In 1821 he published *Sketches of Scenery in Perthshire* and illustrated several major works of literature in the 1830s. He was secretary of the Royal Scottish Academy from 1830 to 1869 and exhibited landscape paintings and sketches at the Royal Institution in the 1820s and at the Royal Scottish Academy from the 1830s to the 1860s.

Robert Adamson was born in Burnside, Fife, Scotland on 26 April 1821 as one of 10 children to farm proprietors Alexander Adamson and Rachel Melville. He developed an early interest in science and technology and apprenticed with a millwright before learning photography from his older brother Robert in 1842. The two collaborated for several months and in May 1843 Adamson opened a

professional studio at Rock House in Edinburgh, where he was joined by Hill within a month.

Hill and Adamson were in partnership from 1843 to 1848 and produced commissioned portraits and sold prints through Alexander Hill's Princes Street gallery. Unsuccessful at publishing proposed albums on Scottish themes, they nevertheless produced about three thousand photographs and exhibited at the Board of Manufacturers (1843), the Royal Scottish Academy (1844 and 1845) and, after Adamson's death, at the Great Exhibition at the Crystal Palace (1851).

Adamson never married and died in St. Andrews on 14 January 1848. Hill became a member of the Photographic Society of Scotland in 1856 and ran a studio with Alexander McGlashan from 1861 to 1862, where he published *Some Contributions Towards the Use of Photography as an Art* (1862). He sold the remnants of his studio with Adamson in 1869. He was married to Ann McDonald in 1837and had two daughters, though only one survived birth. His wife died in 1841 and in 1862 he married the sculptor Amelia Robertson Paton. He died 17 May 1870 at Newington Lodge, Mayfield Terrace, Scotland.

Major holdings of Hill and Adamson's work are in the National Galleries of Scotland (Edinburgh), the Glasgow University Library, the National Media Museum (Bradford), the National Portrait Gallery (London), the Victoria and Albert Museum (London), and the George Eastman House (Rochester, NY).

HILL, REVEREND LEVI L. (1816–1865)

In 1850, the Reverend Levi Hill, (a clergyman taking daguerreotypes professionally in Westkill, New York), produced coloured images, which were authenticated by the editor of the *Daguerreian Journal*, who called them Hillotypes. Professional photographers demanded details of the process, but Hill emphasised that he would not divulge his procedures until the proper time, which caused some scepticism.

Two years later, Hill published a statement to the daguerreotypists, which was also available to the American public. He repeated his claim for colour daguerreotypes, but admitted that his uncertainties continued. Exasperated by the decline in sales caused by the first announcement, professionals accused Hill of deception. In 1856, Hill attempted a clarification, but according to Beaumont Newhall, it was "a confused and complicated piece of writing."

On Hill's death in 1865, *Humphrey's Journal of Photography* expressed a sympathetic valediction. The writer did not contest Hill's achievement, but suggested the colour was the result of a fortuitous combination of chemicals, which he had never been able to replicate. The recent rediscovery of a significant number of Hillotypes in the archives of the Smithsonian Institution, Washington, vindicates Hill's claims to have been successful, and recent experiments in the U.S. and the UK have managed to replicate his achievements with some success.

RON CALLENDER

HILLERS, JOHN K. (1843–1925)

German born Hillers settled in America in 1852. In 1871 Hillers was a recently discharged U.S Army Sergeant who met explorer and ethnologist, Major John Wesley Powell. Hillers needed work and Powell needed a boatman for a second expedition through the Grand Canyon. During this trip Hillers changed from being the boatman to the trip's photographer. Hillers worked for Powell, who became the Director of the U.S. Bureau of Ethnology, from the 1870's until around 1900. His photography changed from geological documentation to documenting people, e.g., the Hopi and their surroundings. He was part of the first team to photograph the Zuni and surrounding pueblos, from a anthropological perspective, in 1879. Hillers' photography played a vital role in the U.S. Government's plan to promote the West to settlers and investors. By capturing the lush, vast expanses of land that settlers could obtain, coupled with peaceful images of Native Americans, the frontiers were opened and a huge exodus to these territories occurred. Because Hillers spent his lifetime working as a government photographer, his work was seen by a much wider audience than many of his contemporaries. Although well known for his stereographs and oversize albumen prints, an unusual example of his work was recently restored. This was a set of window transparencies of Native American Indians, with a set of landscapes, commissioned by the Riordan brothers.

HILLS, ROBERT AND JOHN HENRY SAUNDERS

The firm of Hills & Saunders was one of the most prominent photographic studios established in 19th century Britain, with 7 branches throughout London and surrounding counties. It remains one of the extremely few Victorian studios to survive to the present day.

Hillers, John K.. Moki Girls.
The J. Paul Getty Museum, Los Angeles

The firm was founded by Robert Hills (1821–82), born in Lambeth, South London, who started his career with the china & glass merchants Spiers & Son in Oxord in 1850. Spiers opened a branch shop as perfumers in 1851, and Hills was appointed manager in the following year, combining this with work as a hairdresser and wigmaker, as well as agent for the British Empire Fire Office. In mid-May 1856, Hills moved into photography, and opened the Oxford Photographic Gallery a few doors from Spiers' shop in Oxford's Cornmarket By the start of 1857, Hills was advertising his collodion portraits in "Jackson's Oxford Journal," and later in the same year, photographed the local militia on parade, as well as the first in a lengthy series of Oxford Colleges.

The studio was partly damaged by fire in April 1860, and Hills took the opportunity to separate it from the hairdressing and perfumery businesses, which were relocated to new premises on the opposite side of the street. The increasing volume of photographic work, even with a staff of 15, led Hills to seek a partner, and in June 1860, he was joined by John Henry Saunders (1836–90), a former assistant. The hairdressing business was finally sold in March 1862.

The 1860s proved a busy period for Hills & Saunders. In June 1863 they photographed Queen Victoria's visit to Oxford, and subsequently were invited to photograph the Royal family at Windsor. The Cornmarket shop was considerably extended in 1864, and the firm received the Royal Warrant in April 1867. Hills was elected councillor for the West Ward of Oxford in 1869, and opened branch studios in Aldershot, Cambridge, Harrow & Eton, as well as Sandhurst later. Outside Oxford, however, their most successful studio was in London, opened in 1868 with premises in Porchester Terrace, Bayswater, under the management of Alexander Cowan (1839–1922), who as a young man had worked for Paul Pretsch's Galvanographic Studio, and would subsequently manage Marion's vast dryplate factory at Southgate in the 1880s. By the end of the 1860s, Hills had moved with his growing family to a mansion on the outskirts of Cambridge, though he continued to sleep on the Oxford premises 3 or 4 nights a week.

The London studio moved a few doors up Porchester Terrace in 1869, but was destroyed in a fire in Api1 1875. It was rebuilt on a larger scale, and continued until 1886. In 1893, it moved to Sloane Street, Chelsea, where its opening was featured in "Westminster Budget." The article gives a flavour of Hills & Saunders' upper class tastes:

> In the Sloane Street studios there is (no) make-believe sumptuousness. Everything is genuine; the curtains and draperies which fall in soft, seeping folds, wherever they are required, are of real brocades and other art stuffs. The tall palma... are very much alive. The gleam of red copper vases and art—pottery pedestals brightens the dim light of the rooms. Thick carpets cover the floor, and all round the walls are pictures old and new of Royalties and eminent men and women of the past and present, of beauties and beasts—that is to say, of prancing steeds, which their proud owners have caused to be immortalised by means of photographs."

Robert Hills died in Oxford July 27 1882, and his share of the business was continued by his widow, Ann (1820–1905) and son Henry James Hills (1857–99). John Henry Saunders died at Gerrards Cross, Buckinghamshire September 15 1890, and his widow, Elizabeth (1846–1918) with 3 of his children, Frank, Eleanor & Catherine continued his interests. Hills left an estate valued at almost £30,000 (c £1.8 million today), while Saunders' estate was sworn at £10,300 (c. £600, 000 today). The premature death of Henry Hills in 1899, however, caused the business to be sold out of the founding families ;the Cambridge branch had been bankrupted in 1892, and the London studio closed in 1895. The Oxford flagship branch, still on its original premises, soldiered on into the 1930s; in February 1931 it was sold to the rival studio of Gillman & Soame in Oxford, who finally closed it in 1935. The branches in Eton & Harrow continued to trade almost to the present day, buoyed by lucrative contracts with the local boys' public schools - indeed, the Eton premises are owned by the school. Both branches were acquired by Richard Schemansky in the 1990s; Harrow closed shortly after, but the Eton branch continues in the Hills & Saunders name as a reminder of its former history.

The educational and Royal connections established by Hills & Saunders have ensured the survival of a considerable body of work. Both Eton College & Harrow School possess collections of both single and group portraits of school personnel from the 1860s to the present, sections of which have been published in various school histories over the last 50 years. The Royal portraits are housed in the Windsor Castle Archives, and have also been widely published in recent years. The National Gallery has a small collection of negatives of celebrities, mostly from the late 19th/early 20th centuries.

HIME, HUMPHREY LLOYD (1837–1906)

Canadian photographer

Humphrey Lloyd Hime was born on September 17, 1833 in Moy, County Armagh, Ireland. Educated in England from the age of 15 where he learned textile manufacturing, Hime emigrated to Canada in 1854 where he worked on land survey crews until January 1857 when he joined the Toronto firm Armstrong, Beere & Hime as a junior partner. He learned photography from William Armstrong (1822?, Dublin, Ireland–1914, Toronto) and Daniel Manders Beere (1833, Ireland–1909, Australia). Hime's two most significant photographic achievements were a nearly 360 degree panorama of Toronto taken in 1856 or 1857 with Armstrong from the roof of a hotel, and his participation as a photographer in the 1858 Assiniboine and Saskatchewan Exploring Expeditions led by H.L. Hind, the first such use of photography by an official Canadian exploration party. Hime had mixed results with his wet-plate photography on this journey, achieving the most success under more controlled conditions at the Red River Colony and Fort Garry in Manitoba. Some of the photographs were published in a portfolio in 1860 to accompany a two-volume commercial edition of Hind's expedition report. After leaving Armstrong, Beere & Hime in June 1861, Hime had wide-ranging business interests, and served in municipal politics. He was also a founding member of the Toronto Stock Exchange, and acted in various official capacities, including two terms as its president. Hime died in Toronto, Canada, on October 31, 1903. The largest collections of Hime's 1858 expedition photographs, none of which have survived in negative form, are at the Library and Archives Canada, the Toronto Public Library, and the Provincial Archives of Manitoba.

Dave Mattison

HINTON, ALFRED HORSLEY (1863–1908)

Landscape photographer

Trained originally as an artist, after he had met and was influenced by H. P. Robinson, Alfred Horsley Hinton took up photography and in 1889 worked at a photographic suppliers. From 1891-93 he managed H. P. Robinson's son, Ralph Robinson's, and Guilford photography studio, then turned full time to journalism. He edited *Photographic Art Journal* (1887), *Photographs of the Year* (1892), and *Amateur Photography* from 1893 until his early death at 45. He wrote several books and articles for *The Times*, *Daily Telegraph*, *Daily Graphic*, and *Yorkshire Post*. Through writing (with texts also translated into French and German), curating exhibitions, lecturing, and his own photography, he became one of the leading advocates of 'Pictorial Photography' (Stieglitz published two of his articles). A founding member Linked Ring Brotherhood (1892–1910), set up by a group of British photographers who left the Photographic Society (later Royal Photographic Society) of Great Britain and held their own salons from 1893–1905, and notable for his romantic depictions of the Essex flats and the Yorkshire moors, J Dudley Johnston described him as the father of the 'British School of Landscape Photography.' Hinton believed in photography as an individual form of expression but fundamentally that also meant that, in order to be an art form, it had to be capable of the same capacity for manipulation as painting or printmaking. Using the platinotype, often with combination negatives, and additions in pencil, George Bernard Shaw described him as a 'fuzzographer.' The praise and respect he earned has evaporated today, perhaps due to the lack of surviving images in significant numbers and the animosity which continues towards the 'Camera Clubs,' which still operate, thanks to Hinton *et al*, in the wake of the Pictorialist tradition.

Alistair Crawford

HISTORIOGRAPHY OF NINETEENTH-CENTURY PHOTOGRAPHY

Although the 20th century has defined photography primarily as a medium of visual expression, the 19th-century experience of photography cannot be understood without giving due credit to its novelty and its status as invention. That photography was an invention may seem trivial, but it needs emphasizing because the novelty and the technicality of photography to the 19th-century mind were effaced by the advent of popular photography around 1900, and because the ensuing reevaluation of photography's visual heritage resulted in obscuring much of the 19th-century cultural reception of photography.

The idea that photography was an invention—and not a method, craft, or art—was decisively embodied in the 1839 French law on the daguerreotype, which awarded a pension to the inventors in return for the publication of their process. The bill's justifications paradoxically stated that the process was too simple to be patented, that it was more of an idea or discovery than of an industrial process, and that once it was known, anybody would be able to use it (and thus to "make drawings as adroitly as a skilled artist") without paying a fee. This paradox

reflected a deeper hesitation between the notions of invention and discovery, i.e. between the photograph as mechanical product and as natural image. As is known, however, a patent was taken out for the daguerreotype in England, and for most of the 19th century the practice of photography remained esoteric, and mostly limited to professionals. In 1839, moreover, Daguerre and Niépce's son were honored as inventors, and the whole rationale of the French bill was that their process was indeed an invention—original, practical, historic, and so useful to science and society that it behove the government to buy it and make it public. Thus, the law on the daguerreotype programmed and legitimized the formidable spread of photography into every corner of the globe and into every branch of activity, which was often rationalized in terms of "applications" to particular goals when in fact it betrayed a self-justifying ideology of modernity. By the same token, it emphasized a connection between the definition of photographs as exact images obtained by a natural or mechanical process (without the artist's hand) and the perspective of everybody making such exact images (since they required no special skills)—in other words, between the idea of an artless image and that of a democratic art. This idea of photography as an invention that made a technique of both viewing and making unquestionably realistic pictures of the world accessible to everybody was just as revolutionary as the magical, eerie realism of photographic pictures.

Although this idea was contested in the parallel, epoch-making invention of the negative/positive process and the practice of the calotype as expressive art by William Henry Fox Talbot, many other signs confirm that 19th-century culture generally treated photography as an invention. The inaugural Franco-English quarrel over the real father(s) of photography, the obsessive quest of later historians for the true inventor, the many lawsuits of photography's first decades, and the prominent place of photography in popular science compendia on the "wonders" of the century—these were only some of the facets of a framework that defined, valued, and limited photography in terms of invention and technology, as opposed to other forms of culture. Although after 1855 photographs were sometimes exhibited in art expositions, they were usually separated from the fine arts, and more commonly, as in world fairs, they belonged with the products of industry. And yet, because this invention set a new standard of pictorial truth, it very forcibly projected technology into the realm of art and into philosophical and aesthetic discussions of images, truth, and reality. Because it heralded universal access to pictures and to picture-making, and therefore questioned traditional privileges, it raised broader issues about the place of art and pictures in society. Finally, it must be noted that in the strongly emotional response that everywhere greeted the advent of photography, the striking faithfulness of photographic images was inseparably linked to the dramatic—in some cases almost fantastic—novelty of the experience of seeing them. This response was not always favourable, but it was clearly and durably hyperbolic, and thereby expressive of a deep perturbation of the cultural order, as shown especially by the famous essays of Lady Elizabeth Eastlake (1857), Charles Baudelaire (1859), and Oliver Wendell Holmes (1859–1863), which twenty years after the first announcement of photography recorded that upheaval with the same emphatic tone, albeit with different judgements. In writing on photography, artists, writers, critics, and philosophers (such as Baudelaire, Schopenhauer, Emerson, or Ruskin) addressed not only the supposedly uncontrovertible character of photographic evidence, which was almost immediately put into question on a variety of grounds, but the compelling and fascinating novelty of the photographic image, towards which they displayed deep ambivalence. In sum, the 19th century as a whole kept echoing the novelty of photographic images and, inseparably, the power of inventions and inventors to transform society and culture.

In keeping with this global definition of photography as invention, its development was predominantly categorized under the label of technology. This was most obvious with commentators within the profession of photography, which was perhaps especially prone to pride itself on its technical achievement since it was generally refused a more academic recognition. The overwhelming majority of articles published in the specialized magazines that appeared in several countries after 1850 were of a technical nature. Much of this specialized writing was generated by an ongoing technological evolution, which constantly changed instruments, materials, and procedures. Even, however, when they expressed artistic concerns, as indeed they often did, photographic authors typically translated these concerns into technical language, as for instance in early discussions of soft focus as a means of achieving atmosphere and ideality. Likewise, and in the wake of the inquiry into the origins of the invention that started in 1839, 19th-century histories of photography were technical histories. Generally written by practitioners and most often intended also as manuals, these books would summarize the chronology and the technology of the inventions and various processes, typically describing methods in detail, discussing "applications," and emphasizing the spread of photography into the most diverse branches of human activity, as befitted trade publications. This professional discourse echoed the social perception of photography as a technical activity, involving cumbersome apparatus, suspicious chemicals, and occult operations, all the more intriguing since their primary use was to draw one's portrait; and yet it often embodied artistic concerns, as in Marcus Root's *The*

Camera and the Pencil (1864). As many recent studies have shown, the professional arena indeed included, through its practices of association, publication, exhibition, evaluation and training, active channels of critical evaluation, and even technical concerns were rarely devoid of aesthetic intent. Meanwhile, a fair amount of specialized technical information found its way into general-interest publications, insofar as photography was widely perceived, down to the last years of the century, to be full of evolutive potential, towards new frontiers such as color and instantaneous photography, and popularization of the basic processes. In fact, the dominant feature of non-specialized discourse on photography, notably artistic discourse, was a similar emphasis on the technical nature of photography, except that it stressed a mechanical rather than a strictly technical character, leading often to exaggerated dichotomies between art and industry, inspiration and imitation, naturalism and symbolism, and so on, but also, especially in literary reflections, to a more profound questioning about the potential role of photography as an esthetic model. In short, despite conflicting judgements on the values of photography, 19th-century culture fundamentally agreed on its status as invention and technology, which served both as the unifying category in the realm of professional expertise and as a threatening or fascinating Other in general discourse on art and culture.

As late as the very last years of the 19th century, and into the 20th, authors of histories of photography such as the Frenchman Gaston Tissandier or the Briton John Werge construed the history of photography as that of an invention. Things quickly changed after 1900, that is to say after the advent of popular photography and the emancipation of artistic practices and institutions, and just as collectors started accumulating traces of a bygone era—prints and plates as well as equipment. The old-style, professional kind of history was on the decline, although it survived in the 1920s in works such as those of Georges Potonniée, and although the subject of photographic technology was renewed in German-speaking countries, in the wake of the monumental researches of the chemist Josef-Maria Eder, whereby technical history became explicitly scholarly, in fact closer to the history of science. Meanwhile, and especially after 1930, a new trend appeared that gave an organizing role to the artistic achievement and the cultural significance of photography. Although this trend was partly linked to the strategies of particular collectors and museums (the classic example being Beaumont Newhall's collaboration with New York's MOMA), it reflected, more globally, the growing recognition of photography as art, and even more importantly the growing experience of photography as a familiar hobby and as a popular vector of memory and culture. This transformation thus went well beyond the Modernist emphasis on art photography, as is shown by the contemporary endeavors of explicitly "social" historians of photography, such as Gisèle Freund, Robert Taft, and even Walter Benjamin. Although it was fairly eclectic and did incorporate the technical element, the new model of photographic history which emerged from these pioneering efforts, and which flourished after 1970—essentially the field of photographic studies as it is known—focussed on the visual heritage of photography, which it made available in ever finer reproductions to ever wider audiences. Because pictures were easier to make and to reproduce, the history of pictures became more significant than the history of their making. Thus, the popularization of photography and photographic culture resulted both in the rise of a broader interest in its history, and in the gradual marginalization of the very dimension—technology—that had theretofore dominated that history. But this was a minor regret in the face of the new visual culture that emerged from these efforts, and in view of the historic achievement that this evolution represented. For indeed the history of photography, in evolving from a history of processes and practices to a history of pictures and meanings, mirrored the very evolution of photography towards its own historical aspirations for a simplified method of making pictures and a universal form of visual expression.

Beyond the concern of early 20th-century critics for the place of art photography in art history, this view of photography as a universal visual mode of expression has led to important redefinitions of the field since 1970. Thus, first of all, the worldwide expansion of photography in the 19th century has been more accurately accounted for. Whereas earlier generations of historians and commentators addressed almost exclusively the development of photography in Western Europe, research in or about other parts of the world has considerably renewed the field. A major example of this phenomenon is the reevaluation of the 19th-century contribution of the United States in the evolution of photography, which was largely ignored in the specialized literature at least until 1900, in spite of awards granted to some American photographers at various international exhibitions in the 19th century. Because of the leading role that American critics and museums took in the development of the field in the 20th century, 19th-century American photography became a topic of unequalled interest and documentation, the U.S. emerging as a particularly active, creative, and culturally open photographic nation, while prints and albums by some especially sought-after 19th-century American photographers reached market prices comparable to those of great French and English calotypes. Although this example shows that historiography and the market will follow global economic and political hierarchies, the development of photographic studies has also focussed increasingly on

areas other than Western Europe and North America, such as Asia (and especially the Middle East), Japan and China, South America (and especially Brazil and Argentina), the Pacific, and Southern, Northern and, especially, Eastern Europe. A classic illustration of this phenomenon is the ever-growing list of precursors of photography, with spectacular examples such as that of the French-Brazilian Hercule Florence, whose early photographic researches only came to light in the 1970s. Studies of the reception of photography in Japan and China have revealed not only previously unknown images but also significant reactions to and deviations from the ideas that Western explorers introduced along with photography. More discoveries are still to be expected from areas and cultures which, although underdeveloped and subject to colonial rule—and therefore generally ill-documented—were nonetheless affected by the spread of photography: thus the 19th-century African, Caribbean and African-American experience of photography, albeit in colonial and institutional contexts, largely remains to be investigated. The history of 19th-century photography has inevitably been written mostly from the point of view of the powers that often organized its uses, and much remains to be discovered about the point(s) of view of its subjects, from colonized nations to ethnic or political minorities to ordinary men and women in the leading countries.

Indeed, whereas early scholarship focussed on the leading nations' artistic circles, academic institutions, and cultural and economic centers, the increasing recognition of the social and local impact of photography has led to more diversified appraisals. Studies of the development of photography in regions of France, Great Britain, or the U.S. may not change the global picture of how photography was conceptualized or practiced in the 19th century, but they show how it was transmitted through society, how it was taken up by local practitioners, how these related to centers of business and power, and how local populations and even individuals—still neglected in accounts of 19th-century photography—responded to the possibility of having their pictures taken, to the kind of spectacles that photography presented them with, or to the option of going into photography as a business. Local studies may yet unearth significant bodies of images, but perhaps more importantly they contribute to a more concrete understanding of the historical phenomenon of the propagation of photography in the world, as does the investigation of the social reception of photography beyond the cultural elites. Although the intellectual and artistic reception of photography remains a priority subject, many 19th-century texts show that it was often influenced by the social dimension and even underwritten by lay discourses and attitudes, as in the example of pictorialism in its relationship to popular photography. Even when limiting the scope of relevant reception to intellectual discourse, the many existing anthologies show that this field itself is no longer so unified as it once seemed. Links have been documented between photography and every aspect of 19th-century intellectual activity, making it difficult to maintain the bias of earlier historians in favor of the sole discourse of professional artists, art institutions, and art publications. Within the sphere of art itself, the relationship of painters (but also writers) to photography has been shown to be more diverse and sometimes more technical than was once thought; meanwhile, it has emerged that photography came to represent a dividing issue, or an organizing model, in debates on realism, representation, the goals and values of art, or methods of documentation and teaching. Meanwhile, studies on scientific and institutional uses of photography have shown that the general enthusiasm of 19th-century scientists for photography left room for reticence, even opposition, and sometimes for elaboration of specific photographic methods. Conversely, when such methodological adaptation did not take place, it appears that the use of photography was often self-justified and resulted in countless supposedly documentary archives—such as ethnographic and geographical collections, and medical or police records—with little or no scientific justification, and which perhaps for this reason have come to be regarded as a cultural and artistic heritage. Many 20th-century (re)discoveries of 19th-century photographic oeuvres have highlighted work that was done outside of the established professions and institutions of art, as in the example of expeditionary photography, which was not generally appreciated in major artistic circles, and which has come to be considered an important field. In sum, the scope of the inquiry into intellectual and artistic reception has broadenend, and traditional divisions between art and science, or art and picture-making, have been increasingly called into question. This broadening has remained limited (many ordinary, anonymous or vulgar photographs have not been given much attention), and it has not seriously challenged the hierarchy of confirmed photographic masters—which was, in part, already in place in the 19th century, and then took a more definitive shape between 1900 and 1950 under the influence of collectors, avant-garde critics, and a few museums; but it has enriched and renewed the global understanding of the 19th century's experience of photography.

It should be emphasized, by way of conclusion, that this experience cannot be summarized by simplistic views about a naively enthusiastic 19th century, sometimes represented as a kind of Dark Age of photography, imbued with technical secrets, intense commercialism, and naive conceptions of truth and art. The reevaluation of 19th-century photographic oeuvres has too often been governed by the assumption that such oeuvres were not duly recognized in their day, and that 19th-century

culture was generally reluctant to view photographs as anything other than mechanical artefacts with utilitarian functions. Much effort has been put in demonstrating that 19th-century culture was naive, positivist, utilitarian or otherwise uncritical: unable to see the mark of art (or of artifice or playfulness) in a photograph, blindly faithful to the "myth" of photographic objectivity, and profoundly misled in its infatuation with novelty and progress. Yet the result of decades of specialized scholarship has been to unveil the unique visual and cultural heritage that this supposedly naive century created; and as some of the most incisive 20th century critics—notably Walter Benjamin and Roland Barthes—have suggested, the 19th-century fascination with photography was an accurate response to a major event in the history of civilization.

HISTORY: 1. ANTECEDENTS AND PROTOPHOTOGRAPHY UP TO 1826

The announcements of the invention of photography in January 1839 by Louis Jacques Mandé Daguerre and William Henry Fox Talbot were preceded by at least four decades of experiments by themselves and others towards this specific goal. Indeed, following these announcements, as many as twenty people, from seven different countries (Britain, France, United States, Brazil, Switzerland, Germany, Spain), were mentioned as having already attempted a photographic process of one kind or another. Among these earlier experimenters were such figures as Elizabeth Fulhame, an Englishwoman who published a book on the 'Art of Dying and Painting' (1794); Henry Brougham, a Scottish politician and intellectual (1794); Thomas Wedgwood, the son of the famous English potter (c. 1800); Nicéphore and Claude Niépce, French brothers and inventors (1814); Samuel Morse, an American painter working in New Haven (1821); James Wattles, a 16-year-old art student living in Indiana (1828); Eugène Hubert, an architect living in Paris (1828); Hercules Florence, a French-born artist and inventor living in a small town in Brazil (1832); Philipp Hoffmeister, an obscure German clergyman (1834); Friedrich Gerber, a Swiss veterinary surgeon teaching at Berne University (1836); John Draper, an American chemistry professor (1836); José Zapetti, a Spanish painter from Saragossa (c. 1837); and Friederike Wilhelmine von Wunsch, a Prussian woman artist living in Paris (1839). All these people, and probably many more, conceived (or later claimed to have conceived) of something approximating photography, but none of them could ever quite perfect a technique that actually resulted in permanent photographic pictures.

If nothing else, this bevy of claimants suggests that photography's conception was the product, not of an individual flash of genius, but rather of various develop-

ments in European culture as a whole. It was only the confluence of these developments in the early nineteenth century that made photography conceivable and perhaps even inevitable. They included general shifts in European society, such as the advent of the Industrial Revolution and consumer capitalism, as well as more particular changes in scientific thinking and technology that led to new theories of light and optics and the production of more refined chemicals and improved lenses. But this significant historical moment was also accompanied by revolutionary changes in the experience of time, space and subjectivity that were equally important to what might be called photography's conditions of possibility. It was the representational demands accompanying these changes that encouraged experimenters to imagine bringing together the basic components, some of them available for some time before 1839, that eventually constituted a workable photographic apparatus. The advent of photography, therefore, was a complex historical event involving social, cultural and technological changes in about equal measure.

The two most important technical components of the photographic apparatus were the camera and light-sensitive chemicals. The photographic camera was a modified version of the camera obscura, an instrument that had been used in one form or another by European artists since at least the sixteenth century. Originally comprised of a darkened room into which light was allowed to enter through a small hole in one wall, the camera obscura eventually became a portable box with a lens at one end and a ground glass sheet at the other. A skilled draftsman could trace an exact copy of the image focused on the glass by the light that has passed through the lens (an improved lens for this purpose was designed by William Wollaston in 1812, and Niépce and Daguerre experimented with a number of different versions in the 1820s). Although moving, reversed and upside-down, this projected image was regarded as a faithful facsimile of the outside world because the light which formed it had passed through the lens and into the camera according to the objective geometric laws of perspective, itself an invention of the fifteenth century. By the time of photography's conception, the camera obscura was one of a number of mechanical instruments—another was the camera lucida, a three-sided glass prism on a retractable stand patented by Wollaston in 1806—employed by artists in an effort to produce more accurate drawings than could be made by the unaided human hand. However such instruments still required some skill to operate successfully. As Talbot famously recalled in 1844, he tried to use both the instruments just described while drawing at Lake Como in Italy in 1833, but the results were "melancholy to behold." It was then, he says, that an idea occurred to him: "how charming it would be if it were possible to cause these natural images to imprint themselves durably, and remain fixed upon the paper!"

The realisation of this idea required Talbot to apply what was already common knowledge amongst those like himself who studied chemistry and physics; namely, that light had a discernable chemical effect on certain silver salts, causing them to oxidise and change colour. This reaction had been noted by the German natural philosopher Johann Heinrich Schulze as early as 1727 and his experiments, which included making stenciled words appear in purple against his white solution of carbonate of silver, were repeated and confirmed by others. Swedish chemist Carl Wilhelm Scheele, for example, undertook experiments on the action of light upon silver chloride and published his findings in 1777, and these were subsequently translated into German, English and French. Swiss librarian Jean Senebier published further experiments along these lines in 1782, timing the effects of different coloured light on chloride of silver. Light was also a subject of much discussion in the period, with the corpuscular theory of light proposed by Newton in the eighteenth century being gradually replaced by the wave theory developed by Thomas Young in England and Augustin Fresnel in France. In 1803 Young, a colleague of Humphry Davy's, even conducted some photographic experiments with light by projecting microscopic images on to a sheet of paper soaked in silver nitrate. Both Scheele and Senebier were among those referred to in the essay by Davy that is generally considered to be the first publication specifically about photography.

This essay, appearing in the *Journals of the Royal Institution of Great Britain* in June of 1802, described various experiments that Davy and his friend Thomas Wedgwood had undertaken with white paper or leather moistened with a solution of silver nitrate and exposed to light. These experiments included attempts to produce both contact prints and images formed in a camera obscura.

> White paper, or white leather, moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but, on being exposed to the day light, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black…The condensation of these facts enables us readily to understand the method by which the outlines and shades of painting on glass may be copied, or profiles of figures procured, by the agency of light...The images formed by means of a camera obscura, have been found to be too faint to produce, in any moderate time, an effect upon the nitrate of silver. To copy these images, was the first object of Mr Wedgwood, in his researches on the subject, and for this purpose he first used the nitrate of silver, which was mentioned to him by a friend, as a substance very sensible to the influence of light; but all his numerous experiments as to their primary end proved

> unsuccessful.... Nothing but a method of preventing the unshaded part of the delineation from being coloured by exposure to the day is wanting, to render the process as useful as it is elegant.

Although the two men could not find a way to stop their images from continuing to develop and going completely black, their findings were republished in at least fifteen different journals or books in England, Italy, Scotland, Switzerland, the Netherlands, the United States, Germany and France. Widely known in the scholarly community, these first steps towards photography informed the later and more successful experiments of, among others, Daguerre and Talbot.

As Joel Snyder has pointed out, it is important to recognise that what made these later experiments successful was the ability of people like Talbot to utilize reliable and dependable quantities of chemicals like silver nitrate and silver chloride and work with new elements and compounds, such as iodine, bromine and sodium thiosulphate, all of which were simply unavailable before the 1830s. However the story of photography is interesting precisely because, as evidenced in the experiments of people like Wedgwood and Davy, its conception preceded the ready availability of these chemicals—the desire to photograph emerged well before the scientific ability to fulfill that desire. Indeed photography's various inventions were as dependent on available materials and trial and error as on modern scientific knowledge. Attempts to perfect a photographic process were also often conducted in the context of other experiments. The Niépce brothers, for example, initially attempted to make photographic reproductions of engravings using light-sensitive bitumen, inspired by the establishment of the first successful lithographic premises in Paris in 1813 and by a financial incentive scheme offered by the French government to improve the process. They went on to attempt to capture views of landscape formed in the back of a camera obscura, using paper soaked in silver chloride, as early as 1816, and then, in their heliographic process, using pewter plates coated with their light-sensitive bitumen solution. The earliest extant example, a view from their studio window, dates to about June 1827. Wedgwood and Davy were both involved in industrial research on ceramics and dying textiles in the 1790s, Samuel Morse worked on a sculpture-copying apparatus at the same time that he first experimented with photography and later developed an electric telegraph system, the Niépce brothers also built a marine engine and attempted a perpetual motion machine, and Talbot took out numerous patents on processes that he hoped would have profitable applications. Photography was, in other words, one of many inventions driven by the combined forces of the Industrial Revolution and consumer capitalism.

This context reminds us of the larger history of which the invention of photography was but one small part—the ascendancy to political and economic power of the middle classes and the attendant proliferation of their values and desires. The influence of middle-class ideology is evidenced, for example, in the emphasis placed within this Romantic period on the sensory and emotional experience of the individual human subject. This licensed an exploration in both art and science of the extremes of human experience—sexual desire, madness, grief, nightmares, fantasy. But it also had important ramifications for philosophy and political theory. The rights of the individual, both political and personal, were a topic of great interest in the later eighteenth century. The most provocative of the various commentaries on these issues came from Frenchman Jean-Jacques Rousseau, especially his idea that the state derives its authority, not from some divine right, but from the consent of the citizenry (from a "social contract" between monarch and citizens). Henceforth, every individual should have the freedom to seek happiness as long as it was compatible with the general good.

This new concept of the nature of human nature was expressed most forcefully in the ideals of the French Revolution of 1789 ("Liberty-Equality-Fraternity"). But it was also manifested in the demand for portraits from members of the European middle class seeking to confirm their new social status and sense of self in the form of an image. Few members of this class could afford a painting, so alternative ways of producing portrait images had to be found. In the 1750s, for example, the silhouette was invented, involving the production of the outline of a shadow profile that was cheap, rapid, portable and relatively easy to make. A machine was soon devised for making these kinds of portraits even more easily. A further improvement on this process, the physionotrace, was invented by Frenchman Gilles-Louis Chrétien in 1786. This comprised a mechanical combination of silhouette and engraving, requiring only a single sitting and enabling multiple reproductions of the portrait image to be prepared. The physionotrace portrait was inexpensive and convenient (requiring even less skill to make than the silhouette), but tended to produce a stylized, static expression on the face of the subject. Although portraiture was not the primary aspiration of the early photographic experimenters (successful portrait photographs would not be made until the 1840s), it is important to remember that their experiments took part in the midst of this general push to mechanise and automate all representational processes.

We seem to have strayed some distance from the practical problem of inventing a workable system of photographic image-making. But we have to remember that, as Talbot concedes in his 1844 essay, photography began as an idea, as a "philosophic dream." A history of the technical development of the photographic ap-

paratus tells us something about *how* photography came to be realised but not much about *why*. To explain the motivation behind photography's conception, we need to identify what it was, philosophic or otherwise, that the early experimenters were dreaming about.

As it happens, most of the earliest accounts we have of the desire to photograph talk of it in representational rather than technical terms. In his first letter to Niépce, written in 1826, Daguerre described them both as "seeking the impossible," by which he meant an image, as Niépce described it the following year, "obtained spontaneously by the action of Light." When Niépce prepared a synopsis of his experiments in November 1829, his title further elaborated their aspirations: "On Heliography, or a method of automatically fixing by the action of light the image formed in the camera obscura." Daguerre's subscription broadsheet, issued in December 1838, again claimed that the daguerreotype "consists of the spontaneous reproduction of the images of nature received in the camera obscura...the daguerreotype is not merely an instrument which serves to draw Nature; on the contrary it is a chemical and physical process which gives her the power to reproduce herself." In his first published paper on photography, presented in January 1839, Talbot described the image he wanted to capture in more poetic language: "the most transitory of things, a shadow, the proverbial emblem of all that is fleeting and momentary." This image, the kind projected into the back of a camera, may, he now claimed, "be fettered by the spells of our '*natural magic*,' and may be fixed for ever in the position which it seemed only destined for a single instant to occupy."

These three brief extracts describe the desire to photograph in terms of a "spontaneous" (meaning, self-generated) representation of a camera image. This was a radical idea. Photography, by allowing nature to represent itself by means of the indexical agency of light, would remove the human hand from the act of representation. But photography would also work to stop the world in its tracks, grabbing a single freeze frame from the passing parade of possible pictures seen in the back of a camera. In other words, these experimenters wanted to make a kind of image that solved two representational problems that had taken on a particular urgency in the early nineteenth century—subjectivity and time.

As described by French philosopher Michel Foucault, this particular moment in European history marks the beginning of an unprecedented relationship between individual citizens and state power, embodied in new social structures and new notions of subjectivity. There was, for example, a general shift in the disposition of power such that the absolute domain of the king over his subjects was transformed into a more diffuse arrangement of legal and social networks involving each citizen in a self-perpetuating system of constraints and incentives. Foucault points to the design of the panopticon by the English utilitarian philosopher Jeremy Bentham in 1791 as an apt metaphor for this new arrangement. The panopticon was to be a form of prison architecture in which incarceration was enhanced by a system of looking. A ring of barred (and therefore transparent) cells was to be built around a central viewing platform, so that a single warder could efficiently survey many prisoners at the same time. A light would always shine down into these cells so that the prisoner couldn't see the warder's platform and thus never knew whether he was being surveyed or not. In this situation, the prisoner must live under the assumption that he is always under surveillance and thereby is induced to behave as if it is so. In a sense, the prisoner ends up watching himself and regulating his own behaviour. The subject in his cell becomes both the prisoner and the warder, both the surveyor and the surveyed, both the vehicle and the victim of incarceration. This, says Foucault, is the general principle for the whole of social organisation in the modern era, and also for the constitution of each individual subject.

The panopticon turns the gaze back onto the subject who gazes, in effect dividing the subject from himself. And indeed, as Enlightenment reason increasingly addressed itself to the question of the nature of the human subject, "Man" himself became an object of study, finding himself examined for the first time in taxonomic terms. As a consequence, the years around 1800 witnessed the disintegration of Natural Philosophy and the birth of a whole archipelago of sciences of the human, including all the comparative social sciences, such as anthropology, sociology, criminology, clinical medicine and so on. This scientific study of "Man" necessarily had to include his physical capabilities and limitations. Human beings, once thought to be God's mortal incarnation, had turned themselves into specimens to be examined and analysed like any other.

The emergence of biology as a separate science involved, for example, the systematic study of sight, science's primary means of investigation, and of sight's instrument, the human eye. Like the camera, the human eye was known to operate according to the rules of perspectival geometry, allowing light to form images on the back of the retina; therefore sight has reason as its very means of operation. Accordingly, knowledge and sight had long been thought to have a close association. But around 1800 it was found that the human eye is also fraught with physiological frailties. It was found, for example, that the eyeball was in constant movement, and simple tests showed that not everyone saw things in the same way. In 1818 Talbot wrote to his mother to tell her that he had been "reading books on the structure of the eye" and about his own experiment in this area. He had gently pressed his eye with his finger to try and improve

his congenital shortsightedness; a more distinct vision was the result. Through such simple experiments as these, the human body, in all its contingency and physical specificity, was shown to generate its own images. Eight years earlier, the German philosopher Goethe had proposed a series of simple experiments in which one stared into bright light or at colored objects and then closed one's eyes. His point was that the observer continued to see colors and shapes, a retinal afterimage produced, he argued, by the eye itself. The human body, in all its contingency and specificity, generates its own spectrum and thus becomes the active producer, not just the passive receiver, of optical experience. Thus by the early nineteenth century, seeing, once thought to be an action composed of a reliable and unmediated reflection of an outside world, is situated in and identified with the specific body of the individual human subject.

The observer is no longer presumed to be the passive and transparent conduit of God's own eye but is now imagined to actively produce what is seen. Moreover, scientific study showed that seeing was inseparably tied to the particular exigencies of the time and circumstances within which that act of seeing takes place. In that sense, the subject seeing and the object being seen could be said to be continually producing one another. These conclusions were in accord with the basic tenets of German Idealist philosophy that was then being propagated throughout Europe. Immanuel Kant considered the human mind to be not a mirror but a legislator of nature; human beings actively constitute their world through their representations of it. The act of this constitution, he argued, is at the same time a self-realisation, a constitution of the self. Thus the subject makes the object, even as the object makes the subject. Georg Hegel took this idea and located it within a grand system of historical and human forces (such that being is not fixed but is rather a never-ending process of becoming). The instigators of the French Revolution were acutely aware of their differences from past generations, and demanded histories that recognised this fact. Hegel's arguments about human subjectivity as something continually in process were formed in the midst of this general expansion in historical consciousness. In 1798 the poet Samuel Taylor Coleridge was sponsored by Tom Wedgwood and his brother to travel to Germany and study this philosophy at first hand. His subsequent writings, which influenced Wedgwood, Davy and, a little later, Samuel Morse, could be taken as an attempt to articulate these new ideas in poetic form. As Coleridge put it in 1825, to understand the modern subject, what had to be imagined was a "self-conscious looking-glass" or even "two such looking-glasses fronting, each seeing the other in itself, and itself in the other." The traditional camera obscura could no longer fulfill this radical new world-view. What had to be invented instead was an apparatus of seeing that involved both reflection and projection, that was simultaneously active and passive in the way it saw things, that incorporated into its very mode of being both the subject seeing and the object being seen.

We have one notable reference by Coleridge that explicitly links his imagined apparatus of seeing to Tom Wedgwood's photographic experiments. On November 16, 1802, Coleridge wrote a letter home to his wife while on a hiking expedition to South Wales with his friend Wedgwood. "He will be out all the mornings—the evenings we chat, discuss, or I read to him. To me he is a delightful & instructive Companion. He possesses the finest, the subtlest mind and taste, I have ever yet met with.—His mind resembles that miniature Sun seen, as you look thro' a Holly Bush, as I have described it in my [1798 poem] *Three Graves*:

> A small blue Sun! and it has got
> A perfect Glory too!
> ten thousand Hairs of color'd Light,
> make up a Glory gay & bright,
> Round that small orb so blue!"

Coleridge here compares Wedgwood's mind to an image created by the lens-effect of a leafy tree projecting the image of the sun, by, in other words, a natural camera obscura. Given that he is writing only a few short months after Wedgwood and Davy's essay appeared in the *Journals of the Royal Institution*, an appearance they must surely have discussed in detail, Coleridge is, in effect, likening Wedgwood's ever-inquiring mind to a photographic image-making process.

Philosophy was not the only discipline dreaming of such a process. If the naked human eye is prone to mistakes and physiological imperfections, the sciences had to devise a more dependable method of 'seeing' and recording visual information. This effort coincided with the increasing importance of empirical science as an ideological discourse. By the 1830s this discourse had been theorised as Positivism, based on the idea that truth is confined to forms of knowledge which can be empirically and repeatedly tested under scientific conditions (truth is knowledge which can be made *visible*). But even in the previous century, the Royal Society and similar organisations were putting more and more stress on the need for objective forms of representation and calling for the production of accurate pictures that allowed different specimens and views to be directly compared and studied. The early photographic experiments with botanical contact prints by Wedgwood and Talbot, for example, sought to improve on nature printing, a centuries-old procedure in which a physical specimen would be inked and pressed directly onto paper. An image that could be made to spontaneously represent itself in a camera would be similarly true to nature, being not only an accurate

picture of the world but, through photography's harnessing of the "natural" laws of chemistry and physics, also true to nature's own way of being.

By the nineteenth century this way of being was conceded to be a difficult thing to pin down, precisely because nature was itself constantly on the move. Where once the earth had been regarded as eternal and static, looking now much as it did on the day of Creation, scientists began to uncover increasing evidence that the world around them had a long and tumultuous history. In 1774, in his *Théorie de la terre*, French naturalist Georges Buffon gave the earth an age of "approximately" 74,047 years; with the advent of the science of geology and the theory of evolution in the early nineteenth century this figure was extended into the millions of years. Nature was apparently an entity always in process, a fact that could be witnessed by any individual, just by looking around them and trying to describe that they saw.

Coleridge is a prime example of such an individual. Calling himself "an Eye-servant of the Goddess Nature," his poetry sought to somehow represent in images made with words the lived experience of seeing the world. Informed by modern science, with which he was very familiar, he regarded nature as "an ever industrious Penelope for ever unravelling what she had woven, for ever weaving what she had unravelled." In much of his work he tries to capture the instant of perception, that image which is in the eye for only a moment before it changes forever. But he has to do so through a form of representation (writing) that is permanent and fixed in place. His problem, as he often laments, is that the moment always passes faster than his words can cohere. How can he produce a representational form that solves this 'time anxiety,' that combines both permanence and the instant, both fixity and transience?

In 1817, Coleridge described this ambition with a strikingly photographic metaphor; he desires, he says, "creation rather than painting, or if painting, yet such, and with such co-presence of the whole picture flash'd at once upon the eye, as the sun paints in a camera obscura." In poems like *The Eolian Harp* (1795) and *This Lime-Tree Bower My Prison* (1797) he again compares this 'co-presence' to the fleeting image stilled by the camera obscura or its equivalent (specifically, an Eolian Harp, which allows the wind to create its own music, and a leafy bower that projects an image of those leaves onto the ground below). Stretched out on the side of a hill at noon, he looks upwards through half-closed eyes, seeing nothing but "the sunbeams dance." He becomes, he tells us in *The Eolian Harp*, a kind of living camera.

Full many a thought uncall'd and undetain'd,
And many idle flitting phantasies,
Traverse my indolent and passive brain,
As wild and various as the random gales
That swell and flutter on this subject Lute!

Hovering between passive reverie and active thought, the object of Coleridge's vision is nothing less than his own subjectivity. True to idealist philosophy, he assumes that "a great mind becomes that which it meditates on." In other words, Coleridge recognises that the image he sees is an interaction of nature and his own eye; becoming a camera involves witnessing the spontaneous production of both. What else could Coleridge's "unregenerate mind" be shaping here but the equivalent of a desire to photograph, a desire to take his particular, evanescent and contingent vision of nature and, as Talbot later put it, have it "fixed for ever in the position which it seemed only destined for a single instant to occupy"?

This struggle to overcome the passing of time, to fix an image that would otherwise be temporary, can be found articulated throughout early nineteenth-century European culture. Compare Talbot's description of photographs, for example, to the description of landscape paintings offered in 1833 by English painter John Constable: "an attempt has been made to arrest the more abrupt and transient appearance of the Chiar'oscuro in Nature...to give 'to one brief moment caught from fleeting time' a lasting and sober existence, and to render permanent many of those splendid but evanescent Exhibitions, which are ever occurring in the changes of external Nature." Throughout the 1820s and 1830s, Constable produced a whole series of paintings of "skies." At first glance many of them appear to be pictures of nothing much at all. A thin horizontal strip of landscape anchors what is an otherwise empty sheet of paper or canvas, empty, that is, but for some rapidly applied strokes of paint meant to represent clouds scurrying about in the wind. These are, in fact, attempts on Constable's part to make time visible. The attempt can never quite succeed of course, as he implicitly acknowledges through the rapidity and insubstantiality of his paint-application, and his demonstrated need to paint this same subject over and over again. Time, it seems, stops for no man.

To a degree foreign to earlier generations of painters, Constable is interested in representing the reality of immediate and momentary perceptual experience. He deliberately shows us a landscape as it is being seen by an imperfect human eye rather than by the ideal, eternal gaze of God. He depicts what a particular person saw standing in a particular place at a particular time looking upwards at the sky under quite particular atmospheric conditions. The picture not only acknowledges and presumes the presence of this viewer; it puts that viewer firmly in place, inscribed as it were in the very fibre of its being. As Peter Galassi has argued in *Before Photography*, Constable was only one of many European artists working around 1800 who ventured out into nature to wrest permanent images from the contingencies of vision and time. Another was Louis

Daguerre. In 1822, two years before he commenced his photographic experiments, Daguerre and Charles Marie Bouton opened their Diorama in Paris. In the Diorama, viewers sat on a platform that slowly moved so that different views of the same painted scene, enhanced by special lighting and other effects, could appear to gradually reveal themselves. This apparatus was described by its inventors as "imitating aspects of nature as presented to our sight, that is to say, with all the changes brought by time, wind, light, atmosphere." Again, their interest is in the representation (that is, the fixing in place, in space) of transcience, of the capturing in pictorial form of the passing of time, of the momentary. Their interest, in other words, is in providing what we would now call a photographic mode of representation.

It has been suggested that photography's conception in the decades around 1800 emerged from a unique and complex confluence of social, cultural and technical developments. As a consequence, photography as a general historical phenomenon has to be understood not just as a new art form or a product of modern science, but as a conceptual consequence of dramatic shifts in our notions of representation, knowledge, power, and subjectivity.

HISTORY: 2. 1826–1839

The period 1826-39 is dominated by the experiments and inventions of the French artist Louis Jacques Mandé Daguerre and his compatriot Joseph Nicéphore Niépce. By January 1826, when Daguerre wrote to Niépce about the possibility of fixing the images of a camera obscura, the latter had already worked out the fundamentals of his photographic process, which he called heliography. Niépce had begun experimenting with photochemical processes as early as 1816, achieved notable results by 1824, and produced the world's earliest extant stabilized camera image sometime in 1826–27 (*View from the Window at Gras*, Austin, Harry Ransom Humanities Research Center). Niépce visited Daguerre in Paris in August of 1827. He then travelled to London where he failed to interest the Royal Society in his heliographic process, which was based on the photosensitivity of bitumen of Judea, an asphalt used in printmaking. Unlike Daguerre, Niépce was concerned throughout his experimentation with the possibility of multiplying images through engraving. The earliest known image of this kind, an etching of a horse and its leader, was produced on a copper plate in July or August 1825 (Paris, Bibliothèque nationale). Several other plates, reproducing different prints through contact on various metals, have also survived, the most famous of which is the *Cardinal d'Amboise* (Chalon-sur-Saône, musée Nicéphore-Niépce). In order to reproduce engravings, Niépce varnished the back of a proof, thereby rendering it translucid. He then placed the print on a plate coated with bitumen. Upon exposure to light, the bitumen hardened under the un-inked areas of the print, but remained variably soluble under the inked areas. He then brushed the plate with acid diluted with water, which gradually attacked the metal, according to the thickness of the bitumen covering it. After repeated washes, he produced a reversed image etched onto the plate, which could then be used to print paper copies on an engraver's press. Niépce initially wished to engrave views produced on plates in the camera in the same way, although no such plates or proofs have been found. The *View from the Window at Gras* is rather a direct image obtained with bitumen on a pewter plate, which appears positive under raking light.

Before meeting Niépce, Daguerre had been working with phosphorescent materials in a camera obscura in an attempt to produce incandescent paint for his Diorama. The Diorama was a building designed by Daguerre that housed two large, semi-transparent paintings illuminated by natural light. Through the use of colored screens interposed between the paintings and the windows that lighted them, Daguerre achieved various effects of time, light, and movement in the painted scenes. He was an astute critic of Niépce's heliographic plates not only because of his extensive knowledge of lighting effects gained through the Diorama, but also from a solid understanding of printmaking techniques. Prompted by Daguerre's criticism of his photoengravings, Niépce focussed his attention after his return from London on camera images, which he called "*points de vue*." At Niépce's suggestion, the two men formed a company on December 14, 1829 in order to exploit the invention

of heliography, along with Daguerre's improvements to the camera obscura. By this date, Niépce had begun using iodine vapors to darken the light parts of camera images produced on silver plates, thereby restoring the normal relationship between light and dark that had been reversed in images in his earlier process. Daguerre preferred the quality of the original ("negative") image obtained on bitumen, and together they invented a new process that rendered a single, unique image, the physautotype. This process, based on the photosensitivity of the residue from oil of lavender dissolved in alcohol, resulted in an image that, like the daguerreotype, appeared either positive or negative depending on the angle of reflected light. After Niépce's death on July 5, 1833, Daguerre remained determined to perfect a process that would render a similar, unique image. He returned to the use of iodine, no longer as a darkening agent, but because of its photosensitivity when applied to silver plates as a vapor. This discovery led Daguerre to the invention of the daguerreotype process, in which mercury fumes brought out the latent image in the silver iodide on plates exposed to light in a camera.

Daguerre probably produced his first successful daguerreotypes as early as 1834 and announced his invention in the *Journal des artistes* on September 27, 1835. Daguerre had signed a new contract on May 9, 1835 with Niépce's son, Isidore. The new contract changed the name of the partnership from "Niépce-Daguerre" to "Daguerre and Isidore Niépce," in light of Daguerre's recognition of the chemical bases of the daguerreotype. A final contract was signed on June 13, 1837, naming Daguerre as the sole inventor of the new process, which was announced by the politician and scientist, François Arago, on January 7, 1839. Arago formally divulged the process to a joint meeting of the Académie des Sciences and Académie des beaux-arts on August 19, 1839, after King Louis-Philippe signed the law granting lifetime pensions to Daguerre and Isidore Niépce on August 7. Following Arago's announcement, Daguerre sent daguerreotypes to Ludwig I of Bavaria (Munich, Fotomuseum, Münchner Stadtmuseum), Ferdinand I of Austria, Nikolaus I of Russia, Friedrich Wilhelm III of Prussia, the Austrian chancellor Klemens Metternich (Prague, National Technical Museum), and Austrian ambassador to France A.G. Aponyi (Budapest, Museum of Science). Daguerre also offered daguerreotypes to Arago (Perpignan, Musée Hyacinthe Rigaud) and Alphonse de Cailleux (Paris, Société française de photographie).

Arago's announcement of Daguerre's invention in January 1839 provoked numerous claims of priority for other photographic processes, the most notable of which came from a member of the Royal Society of London, William Henry Fox Talbot. Talbot, a scholar known for his work in mathematics, presented examples of his photogenic drawings to the Royal Society on January 25, 1839, followed by a formal paper explaining his process on January 31. Talbot had first considered the possibility of fixing the images of the camera obscura in 1833. In 1834, he had developed both a form of cliché-verre, in which drawings scratched onto varnished glass plates were printed by contact onto silver paper, and photogenic drawings, in which the shadows of objects were imprinted through direct contact onto paper sensitized with silver nitrate. Talbot produced his first images in a camera in 1835, although these, like the contact images, had reversed light and dark areas. While he had already conceived of the idea of restoring the image to its proper disposition through a second contact printing, he did not pursue the idea of printing multiple positives from the initial paper print until the fall of 1840. At that time he began producing multiples by using the initial photogenic drawing image produced in the camera as a photographic negative, from which to make a positive image by taking a fresh piece of photogenic drawing and exposing it in contact with that negative. Until then, he was still attempting to meet the challenge posed by Daguerre, of producing a single image in which lights and darks could be perceived in their natural disposition.

Talbot's photographic process was not the only one in competition with the daguerreotype in 1839. The English physicist and astronomer John Herschel also invented several independent processes, including the cyanotype, and presented his paper on photography to the Royal Society on March 14, 1839. He is best known today, however, for having coined the term "photography" and for introducing sodium thiosulphate, or "hypo," as a fixing agent. Hercules Florence, a French immigrant living in Brazil, claimed to have captured images in a camera obscura by 1833, although he presented his findings only in October of 1839. Hippolyte Bayard, a French civil servant, invented an original process within the first few months of 1839 that rendered direct positives on paper. Although he received little support from Arago, Bayard's process received a favorable report in Paris from the Académie des beaux-arts, as did those of Talbot and an English engraver, James Tibbits Willmore. Willmore's process of "photogenic engraving," which was similar to Talbot's cliché-verre, was presented to the Académie des beaux-arts in April of 1839. In August of the same year, a French painter and drawing instructor, Auguste Berry, presented Arago with yet another photo-based process of producing multiples of original drawings. Such artistic applications were not pursued by the Académie des sciences, which rather supported Alfred Donné's use of the daguerreotype as an engraving plate for images taken through a microscope. Apart from Donné and the photoengraving process Hippolyte Fizeau used to print some of the plates of Nicolas Marie Lerebours' *Excursions daguerriennes* in 1841,

photomechanical printing would not be pursued seriously for another decade. These early attempts, along with silver-salt based paper photography, initially were eclipsed by Daguerre's process.

Many reasons exist to explain this triumph of the daguerreotype. The photosensitivity of silver nitrates had been known since the 18th c. and Thomas Wedgwood's experiments with the camera obscura at the turn of the 19th had been circulated through the scientific community by his friend Humphry Davy. Other experiments in the first decades of the 19th century (by Thomas Young in England and Samuel Morse in America, among others) are also documented. In 1839, then, the daguerreotype process not only seemed to be the most innovative but also, because of its precise detail compared to the first paper photographs, the most immediately useful in terms of scientific applications. Its most tangible scientific success in 1839 was in the field of miscroscopic photography, as practiced by Alfred Donné in Paris and John Draper in New York. Also in 1839, Daguerre's process was employed by Arago and Jean-Baptiste Biot to study the polarisation of light, and by Edmond Becquerel to study the effects of solar radiation. Conversely, the Académie des beaux-arts favored the more traditional processes on paper supports, whereas they dismissed any discussion of the daguerreotype in relation to art. Nevertheless, Daguerre's first images influenced the first generation of photographic artists, many of whom learned the daguerreotype process from the inventor himself during public demonstrations in September of 1839. Also beginning in September, Daguerre began giving weekly consultations to daguerreotypists at the Conservatoire des Arts et Métiers. He also oversaw the production of daguerreotypes at the shop of Alphonse Gustave Giroux, the son of his art dealer and the first manufacturer of daguerreotype equipment. These images produced at Giroux's shop, like the dedication plates Daguerre sent to European heads of state, comprised views of Paris and still-life arrangements of plaster casts, architectural fragments, bas-reliefs, and copies of sculpture.

Views of Paris, in particular vistas of the Louvre, Tuileries, or Notre Dame taken from bridges and buildings along the banks of the Seine, were among the first images produced by aspiring photographers and then exhibited in England, Belgium, Denmark, Poland, Germany, Italy, and the United States. The introduction of smaller, more portable cameras during the course of 1839 facilitated exterior photography. Architectural and city views also were improved through the use of prismatic lenses that corrected the lateral reversal of camera images, although many photographers, particularly in France, continued to produce reversed views. By November 1839, the artists Horace Vernet and Frédéric Goupil-Fesquet left France to photograph Egypt, where they encountered the Canadian, Joly de Lotbinière. Their original daguerreotypes of the Middle East, unlike those of Joseph Philibert Girault de Prangey from the early 1840s, have not been recovered, most likely because they were used in the production of etchings for the *Excursions daguerriennes*.

The widespread production of cityscapes and architectural views was partially due to constraints of the early daguerreotype process, before the use of accelerating substances made commercial portraiture feasible. While the same holds true for still-life arrangements of sculpture, it also can be said that such images fit within the growing 19th century concern with museums, collections, and the preservation of history. Daguerre created his still-lifes at the same time that the French government funded a plaster cast museum at the Ecole des beaux-arts and was considering a proposal for a new museum of French historical monuments. In his still-lifes, Daguerre sometimes included reproductions of sculpture from France or in French collections, such as Germain Pilon's *Les Trois Graces*, the 13th-century *Justice* bas-relief from the Saint-Etienne portal of Notre Dame cathedral, or the *Crouching Venus*, a version of which was installed at the Louvre in 1828. He also included sculpture not in French collections, and thus available only through copies or casts, such as a bust copied from the *Verospi Jove* at the Vatican or the *Venus de Medici*, which had been returned to Florence after the fall of Napoleon in 1815. These still-life combinations of sculpture from different periods and schools influenced many of the first daguerreotypists, including Alphonse Eugène Hubert, Alphonse Fortier, Baron Armand Pierre Séguier, and Bayard.

HISTORY: 3. PHOTOGRAPHY IN THE 1840s

The British *Quarterly Review* of June 1842 wrote of "… those *new arts* which are on the eve of altering the forms and habits of social life." It listed railways, locomotive engines, tunnels, steam-boats, and steam-guns, improvements in gas-lighting, and lighthouses; the electrotype, voltaic gilding and plating, the electro-magnetic telegraph and the electromagnetic clock. Significantly, it went on to claim that these new arts, "…along with the Daguerreotype of Niépce and Daguerre and the Calotype of Mr Fox Talbot, constitute the leading inventions of the day," This is a revealing insight into the range and scope of technological innovation that was transforming the lives of millions of people during the first half of the nineteenth century, but also a reflection of the impact made on contemporary opinion by the invention of photography. Although the earliest images shown in 1839 were produced with difficulty and were far from perfect, they had been received with astonishment and delight. The decade that followed was a period of trial and experimentation as the first practitioners of the new art struggled to improve processes and techniques they imperfectly understood using equipment barely adequate for the task.

For a few months following the announcement of photography, there was considerable confusion about the nature of the two pioneer processes, which was not surprising as there were few examples of images from either process to be seen. Opportunities outside of the major cities were negligible. The English photographer, John Werge, later described how as a fourteen year old, hundreds of miles from London, he was " fired with a desire to obtain a sight of these "sun pictures" but the fire was kept smouldering for some time before my desire was gratified." By the beginning of 1840 however, more examples were becoming accessible to the public and the differences between the mirror-like images of the daguerreotype and Talbot's photogenic drawings on paper began to be appreciated. The highly polished metal plates of the daguerreotype image could contain exquisite detail but their soft surface required protection by glass and each image was a unique direct positive; no negative was involved. Talbot's images on paper were crude by comparison but, most importantly, his process involved production of a negative from which an almost unlimited number of positives could be produced. Both processes required long exposure times, which allowed only static subjects to be captured on plate or paper, even in ideal conditions. They were also imperfect in many other respects but both were soon dramatically improved.

Improvements to the daguerreotype process took place by a series of small steps. In London during 1840, John Goddard found that bromine vapour could be used to increase the sensitivity of the plates and Antoine Claudet discovered that mixtures of bromine and chlorine had the same effect. Similar discoveries were made independently in Vienna. The French physicist, Hippolyte Fizeau's method of toning with gold, which toughened the fragile surface of the daguerreotype plate and increased the contrast of the image, was another widely adopted innovation of 1840. Improvements were also made to daguerreotype camera lenses. Particularly significant was a lens designed by the Austrian scientist, Josef Max Petzval and manufactured for him by the optician, Peter Friedrich Voigtlander. The mathematically computed Petzval was a large aperture lens, twenty times faster than the lens fitted to Daguerre's original camera.

Talbot also worked hard to improve his photogenic drawing process and by the summer of 1840 had made some progress. Samples of his work received good reviews in the press and from his friends. Examples shown to the young Queen Victoria and her new consort, Prince Albert, were also favourably received. In September 1840 he discovered that by using gallic acid as a sensitising agent a latent image was formed, which could be developed to a visible image. This was a dramatic discovery that shortened exposure times to a few minutes, even seconds under ideal conditions. Talbot called his new process the calotype, which also became known as the Talbotype.

During 1840 it became evident that the improvements to both pioneer processes would allow the exciting prospect of commercial portrait photography to become a reality. In this application of photography, the New World was in advance of the Old. Americans became interested in using the daguerreotype process to capture living subjects as soon as full practical details became available in September1839. John W Draper and Alexander S Wolcott may have been successful within a month. It was certainly Wolcott who opened the world's first commercial photographic portrait studio in

March 1840. He was able to reduce exposure times by using an ingeniously designed camera, in which a concave mirror replaced the usual lens. Although this novel optical system restricted the plate size and the quality of the daguerreotype images left much to be desired, they were received with enormous enthusiasm. Wolcott's system was taken to London by his partner's father, William S.Johnson, who entered into a partnership with Richard Beard, a coal merchant and patent speculator. Beard was a licensee for Daguerre's English patent for the Daguerreotype process and in June 1840 he also took out an English patent for Wolcott's camera design. The system was further improved by incorporating Goddard's bromine accelerating process. In March 1841, Beard opened Europe's first daguerreotype portrait studio at the Royal Polytechnic Institute in London's Regent Street. In what was then the richest city in the world, such a novelty meant that success was almost certainly assured. A review in *The Spectator* noted "if the charge be moderate…thousands will flock to the Polytechnic portrait room and the patentee, Mr Beard, will make a fortune." Thousands did flock and Beard did indeed make a fortune. Three months after Beard's opening, Antoine Claudet opened a rival daguerreotype studio on the roof of the Adelaide Gallery in London. Other studios followed and within a few years almost every major town in Britain had its daguerreotype portrait studio. Similar events took place in France, the home of the daguerreotype. Paris became the world's centre of excellence for daguerreotype equipment and materials. It was the introduction of the Petzval portrait lens that promoted the establishment of daguerreotype portrait studios in Austria and Germany, where they were again received with acclaim. Daguerreotype portraiture became a world wide phenomenon. By the end of the decade, studios were operating as far away as India and Hong Kong.

The American people's enthusiasm for the minute detail of the daguerreotype was unrivalled. As in Europe, many early commercial practitioners saw photography as a lucrative sideline to a more traditional trade and the quality of early portraits was often poor. This did little to dampen enthusiasm and quality improved as the more skilful operators became established. From the early 1840s, businesses such as the galleries of John Plumbe and the partnership of Albert Southworth and Josiah Hawes began earning reputations for high quality. One of the most distinguished names in American photography, Matthew B. Brady, opened a daguerreotype studio in New York City in 1844. By the end of the decade American daguerreotypes were beginning to be recognised as the finest in the world. The calotype process was never widely practised in America. William and Frederick Langenheim, who had been operating a daguerreotype studio in Philadelphia since 1841, purchased rights to the calotype from Talbot in 1849. They were enthusiastic about its prospects but totally failed to convince American customers of its merits.

In England, Talbot had harboured hopes that calotype portrait studios could emulate the popularity of the daguerreotype studios. In August 1841 he licensed the first professional calotypist, Henry Collen, a miniature painter by profession. The first press reviews of Collen's portraits in the spring of 1842 were generally favourable. The *Morning Post* reported that " The portraits, those at least we have seen, are very satisfactory. There is a rough air of truth about them, which reminds one of the first, and sometimes the best, sketches of the artist…." Emphasising the one great advantage the calotype enjoyed compared to the daguerreotype, the *Gentleman's Magazine* noted, "the likenesses produced by Mr Collen of Somerset Street, may be multiplied to any extent." However, calotype portraiture failed to capture public imagination. Possibly this was because neither Talbot nor Collen displayed any flair for business but even when the fashionable daguerreotypist, Claudet, was licensed to take calotypes, there was little interest.

Talbot showed that the calotype process could be a suitable medium for portraiture by making charming private portraits of his family and friends but perhaps the most convincing proof was provided by two Scottish calotypists, Robert Adamson and David Octavious Hill, who became partners in 1843. Adamson was responsible for technical matters, the chemistry and manipulation, while Hill looked after the artistic side of the business, posing the sitters, backgrounds and lighting. Until Adamson's death in 1848, they produced around 1,500 calotype portraits and groups, which most modern commentators accept are amongst the most masterly images of the decade. Hill, a painter, was a champion of the artistic qualities of the calotype process. He had little time for what he called " the livid pictures of Daguerre."

In 1844 Talbot set up a calotype printing establishment at Reading where he produced the world's first commercial photographically illustrated book, *The Pencil of Nature*. During the next three years, Talbot used the Reading establishment to produce enormous numbers of prints from his own negatives and those of his friends and associates. Amongst the most interesting are Talbot's London views, the earliest important photographic record of a great city. Photography on paper was most popular amongst Europeans and particularly the gentleman amateur photographers in Britain. Many of these early calotypists were part of Talbot's circle of family and friends. They included, his Welsh cousin, Christopher Rise Mansel Talbot, cousin by marriage, John Dillwyn Llewellyn, the Reverend Calvert Richard Jones and the Reverend George Bridges. The calotype process was also widely practised in France, particularly after the introduction of Louise-Desire Blanquart-Evard's improved method announced in 1847.

It was quickly recognised that a public who travelled little and were used to seeing strange and exotic foreign lands solely through the eyes of an artist would be fascinated by foreign photographic views. As early as 1839 a French journalist had written, "travellers may perhaps soon be able to procure M. Daguerre's apparatus and bring back views of the finest monuments and of the most beautiful scenery of the whole world." From Paris, Noel P Lerebours commissioned and collected daguerreotypes from all over the world and is reputed to have acquired more than a thousand pictures of foreign lands. The British were particularly prominent in the Mediterranean regions. During 1840 and 1841 Dr. Alexander John Ellis took over 150 Italian views using Daguerre's original process. Talbot's associates, Calvert Jones and George Bridges took scores of calotype views of Malta, Italy and the Holy Land in 1845–46, many of which were printed at the Reading Establishment. In America, the Niagara Falls was a popular subject for daguerreotypists from as early as 1845. Commerce may have been the driving force for much of the above work but in an age of exploration and empire, photography was beginning to be seen as having other applications. Edward Anthony was reported to have been asked to make daguerreotypes of parts of the north-east boundary of the United States as aids to resolving a frontier dispute with Britain. In India, John McCosh practised calotype photography while serving as a surgeon in the East India Company's army during the Second Sikh War (1848–49) and wrote 'I would strongly recommend every assistant surgeon to make himself master of photography in all its branches.'

The scientific community of the 1840s was deeply involved in photography, both in furthering its progress

and in applying it to science. Talbot, Sir John Herschel and Sir David Brewster in Great Britain, Jean Baptiste Biot, Hippolyte Fizeau, and Leon Foucault in France, and Samuel Morse and John Draper in the USA, are just some of the scientists that made invaluable contributions. Much of scientific work involves careful observation and the potential of photography to be an invaluable aid to the information gathering, analysing, recording, and storing process was immediately recognised. Anna Atkins' privately printed *British Algae: Cyanotype Impressions*, was a collection of contact impressions produced in what later became known as the 'blueprint process,' invented by Herschel in 1842. Issued in parts between 1843 and 1853, it was possibly the first serious application of photography to scientific publication. The study of the infinitely small and infinitely distant were revolutionised by photography. Talbot's first views through a microscope were made in the 1830s, as were daguerreotype specimens by the Frenchman, Alfred Donne. In 1844 Donne, with Leon Foucault, was able to produce daguerreotype plates of blood cells as an aid for illustrations for an atlas of microscopic anatomy. As the 1840s progressed increasing numbers of investigators using both of the major processes produced photomicrographs of an astonishingly high quality. John Draper at New York University made the first recorded photograph of the moon through a telescope in 1840 and two years later made a daguerreotype of the spectrum of the sun. During the next few years, several photographers recorded solar and lunar eclipses. As Talbot perceptively wrote to Herschel as early as 1841, "there appears to be no end to the prospect of scientific research which photography has opened out."

The great debate as to whether photography was itself an art began during the 1840s. During its early days, photography was widely termed "the new art" but that did not mean that it was automatically seen as being artistic. In the 1840s the word art had a wider application than is common today and was applied to any number of skills, crafts, practices and industrial pursuits that would not now be accepted as artistic. Nevertheless, in high art's Romantic period, perhaps photography had that hint of mystery that appealed for the influence of painters on early photography was immediate and profound. Unsurprisingly, paintings and drawings influenced the composition of many early photographs. As Hill demonstrated, an artistic eye could be a great asset, even to a commercial photographer. Many painters took up photography; some practised their traditional skills alongside photography. A host of minor artists were used to hand colour daguerreotypes; photographs on paper were also sometimes coloured or retouched by hand. Photography was widely used to copy works of art and was to become a major factor in the popularisation of art during the nineteenth century.

By the end of the 1840s, photography was firmly established and becoming organised. Patent restrictions in England were irksome but that was a problem for the next decade. The first photographic societies were being formed and a growing number of people, albeit from a limited privileged group, were practising photography as a hobby. People were becoming more used to seeing photographic likenesses and to appreciate that photography could represent the world around them with an accuracy undreamed of by previous generations. After the rapid improvements earlier in the decade, technical development was steady rather than spectacular. The typical camera still resembled the pre-photographic camera obscura but was usually purpose built and professionally made. The home-made cigar box and spectacle lens type of instrument described by Draper in 1840 was likely to have been discarded. A new industry was growing up as certain chemists and instrument makers began to specialise as photographic manufacturers and dealers. By 1847 the London dealer, Horne, Thornthwaite and Wood, was advertising a range of over a dozen cameras with prices ranging from a guinea to forty pounds. Improved lenses were being offered although the Voigtlander Petzval remained highly regarded. The anonymous author of a British manual, *Photography Made Easy* (c 1845), complained of "no English lens being at all comparable, as we believe, with the Voigtlander for inducing beauty of detail, correct delineation, or, indeed, rapidity of operation." Alternative processes were suggested but advantages over the processes devised by Daguerre and Talbot were minimal. The direct positive process on paper announced by the Frenchman, Hippolyte Bayard, in 1839 received no support in France and had no influence on the development of photography. Abel Niépce de St-Victor's albumen on glass process of 1847 was a step into the future but, again, was not widely influential. The typical photographs throughout the 1840s were the finely detailed daguerreotype images on metal by the professional portrait photographer and the coarser calotype images on paper favoured by the amateur or where numerous duplicates were required.

In the wider world, photography was born into an age of change, uncertainty and social unrest, partly driven by rapid technological innovation. During the 1840s, there was economic depression in Europe and America. There was famine and riot in Great Britain, revolution in Paris and Vienna, and war with Mexico in the United States. Yet the technology driving this change, was also creating the seeds of recovery and prosperity. This was the great age of the machine and steam power. Railways were opening up countries and continents to new goods and new cultures. Against this background photography survived and thrived. Despite the problems, the pio-

neers succeeded in laying the foundations of modern photography. They left a multitude of striking images as evidence of their skill and vision as well as a unique record of the age. The end of the decade was a turning point for the world economy as trade increased and prosperity improved. It can also be seen as a turning point for photography. During the 1840s, photography had been enthusiastically received by the educated and the fashionable but for great masses of the population, it remained just one of many novelties of an innovative age. In the early 1850s technological change brought a new process that was to displace the pioneer processes from favour and bring photography to the attention of a wider public than ever before.

HISTORY: 4. 1850s

The 1850s were, arguably, the most important years in the establishment of photography in both Europe and America, and during that decade, some of the finest photography of the Victorian era was produced. Many of the key applications of the medium were introduced and developed, the photographic press was established, and the world's first photographic associations were set up.

The decade opened with the high cost daguerreotype being used to make 'likenesses' for the rich, and ended with the ubiquitous carte-de-visite—which would eventually bring portraiture within the price range of everyman—definitely in the ascendancy.

The daguerreotype and the paper negative were the two dominant processes as the decade opened, and predictions of the immediate demise of the daguerreotype were to prove considerably premature. Writing in 1850 on the future of photography, Baron Jean Baptiste Louis Gros—who in the following year would become a founding member and the first President of France's Société heliographique—asked, "Is it not easy to foresee that the daguerreotype has almost run its course, and that its rival on paper is destined by its indisputable advantage to carry the day against it?" While many recognised that the negative represented photography's future, opinions varied on whether paper or glass constituted the ideal carrier for the negative image. Gustave le Gray, quoted in the English translation of his pamphlet *A Practical Treatise on Photography upon Paper and Glass*, also in 1850, observed that, "The future and extensive application of photography will doubtless be confined to the paper process and I cannot too much engage the amateur to direct his attention and study to it. The negative proof on glass, it is true, is finer, but I think it is a false road and it would be much more desirable to arrive at the same result with the negative on paper."

As the decade unfolded, neither prediction would prove to have been especially perceptive, nor immediately likely to come to pass. Many of those who would are today considered to be amongst the daguerreotype's most articulate exponents had not yet entered the arena at the time of Gros's remarks, and despite the paper negative evolving considerably throughout the decade in Europe, it would ultimately be 'the negative proof on glass' which would win the day.

In the United States, the daguerreotype reigned supreme and almost unchallenged in the early 1850s. Attempts to introduce Talbot's calotype into America had met with only very limited success, although some photographers persevered with the process into the early 1850s, eventually attracting praise for their achievements. Roger Fenton attributed the phenomenal growth of photography in the 1850s—especially in Britain—directly to the impetus generated by its

inclusion in the Great Exhibition at the Crystal Palace, London, in 1851. The restrictive effects which Richard Beard's patents had imposed on the development of photography in Britain were underlined when the three prizes awarded by the jury at the Crystal Palace all went to American photographers—Matthew Brady, Martin Lawrence and John Whipple.

The *Illustrated London News* described the American daguerreotypes—some of them more than 12 by 10 inches in size—as 'super excellent' while the American response was an unequivocal 'in daguerreotypes we beat the world.' John Werge later attributed the American successes to the fact that they could buff their daguerreotype plates without leaving marks on the delicate silver surface which, he insisted, most British practitioners could not.

Writing in his book *The Evolution of Photography* in 1890, Werge recalled his visit to the Hyde Park Exhibition—coincidentally his first visit to London

> After a night's rest, which was frequently broken by cries of "Stop thief!" I arose and made an early start for the Great Exhibition of 1851. Of all the wonderful things in that most wonderful exhibition, I was most interested in the photographic exhibits and beautiful specimens of American Daguerreotypes, both portraits and landscapes, especially the views of Niagara Falls, which made me determine to visit America as soon as ever I could make the necessary arrangements.
>
> While examining and admiring these very beautiful Daguerreotypes, I little thought that I was standing, as it were, between the birth of one process and the death of another; but so it was, for the newly born collodion process very soon annihilated the Daguerreotype, although the latter process had just reached the zenith of its beauty. In the March issue of the *Chemist*, Archer's Collodion Process was published, and that was like the announcement of the birth of an infant Hercules, that was destined to slay a beautiful youth whose charms had only arrived at maturity. But there was really a singular and melancholy coincidence in the birth of the Collodion Process and the early death of the Daguerreotype, for Daguerre himself died on July 10th 1851, so that both Daguerre and his process appeared to receive their death blows in the same year.

Forty years after the event, Werge's memory of the early 1850s was imperfect. The daguerreotype and the collodion process, together with countless variations on the paper negative, co-existed in the British and European markets for many years after Daguerre's death. In April 1853, he did realise his ambition, and set sail from South Shields to the United States, where he practised as a daguerreotypist with a number of American studios. Despite his recollections of the process's almost-immediate demise, he himself did not abandon the daguerreotype until 1857.

Of British daguerreotypes in the Crystal Palace, Werge made not a mention. The smaller number of English practitioners at the time, limited by Beard's imposition of a geographical licensing regime must, however, have played its part. Britain was the only industrial country where the process was so strictly controlled.

While the Crystal Palace was only one of the influences which fuelled interest in the medium, it was, however, as a direct consequence of that display that Fenton and others organised the world's first exclusively photographic exhibition at London's Royal Society of Arts in December 1852. With interest in photography fuelled by the Great Exhibition, the organisers of that 1852 exhibition at the Society of Arts must have felt assured of wide coverage in the journals of the day.

The exhibition was large, and the *Illustrated London News* was not entirely supportive of the selection, noting, in the issue for New Year's Day 1853 that

> The works of Mr Fenton, Sir William Newton, Mr Shaw, Mr Goodeve, Mr Archer, Mr Horne and Dr Diamond are, with several others respectively, examples of much interest. Many among them are pictures of exceeding beauty, and curiously suggestive; but many would not have passed beyond the portfolio of the artist, since the subjects have been badly chosen and the results obtained are very unsatisfactory. Mr Fenton, on the occasion of the opening the exhibition, read a paper on the 'Present Position and Future Prospects of the Art of Photography' in which he sketched briefly the present state of our knowledge, and judiciously pointed out the most important points for research. 'Though the excellence of the specimens now exhibited' says Mr Fenton, 'might allow photographers the indulgence of self-complacency, still everybody feels that, as an art, it is yet in its infancy, and that the uses to which it may be applied will yet be multiplied tenfold'.

The lack of selection of subject, of viewpoint, and of lighting conditions were failings to which many photographers succumbed throughout the 1850s, an era when the successful navigation through the complexities of the procedures was often seen as justification in itself for exhibition. Photographers who saw the medium simply as a technical challenge would increasingly attract the wrath of writers and lecturers. In a lecture to the Manchester Literary & Philosophical Society in April 1856, the disdain in remarks made by James Mudd echoed with a resonance which continued for years. Mudd stated, "Nature does not show her loveliest things to such careless seekers; and if she did they could not see, for they have not the educated eye to discern them. These are the mechanical workers who believe that processes, lenses, and apparatus make pictures."

Much of the photography in the exhibition was by le Gray's waxed paper process, while the majority of images had been produced by the full range of paper negative processes then available. A smaller proportion

were taken with wet collodion, the process relatively newly introduced by Archer, and the one British-invented process which, at the time, all believed would be free of patent restrictions. Talbot's legal proceedings against Martin Laroche and other wet collodion users for claimed infringements of his calotype patent would be initiated in 1854.

In America, where the daguerreotype had reigned supreme for so long, even writers such as H. H. Snelling were (perhaps grudgingly) changing their opinions about the potential of the paper negative. Writing in the *Photographic Art Journal*, at the end of 1852, Snelling conceded that, "if we are to judge from the constantly increasing demand for photogenic paper and paper chemicals, it will not be long before photography on paper will be as extensively practiced as the daguerrean art. The beautiful results obtained by Messrs. Whipple and Black, of Boston, have undoubtedly contributed to enhance the interest in the paper processes." The writer made no attempt to conceal his opinion of the standards of work being produced on the eastern side of the Atlantic, continuing

> These gentlemen have produced proofs upon paper far excelling any of those coming from either English or French manipulators. We consider them superior, because they come from their hands in a finished state, fine in tone and softness, excellent in color, and almost perfect in outline, soundness and perspective, without the aid of the brush, which cannot be said of the European photographs, they being more or less retouched.

In an intriguing twist to the evolution of photography in America where the daguerreotype had always been practised freely, James Ambrose Cutting was granted a patent for a slight variation on Archer's collodion negative and positive processes in 1854, and through it attempted to control the development in America of the one process which was, after the collapse of the action against Laroche, freely available elsewhere at the time. It took fourteen years for the issue to be resolved in

the American courts, and for Archer's process—given freely to the world—to be freely available in the New World.

The initial announcement of Archer's wet collodion process, however, and the dramatic improvement in image clarity which that process permitted, was at least as important a trigger as the Great Exhibition in launching photography as a mass medium. Of similar importance was the introduction of Blanquart-Evrard's albumen printing paper—although it would be the early 1860s before that became widely used outside Europe.

Blanquart-Evrard's printing establishment in Lille, the "Imprimerie Photographique" that opened in the summer of 1851, was where some of the finest photography produced in France during the decade was actually printed. That printing works produced, amongst many others, the magnificent albumen prints from Maxime du Camp's pioneering 1852 journeys through Egypt, Nubia and Palestine, and John Beasley Greene's 1854 journey up the Nile, as well as many magnificent architectural views by Bisson Frères and others.

Upwards of thirty local women were employed in printing tens of thousands of prints per year, and the combination of albumen paper, rapid printing times and cheap labour, enabled the factory to reduce the unit price of an albumen print to less than a tenth of the cost of a salt print.

When the factory closed in 1855, Blanquart-Evrard moved to Jersey, where he opened a new factory in collaboration with Thomas Sutton who, in 1856, would become the founder–editor of the influential, if rather opinionated, magazine *Photographic Notes.*

Albumen paper, gold-toned as an aid to permanence, defined the photographic image of the 1850s, 60s, and 70s. It also marked photography's first tenuous step into the world of mass production. Albumenised paper—already coated with albumen, and needing only to be rendered sensitive to light—became commercially available in the mid-1850s, and relieved photographers from one of the many tasks involved in the preparation of their materials.

Given the enhanced detail and sumptuous tonal range of the albumen print produced in capable hands, Fenton's decision to stick with the tried-and-tested salt print for his 1855 Crimean oeuvre is perhaps surprising.

Had the albumen print not been introduced, the multiplication of the photographic image would have been severely impaired, and the growth of photography undoubtedly slowed down. Collodion and albumen, despite the intricacies of the former, were the combined keys which unlocked photography's potential, and both were born at the start of the decade.

Interestingly, while the majority of photographers and photographic printing establishments used it as a printing-out paper, Blanquart-Evrard conceived albumen as a developed paper, requiring much shorter exposures, and considerably increasing the number of prints which could be produced in a day. His Lille printing establishment was one of only a very few places where the developed albumen print prevailed.

The complexity of the collodion process, and the availability of only a few published manuals on photography, was an obvious encouragement for photographers to get together to share technical information. That practice had been established for several years in Britain—the Photographic Club, often referred to as the Calotype Club, had evolved in the 1840s as an informal gathering of like-minded photographers enthusiastic about sharing information. Amongst its early participants, Peter le Neve Foster, Peter Wickens Fry and others would, in 1853, be instrumental in establishing Britain's first photographic association.

Most of the formal photographic organisations grew out of informal groupings of similar like-minded photographers who saw the sharing of information and ideas, both technical and aesthetic, as being essential elements in the development of the medium.

America's first attempt at setting up a photographic association was initiated in July 1851, with the inaugural meeting of the New York State Photographic Association, later known as the New York State Daguerreian Association. The rival American Heliographic Association was set up three days later, quickly changing its name to the American Daguerre Association, with Jeremiah Gurney as its first chairman, and Albert Southworth amongst its founding members. The two associations reportedly developed an acrimonius relationship—with the American Daguerre Association being branded a 'secret society' by some of those excluded from membership. Despite its title the ADA was not a national organisation. By 1854 both associations has ceased to exist.

France's first society, the Société héliographique, enjoyed only a similarly short existence, being superseded in 1854 by the Société française de photographie. In Britain, however, the Photographic Society of London—which later changed its name to the Royal Photographic Society of Great Britain—established in 1853 by Fenton, Claudet, and others, had enjoyed more than a century and a half of uninterrupted activity.

1852 was, in most parts of the photographic world, a watershed year. It was the year which saw the start of widespread acceptance of the wet collodion process, and the glass plate replacing the paper negative in all but a few areas of operation. One of the exceptions was in photography far from home, where the transportation of the bulky paraphernalia of collodion photography was not immediately practicable. Thus Fenton and John Cooke Bourne travelled to St Petersburg, Moscow and Kieff in the autumn of 1852 with pre-prepared waxed

paper negatives for their pioneering industrial photography project on the construction of Charles Vignoles' suspension bridge over the River Dneiper. Even so, their cameras and ancillary equipment, according to Vignoles' diaries, filled two coaches on the railway journey from St Petersburg to Moscow.

Gustave le Gray and O. Mestral used le Gray's waxed paper process for their contributions to France's *missions héliographique*, and Dr. Thomas Keith used his variant on the same process to create a significant body of soft romantic views of Edinburgh and central Scotland. In America Victor Prevost was probably the first of a very small group of photographers to experiment with le Gray's process.

One application where the glass plate was slow to gain acceptance was high-class studio portraiture, where the daguerreotype endured for several years into the so-called "collodion era" in Europe, and even longer in the United States. Leading photographers in Paris and London stayed loyal to the process well through the decade. Antoine Claudet, William Kilburn, and T. R. Williams, amongst others, produced some of their finest daguerreotype portraiture in the mid 1850s, many of them stereoscopic.

The stereoscopic daguerreotype also played a prominent role in the commercial photography of the Exposition Universelle in Paris in 1855. But while the great portraitists displayed their names prominently on labels on the reverse of their work, the photographers who produced multiple views of the great halls and gardens of the Exposition remained largely anonymous.

For photography's first decade, camera design had evolved little. Cameras for large format paper negatives were constructed as larger versions of the small sliding box cameras used for daguerreotypes. In a number of Roger Fenton's photographic views in Kyiv, these large instruments can be clearly seen, and their weight must have been considerable.

But with the granting of an American patent to William Lewis in November 1851 for a new daguerreotype camera, a feature was introduced which influenced large format camera construction for a century. The considerable weight and bulk of the simple sliding box design of instrument was dramatically reduced by the introduction of square-section concertina bellows. The 'tailboard' design of camera had arrived.

A plethora of lighter-weight camera designs followed, and for photographers who used le Gray's waxed paper process—which allowed negative papers to be prepared days in advance—the weight of equipment the photographer had to carry when working in the field seemed destined to reduce considerably. However, with many photographers converting to collodion as soon as Archer's process became known, all such weight benefits were quickly cancelled out, triggering the design and marketing of a wide choice of backpacks, wheelbarrows, and other means of transporting darktents and all the other paraphernalia of the wet plate.

In a short presentation to the recently formed Photographic Society of London on 21 April 1853, Marcus Sparling, later Fenton's assistant in the Crimea, demonstrated Major Halkett's design for a large format 11x8 inch field camera, fitted with a conical India-rubber tube connecting lens panel with back standard, and remarked that, "the camera sent by Major Halkett is not a new one, but has been now for some years in use in the army in most parts of England and Ireland." The use of a flexible material in this way was not new. Richard Willats had exhibited a camera with a fabric body at the Great Exhibition, and although the source of the army design is unknown, it may well have been developed from Willats' prototype.

The ingenious construction of Halkett's camera, however, permitted the use of rising front for perspective control, and combined lightness of weight with a collapsible design which enabled it to be folded down into a very small unit packed in a small bag for ease of transportation. Scottish photographer Charles Kinnear's design of 1856–1857 for a lightweight camera for the travelling photographer introduced tapered bellows for the first time, as well as several other features which became standard.

The photography of the Crimean War (1854–1856) was one of the milestone's of the decade, albeit after a somewhat hesitant start. The ill-fated Richard Nicklin, and the unsuccessful military photographers Ensigns Brandon and Dawson were followed by photographers of several nationalities who ensured that, while photographs 'of war' were still a practical impossibility, the camera 'at war' established itself as a potent illustration medium.

Historically, accounts of photography in the Crimea are dominated by Roger Fenton, but he was just one of many. The Romanian Carol Popp de Szathmari, the Frenchmen Colonel Charles Langlois, George Shaw Lefevre (Baron Eversley), Léon-Eugene Mehedin, Pierre Lassimonne, and Jean-Baptiste Durand-Brager, the German Friedrich Martens, and British born James Robertson, then resident in Constantinople, all contributed to a very rich legacy of images taken during and immediately after the conflict. The Russian author Leo Tolstoy is also believed to have photographed in Sevastopol at the time of the lengthy siege of that city.

Other photographers added to the story. The British photographers Joseph Cundall and Robert Howlett photographed soldiers before they embarked for the war zone—and published them as *Crimean Heroes* and *Crimean Braves*—while le Gray and Nadar did the same for French commanders and officers. At the cessation of hostilities, Parisian portrait photographers Mayer & Pierson photographed the signing of the peace treaty.

As far as the general public was concerned, their only contact with these photographs was via wood block illustrations drawn from photographs in journals such as the *Illustrated London News*. However important the coverage of the war was in the history of photography, it was not a commercially viable proposition. The length of time taken to make the thousands of prints from Fenton's negatives delayed publication of the portfolios, and the publishers Agnew, Colnaghi and others were left with hundreds of unsold prints when interest in the war finally faded.

Other major publishing projects achieved much greater success. Francis Frith's series of photographs of Egypt, Nubia and the Holy Land taken in 1856–59, published by James Virtue, sold in large numbers. Indeed the photographic exploration of the Nile valley, inspired by the work of the late 18th century French scholars who first explored the region, and later by eminent painter David Roberts RA, did much to demonstrate the value of photography as an aid to scholars. Frith may have taken his camera further up the Nile than anyone before him, but the majority of his travels were in the footsteps of, amongst others, Frenchmen Maxime du Camp (1850–52) and Félix Teynard (1851–52) the American John Beesley Greene (1854).

The 1850s was the decade which saw the foundation of the photographic press. As much of the development of the medium was driven by debate, discussion and the sharing of information—carried in general interest magazines through the 1840s—the emergence of journals specifically devoted to photography was an obvious progression. In Britain, journals like *Notes & Queries* had established themselves as conduits for the exchange of information on photography, but the first dedicated photographic periodical emerged not in Britain but in the United States.

The Daguerreian Journal first appeared in January 1850, but within little more than two years had changed its name to *Humphrey's Journal*, becoming one of the most influential photographic publications over a period of two decades, before folding in 1870.

The Photographic Art Journal first appeared a year after *The Daguerrian Journal*, also later changing its name—to *The Photographic and Fine Art Journal*. An early issue in 1851 carried an article on Matthew Brady, noting that, due to failing eyesight, Brady was not himself taking pictures, but concentrating on running his business.

In France, the proceedings of the Société héliographique, formed in 1851, were published in *La lumière*, and once Ernest Lacan had taken over as editor in late 1851, the journal became, for a time, the authoritative voice of organised French photography.

The first British periodical devoted specifically to photography was the *Journal of the Photographic Society of London*, which was published for the first time on March 3 1853. In his opening remarks on the purpose of the journal, carried in its first issue, Roger Fenton made an oblique reference to *La Lumiére* and the London society's journal was clearly modelled on what he knew of its French counterpart. For several years, translations of key articles published in Paris were carried in the pages of the *Journal of the Photographic Society*, widening yet further the interchange of ideas. Through a number of slight name changes, it has endured for over 150 years and is still published today as the *RPS Journal*.

It was followed in 1854 by the first issue of the *Liverpool Photographic Journal*, which became the *Liverpool and Manchester Photographic Journal* and briefly *The Photographic Journal* before eventually becoming the *British Journal of Photography* by the end of the decade. Under that name it still thrives today and it too has a record of more than a century and a half of continuous publication.

Thomas Sutton's *Photographic Notes* published its first issue in 1856. *The American Journal of Photography and the Allied Arts and Sciences* was first published on June 1 1858, and across the Atlantic in Britain, *Photographic News* first appeared in September of that year.

If, as was generally the case, the emerging photographic press largely confined itself to dealing with the technical and scientific manipulation of the medium, and the myriad variations on every available process, other writers did introduce critical discussion of photography's ability to capture a realistic, pleasing and satisfying chiaroscuro, and its claims to be accepted as an art form. Attempts to reconcile science, technique and aesthetics when discussing photography were only sometimes successful.

Writing in the *Journal of the Photographic Society* as early as 1853, John Lieghton attempted to identify the challenge facing photography's attempts to be accepted as 'art.'

> Fine art seeks to elevate the imagination by lofty images derived from nature in its most agreeable forms. Nature may be and is conventionalized in the noblest and highest and highest art; the abstract is given without the minutiae. In photography this is reversed; breadth being sacrificed to detail. For purposes of science, however, for example, for natural history, for the architect also, or the engineer, the utmost detail obtainable in a photograph is advantageous; but the artist will not descend to minutiae; he desires breadth of effect; "his most perfect pictures may be out of focus, his distances may fade away, his foregrounds look indistinct, his trees may appear in masses, and his figures may be obscured by positive shades."Photographic pictures are at present too literal to compete with works of art.

Eugéne Durieu, writing in 1855 summed up photography's dilemma:

> As it reproduces pictures of nature with extreme accuracy, and often with a perfection and finish that the cleverest draughtsman would not know how to achieve, those who see in art only an imitation of nature have had to accept photography as the final and most complete expression of art. Many, therefore, have allowed themselves to be seduced by this idea and, applying themselves to the mechanical side of reproduction, they believe they have in photography reached the extreme limits of perfection, when they have managed to fix on the paper a sharp, clear image, finely detailed, of some scene. The more exact the copy is, the more it seems to them they have succeeded.

One of the seminal discourses on photography in the 1850s was written by Lady Elizabeth Eastlake in 1857, and published, unattributed, in the *London Quarterly Review*. Her husband, Sir Charles Eastlake was, at the time President of both the Royal Academy, and the Photographic Society of London. In a perceptive essay, and drawing on her understanding of Hunt's writings on the actinic values of light, she observed that

> So impatient have been the blues and violets to perform their task upon the recipient plate, that the very substance of the colour has been lost and dissolved in the solar presence; while so laggard have been the reds and yellows and all tints partaking to them, that they have hardly kindled into activity before the light has been withdrawn.
>
> Thus it is that the relation of one colour to another is found changed and often reversed, the deepest blue being altered from a dark mass into a light one, and the most golden-yellow from a light body into a dark.
>
> It is obvious, therefore, that however successful photography may be in the closest imitation of light and shadow, it fails, and must fail, in the rendering of true chiaroscuro, or the true imitation of light and dark.

Despite her clear understanding of the limitations of the 'ordinary' blue sensitive emulsions of all the early processes, Lady Eastlake went on to overlook those same failures which she had just been considering

> And this brings us to the artistic part of our subject, and to those questions which sometimes puzzle the spectator, as to how far photography is really a picturesque agent, what are the causes of its successes and its failures, and what in the sense of art are its successes and failures? And these questions may be fairly asked now when the scientific processes on which the practice depends are brought to such perfection that, short of the coveted attainment of colour, no great improvement can be further expected.

More than a decade and a half would pass before the spectral sensitivity of plates was extended—thanks to Hermann Vogel's discovery of dye sensitisation in 1873—but despite the limitations of negative materials sensitive to only blue and violet, some of the finest photography of the nineteenth century had already been created by the time Lady Eastlake wrote her essay.

The decade thus saw the emergence of debate about whether or not photography was an art or a science, about what constituted an artistic photograph, and whether or not the true art of photography was the 'perfection' with which it could replicate nature. While many proposed that to be accepted as an art, the new medium ought to borrow the traditions and trappings of painting, others argued that there was a unique photographic aesthetic which ought to be explored and developed, establishing photography as an independent art. Others saw photography as the death of art itself.

Baudelaire, writing in 1859, was not alone in his belief that photography was, "the refuge of every would-be painter, every painter to ill-endowed or too lazy to complete his studies … [and that] … I do not believe, or at least I do not want to believe; but I am convinced that the ill-applied progress of photography, like all purely material advances, have contributed much to the impoverishment of the French artistic genius already so rare. Baudelaire's dismissive remarks may have contained a germ of truth, but amounted to an unsustainable generalisation. Many of the finest examples of the art of photography produced in France in the 1850s were created by photographers who had first trained as painters—Charles Nègre, le Gray, Henri le Secq, André Giroux, Charles Marville and Edouard Baldus amongst them.

The understanding of the photographic perspective, the importance of light and shadow—so ably demonstrated in the early 1840s by Talbot—or the potential for creative interpretation rather than simple representation, which would help define and develop the photographic aesthetic, would take many more years to permeate the growing photographic community.

HISTORY: 5. 1860s

As one might expect, a study of photography in the 1860s must make allowance for some overlap in seeking to frame the ten years or so during which changes occurred in the medium with respect to technology, culture, and society. From a curatorial and scholarly perspective, the decade has been viewed as part of an ascending arc, a "golden age" wherein photography's rising fortune no longer depended on the rivalry between photography on paper and the daguerreotype, but on Frederick Scott Archer's system of wet collodion on glass plates. The process in essence provided the best of both earlier techniques, retention of detail as well as tonal breadth, and therefore met the requirements of an age marked by the appreciation of traditional artistry and the economic, industrial, and scientific embrace of empiricism. The technical shifts, shaped as they were by both aesthetic and utilitarian considerations, are also indicative of public ambivalence at the time with respect to the photographic image as art and as truth.

While the importance of the medium for both documentary use and artistic expression had certainly been recognized in its first two decades, the late 1850s saw the emergence of more organized efforts to use the camera as an agent in the gathering of visual evidence on a global scale. The advancement of an educated modern American and European public included a desire for knowledge of a world still relatively unknown to the vast majority. In the fervor of aesthetic debate, the critical proponents of artistic imagination denied a place for photography as "Art" in contemporary culture, or only reluctantly accorded it a secondary position with respect to conventional pictorial means. Yet scarcely contested were its alleged superior powers of verisimilitude and potential for recording all manner of phenomena from microscopic forms to heavenly bodies. Unlike other implements of mapping, measuring, and visualizing the geography of a region for scientific, historical, commercial, and political reasons, the camera became an integral tool in creating an awareness of national identity as well as of one's self with respect to the rest of world. In hindsight, the general 19th-century view of the medium's neutrality has come under increasing critical dispute, for the production and reception of photographs led to meanings closely aligned with the ideological persuasions of the day. In documentary work, photographers were guided by a sense of social, cultural, and historical import of the subjects which they pursued; their achievement depended to a large degree on how well the results of their enterprise met the demands of both the public imagination and government agendas.

Art criticism of the late 1850s carried the debate into the new decade regarding photography's role in modern society. Could photographers legitimately engage in earnest attempts to create symbolic narratives or *tableau* that had previously been the preserve of traditional iconography in painting, drawing, and printmaking? Was not the medium's mechanical nature better suited to applications that simply required recording of subjects as a means of enlightenment, the production of new knowledge? In European and American circles of social privilege, wherein well-established codes of cultural refinement and taste were closely followed, many could not accept photographs as equal to art for conveying the depths of the human imagination, for translating the raw material of life and nature into the grand ideals and noble sentiments of tradition. Reservations abounded, despite the efforts of sophisticated practitioners with aspirations to create pictures with artistic appeal.

In England, the influential critic John Ruskin had considered photography useful for artistic studies, and had even tried his hand at it on several occasions. By the end of the 1860s, however, despite the element of veracity that was central to his support of Pre-Raphaelite and landscape aesthetics, Ruskin had judged photographs the product of a mechanical device, which art was most certainly not. His contemporary Lady Elizabeth Eastlake had written of her uncertainty, too, observing that photography could only ever imperfectly portray "Nature," meaning a nature considered in the academic sense, which required selectivity through "artistic feeling" to represent anything truthfully. Across the English Channel, French poet and critic Charles Baudelaire had expressed his sentiments with far greater disdain, as witnessed in his 1859 Salon review: "let it be the secretary and clerk of whoever needs an absolute factual exacti-

tude in his profession…But if be allowed to encroach upon the domain of the impalpable and the imaginary, upon anything whose value depends solely upon the addition of a man's soul, then it will be so much the worse for us!" (Goldberg, 1981, p. 125) Thus the camera was relegated to the status of recording instrument, a product of the industrial age.

Despite such criticisms, professionals and skilled amateurs alike produced evocative landscapes, portraits, and tableau of pronounced sentiment. Among British photographers, several have displayed qualities that have secured them a place in the "canon" (i.e., widely recognized as culturally and historically significant) including Julia Margaret Cameron, Lady Clementina Hawarden, Oscar Rejlander, and Lewis Carroll. These Victorians would not allow the medium's relationship to the material world and surface appearance to stand as obstacles in the way of expressive purpose. Cameron, for instance, is well known for her subtly mannered portraits of contemporary literary and theatrical personalities, and her staging of poetically effusive characterizations of children and adults. She used the vagaries and variables of exposure and focus to aesthetic advantage in order to soften features and heighten the expressive properties of light and dark. Rejlander, Cameron's friend, was perhaps the most extreme in his attempt to approximate Victorian painting of the genre and anecdotal variety. For dramatic ends in his final prints he frequently manipulated two or more negatives in combination, thereby partially liberating photography from its direct causal (or in semiotic terms, *indexical*) relationship to the subject before the lens at the time of exposure.

The portrait photograph, though evident as a key subject area in preceding decades, became a thoroughly entrenched commodity amid the growing urbanization of Europe and the United States and the spreading of western social institutions in the colonized world. Nadar's (née Gaspar-Félix Tournachon) bold pictorial record of celebrated personages of Paris in the late 1850s and 1860s best exemplifies how pose, careful lighting, and attention to technique could secure a place for luminaries belonging to the cultural vanguard of the city. Portrait photography vastly exceeded the painted portrait in popularity during the decade. Nadar's career had begun in 1853 with his investigations into photography while attempting to create a series of lithographs that collectively displayed notable visages of Parisian culture—his *Panthéon Nadar*—but abandoned the printmaking project for the camera. The cult of personality in today's media can perhaps be traced to this particular moment in the history of the portrait in photography, during which the faces of acclaimed or notorious individuals entered the public domain in ever increasing numbers. Political fortunes could be staked on such images. One of the best known instances involves Mathew Brady's small photograph of Abraham Lincoln taken before his election to the presidency in 1860. The image was reproduced in the press during the campaign, thus spreading Lincoln's clean-shaven, pre-Civil War likeness throughout the U.S. and beyond. By the late 1840s Brady had already established daguerreotype portrait studios in New York and Washington, D.C.; he had envisioned a "Gallery of Illustrious Americans" that would have implications for the acceleration of similar endeavors at least through the 1860s. Portrait operators like Nadar and Brady thus helped to shape a modern society dependent on the visibility of public figures through the media, as much for entertainment and personal fantasy as for an awareness of the influential political and cultural figures of the age.

While Nadar, Étienne Carjat, and other talented practitioners in Paris of the 1860s set a high standard for artistic portraiture, photography also enabled the production of relatively cheap pictures of people from all stations of life. Adolphe-Eugène Disdéri, also operating in Paris, had patented in 1854 a commercial breakthrough in the form of multiple exposures of a sitter on a single plate. The process resulted in the *carte-de-visite* (Brady's *Lincoln* is an example), a small, easily exchanged photograph mounted on thin cardboard stock. *Carte-de-visites* reached their peak of distribution in the 1860s; in exchange for the expense and labor involved with an elevated artistic portraiture was an economy of production, and hence an increase in the mass reception of images unlike anything that had occurred prior to the period. The *carte-de-visite*, the cabinet card, a slightly larger format which appeared later in the decade and fulfilled a similar social function, and the tintype (which would replace the ambrotype in the '60s) would enable the public to afford the acquisition of images of one another, of individuals of distinction, of peoples and landscape views from geographical locations around the world. Add to this the growing numbers of stereographic views, extremely popular among the middle class at least through the remainder of the century, and one begins to realize how photographs became pervasive in the private lives of ordinary people. Though difficult to isolate as a function of our timeframe, the impact of images during the decade on the formation of a mass subjectivity or collective psychology must seriously be considered—matters related to all the emotional turbulence of an individual's life: love, trauma, death, faith, childhood, aging, memory, fear.

The growth in photography of individuals can been seen as part of a larger phenomenon that advanced considerably in the 1860s. This may be characterized as a zeal among advancing nations for making more tangibly visible people, places, and occurrences which had formerly been conveyed through paintings, drawings, and words. Photography's position as a credible

agent among these prior modes of testimony was all but established by the new decade. Pictures were not only accessible in both single image and stereograph formats, in albums, and in books, but as an accompaniment to printed scientific, scholarly, and popular material. Among the more poignant instances of this accessibility were images of war. While action views were produced on a restricted basis, mostly limited to stereo pictures because of the still relatively long exposure times for the larger photographs, the 1860s saw a proliferation of imagery related to the devastation of battle and the soldiering life. Following his experience in India at the scene of the Indian Sepoy rebellion in 1857 and 1858, Felice Beato next traveled to China to produce a photographic response to the Second Opium War of 1859 and 1860. Photographs of the U.S. Civil War were initially marketed by Mathew Brady, who had the original idea to hire a corps of operators to follow the Union forces. Alexander Gardner and Timothy O'Sullivan are the best known of Brady's men, both of whom broke with the senior portraitist to produce albums of the war, such as *Gardner's Photographic Sketchbook of the War* (1866), which included some of the earliest images of fatalities on both sides. Gardner's choice of the term "sketchbook" is perhaps an acknowledgement of the still tentative reception of photography for on-the-spot visual reportage, yet undoubtedly also served to remind viewers that photographs could now graphically communicate the weight of the experience as well as any hand drawn picture.

As marvels of revelatory experience for the 1860s observer, photographs worked in intriguing, often contradictory ways to serve scientific agendas on the one hand, and the world of popular culture and entertainment on the other. Nadar took his camera into the catacombs of Paris in 1861 for a rather startling look at the subterranean, and on more than one occasion between 1858 and 1868 had gone up in a balloon to secure the first aerial views of the city. G.-B. Duchenne de Boulogne had produced photographic studies of human expression in the mid 1850s. These were published in 1862 in a book demonstrating his experiments that included the electrical stimulation of the facial muscles: *Le Mécanisme de la physiognomie humaine, ou analyse electro-physiologique de l'expression passions applicable à la pratique des arts plastique*. Scientific inquiry thus went hand in hand with possible applications to the arts and generally revealed a fascination with strange, scarcely seen phenomena. In the most extreme of cases photography was recruited to bear witness to manifestations of the occult, spirit worlds beyond the living. The Spiritualist movement had its photographic proponents, like William H. Mumler of Boston, who also seized an opportunity for profit by picturing the "ghosts" of the deceased together with their living family or friends. His studio, opened in the early 1860s, served clients as well known as Mary Todd Lincoln, who posed with the spirit of her dead husband, the former president. Progress in science in the 19th century was predicated on empirical data—firsthand experience informed its reports and treatises, but the methods of science were often co-opted to give dubious or even insidious theories an authoritative cast. Thus the photograph's alleged objectivity served well to reinforce the positivist philosophy underlying the investigation of the world at this time, while giving credence to assumptions about life (and death) that have since been discredited.

Photography's utility in the authentication of encounter, theory, and speculation is further reflected in the increase of ethnographic projects in the 1860s. The camera assisted (and some would say *abetted*) systematic attempts to identity distinct groups within Western society, as well as within geographically far ranging peoples. In the eight volumes comprising *The People of India*, published between 1868 and 1875, the editors John Forbes Watson and John William Kaye capitalized on the medium in a colossal pictorial study with accompanying letterpress, effectively categorizing Indians by race, caste, and tribe. Far from neutral or objective, however, different groups are assigned specific traits, indicating for example those who might make trouble for civil authority, and so proving useful in the continued administration of India under the British Raj. Hence, through the orderly assemblage of images and text, pioneers of anthropology attempted to make scientific sense of the disarray of humanity, which resulted in a typecasting that reinforced an ideology of European imperialism even as such work bore witness to disappearing cultures. "Native groups" (as they were often known in the commercial trade), sometimes posed with the accoutrements of their respective occupations, became increasingly common through the commercial trade in photographs. Related views of vernacular dwellings and surroundings also figured into the an ever-expanding "knowledge" base that stimulated both scholarly study and popular dissemination. Commercial operators cultivated a popular fascination with the exotic in a manner that projected a notion of the "East" as different and perverse, but nonetheless oddly compelling to the European and white American imagination. Constructed versions of certain non-western locales and peoples have been critically assessed as a facet of Orientalism, which examines the subtle ideological currents underlying western cultural representations of a wide global sweep extending from north Africa to the Middle East, India, and the Asia of the Far East. The portrayal of native Americans, especially the Indians of the Plains and Western territories, forms a separate area for inquiry in relationship to photography of before, during, and following the 1860s. Yet, the image of the

The J. Paul Getty Museum, Los Angeles

"Red man" had become subject to its own peculiar kind of *orientalism* particularly by the end of the century. Current conditions and rapid changes occurring in the lives of indigenous peoples, the results of cultural clashes with Anglo-Americans and Europeans, were relatively little depicted through the lens compared with natives perceived as specimens of peoples on the brink of extinction.

Legendary or imaginative associations of place no less than historical significance became major motives for taking numerous corresponding pictures of architectural monuments and their environs. Astute photographers came to understand that profits were to be made by tracking down a variety of culturally and politically important subjects. George Washington Wilson, a native of Scotland, developed an eye for the best view to be sure the growing tourist market for domestic scenery would be satisfied. His business, started in the early 1850s, realized continued success in the following decade with photographs and books of Scottish and English subjects of literary renown, including Fingal's Cave at Staffa (c.1863-67) and Scott's Tomb at Dryburgh Abbey (c. 1863–68). Francis Frith had launched his Reigate firm in 1860, having just returned from a third and final journey to Egypt and the Holy Land. His acclaim grew from several publications of his large format prints (e.g., *Cairo, Sinai, Jerusalem, and the Pyramids of Egypt*, 1860), exquisite in their delineation of ancient monuments, profound in their association with Biblical places. In 1862, Frith and Company was established, which became a huge commercial concern; Frith had decided to cast his net even further from England by hiring other operators to photograph on the Continent, while also buying inventories of photographs taken of India and elsewhere. To re-photograph the same subjects and to market them under different imprints was hardly unusual for the period, especially if they had a proven record of popularity. With the increased competition among photographers of the 1860s, the systematic cataloguing of each new series of pictures by place and subject, with corresponding negative numbers, became an important marketing strategy (Wilson and Brady had adopted just

such a practice with their work). Catalogues, in contrast to books and other closed systems of printed material with pre-selected pictorial accompaniment, allowed for individuals as well as collecting institutions to select the images and to compile them as they pleased. The open format of distribution thus lent itself to specific interests or areas of inquiry, for mementos of a lived experience through foreign residency or travel, for satisfying one's historical or scientific curiosity, for scholarly research, or perhaps a combination of these concerns.

The work of traveling photographers of the period were compelled by several, sometimes conflicting motives to get their views. They often went to extraordinarily lengths to do so, and the widespread use in the 1860s of wet collodion on glass for landscapes makes these adventures even more astounding in light of the physical encumbrance of equipment necessary for any serious traveling photographer. In the tradition of the Picturesque, landscapists often looked for features that matched their conception of the pleasant prospect; if the scenery fell short of such expectations, the inclusion of a rustic or exotic dwelling, a fore-grounded tree with background hills, or a figure or two situated in the view would suffice. One detects, however, a change in awareness that enlarged the conception of earlier artists concerning the pictorial interest of unusual or unconventional subjects. Photographs were, after all, unavoidably informed by the very shape of the terrain and the impact of its inhabitants. And the majority of professional photographers—in contrast to talented "amateurs" without pressure to sell their work—were scarcely at liberty to pursue their individual subjective vision and interests exclusively, but must frequently adhere to the mandates of the various circumstances underlying their presence in the field, from entrepreneurial to political and scientific.

Samuel Bourne's seven years in India, beginning with his arrival from England in 1863, provides an significant instance of a photographer who worked abroad in order to build a successful enterprise particularly based on landscape and architectural views, in this case with his partner Charles Shepherd. Bourne and Shepherd's vast archive of images of the subcontinent encompassed Bourne's extensive photography of the Himalayas and architectural monuments. His sensitivity to both current public and scientific interest undoubtedly served him well to achieve acclaim for his work in photographic societies in India and in Europe, and to find their way into multiple collections and texts of use to a variety of disciplines. Bourne's work shares with others of the period a personal attraction to the extremes of nature, particularly with his counterparts who ventured into the North American wilderness. Carleton Watkins and Eadweard Muybridge offer perhaps the closest parallels, insofar as they too had a taste for the spectacular in nature. Both Watkins and Muybridge made several trips into California's Yosemite Valley in the High Sierra wilderness in the 1860s, while seeking to market their views to the public. Each strongly displays a distinctive approach to framing the natural environment. They also align themselves with others of their contemporaries who, unlike Bourne, worked under government patronage at one time or another. Watkins had photographed for Josiah Whitney's California State Geological Survey in the mid-1860s and Muybridge had received government commissions between 1868 and 1871. Perhaps most controversial with respect to government survey photography was Timothy O'Sullivan, a rather enigmatic character who had worked for Brady and Gardner during the Civil War. O'Sullivan was hired in 1867 to join the first of several campaigns under the leadership of geologist Clarence King, the U.S. Geological Exploration of the Fortieth Parallel. The area of exploration mainly comprised the exceedingly vast, decidedly non- picturesque desert and mountain wilderness of the Great Basin region. Though difficult to gauge precisely, King's relationship with O'Sullivan was surely a mutually reinforcing one, with the scientist assisting to direct the photographer's vision, while conversely, the striking formations pictorially articulated by O'Sullivan necessarily impacting King's ideas concerning theories of geologic time.

O'Sullivan's work for the King survey also exemplifies a direct correlation between the wilderness view and political ideology that was consistent with U.S. expansionist policies, readily evident in the way King used the photographs as illustrations in his reports to identify economically promising areas. More subtly, photographs could be construed as symbolic appropriations of regions otherwise occupied by indigenous peoples, or instrumental in the surveillance of areas of political or economic interest to multiple conflicting powers. Even the archaeological documentation of India, which became extensive from the 1860s, and ostensibly neutral in its collective efforts to construct a viable history of architecture (see, e.g., the treatises of James Fergusson), can be demonstrated to have supported the British justification of political control of the subcontinent. Further, individual civilian efforts to document a land and its people might also be interpreted as reinforcing the paternalism of the imperialist project, as witnessed in John Thomson's narratives and photographs of his travels in China between 1867 and 1872 (see *Illustrations of China and Its people*, 4 volumes, 1873–74).

Thus the proliferation of photographs in the late 1850s and 1860s reflects a diversity of image types and channels of dissemination, which implicates how the subjects portrayed could be open to multiple interpretations based on the social and economic conditions sur-

rounding their reception and the particular perspective of the viewer. At a time when western nations continued to establish their power both politically and culturally, photography flourished as an agent in the production of new and remarkable bodies of visual information. It provided a more knowledgeable, educated, and prosperous citizenry with further grounds for the rigorous affirmation of progress and self-determination, both hallmarks of modernism.

HISTORY: 6. 1870s

Writing in *The Year-Book of Photography* for 1870, the editor, G. Wharton Simpson, began his review of the previous year by remarking "The history of photography has passed into the uneventful stage: the art has acquired a steady, healthful being, and great discoveries no longer disturb the even tenor of its existence." This was a reflection of a widely held view that photography was passing through a period of steady but unspectacular progress along well-trodden paths. With hindsight, we can see that Wharton Simpson and his peers were, in fact, entering a decade that was a pivotal period in the history of photography. The main agent of change was the introduction of reliable gelatine bromide emulsion dry-plates in Britain. By the end of the decade gelatine bromide plates were being mass produced and increasingly adopted by photographers of all classes. The consequences of this and other technological advances were to completely transform the practice and nature of photography.

The 1870s could perhaps be termed the British decade of photography. It was no quirk of fate that the key development of the 1870s took place in Great Britain, or that many of the distinguished photographers remembered today were British. Britain was the richest country in the world. Relatively untroubled by events abroad, political stability, empire, industry and trade had all helped to create a prosperous middle class with time and cash to spare. In contrast, Continental Europe began the decade preoccupied with the Franco-Prussian War, which was then followed by periods of violent political instability. French photography in particular was profoundly disrupted by the social changes arising from wider events. Across the Atlantic the United States was a growing industrial and trade rival but in the 1870s still tended to follow European trends and was still a frontier country struggling to come to terms with the trauma of its Civil War.

In 1870, professional photographers could be found plying their trade all over the world. Despite a world-wide trade depression, New York photographic studios remained as Werge had described them five years earlier. "Their number is legion, and their size is mammoth…and mammoth is the amount of business done in some of those "galleries." (Werge 1890, 199). In London, *Kelly's London Post Office Directory* for 1870 listed more than 250 addresses of "Photographic Artists," 28 photographic apparatus manufacturers, and 26 photographic materials dealers, which included printers, paper makers and dealers, publishers and album manufacturers. The photographic artists listed were mostly professional portrait photographers practising the wet collodion process in studios much the same as those of 20 years earlier. Studios would be equipped with traditionally made mahogany sliding box or square bellows cameras fitted with brass lenses and mounted on stands or tripods. Other studio equipment would commonly include the headrest and painted backcloths with appropriate furniture. During the 1870s, gardens or rural scenes, complemented with items such as rustic chairs and stiles were fashionable.

The standard portrait form of the period remained the *carte-de-visite* but the larger cabinet portraits introduced

in the mid 1860s were becoming increasingly popular. According to one contemporary they allowed "greater scope for the display of an artist's skill, and a more commanding picture produced." (Cox 1876, p.40). Attempts were made to popularise larger formats. Valentine Blanchard in England introduced the boudoir portrait, which was described as having similar relative proportions to the carte-de-visite but larger. It was designed to show the full-length figure. An American introduction, of a similar size but with slightly different proportions, was styled the promenade portrait. Only the wealthiest clients would ask for portraits in whole-plate or 10 × 8 inches. The increasing popularity of larger portraits helped promote a renewed interest in enlarging. Enlarging was generally seen as a tedious business involving cumbersome solar enlargers and long exposures. Most earlier photographers seeking a large image had preferred to use a large camera. However, in 1873 John Trail Taylor reported "it is significant that several London photographers of reputation have already disposed of their large lenses as instruments for which they have no further need" *(British Journal Photographic Almanac 1873*, 19). By using a long extending focus camera to produce an enlarged intermediate transparent positive, which could then be further enlarged using the same procedure, it had been found that good images of up to 12 × 10 inches were possible. Such techniques required skill, exposures remained long and most photographers were still reliant on natural light. Enlargements could be made by artificial light using oxy-hydrogen limelight and appropriate equipment was marketed but there is little evidence it was widely used. Although continuing to make extensive use of the solar enlarger, American studios had a reputation for producing exceptionally fine enlargements. Interest in stereoscopic photography continued to decline in Europe but remained popular in America. Negative retouching became widespread in European and American studios of the 1870s although there were many critics of the practice and it became one of the major controversies of the decade. Wharton Simpson in Britain perhaps summed up the trade attitude when he claimed "The introduction of the practice of working on the negative has given to negatives of inferior quality a factitious appearance of better work; the smoothness, and apparent delicacy and finish, recalling in some qualities the characteristics of really artistic portraiture. This dead level of qualities which please the public taste is a doubtful benefit to the art, but it has undoubtedly done something to stimulate the trade in photographic portraiture."(*The Year-Book of Photography 1876*, 18–19). Experiments to make portraits by the light of burning magnesium powder were abandoned in the 1860s. The first portrait studios to successfully use artificial light were the electric light studios in Paris of Van der Weyde in 1878 and Liebert in 1879 but they were not typical of the period. Tintype portraits continued to be popular in America but were generally held in low regard in Europe.

The better studio photographers of the 70s made subtle use of posing, lighting and backgrounds to achieve the desired artistic impression. The most famous professional studio portraitist of the day was probably the French "Titian of Photography," Nadar (Gaspard Felix Tournachon), although following the siege of Paris and the subsequent social unrest, much of the work coming from his studio was by his assistants and his son, Paul. Also active until the middle of the decade was another notable French photographer, Etienne Carjat. Like Nadar, Carjat's reputation was based largely on his portraits of contemporary celebrities. The work of both appeared in *Galerie Contemporaine*, a series of portraits and accompanying biographical text, of distinguished French artistic and political figures that was published weekly between 1876 and 1880. There was a view that the overall quality of British portrait photography was inferior to that of their French contemporaries although the French artist and photographer, Antoine Adam-Salomon, wrote in 1871 of 'the marked progress made in artistic portraiture by English photographers' (*Year-Book of Photography 1871*, 23). In America, William Kurtz's "Rembrandt" portraits, Napoleon Sarony's, unconventional posing and J.M. Mora's use of exotic backgrounds, earned them nation-wide recognition.

While it was commonplace for the most humble studios to advertise their portraits as artistic, there were some photographers continuing to suggest that photography should have more lofty ambitions and the question of whether photography was capable of a position amongst the fine arts remained a hotly argued debating point. Three of the most distinguished 'high art' photographers of the period were active in England during the 1870s but Julia Margaret Cameron, Oscar Gustave Rejlander and Henry Peach Robinson had made their reputations, and arguably produced their best works, in the previous decade. Cameron is celebrated today primarily for the large close-up portraits of famous men such as Darwin, Herschel and Tennyson, all taken in the 1860s. Tennyson later suggested she should create images for his *Idylls of the King* and these were published in 1874 and 1875. Even the best of Cameron's genre studies are mawkish to modern eyes and the Tennyson pictures are not her best work. Cameron and her husband soon left England for Ceylon. She continued to practice photography but produced no further major work and died in 1879. The painter-photographer, Oscar Rejlander was also close to the end of his career. His moral allegory printed from thirty separate negatives, *The Two Ways of Life,* had provoked a minor sensation in the late 1850s. Other moralistic studies followed and for a time he was an influential figure. By the 1870s

however, he was working in less controversial areas as a London portrait photographer and supplementing his income by supplying photographic studies of children and adults to artists. His last major work consisted of illustrations for Charles Darwin's book, *On the expressions of the Emotions in Man and Animals*, published in 1872. Henry Peach Robinson was perhaps the most influential art photographer of the day and was to have a longer career. Robinson was a competent painter who had turned to portrait photography in the 1850s. Following Rejlander's path, his 1858 combination print, *Fading Awa*y, had been widely admired, both in Britain and abroad. Other genre combination prints, often in a Victorian sentimental style, soon followed. His most admired print of the 1870s was probably *When the Day's Work is Done* (1877). Robinson was a prolific author and despite periods of ill health, contributed numerous articles to journals throughout his career. His first book published in1869, *Pictorial Effect in Photography,* was based on the principles of the art education programme of the Royal Academy and became a seminal text for the rest of the century. Despite his influence and the esteem in which he was held, Robinson had his critics who accused his combination printing technique of misrepresenting the truth. Robinson was a complex figure. As a photographer, he specialised in producing representations of nature that never existed in reality. Yet when contributing to one of the burning debates of the period, he wrote in the *Photographic News* (Jan. 26, 1872, 41). "The chief charge against retouching is, that it destroys the truth of nature as represented in photography." Joseph Gale's images are less well known today but he was an admired and respected English photographer who first came to notice in 1874. His gentle rural landscapes and views with carefully posed models were perfectly in tune with English fashion of the period.

Away from the studios, landscape and architectural photography remained widely practised activities by specialists. Francis Bedford had taken up photography in the 1850s and photographed in the Holy Land in the 1860s. During the 1860s and 1870s he travelled widely in Britain taking wet plate-views on his large format cameras. Thousands of his views were sold in single print and stereoscopic form. He also found time to contribute regularly to the photographic journals. Similarly, the commercial concerns of the photographers James Valentine and George Washington Wilson were firmly established. Based in Scotland, enormous numbers of their views were marketed throughout Britain and abroad. Henry Taunt's wet-plate views of Oxford and the Thames taken in the late 1860s and early 1870s were greatly admired. Taunt included many to illustrate his book published in 1872, *A New Map of the River Thames.* The Scottish photographer, John Thomson, published much of his work in photographically illustrated books, which were eagerly purchased by the educated middle class in England. His views of China taken between 1870 and 1872 were published in 1873–4. The prints appeared in the form of carbon prints and collotypes with a written text by Thomson. Perhaps Thompson's most influential work was *Street Life in London*, prepared in association with Adolphe Smith and published in twelve monthly parts in 1877–78. The 36 Woodburytype images of the working class in London were derived from carefully posed negatives but are a landmark in social documentary photography. French architectural photographers also produced striking social documents. Charles Marville's views of the rebuilding of Paris between 1865 and 1878 are amongst the finest examples of architectural photography using the wet plate process. Also notable was the partnership of Delmaet and Durandelle that recorded the building works of the Paris Opera and the Church of Sacre-Cour during the 1870s. Many photographs of the devastation caused by the Franco-Prussian War were taken during the conflict but few have achieved the iconic status of Fenton's Crimean War views or the images of the American Civil War. The photographs taken during the subsequent insurrection in Paris have received more exposure although many of the photographers are unknown. Among those identified are Alphonse Liebert who published one hundred views of the destruction of Paris and events of the Commune in 1871 and the French commercial photographer Hippolyte Collard who photographed views of the street barricades. Documentary photography of a completely different order took place in America. The four US Geological and Geographical surveys of the Western Territories of 1867-1879 were conceived purely as scientific and documentary exercises but the powerful images of the rugged landscapes that were produced profoundly influenced the American public. The Photographers included Eadweard Muybridge, William Henry Jackson, Timothy O'Sullivan and Carlton E. Watkins. Although some rough prints were made in the field, regular shipments of wet-plate negatives were sent to Washington for printing. By the mid 1870s clever marketing had allowed an eager public to purchase enormous numbers of views sold in the form of prints and stereographs, images that have shaped the view of the American West to the present day. Jackson later had a long career marketing views of the west but his photographs of the 1870s, taken in association with a landscape artist, Thomas Moran, can be ranked alongside the most powerful images of American photography. The work of the survey photographers inspired the beginning of a professional 'landscape school' of American photographers.

The applications of photography to unrelated fields of observation, record and investigation continued to

widen during the 1870s. The first photographic analysis of movement by Eadweard Muybridge in America was an impressive achievement. In 1872 the former governor of California, Leyland Stanford commissioned Muybridge, to photograph a trotting horse, in order to determine whether at any point all hooves left the ground. Muybridge's early attempts in 1872 and 1873 were only partially successful. His chaotic personal life prevented immediate further work but he returned to the investigation in 1877. Armed with a faster shutter, Muybridge produced pictures sufficiently improved for Stanford to finance the conclusive project. In 1878 Muybridge adopted a method first proposed by Rejlander. Using a battery of cameras, he produced sequential photographs showing that a galloping horse did indeed briefly lift all four legs off the ground. That he was still using wet plate photography makes his success even more impressive. By the 1870s police forces were making increasing use of photography as an aid to identifying criminals and systematic picture archives were beginning to be assembled in the major European cities. The classification of thousands of images was a particular problem. In the late 1870s Alphonse Bertillon in Paris began devising a practicable system involving the measurements of specific anatomical details and strict standardisation of identification portraits, which were to bear no relation to commercial portraiture. Scientific studies by Cesare Lombroso in Italy and Francis Galton in England were undertaken to discover whether criminality could be determined from facial features. Galton's 1870s investigations led him to devise composite portraiture, successive brief exposures of several different portraits on a single plate. His work on criminal physiognomy was never accepted but he went on to use composite photography to confirm Muybridge's studies. During the Franco-Prussian War of 1870–1871, the use of microphotographs transported by 'Pigeon Post' created widespread interest. The chief architect of the scheme was the French photographer, Prudent Dagron, who used his experience gained making microphotographs for jewellery and trinkets to prepare microphotographs of written messages that were transported by pigeons to and from Paris during its siege. Photographic techniques were a key component of the many expeditions organised to observe the 1874 Transit of Venus and there was much speculation in contemporary photographic journals. Photographers and scientists had high hopes but most were disappointed with the quality of their final images. The wet collodion plates the majority of observers favoured were unable able to produce the sharp images required. The notable exception was the good results achieved by the French astronomer, Pierre-Jules-Cesar Janssen, who built an 'astronomical revolver' camera using circular daguerreotype plates. The insensitivity of the obsolete process was no handicap when photographing the sun.

One of the most significant technological developments in photographic history was brought about unwittingly by British amateur photographers. The gentleman amateur had been an important and influential figure in British photography since the days of the pioneers and by the early 1870s there were more amateur photographers in Britain than in any other country. The standard way of making photographic negatives remained the wet collodion process, reliable and practicable in a studio but the chemical manipulations involved, along with the necessary equipment and materials, made it far less suited to work in the field. As a consequence, many amateur photographers favoured dry processes, which allowed them to roam far and wide burdened by little more than a supply of pre-prepared plates and a camera. Unfortunately, early dry plates were unreliable and exposure times almost always longer than that for wet collodion, which was a continual source of frustration. New and supposedly better dry plates were a regular feature in the photographic press. Much space was taken up with discussions of their relative merits with firm conclusions rarely reached. A popular instruction book of the period describes no less than six different dry plate processes (Hughes, 1870, 66–74). Richard Leach Maddox's seminal *British Journal of Photography* paper of 1871 suggested that gelatine silver bromide emulsions might produce a dry plate that could match the qualities of wet collodion but it made little immediate impact. However, In 1873 a London photographer, John Burgess, marketed a bottled emulsion of gelatine bromide and later sold pre-prepared plates. The same year Richard Kennett patented a dried gelatine bromide emulsion, which was also marketed. Although many amateurs welcomed both products they enjoyed only limited commercial success. Reservations about the early products of Burgess and Kennett were partly due to their inconsistent quality but a major problem was the extraordinary sensitivity of gelatine bromide plates. Photographers of the period were totally unprepared for the short exposures possible with the new emulsions and regularly over-exposed their plates. But as amateur photographers slowly became more familiar with the characteristics of gelatine bromide, the advantages of short exposures became apparent, while refinements in the process and in manufacturing led to plates of improved and consistent quality. The Liverpool Dry Plate Company began selling Kennett's plates in 1876 and Charles Bennett's improved plates in 1878. Demand increased and other companies eager to exploit the enormous amateur market rapidly entered the business. By the end of the decade there were over twenty companies manufacturing and selling gelatine dry plates and many exhibitions now included amateur

photographs from gelatine negatives. A picture by Joseph Gale that captured a swallow in flight caused a sensation when it was exhibited in 1879. Professional photographers were much slower to take advantage of gelatine emulsions. John Werge later wrote of his "vivid recollection of the scepticism and conservatism exhibited by the most eminent photographers on the introduction of gelatino-bromide dry plates" (Werge, 1890, 96). Only towards the end of the decade did British professionals begin to use gelatine plates in any numbers and scepticism continued into the 1880s. The same was true of the professionals of continental Europe and America. Yet within a decade gelatine plate manufacture was to transform photography from a craft skill to a giant industry.

The fading of mass produced silver prints was a problem that had troubled photographers since the 1840s. By the 1870s several of the causes of fading had been identified but the problem persisted. John Trail Taylor claimed that "The balance of evidence is, we believe, in favour of the greater permanence of photographs printed on other than a surface prepared with albumen." (*British Journal Photographic Almanac, 1870*, 19). Printing in permanent pigments offered a solution. Carbon printing featured regularly in photographic journals, manuals and catalogues throughout the 1870s. Joseph Swan's carbon tissue process, introduced in the 1860s, had began to be adopted and Trail Taylor went on to advocate an improved version by J.R. Johnson, a director of the Autotype Fine Art Company. The Autotype Co. supplied carbon printing materials and made carbon prints for the trade as well as selling prints directly to the public. Carbon printing became widely favoured throughout Europe for reproducing art subjects. Notable European practitioners included Braun in Alsace, Hanfstangl in Munich and Goupil in Paris. The process did not have the same impact in America. William Willis's platinotype process, patented in 1873, was another non-silver process capable of producing permanent prints. It made little immediate impression but Willis improved the process and established a company to market platinotype papers in 1879. The platinotype process later became a particular favourite of artistic photographers wanting permanent exhibition prints. Carbon tissue formed the base component of the gelatine relief used in the Woodburytype process, a photomechanical process devised in the 1860s. Woodburytype prints were frequently used to illustrate printed books in the 1870s. Another photomechanical process that came to prominence was the collotype. This photolithographic process was devised by Poitven in 1855 but only came too wider attention when an improved form was commercially introduced by the German photographer, Josef Albert the late 1860s. Albertype, as it was known at the time, was described in detail in 1870s journals and was widely praised. An example published in the *Photographic News* (June 24, 1870) showed the interior of Albert's Printing Establishment in Munich. A subsidiary of the Autotype Company worked the process in the early 1870s as collotype, and they later sold collotype prints, often failing to distinguish between them and carbon prints. By the end of the decade there were 22 collotype printers trading in London. Yet more important in the longer term was to be the work of Karel Klic who invented modern photogravure in 1879 but the process was not widely worked until the 1880s.

By the end of the 70s some photographers were beginning to glimpse a different future for their art. Dated "Christmas, 1879," just a few weeks before his sudden death, Wharton Simpson wrote the preface to the first issue of *Photographic News* of 1880. It began, " The volume of the Photographic News just completed is, like those which have preceded it, a chronicle of twelve months' research, experiment, and result—a chronicle, in fact, of a year's work in photography throughout the world. But, unlike all others, it is chiefly devoted to the history of a revolution. The twelve months have witnessed a greater change in the practice of the art than has been seen by any former period." Wharton Simpson was referring to the increasing acceptance of gelatine bromide emulsions but other technical developments were also to have profound consequences. The 1870s were the last years when working photographers were required to master some of the theoretical and manipulative skills of the scientist in the manner of the pioneers. Two of the most distinguished pioneer scientists had left the stage—Sir John Herschel died in 1871, William Henry Fox Talbot in 1877. New scientists were coming to the fore. The work of Sir William Abney in Britain, and Josef Maria Eder and Hermann W. Vogel in Germany was to facilitate the development of greatly improved gelatine emulsions. In 1876 the French scientist, Ducos du Hauron, took out an English patent that established the basis of subtractive colour photography. Alongside the new photomechanical processes that were to revolutionise the printing industry and Muybridge's motion studies, the precursor of moving pictures, a new future was emerging. The tipping point had been reached; the foundations of modern photography can be discerned.

HISTORY 7: 1880s

The invention of photography was a significant moment in the history of art, in fact it meant the acceptance and assimilation of a new art form. It was characteristic of this development 50 years later that its practioners invariably opted for those motifs, themes and genres, which had traditionally been those of painting and graphic arts. There are also countless parallels and similarities in the schooling, background and studio methods of painters and photographers. The domination of the prevailing convention was extremely strong, forming a kind of leitmotif, which runs through the history of photography. Portraits, landscapes, genre scenes and literary themes were the favored subject matter.

In 1878 an Englishman called Charles Harper Bennett put the finishing touches to a method using gelatine-silver bromide which reduced exposure time to one twenty-fifth of a second. Soon after, plates which had been industrially adapted became available to the wider public.

Between 1880 and 1890, the very first portable cameras, which folding darkrooms attached, appeared on the market. These were used by painters such as Edgar Degas, as we know from the writing of his friend Daniel Loppé, a specialist in alpine landscapes who was also an amateur photographer.

Newspaper illustrations made their appearance in the 1830s. Among the first in an American newpaper was a woodcut view of the ruins of the great New York fire of December 16–17, 1835. But after 1850, newspapers virtually ceased using illustrations, and the public obtained its visual accounts of people, places, and events through the pages of such illustrated weeklies as Harper's and Leslie's. In 1873, the *New York Daily Graphic* made its appearance, using lithography for the printing of both type and illustrations (photolithographs). Stephen H. Horgan was hired as a photographer, but soon took over management of the paper's photomechanical printing operations. As he said later, the appearance of this newspaper was going to usurp the place of wood engraving. He did it for the first time on March 4, 1880.

Concurrently, with the progress of the presidential campaign of 1880, in which James A. Garfield won election by a narrow margin, photographers across the land began switching tot dry-plate practice. Albert Levy's gelatine dry plates and E. & H. T. Anthony & Co.'s Defiance plates were taken off the market by January 1881. But others were appearing on the scene. In St. Louis, Gustave Cramer teamed up with Herman Norden to perfect a commercial plate that would be better than anything previously offered. Their activity was another of the proverbial "burning the midnight oil' variety.

Eastman's dry plates were placed on the market by the Anthonys in December 1880. In Europe, meanwhile, photoengraving modes using a screening process, such as Baron von Egloffstein had used in 1865, were adopted by Joseph Swan in 1879, and by George Meisenbach, a Munich engraver, in 1882. First single-line screens which were rotated or turned during exposure with a negative to achieve a cross-line effect in the image secured on the sensitized printing surface, later a cross-line screen which consisted of two single-line screens cemented together face-tot-face at right angles.

Electric light on the market in 1882 brought a new brightness and bustle to cities at nighttime, and this tended to focus increasing public interest on theatrical personalities, adding further to an already popular craze of collecting cabinet card and carte de visite portraits of celebrities in all fields.

In 1883 William Schmid of Brooklyn, NY, was awarded an American patent for the first commercial version of the hand-held 'Detective' style box camera. It weighed 3.3 pounds and provided a rectangular viewing window which enabled the user to see the photograph he or she was about to take. The rear of the camera accepted one double plate holder, which could be used twice to make a 3¼ × 4¼ exposures on two separate negative

plates. The Schmid portable view camera was to have practically revolutionized the taking of instantaneous photographs.

By 1884, vast numbers of new recruits had joined the ranks of amateur photographers, attracted by the simplicity of the new hand-held or easily transportable cameras using dry plates. 1884 also marks the start of the career of the famous American photographer, Alfred Stieglitz. Initially, Stieglitz's father took his son to Europe when Alfred was seventeen and entered him in the Berlin Polytechnic Institute, believing that the future belonged to engineers. But Stieglitz became attracted to photography after seeing an inexpensive camera outfit in a Berlin shop window, and when he learned from a co-student that Dr. Herrmann Wilhelm Vogel was lecturing on aesthetic theory as applied to photography in another course at the Institute, he enrolled immediately in Vogel's class. One day in 1884, Dr. Vogel asked to show some of Stieglitz's photographs to a group of distinguished painters. While Europe's awakening to the potential of artistic expression in photography was still several years away, it appears that this twenty-year-old American in Berlin was among the first to awaken this interest among some of German's leading artists. Of the group who were shown Stieglitz's prints, several expressed the desire to have copies: one, according to Stieglitz, remarked: 'Isn't it too bad your photographs are not paintings. If they had been made by hand, they would be art.'

Stieglitz at first worked the wet-plate, but soon acquired dry-plate equipment. Speed in the taking, developing and printing of his photographs became a mania with him, and when he was asked why this was so, he responded that newspapers would in future be reproducing photographs more frequently, and that speed would become of increasing importance in this type of activity. If Alfred Stieglitz's thoughts were running to the mechanization of photography, one of Japan's earliest photographers—a man only four years older than Stieglitz—was at this time also considering the possibility of large-scale book illustration with photography. This was K. Ogawa, the son of a deposed landowner of the Japanese feudal system. A love of photography had become a consuming passion with Ogawa to the same extent it had with Stieglitz. Ogawa learned the rudiments of the wet-plate collodion process and even took up the manufacture of collodion. Just about the time that Stieglitz signed up for Dr. Vogel's course in Berlin, Ogawa got himself hired as a sailor aboard the American Asiatic frigate Swatara, and set sail to seek his fortune in the United States. He disembarked in Washington D.C. in January 1883 and remained until June 1884. He studied portraiture, carbon printing, collotype printing and dry-plate making.

The parallel between Stieglitz's and Ogawa's careers did not end with their respective beginners in foreign lands. Ogawa returned to Japan where, for a time, he operated a large studio in Tokyo. Soon he was photographing the heir apparent to the Japanese throne—a vastly greater honor in Japan than for a similar feat performed in a any capital of the western world. He founded the Shashin Shimpo, Japan's only photographic periodical, and established a photomechanical printing factory in Tokyo. Alfred Stieglitz, meanwhile, remained in Europe until 1890, after which he returned to the United States to become the protagonist of the American fine-arts photography movement, and founder of two of the country's most influential turn-of-the-century journals, *Camera Notes* and *Camera Work*.

Amateur photographers were in 1885 counted by the thousands and in the different cities were organized into flourishing and growing societies. In 1885 the Society of Amateur Photographers of New York held their first annual exhibition.

In 1881, Eadweard Muybridge visited the French physiologist Etienne Marey, but the photographs he brought with him of birds in flight were unsatisfactory for the scientific studies, which the Frenchman was then conducting along similar lines. After Muybridge returned to the United States, he began in 1885 a new series of photographic experiments at the Philadelphia Zoo.

Technical elements also developed progressively in the 1880s. The outset of photography's second half century coincided with the introduction of the Kodak camera and nitrocellulose film—both hallmarks of a new era for the medium. The new negative film process was an American development, resulting from independent research and development activities in Philadelphia, Newark, New Jersey and Rochester. The Kodak camera was actually patented in September 4, 1888 and was on the market at the outset of 1889. It was a small and lightweight and was strictly a film camera. Although it was still not possible to make color photographs in the modern senses, photographers by this time had at their disposal an assortment of special plates and color screens, the use of which would enable them to render better color values in their black and white prints. During the 1880s numerous other dyes were introduced for orthochromatic plates as erythrosine and xanthophylls.

In 1880 the American industrialist George Eastman, at the of age 24, set up Eastman Dry Plate Company in Rochester, New York and created the first half-tone photograph which was published in a daily newspaper, the New York Graphic. In 1886, George Eastman perfected a negative film, which had a photographically sensitized layer on it. It could be rolled up into a camera which one could be rolled up into a camera which could actually hold in one's hand, and then the film could be printed by professionals. Eastman called it a Kodak: "All you

have to do is press a button, and we'll take care of the rest," was the advertising slogan which helped insure the camera's worldwide success. It was patented in 1889. The Kodak was so handy that the most daring kind of pictures could be taken, completely breaking away from traditional perspectives, while its much smaller viewfinder produced images that were systematically cut off by the frame, and thus no longer composed. On the whole, with al few exceptions, it was mainly painters, who first realized how useful these little boxes could be, and what the visual possibilities were. They were a minority: most Kodak users at the time just aimed their cameras face on at the subject and clicked. In the spring or summer of 1886, George Eastman selected Paul Nadar, son of the just-retired Parisian photographer, as his agent in France for the new Eastman roll film system. By happenstance, the editors of Le Journal Illustré at about the same time asked Nadar to make photographs of the famous chemist Michel Chevreul in celebration of the latter's one hundredth birthday on August 31. The result was that the younger Nadar used a camera fitted with Eastman roll film to record the world's first photographic interview for a news publication.

In 1888 the first Kodak camera was created, containing a 20-foot roll of paper, enough for 100 2.5-inch diameters circular pictures. In 1889 an improved Kodak camera was made with roll of film instead of paper. Until the time of Eastman, photography, though already popular, was still considered too complicated for ordinary users, and George Eastman is remembered for having made photography accessible to all.

Eastman started off as a bank clerk, and then became interested in photography. He is particularly remembered for introducing flexible film in 1884.

Four years later he introduced the box camera incorporating roll film, and with his slogan "You press the button, we do the rest" he brought photography to the masses.

The box camera had a simple lens focusing on 8 feet and beyond. One roll of film could take a hundred images, all circular in shape. The entire camera was posted to the factory where the film was processed and the camera re-loaded and returned to the user, the charge for this being a few dollars. The photographs had a diameter of about 65mm, and opened up a new world for popular photography.

Eastman's contribution not only made photography available to all, but also resulted in a gradual change in what constituted acceptable photography.

Popular in the Victorian times was stereoscopic photography, which reproduced images in three dimensions. It is a process which popularity waxed and waned—as it does now—reaching its heights in the mid-Victorian era.

During the 1880s the press played a leading role in the social movement, which brought the harsh realities of poverty to the public's attention. The camera became an important instrument of reform through the photo documentary, which tells the story of people's lives in a pictorial essay. It responded to the same conditions that had stirred Courbet and its factual reportage likewise fell within the Realist tradition. Before then, photographers had been content to present the same romanticized image of the poor found in genre paintings of the day. In 1870, when he was twenty-one, Jacob Riis emigrated from Denmark to New York and spent the next seven of those American depression years going from job tot job often hungry, and once walking all the way to Philadelphia to seek a job from a Danish family he knew. The invention of gunpowder flash allowed Jacob Riis to rely for the most part on the element of surprise. Riis became a police reporter in New York City, where he learned first-hand about the crime-infested slums and their appalling living conditions. He kept up a steady campaign of illustrated newspaper exposés, books, and lectures which in some cases led to mayor revisions of the city's housing codes and labor laws. His photographs' unflinching realism has lost none of its force.

In 1887 he became informed on the advantages of taking photographs by flashlight. In practicing and doing so, he became America's first celebrated photojournalist and its first social documentation photographer. He soon produced a visual record, which clearly achieved the impression he had long sought to make on the New York community at large. With the publishing of his book, How the Other Half Lives, in 1890, he singlehandedly altered American society's perception of the term Social Justice.

In the 1880s the Pictorialist movement grew in Great Britain and the United States, where photographers concentrated on the artistic dimension of the medium.

England was the birthplace of Pictorialism, a movement created by experienced amateurs at the turn of the twentieth century. They felt that photography deserved to be given the same recognition as great art, as original prints has been. Two Englishmen founded the movement: Henry Peach Robinson and Peter Henry Emerson. The former published Pictorial Effect on Photography (1869), from which the movement derived its name. This hugely successful work was translated into French in 1885 under the title The Artistic Effect on Photography: Advice for Photographers on the Composition of Art and the Use of Light and Shade. As an artist, Peach Robinson made photomontages by bringing together negatives into a single print, a technique that never became popular with the Pictorialists.

The photographer and polemist Peter Henry Emerson a distant cousin of the American philosopher Ralph

Waldo Emerson built up a body of work so intense and remarkable that he is considered to be the father of a revival in artistic photography. The son of a rich Cuban planter, he came to England to study medicine, a field in which he excelled. However, after purchasing a camera in 1880, he decided to devote his life to photography. His professional career only spanned fifteen years, for after 1895 he stopped working but continued to encourage artists such as Alfred Stieglitz and, later on, Gyula Halàsz Brassaï. Emerson upheld that photography should be essentially naturalistic. He expounded this theory scientifically in an essay entitled Naturalistic Photography for Students of the Art (1889), in which he argued that photography was superior to painting as a means of expression through plasticity, and as a means for transporting the naturalistic vision. In 1890, after a period of crisis, he renounced these theories.

Emerson had always conceived his photographs for publication, with the text playing a subordinate but complementary role to the pictures. Like Jean-François Millet, whom he greatly admired, he was interested in the daily life of pleasants. He portrayed their movements and daily rituals, imbuing them with a feeling of the monumental and of timeless gravity. Over a period of then years, Emerson produced no less than twelve albums of photographs of the lives of peasants in East Anglia.

The photographic images in the 1880s of Hameter, Muybridge, Jackson, Watkins, Vroman, Thomson, Von Stillfried all have a pictorial and consciously, artistic accent.

An entirely new direction was charted by Eadweard Muybridge (1830–1904), the father of motion photography. He mixed two different technologies, devising a set of cameras capable of photographing action at successive points. After some trial efforts, Muybridge managed in 1877 to get a set of pictures of a trotting horse, which forever changed artistic depictions of the horse in motion. The photographs of Muybridge convey a peculiarly modern sense of dynamics reflecting the new tempo of life in the industrial age. However, because the gap between scientific fact and visual perception on the other was so big, the Futurists would realize their far-reaching aesthetic implications only later.

Edward James Muggeridge was born in Kingston on Thames, and it is said that because this area is associated with the coronation of Saxon kings, he took on a name closely resembling (as he saw it) the Anglo Saxon equivalent. In his early twenties he moved to America, and became famous for his landscape photographs of the American West. As he used the collodion process, like other traveling photographers, he needed to take with him all the sensitizing and processing equipment, as all three processes of sensitization, exposure and processing needed to be done while the plate was still wet.

During the late sixties and early seventies he made some two thousand pictures, exposing negatives of a size of 20 × 24 inch. Though he is not given the acclaim he deserves, many his landscape studies rank with the best.

However, Muybridge's main claim to fame was his exhaustive study of movement. Just at same time the French physiologist Etienne Marey was studying animal movement, and his studies began to suggest that a horse's movements were very different from what one had imagined. One of the people who became aware of this research was Leland Stanford, a former governor of California, who owned a number of racehorses. Stanford was determined to find the truth about this. It is said that he bet with a friend that when a horse gallops, at a particular point all four feet are off the ground simultaneously. To prove his case he hired Muybridge to investigate whether the claim was true.

Muybridge's studies are very comprehensive, and include some detailed studies of men and women walking, running, jumping, and so on.

In 1878 an article in *Scientific American* published some of Muybridge's sequences, and suggested that readers might like to cut the pictures out and place them in a "zoetrope" so that the illusion of movement might be re-created. Intrigued by this, Muybridge experimented further, and later he invented the zoopraxiscope, an instrument that paved the way for cine photography. This invention was greeted with enormous enthusiasm both in America, whilst in England a demonstration at the Royal Institution in 1882 attracted people like the Prince of Wales, the Prime Minister (Gladstone), Tennyson, amongst others.

In 1884 the University of Pennsylvania commissioned Muybridge to make a further study of animal and human locomotion. The report, "Animal Locomotion" was published three years later and still ranks as the most detailed study in this area. It contains more than twenty thousand images.

Eadweard Muybridge began a new series of lecture tours in the United States, Britain, France, Germany, Switzerland and Italy following publication of his Animal Locomotion in 1887.

At that time photographers were also able to look back at the work of their predecessors. Thomas Annan's son James Craig Annan made a major contribution to our knowledge of early English photography, and was instrumental in the publication of a great deal of photographic material. He reprinted the work of Hill & Adamson, whose studio and negatives had been taken over by his father in 1899. The subjective impression and the expression of inner experience had become major elements of the light drawing.

There was a highly stylized quality in the work of

photographers such as Jackson, Watkins, Vroman and Thomson who carefully directed the 'types' they were photographing. Looking at the composition and photographic approach used by these photographers, one gets curious to know more about their training, their remarkable interest in (non-)Western influences and the manner in which they incorporated these influences into their work.

Developing mechanical means for printing photographs with a printing press or lithograph was a major concern for 19th century inventors. Finally, around 1870 a practical means of photomechanical reproduction became available, but it was not very good at reproducing gray shades. Later, around 1880, the halftone method was perfected, allowing accurate reproduction of photographs at reasonable cost and giving rise to many illustrated magazines and newspapers.

Pictorialism was an international movement, but the first Pictorialist association, the Photo-Club de Paris, was set up in France in 1888 by Robert Demachy, and the first Salon was not held until 1894. Demachy was a independent rich man from a banking family who was passionate about photography. He was highly cultivated and a remarkable technician who, with the help of Alfred Maskell, encouraged an interest in the typically Pictorialist gum bichromate method developed by Rouillé-Ladevèze in 1894. Demachy choice of theme was often inspired by Depas'painting, although there can also be a symbolist side to his work.

Initially, photographs were limited in size by the size of the camera and photographic plate. One of kind photos like daguerreotypes were of course of the size of the plate used to make them. With glass plates, placing the plate against a sheet a paper and letting light pass through the negative, produced a photo of exactly the same size as the negative. A process for enlarging prints was invented in the late 1850's but it was only during the decade1880–1890 that it became widely available.

The magic of photography caught the popular imagination as soon as it became known and available. After 1888 almost every aspect of everyday life became subject to photographic record, and a boom that goes on even today, was born.

HISTORY: 8. 1890s

Nineteenth-century international photography is a rich and above all surprising field. To those accustomed at looking at drawings or prints, the photographic medium was characterized by extreme directness and clarity. The photograph, or 'light drawing,' had a strong attraction. Its qualities were considered to be the realm of depiction, the composition of light and shade and the rendering of space. Art critics summed up the strength of the new medium's 'secrets of light and brown.' Right from the start, photography was used for various scientific and documentary purposes. It was also the object of artistic interest. Even by the pioneers: William Henry Fox Talbot practiced photography as a kind of alchemy, seeking tangible depictions. David Octavius Hill and Robert Adamson used the medium as an exercise in portraiture. Samuel Bourne, accompanied by a large retine of sherpas, toured the Himalayas in order to register photographic impressions of great heights.

The first photographs were exhibited to the public as early as the first decade after its invention. At first the results of photography were displayed alongside other exhibits at world fairs. Very quickly special –often-international—photographic fairs were held, where photographers showed their prints. Clarity, definition, color and the choice of photographic procedure were the criteria applied in judging the exhibits.

The appearance and treatment of this new art form constitute an interesting facet of 19th-centrury-art history. Photographers adopted the genres and pictorial traditions of paintings and printmaking. Portraits, landscapes, architectural views and genre scenes were popular photographic themes. Photography was viewed and assessed in the context of historical and contemporary artistic movements. The photographers of the late 19th-century took their subjects and genres from 17th-century Dutch painting or the literary themes of their artist-contemporaries. Raphaelesque compositions and Rembrandesque chiaroscuro were stylistic devices, which were imitated in photography. Numerous links and correspondences can also be observed in the training, background and studio practice of painters and photographers.

The explosion during the 1890s in amateur photography came at a propitious moment in the cultural history of America. Despite the boom in the camera market, the term detective continued to be applied to a variety of the hand cameras introduced to be applied to a variety of the hand cameras introduced before the turn of the century. Among the professional photographers, considerable discussion began to take place among those who advocated the use of small versus large cameras. Cameras able to accept large plates had traditionally been used to make many of the finest photographs of exhibition caliber, but enlargement had become a simpler matter from negatives made with the new hand cameras.

There was plenty to discuss in the professional trade, as well as among the amateurs, and from these discussions and debates appeared a new group of periodicals, particularly aimed for a permanent market of amateur readers. The three prime new publications, all of which first appeared in 1889, were the American Amateur Photographer, the *Photo-American* and the *Photo-Beacon*. All were discontinued in 1907, perhaps a telling indication of just how long their subscribers were interested in reading up on photography before accepting the camera as just another adjunct of everyday living.

In many aspects this was photography's most eclectic moment. Not only was there much that was new to choose from in equipment and apparatus but there were many choices to be made, as well, in processes. Still to come were entirely new dimensions, both in portraiture and in the means of printing artistic photographs for public exhibition and sale. Perhaps because of all thee innovations there something of a lull in commercial business in 1892. It was a rush to cheapness and quantity which blamed for the fact that among people an the class who in former years were liberal patrons and are able to pay good prices, it is no longer fashionable to display photographs, except as mere cheap souvenirs, and as a possible basis for future use in copying.

When Alfred Stieglitz returned to the United States in 1890, he soon realized, he said 'that photography as I understood the concept, hardly existed in America.' Because of his first-prize award at an 1887 London amateur photography competion, and the favorable recognition accorded him by European artists as well as photographers, Stieglitz became the sole American to actually participate in the movements begun at that time in England, France, Germany and Austria to elevate photography to its rightful position as a fine art. Stieglitz was generally correct in his 1890 appraisal of the death of fine-art photography in America, but there was an encouraging note, which had occurred prior to this at the 1887 joint exhibition of photographs in NY by the amateur societies of NY, Boston and Philadelphia. In the period 1890-94, there other isolated events which indicated that the movements across the Atlantic were having an effect on American photographers. In 1890 for example 'impressionism' in photography was chosen as a topic of discussion at the Pacific Coast Amateur Photographer's Association and in 1891 forty American

photographers attempted to exhibit 350 photographs at art photography exhibit in Vienna.

More than any other single individual, Alfred Stieglitz provided a motivating force for an American art photography movement. This was further by his assumption of co-editorship of the American Amateur Photographer in 1893. At the time this occurred, Stieglitz and several partners were operating a photoengraving company which after 1893 supplied a number of halftone reproductions as illustrations for the American Amateur Photographer. About 1892, Alfred Stieglitz saw some prints of size 4 × 5 inches made with a hand camera, which he found extraordinarily beautiful. Thereupon he decided to buy a hand camera and master its use. He made a series of photographs provided photography and art 'with a new motive' as city snow scenes. He played a major role first in the amalgamation of the NY societies in 1896 and ultimately in the founding in 1902 of Photo-Secession, the American counterpart to the Linked Ring.

The best that could be achieved with color photography in the nineteenth century was perfected experimentally, or bought to a viable commercial status in the period 1893 to 1895. Although prints in color could not be obtained from color negatives or color film in an ordinary camera, several methods were perfected which allowed people to view photographs in color on a screen, and, after 1893, good half-tone illustrations could be produced in color on a photoengraver's letterpress.

The choice of which paper to use in making photographic prints—whether for professional studio work or for exhibition purposes—remained more of a problem in the last decade of the nineteenth century than is perhaps generally recognized. Frequently, it is simple stated that the old reliable albumen paper was replaced by the gelatine-bromide papers about 1890.

The flowering of American fine-art photography, which had begun in a small way after 1890, came to its first fruition with the staging of an European-style photographic salon at the Philadelphia Academy of Fine Arts.

Photography was poised for a coming age of mechanization as the world passed into its twentieth century. There were by this time 100,000 Kodak cameras alone in the hands of amateurs making photography easier and more accessible.

Printers and sculptors discarded traditional methods, using photographs as preparatory for their compositions. From 1890 as photographic techniques were radically simplified an increasing number of artists, painters or sculptures began to take their own photographs of models or ask professionals to take shots according to their instructions.

Pictorialism only represented one part of the artistic production of the period 1890s. Most photographers were forced to work to earn a living and so continued to do journalistic work, in which they reproduced and documented the real world without trying to filter it through any particular techniques meant to reflect their individual artistic vision.

Eugène Atget is of quite a different stature. Between 1898 and 1927, the year of his death, he systematically roamed Paris documenting every street, which was destined for destruction in the near future. Thousands of church facades and townhouses from the Middle Ages right up to the 18th century were recorded photographically on an impressive scale. His style and visual technique were original and innovative as his project. He was probably well aware of hiss abilities, despite the fact that he worked more like a simple craftsman than an artist, selling his work to architects, illustrators and painters. The Surrealist were the first to draw attention to his work for its artistic merit, by publishing it in their journals.

The issue of whether or not photography could be art became an important issue in the early 1890s with the Secession movement, which was spearheaded in 1893 by the founding in London of the Linked Ring, a rival group to the renamed Royal Photographic Society of Great Britain. Seeking a pictorialism independent of science and technology, the Secessionists steered a course between academicism and naturalism by imitating every form of late Romantic art that did not involve narrative. Equally antithetical to their aims were Realist and Post-Impressionist painting, at that time at their zenith. In the group's approach to photography as art for art's sake, the Secession had most in common with Whistler's aestheticism. To resolve the dilemma between art and mechanics, the Secessionists tried to make there photographs look as much like paintings as possible. Rather than resorting to composite or multiple images, however, they exercised total control over the printing process, chiefly by adding special materials to their printing paper to create different effects. Pigmented gum brushed on coarse drawing paper yielded a warm-toned, highly textured print that in its way approximated Impressionist painting. Paper impregnated with platinum salts was especially popular among the Secessionists for the clear grays in their prints. Their subtlety and depth lend a remarkable ethereality to Gertrude Käsebier's photographs in which spiritual forces are almost visibly sweeping across the photograph. Through Käsebier and Alfred Stieglitz the Linked Ring had close ties with America, where Stieglitz opened his Photo-Secession gallery in New York in 1902.

Peter Henry Emerson felt the artificiality of the Robinson school, and he put forward another point of view against the latter's theories which he named naturalism, and which he described in his Naturalistic Photography, first published in 1889. He believed that

photography was potentially a great creative art, and that it did not need to be bund down to rule set up for painting. 'Naturalism' he wrote, 'is an impersonal method of expression, a more or less correct reflection of nature wherein' truth of sentiment, illusion of truth of appearance (so far as is possible) and decoration are of first and supreme importance.

Emerson sought a scientific basis for pictorial photography. He analyzed the physiology human perception. He reasoned that since the eye sees distinctly only a small part of what lies before it, while the surrounding area appears indistinct, it should be possible to reproduce this phenomenon by controlling the focusing. Only a small part of the photograph should be sharp, the rest should be just slightly out of focus. Today we recognize that this theory of vision is fallacious, because the eye, unlike the lens of a camera, is a living organism, which scans the field of view constantly in such a way that the mind receives a composite report and the impression of full detail. The naturalistic theory was an advance over Newton's; for Emerson believed that the photographer should rely entirely on controls which were they part of the photographic process. In addition to control through differential focusing, he advised the careful use of developing and printing methods.

Emerson took a large number of photographs of the amphibious life of the simple country folk on the Norfolk Broads, which were entirely different of the artificial genre studies of Robinson and very close to the graphic work of J. F. Millet, which Emerson greatly admired. Imbued with a deep artistic feeling, Emerson's photographs fired a number of other amateurs to seek inspiration in nature as the first generation in limited editions in handsome folio volumes as original platinum prints or as photogravures and photoetcings.

There was a profound shift in the perception of photography around 1890. Discussions of photography were largely qualitative, e.g. is it an art or a science? The science of photography was largely of an alchemical sort. The scientific questions were also qualitative, due to the failure of photographic "evidence" to fit existing theories of the behavior of light. Were there new "imponderables" (phenomena without mass) to contend with besides light, heat, magnetism, and electricity? The questions were ones of kind, not relationship. That is, until Hurter and Driffield.

James Clerk Maxwell suggested in 1862 that magnetism, electricity, and light were all manifestations of a larger electromagnetic spectrum. However, it wasn't until he published Electricity and Magnetism in 1873 that the idea began to take hold. Suddenly, the questions asked about the behavior of photosensitive materials took a different form. They became mathematical in nature: what was the relationship between exposure to light and photographic material? Instead of questioning the qualitative nature of light, as researchers such as Hunt and Draper had done, researchers began to look for better methods of measuring light quantitatively and exploring the relationship between exposure and response in photographic materials.

Film speeds were first scientifically measured around the 1880s to 1890s with initial work by Sir William Abney but continued and published in 1890 by Ferdinand Hurter and Vero Driffield, working at the centre of the UK chemical industry in Widnes.

The birth of photography as a modern science seems to have occurred circa 1880, with the invention of the actinograph (light meter) by Hurter and Driffield and the first motion studies of Muybridge. Both these efforts were carefully measured and mathematical in nature. The intense period of experimentation in the 1880s was fueled both by a technological need and a desire to have proof of a measurable nature. The shift during this time from relatively forgiving wet plates and the more tricky but convenient dry plates was part of the equation—photographers needed better instrumentation than "rules of thumb" to get consistent exposures. However, the one of the first uses of the actinography was to mathematically establish the relationship between the position of the sun in the sky to light intensity. Motion studies were used to establish the relationships between muscle groups and motion, rather than to create more accurate depictions of motion. At issue in both types of research were matters of detection rather than depiction.

The culmination of Hurter and Driffield's research was the characteristic curve used to measure photosensitive materials—named the H&D curve in their honor. With the discovery that there was a mathematical relationship between exposure, development, and density in photosensitive materials in 1890, photography became scientific in the modern sense. Their work plotted image density against the logarithm of exposure, producing what became known as 'H&D' or 'characteristic' curves. These curves had a straight line section which could be extrapolated back to the density axis to give a speed point that could be used to compare materials, and speeds based on these were known as 'H&D' speeds.

Around the same time, Jules Scheiner in Germany introduced a cruder method based on the minimum exposure required to give a perceptible image in 1894. The work of Hurter and Driffield was extended by the German company Agfa in the 1920s to incorporate the less steep portion of the curve at lower exposures to produce a more practical measure accepted as a national standard (DIN) in 1931. The Weston Company in America introduced their own speed system designed to work with the integrated light readings of their famous exposure meter in 1932 (WESTON). Similar considerations and the increasing deviation of modern materials and developers from straight line responses led to the

original ASA system (1943) and the BS / DIN / ASA international standards of 1960–62.

The scientific findings of Hurter and Driffield led Emerson in 1891 to renounce the art claims he had made for photography. A great artist, he said, had shown him that the reproduction or translation of nature was not art. The fallacy of this argument was based, of course, in the definition of art. It appeared that 'art' and 'painting' was almost synonymous to Emerson when he wrote his retraction. What really happened was that Emerson preaching on differential focusing led to the use of very focusing lenses and other blurring effects such as the use of very coarse paper. Emerson dramatically announced his views in a black-bordered pamphlet *The Death of Naturalistic Photography*.

In his book Emerson had a good deal to say about photographic exhibitions. He felt that they were poorly organized. He recommended that photographs be framed in simple white molding and that they be exhibited on one line in galleries, not plastered over the wall with the frames practically touching them. He rightly felt that pictorial photographs should be isolated, instead of being lumped together with work done for scientific, technical, and other no aesthetic purposes.

Dissatisfaction with the scientific bias of the Photographic Society under the presidency of Sir William Abney caused a split in the society in 1892. A group of pictorially minded members, under the leadership of H. P. Robinson and George Davison, formed a society for the exclusive purpose of furthering 'the development of the highest form of art of which photography is capable.' The society was named Linked Ring. They held annual exhibitions which they referred to as *salons*, a name borrowed from the painting world, and which demonstrated their artistic motivation. By 1901 it was their proud boast that 'through the *Salon* the Linked Ring had clearly demonstrated that pictorial photography was able to stand alone and that it had a future quite apart from that which is purely mechanical.'

Meanwhile Edward S. Curtis was considering what was eventually to be one of photographer's major entrepreneurs. In 1896 he had begun a survey of Indian Life in North America. Needing financial assistance, he eventually turned to J. Pierpont Morgan and in 1907 published the first of the twenty volumes, which finally made up The North American Indian. The project occupied Curtis until 1930. He began his survey with reports on Apaches, Jicarillas and Navahoes and ended with Eskimo tribes in Alaska.

When Kodak introduced the $1.00 Brownie box roll-film camera in February of 1900, it was an immediate success, but with one problematic flaw—the shoebox-style, cardboard back wore out quite quickly, leaving the roll film inside more susceptible to light leaks. To fix the problem, Kodak engineers created a metal latch to hold a new rear cover in place, and the problem was fixed. The original Brownie Camera was only in production for about two months, and is quite rare today. Eastman Kodak company records indicate that many of these first Brownie Cameras (about 15,000) were shipped to England. The Brownie Camera with its new back door design would go on to be known as the No. 1 Brownie Camera in 1901, when the larger No. 2 was introduced necessitating a new name and model designation. This was the same procedure Eastman Kodak used when it released both the original Kodak Camera, and the first Folding Pocket Kodak camera.

During the nineteenth century, photography struggled to establish itself as art but failed to find an identity. Only under extraordinary conditions of political upheaval and social reform did it address the most basic subject of art, which is life itself. In developing an independent vision, photography would combine the aesthetic principles of the Secession and the documentary approach of photojournalism with lessons learned from motion photography. At the same time, modern painting, with changes in photography undermining its aesthetic assumptions posed new challenges to its credentials as one of the arts. Like the other arts, photography responded to the three principal currents of our time: Expressionism, Abstraction and Fantasy. But because it has continued to be devoted for the most part to the world around us, modern photography has adhered largely to realism and, hence, has followed a separate development. We must therefore discuss 20-century photography primarily in terms of different schools and how they have dealt with those often-conflicting currents.

The course pursued by modern photography was facilitated by technological advances. It must be emphasized, however, that these have enlarged but never dictated the photographer's options. Surprinsgly, even the introduction of color photography by Louis Lumière in 1907 had relatively little impact on the content, outlook, or aesthetic of photography, even though it did remove the last barrier cited by nineteeth-centrury critics of photography as an art. Photography did create a new art form, the cinema. An outgrowth of motion photography also came to perfection in 1894 thanks to Lumière and his brother. Unfortunately, we are unable to treat it in our surrey, because the printed page cannot reproduce continuous action or sound.

Other photographers used the medium far more directly, as a means of registering people, setting and experiences. This specific dimension of photography was eminently reflected in the work of the documentary photographers, showed plied their trade in the far corner of the globe. Despite their commercial concerns, they had ample opportunity to record their exotic surroundings, and they often did so with considerable inspiration. Their cameras enabled them to record not only every-

day events, but also less common scenes and objects. Some of them invented documentary commissions for themselves. The studios of Woodbury & Page, Samuel Bourne, William Henry Louis Skeen and Charles T. Scowen, produced photographs of the highest quality, among them, over and under one another in a more or less haphazard manner.

Stieglitz had been introduced to the technique of photography in Europe, during a period of radical change within the world of the fine arts. Seeing his photographic work, painters proclaimed that it would have been superb if only it had been executed with a brush. The borderline between photography and painting was becoming blurred, a development that was closely linked to what resulted in a revolution in the general approach to painting. Since the advent of Impressionism, the representation—what was depicted in the painting—was becoming less and less important. Abandoning the representation, artists were increasingly using texture and surface structure to create to create a mood or an impression. These views understandably struck a sensitive chord with photographers.

At first nude photography was even banned from some photographic society exhibitions, but gradually a number of conventions evolved—some adapted from painting—which made it respectable in the salons of pictorialism. These involved a strange desexualisation of the aesthetic female nude by strategic placement of props, 'tasteful' posing, soft focus and retouching of all body hair. Such conventions continued in much amateur photography and 'soft pornography' into the second half of the twentieth century.

Another widely available source of pictures of naked and near naked men and women were various photographs and articles of anthropological nature, illustrated by people in traditional costumes from around the world. Perhaps the main scientific finding that could be deduced from these was the fascination of many photographers (and magazine readers) with cultures where young and nubile women lived bare-breasted.

The male nude was both less common as a subject and also less problematic, both largely as it was not regarded as a sexual object by the dominant male heterosexual culture. So long as the male organ was not aroused it was acceptable, and some photographers such as Baron von Gloeden, photographing young boys in a Sicilian village, took great advantage of this freedom. Of course being titled and extremely wealthy also helped.

Outside of the light world of artistic photography other practices flourished—the saucy postcard, so-called artists studies and other soft and hard-core pornography. Much of this has been repackaged as art books in recent years, as well as being available through postcard dealers and web sites.

Among the interesting collections from this period are the photographs taken in New Orleans by E. J. Bellocq. These pictures showing girls from the Storyville brothels in their rooms, relaxing in front of the camera, are an intriguing and valuable document of the era.

During the 1890s photography has advanced by leaps and bounds. The first film was developed late in the 19th century, made of a dried gelatin. This film was very fragile and did not gain widespread popularity. Then in 1889 a nitrate based, plastic roll film was developed. Due to a tendency to curl, this film also lacked popularity, but in 1903 a non-curling variety was developed, and began to be widely used, and in 1913 the film became available in sheet form and began to compete with the glass plate negative, which it eventually supplanted.

The photographic papers in use in this century tend to be sturdier than those of earlier years, so the practice of pasting them to cardboard mounts was mostly dropped. Professional photographers still used cardboard backings, sometimes folding cards that covered the front of the photo as well and could serve as a stand, but the picture was just slipped into slots in the mount, or tacked lightly in one spot to hold it in place.

Having passed through the stages of invention and the first attempts at commercialization, by the end of the 1900s, photography was ready to cross the threshold separating a technological medium, still uncertain of its future, from a commercial and artistic activity recognized and solidly integrated into society from museum, universities and art-schools.

HOFMEISTER, THEODOR (1863–1943) AND OSKAR (1871–1937)

German photographers

Theodor worked as a wholesale merchant and Oskar was a secretary in the county court. The brothers Hofmeister began exhibiting photography in 1897 in Hamburg and produced their photographs as a team effort; later Oskar took the photographs and Theodor made the gum prints, often the scenes to be photographed were firstly sketched by Theodor. In 1895 they were producing picture postcards, from 1897–1899 figure studies of local people in traditional costumes. Influenced originally by Heinrich Kuehn, who taught Theodor gum printing, and the *Wiener Kamera Klub* (Vienna), they were to become known essentially for their gum bichromate landscape images, usually featuring a low horizon, with intelligent and original use of colour and composition that allowed a dialogue on the relationship between man and nature, as distinct from the often trite and sentimental landscapes of fellow Pictorialists. Their photographs were collected by museums, including Hamburg and Dresden and exhibited internationally. In 1909/10 they stopped gum printing and thereafter produced straightforward bromide prints. They were members of the Hamburg Pictorialists, established by Ernst Juhl in 1883, and *Die Gesellshaft zur Forderung die Amateur Photographie*. Along with Rudolf and Minya Dührkoop, also from Hamburg, they became members of the British 'Linked Ring Brotherhood' in 1908. In 1902 they began teaching and were known for being helpful to other aspiring photographers.

ALISTAIR CRAWFORD

HOGG, JABEZ (1817–1899)

British opthalmic surgeon, microscopist, photographer, journalist

Hogg was born in Chatham, the youngest son of John Hogg of the Royal Dockyard. Like his schoolfellow Charles Dickens, Hogg would become a prolific, wide-ranging, and politically conscious author. An overview of Hogg's career points toward the fruitful interconnections in mid-nineteenth-century Britain between science or natural philosophy on the one hand and literature and popular journalism on the other. Hogg's interest in photography may be seen as one of several points of connection between these spheres, as is suggested by his abiding fascination with the metaphor—which struck him as both mechanical and poetic—of the camera as a human eye.

In 1840 Hogg entered the medical profession, indentured to Hugh Welch Diamond. He clearly assisted Dr Diamond in his pioneering experiments in using photography for scientific documentation, for by 1843 he had learned enough from the distinguished physician to publish *The Practical Manual of Photography*. That same year Hogg joined the staff of the *Illustrated London News*, which immediately gave him a forum for disseminating information about the new art-science. (The first specialist journals were of course still a decade away.) The iconic quarter-plate daguerreotype of Hogg making a portrait, often described as the first known image of a photographer at work, was probably made in 1843 to illustrate *The Practical Manual*. A wood-engraved reproduction appeared in the book, and also in the *Illustrated London News* (19 August 1843), where it accompanied "Lines Written on Seeing a Daguerreotype Portrait of a Lady" by Miss Elizabeth Sheridan Carey.

This single image tells us much about early daguerreotype practice in London. According to a footnote accompanying the *Illustrated London News* reproduction, the setting is "Mr. Beard's establishment, Parliament-Street, Westminster." One of Richard Beard's three daguerreotype portrait studios, the Parliament Street establishment had opened on 29 March 1842, about a year after the coal merchant purchased a patent from Jacques-Louis-Mandé Daguerre's agent Miles Berry to practice the technique and to sell licences to others in England, Wales, and the colonies. Hogg—given his extensive prior experience in photography and his diverse commitments as a physician, writer, and editor—was presumably one of Beard's associates and licensees rather than an operator under his employ. Hogg built a studio of his own onto his home in Barnsbury Park, Islington, around this time.

In the daguerreotype of Hogg at work, the camera, positioned on a stand with a rotating plate, helps to date the image to spring or summer 1843. Until that time, Beard's studios had used Alexander Simon Wolcott's concave-mirror cameras with ordinary lenses, ideal for daguerreotype portraiture because they reflected daylight onto sitters through a copper sulfate trough that turned the light blue. Beard had obtained the right to use this invention from John Johnson, Wolcott's partner in New York's "Daguerrean Parlor," who came to London in November 1840 to assist in establishing Beard's Royal Polytechnic studio. Johnson's father, William S. Johnson, had preceded him by some months to initiate the business arrangements, and it is he who is the sitter in Hogg's daguerreotype. However, the camera seen here is not one of Wolcott's design: rather, it features the Petzval-type portrait lens that superceded the mirror camera in terms of speed and focal length. Hogg has removed the lens cap and is timing the exposure on his pocket watch (depending on the lighting conditions, it would have been five to eight seconds). Johnson poses

stiffly in an armchair, his head fixed in a rest and his hands clenched so as not to move. Elaborate studio props fill out the scene: patterned carpet; upholstered footstool with top hat; painted backdrop with a trompe l'oeil birdcage, trellis, flowering plant, and bench; heavy cloth drape; and sculpted bust. Typical products of the Beard portrait studio would have employed these objects in highly conventional ways. Hogg, by contrast, showed greater compositional dexterity in this and other examples of his work.

Although Hogg seemingly practiced photography with experimental and didactic motivations, he maintained a keen awareness of contemporary debates relating to commerce, taking a public stand against the two most bitterly resented patent holders of the period, Beard and William Henry Fox Talbot. In 1845 Hogg anonymously published a pamphlet entitled *Photography Made Easy*, its agenda to rally support for John Egerton, the defendant in a case brought by Beard that was resolved in the latter's favor in 1849—after 5½ years in the courts. In 1853 Hogg took issue with Talbot's patent on all photo-engraving processes, which prevented him from illustrating his book *The Microscope* with photographs transferred onto wood blocks.

Hogg's involvement with photography complemented several other areas of achievement. During a forty-five-year medical career, he served for twenty-five years as a surgeon to the Royal Westminster Ophthalmic Hospital and published books on color blindness (1863), cataracts (1871–82), ophthalmic surgery (1863), and the impairment of vision due to spinal injury (1876). Other medical topics of interest to him were dentistry, skin disease, and arsenic poisoning.*The Microscope* remains the best known among Hogg's many books; first published in 1854, it was in its fifteenth edition by the time of his death. His work in microscopy led him to posit the connection between diseases and contaminated water, and Hogg was among the first to call for the purification of London's water supply. Committed to presenting scientific ideas to a popular readership, he produced a series of "illustrated educational books" under the auspices of the *Illustrated London News* (1850–66), and he edited the periodical's annual *Almanack* for an astonishing 51 years.

In 1894, perhaps reviewing the artifacts of a long and intensely productive life, Hogg gave a collection of 20 daguerreotypes to the Royal College of Surgeons. These images, together with the text of his *Manual* and other writings on photography, demonstrate that Hogg possessed aesthetic sensibilities in addition to scientific acumen. He was certainly moved and inspired by the possibilities offered by the new technology: "When we consider that Photography enables us to preserve from the decay of time and the fickle tenure of mortality, the true type of the features of those we love, our admiration and gratitude can scarcely be excessive." Hogg died in London in 1899.

BRITT SALVESEN

Biography

Jabez Hogg was born in Chatham on 4 April 1817. Trained as a physician under Dr. Hugh Welch Diamond, he was an early practitioner of the daguerreotype, ambrotype, and calotype processes. His *Manual of Practical Photography* was first published in 1843. Hogg served on the staff of the *Illustrated London News* from 1843 to 1895, and also practiced medicine (specializing in ophthalmic surgery) for 45 years. He is best known as a pioneering microscopist. He died in London in 1899.

HOLLYER, FREDERICK (1837–1933)

British engraver, photographer of fine art, and portraitist

Frederick Hollyer was born in London in 1837, the youngest of four boys. His father, Samuel Hollyer (1797–1883), was a line engraver, fine art publisher and collector of watercolours. Frederick began his career as a mezzotint-engraver, reproducing two works by Edwin Henry Landseer, the *Shepherd's Grave* and *The Old Shepherd's Chief Mourner*, published in 1869 (V&A). Around 1860 he took up photography and became a member of the Photographic Society of London in 1865. The same year he photographed sketches by the artist Simeon Solomon who introduced him to the Pre-Raphaelite artists and their followers. In 1870 Hollyer opened a studio at 9, Pembroke Square, Kensington, London. In the early 1870s he was employed by the eminent artist Frederic Leighton to photograph his paintings and drawings.

Although he also photographed the works of old masters, such as the Hans Holbein pictures in the Royal Collections at Windsor Castle, most of Hollyer's output reproduced the work of his contemporaries. His clients grew to include many artists associated with the Pre-Raphaelite and Aesthetic Movement such as Dante Gabriel Rossetti, Simeon Solomon, Sir William Blake Richmond and Albert Moore. Hollyer became particularly closely associated with George Frederick Watts and Edward Burne-Jones and made many fine reproductions in a collaboration with the artists lasting many years. Working closely with such artists, Hollyer made photographs of works in progress—the prints often suggesting modifications to the artists - that are valuable today in revealing the different states of the pictures and the draftsmen's working methods. He established himself as the leading specialist in the photographic reproduction of artworks in England that sold widely in Europe, and did played a major role in popularising the artists' works. Hollyer's reproductions were regarded as more than a type of facsimile. In Mrs. Russell Barrington's *The Life, Letters and Work of Lord Leighton* (London 1908, vol. II, 288*)*, the artist George Frederick Watts noted, "Mr. Hollyer's photographs are not merely copies—they have as art an atmosphere of charm in themselves; they render what may be called the *soul* of a picture." Hollyer himself proclaimed, "I am quite convinced that something, call it art or what you will, but something more than mere mechanical and scientific excellence, not only can, but should, find its way into every print from every negative that leaves the photographer's studio" (*The Studio*, vol. 1, 1893, 194).

Hollyer made albumen prints from collodion negatives, e.g. *Eight Designs for the Song of Songs by Simeon Solomon* (V&A) and prints on unglazed salted paper until around 1878. However, his subsequent use of gelatin dry plates coupled with platinotype printing (introduced in 1873) significantly improved the quality of his reproductions. With their matt finish, platinum prints rendered the surfaces of pencil or charcoal drawings with great veracity and tonal subtlety. Many of Hollyer's platinum print photographs of drawings are difficult to distinguish from the original, especially when presented in mounts and decorative frames of the period. He became well known for his fastidious workmanship and corresponded with Frederick Evans, another of the chief exponents of the medium, on platinum printing techniques.

Hollyer gained a high reputation among artistic and literary circles through his work that gave him a privileged level of access to a wide range of notable society figures. He took this opportunity to make a great many revealing and intimate portraits. His gift for portraiture, which he is modestly said to have practiced "for relaxation," was carried out, for some thirty years, on the Mondays reserved for sitters who visited his studio. Three albums of platinum prints in the V&A collection contain just under two hundred portrait photographs and show the panoply of contemporary celebrities who sat for his camera. The albums are titled *Portraits of Many Persons of Note Photographed by Frederick Hollyer* and are inscribed to Hollyer's daughter, Eleanor, dated 1920. The portraits are meticulously titled, dates and indexed, many accompanied by the sitter's autographs cut from correspondence. They show many artists, including William Morris, Burne-Jones, Ford Madox Brown, William Holman Hunt, Simeon Solomon, G.F. Watts, Albert Moore, Lawrence Alma Tadema, John William Waterhouse, Aubrey Beardsley, Walter Crane and Camille Pissarro, as well as writers such as John Ruskin, Walter Pater, W.B. Yeats, H.G. Wells and George Bernard Shaw and celebrities such as the actress Ellen Terry. Hollyer's self-portrait occupies the final page of the last volume. Collectively, these works form an astonishing profile of late-nineteenth century cultural life in England.

Today Hollyer is best known for his reproductions and portraits, although there is evidence of his involvement in fine art photography - rather than the photography of fine art. In 1893, *The Studio* published an interview with Hollyer that reproduced five of his original landscape photographs, among them a view of the Thames and Waterloo Bridge. The captions note that the photographs are 'untouched' and a large part of the interview is concerned with advocating the purity of making photographs that had not been subjected to what Hollyer described as the 'fatal crime of touching and retouching negative or print'.

In 1893 Hollyer became a member of the Linked Ring and in 1895 Fellow of the Royal Photographic Society. In 1902 an exhibition of Hollyer's photographs was held at Egyptian Hall, London. A number of the photographs were presented in frames designed by Hollyer and by G.F. Watts. The catalogue of the exhibition also lists photographs of works by Botticelli, and other artworks made from collections in Florence and The Hague, by Hollyer's eldest son, Frederick T. Hollyer. Frederick Hollyer retired from active work in 1913 but his two sons Frederick T. and Arthur S. Hollyer carried on the business of fine art reproductions. The Hollyers' large stock of images was advertised in the *Catalogue of Reproductions of Pictures & Sculpture…*(1924). This included much of Hollyer's previous stock as well as reproductions from artworks at The National Gallery and Tate Gallery London, Museums in Dublin and Edinburgh, the Uffizzi and the Louvre. It offered prints ranging from 13 × 10 inches (33 × 25.4cm) to 36 × 24 inches (91.4 × 61cm) available on platinum or bromide paper in grey or sepia tone and with some reproductions produced in colour. For the last two years of his life

Frederick Hollyer lived with his eldest son at Blewbury, Berkshire, where he died at the age of ninety-five on 21 November 1933. The funeral took place at Reigate Cemetery on 24 November.

MARTIN BARNES

Biography

Frederick Hollyer was born in London in 1837. In 1870 he opened a studio in London. Most of Hollyer's output reproduced the work of his artist contemporaries among whom were Dante Gabriel Rossetti, Frederic Leighton, G. F. Watts, Albert Moore and Edward Burne-Jones. Hollyer's fine platinum print reproductions were highly regarded and did much to popularise the artists' works in Britain and abroad. Alongside this work Hollyer also made a great many revealing and intimate portraits. His subjects included many of the most important artistic, literary and society figures of the day. He also made landscape photographs, among them views of the Thames, some of which were reproduced in an illustrated interview with him in *The Studio* (1893). Hollyer prided himself on his immaculate technical skills and advocated making 'untouched' negatives and prints (i.e. images which had not been altered by retouching at any stage during the photographic process). In 1893 he became a member of the Linked Ring and in 1895. He retired from active work in 1913 and died at Blewbury, Berkshire, the age of ninety-five on 21 November 1933.

Collections

National Media Museum, UK: 60 platinum prints, mostly portraits, some London scenes. Sales catalogue, letters, press cuttings.

Victoria and Albert Museum, UK: numerous reproductions of artworks, vertical panorama flower study, portraits of Morris and Burne-Jones families, three albums *Portraits of Many Persons of Note Photographed by Frederick Hollyer.*

University of Middlesex, Silver Studios archive, London UK: collodion and gelatin dry-plate negatives.

Jewish Museum, London, UK: Photographs of works by Simeon Solomon, *Eight Designs for the Song of Songs by Simeon Solomon* (1878) and *The Book of Ruth* (1879).

HOLMES, SILAS A. (1817–1886)

By 1851 Holmes had moved from his native Petersburg, New York and established himself in New York City in his first (of several) photographic studio on lower Broadway, alongside most of the principal photographers of that period. Although in the middle 1850s he made highly praised oversize ambrotype views of Niagara Falls, he is better known and more highly valued for his urban imagery like the handsome studies of the principal streets and monuments of New York, which he rendered as salted paper prints, about eleven by fifteen inches in size, and, sometimes. blindstamped "Holmes photographist." His productions in other formats included albumen print cartes-de-visite, among them one of Washington's tomb at Mount Vernon, and oversize cabinet cards of varying subjects ranging from the bridges of Central Park to the Catskill Mountains. In the 1860s he advertised three hundred stereoscopic views of Manhattan and its surrounds including "innumerable objects of interest surrounding this great city," while in the 1870s his subjects ranged northward to Saratoga Springs.

As well as by consistently exhibiting his work in various processes and formats, Holmes's industriousness and inventiveness were manifested by his patent for a stereoscopic camera and his 1885 publication of *Our Democracy*, a book devoted to solving the problems of "Labor and Capital."

GORDON BALDWIN

HOLTERMAN, BERNARD (1838–1885)

German photographer

Bernard Holterman was born 29 April 1838 in Hamburg, Germany. Migrating to Sydney in 1858 Holterman worked a variety of jobs before teaming up with Louis

Beyers to prospect for gold. Fortune came in 1872 when they found the largest gold nugget ever, weighing 286kg in the remote New South Wales township of Hill End. He wanted to promote Australia choosing photography as one of the main means and he became the patron of travelling photographers Henry Beaufoy Merlin and his assistant Charles Bayliss, who had already photographed many aspects of the Hill End area. They covered parts of New South Wales before Merlin's death in 1873, with Holterman continuing to support Bayliss through his travels that also took in Victoria. Holterman built a grand home on Sydney's North shore in 1874 with a camera obscura in its roof and with Bayliss they took massive panoramic exposures of Sydney on 22 in. × 18 in. plates. In 1876 Holtermann travelled extensively overseas taking Merlin and Bayliss' photographs to the Centennial Exhibition in Philadelphia and thereafter to Europe where he exhibited them at the Paris Exposition Universalle Internationale de 1878. Returning to Sydney in 1878, Holtermann displayed at the Sydney International Exhibition of 1879 and subsequently was elected to the New South Wales Parliament in 1883, practising photography as an amateur making panoramas and stereoviews. He died 29 April 1885 at St. Leonards. A collection of 3500 wet plate negatives he owned form the Holtermann collection at the State Library of New South Wales.

HOOPER, COLONEL WILLOUGHBY WALLACE (1837–1912)

English, active in India, photographer, military officer

Hooper began his career at East India House in the Secretary's Department; then joined the 7th Madras Cavalry in 1858 at which time he left for India where he would serve for the next 40 years. As a young lieutenant, he became known as an enthusiastic and competent amateur photographer. This was a skill valued by Lord Canning, then Governor-General of India (1856–58). Canning had begun an informal collection of photographs documenting the peoples, lands, trades, and monuments of India to which he actively encouraged colonial officers to contribute prints. In the aftermath of The Indian Mutiny or Sepoy Rebellion, amassing information on the complex societies of colonial India became a matter of military interest. Canning, now Viceroy of India, directed the transformation of what had been a private collection into an official project of the

India Office—a vast data base of visual information and descriptive texts which would "fairly represent the different varieties of the Indian Races." The result was *The People of India: A Series of Photographic Illustrations, with Descriptive Letterpress, of the Races and Tribes of Hindustan* (London, 1868–1875), a monumental, eight volume catalogue of ethnic, racial, and caste types which included photographic portraits, physical description, geographic location, and assessment of moral character and political reliability of the subcontinents subject population. The volumes were compiled and published by J. Forbes Watson and John William Kaye of the India Office. Photographs were solicited from amateur photographers in the colonial and military service, as well as acquired from some commercial photographers. It was for this project that Lt. Hooper in 1862 was released from military duties and transferred to the 4th Cavalry, Saugor and Secunderabad, where he devoted himself almost exclusively to acquiring portraits of the peoples of the Central Provinces of India. His portraits, a three-quarter view of a single person against a plain cloth backdrop, are distinctive for the intensity of his subjects' expression and the immediacy of their presence. The portraits stand as, perhaps, the best of his photographic work.

No doubt encouraged by official support for his photography, and as "The People of India" project neared completion, he entered into a commercial venture with photographer George Western to market photographs of Anglo-Indian life under the firm Hooper and Western. Despite the commercial success of a series of twelve, staged photographs entitled "Tiger Shooting" (c. 1872), Hooper elected to remain in military service and advanced in rank: Captain, 1870; Major, 1878; Lieutenant Colonel, 1884; and Colonel in 1888.

Hooper photographed the human toll of the great Madras Famine of 1876–78—emaciated victims neatly organized by sex and age and collected like cordwood in front of official buildings. His photographs were published in Britain and he was caricatured in *Punch*, as reports circulated that he had offered no succor to the starving subjects he had caused to be brought to the settlement to be photographed. In 1885 he took part in the Third Burmese war as Provost Marshall of the Burma Expeditionary Force and made an extensive photographic record of the expedition. This was later published as *Burmah, A series of one hundred photographs illustrating incidents connected with the British Expeditionary Force to that country from the embarkation at Madras, 1st November 1885, to the capture of King Theebaw, with many views of the surrounding country, native life and industries, and most interesting descriptive notes by Lieut-Col W W Hooper* (1887). Hooper's photographic activity during the Burmese campaign led to official censure. He was brought before a Court of Inquiry to answer charges of extorting evidence and for cruel and inhumane treatment of a group of Dacoit prisoners who

Hooper, Colonel Willoughby Wallace. Deserving objects of gratuitous relief.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

had been sentenced to be executed. Hooper's attempt to achieve photographs of the execution by synchronizing his shutter release to the order to fire caused several delays just as the firing squad was on the point of firing. Witnesses felt this added unnecessarily to the emotional anguish of the condemned and he was reprimanded for inhumane treatment and suffered a temporary reduction in pay grade. *Burmah* contains a photograph of Dacoit prisoners but none of the scandalous photographs associated with the execution. A series of glass lantern slides of the campaign, published with a pamphlet of descriptive text, *Lantern Readings illustrative of the Burmah Expeditionary Force and the manners and customs of the Burmese* (1887) was offered through J. A. Laguard of London. And the same year, again with J.A. Laguard, he offered a set of lantern slides with text, *Lantern Readings: Tiger Shooting in India*. He returned to England upon retirement in 1896 and died there in 1912.

HORETZKY, CHARLES GEORGE (1838–1900)

Scottish survey photographer

Charles George Horetzky (Horetski), survey photographer (born Edinburgh, Scotland, 20 July 1838; died 20 April 1900 in Ontario). Educated in Scotland and Belgium, he quit his studies early to go to Australia, then Canada. From 1858 to 1869 he clerked for the Hudson's Bay Company in Canada, during which time he probably learned photography. In 1871 he was hired by the Canadian Pacific Railway to take "views of objects of interest illustrative of the physical features of the country" through which the Railway might run. However, although he did not have the appropriate training, Horetzky considered himself an engineer, not a mere photographer; and when his advice on routes was not accepted published several books and pamphlets—in which he ignores his photographic activities—condemning the final choice of routes. His final years he engineered sewage systems for the government of Ontario.

Horetzky was a pioneer in using dry plate negatives in exploration in Canada, but aside from the whole plates themselves—some of which have been retouched possibly because of defects—there is no record of his problems or successes with them.

Hortezky's importance as a photographer depends on fewer than two hundred images made in western Canada 1871–1874 showing its topography and settlements. Not only was he the first photographer to visit what is now northern Alberta and British Columbia and thus provide the earliest photographic record of the area, but images such as the railway surveyors at the elbow of the Saskatchewan River have become icons of Canadian photography.

ANDREW RODGER

HORN, WILHELM (VILÉM) (1809–1891)

Vilém Horn was born on April 10, 1809, in Boehmisch Leipa (Česká Lípa), studied at the Viennese polytechnic school, worked as a civil servant in several governmental

offices in Prague, and was named to be a skilled amateur portrait painter before he took up photography in summer 1841. His daguerreotype portraits were lively, and the portrayed look well at ease even though the procedure of making which added much to his fame besides his enourmous technical qualities. In 1854, he opened a luxurious study in the center of Prague; the same year, he started the photographic magazine, the *Photographisches Journal* which covered every practical aspect of photography as well as scientific news on methods, materials, and inventions. Most of the articles were written by Horn himself. From 1858 to 1865, V.H. ran a business of photographic supplies in Vienna and edited his magazine from there. After obtaining a concession on all territoric photographs within the Kingdom of Bohemia in 1865, Horn retired from all of his other businesses including the magazine and returned to his native town Česká Lípa. Here he documented the city's and the country's life, and he kept vivid interests in photography's progress until his death on Oct. 15, 1891.

ROLF SACHSSE

HORNE, THORNTHWAITE, AND WOOD (1841–1913)

The London firm of Horne, Thornthwaite and Wood was amongst the earliest to be actively involved in the supply of photographic equipment and chemicals for photography. The firm underwent various name changes and the individual partners appear to have operated together and on their own account at different times.

The original partnership of Horne and Thornthwaite dates from 1841 and the form of Horne, Thornthwaite and Wood from circa 1844 possibly linked to the takeover over the optical instrument business of Edward Palmer in 1845. Palmer had also been an early dealer in photographic materials. HTW was based in Newgate Street, London, and offered an extensive range of photographic cameras and equipment for daguerreotype, paper and glass processes, sensitised papers and chemicals. George Cundell's calotype sliding box camera was sold from 1844. Their 1852 catalogue includes a Traversing camera for panoramic views and J Harrison Powell's stereo camera of 1858 was made by the firm. Horne and Thornthwaite also operated a commercial photographic studio at least into the mid-1860s.

Photography was only been part of the firm's wider scientific and optical instrument making and retailing business and on 1 July 1857 Messrs J [sic] Horne and Thornthwaite was granted a Royal warrant to Queen Victoria as opticians, philosophical and photographic instrument makers.

From the 1860s the firm's optical, philosophical and scientific instrument making appears to have gained in relative importance to its photographic interests. Horne and Thornthwaite continued in business until circa 1913.

All three of the partners were actively interested in photography:

William Henry Emilien Thornthwaite (1819–1894) was described as an optician and philosophical instrument maker. He joined the Photographic Society in 1870 and authored several manuals including *Photographic Manipulation* (1843) published by Edward Palmer and his *Guide to Photography* which went through many editions and was usually bound with the firm's catalogue. Thornthwaite acted as Secretary to a fund to pay for Martin Laroche's legal expenses after his successful court case with William Fox Talbot in 1854. Talbot had considered taking action against the firm and they testified against him at the trial of James Henderson in 1854–1856.

Fallon Horne (died October 1858) exhibited in the Society of Arts exhibition of 1852 under Horne & Co and produced a series of photographs of the Great Exhibition site being prepared. Horne was a strong proponent of this use of collodion and under the auspices of Peter Fry provided the main support to Frederick Scott Archer in bringing his collodion process into general use. Thomas Sutton described Horne as 'an exceedingly clever practical photographer in every branch of the art, but more particularly as a Calotypist.' He published 'On the Calotype Process' in *Humphrey's Journal* in 1856. He was in partnership with W H Thornthwaite and the Horne name continued to be used after his death.

Edward George Wood (1812–1896) manufactured scientific instruments in partnership with his brothers Henry and George and was described as a philosophical instrument maker in 1830 when he is known to have sold magic lanterns. Wood joined the existing partnership of Horne and Thornthwaite as manager of its optical works and his name was added to the firm's title. He was awarded a prize medal for photographic apparatus at the Great Exhibition. Wood established his own business at 117 Cheapside, London, in 1855 issuing his own catalogue of photographic apparatus and chemicals. Wood's main photographic interest was in magic lanterns, slides and projection equipment and he is credited with designing a biunial lantern while working at HTW. He remained in business until a few months before his death and his son A A Wood continued the business.

MICHAEL PRITCHARD

See also: Calotype and Talbotype; and Talbot, William Henry Fox.

HOUGHTON, GEORGE (1836–1961)
English photographic studio

The firm of George Houghton and Son had it's origins before photography was announced and continued as a photographic business until circa 1961. During its history the company absorbed or merged with a significant number of other British photographic businesses, including the lens makers Ross & Co, sensitised material makers Elliott and Sons, chemical producers Johnson and Sons as well as several smaller camera makers.

The origins of the firm date to 1834 when Antoine Claudet established a French glass warehouse at 87 High Holborn selling sheet glass, lamp shades and glass domes. In 1836 he was joined by George Houghton trading as Claudet and Houghton and from the early 1840s began supplying optical glass and photographic materials. Claudet concentrated his efforts on his photographic studio in Regent Street and seems to have had less to do with the glass business. Houghton's son, George, junior (1835–1913), joined the business in 1852 and the firm became Claudet, Houghton and Son. On Claudet's death in 1867 the business was renamed as George Houghton and Son and continued to expand with photographic goods playing an increasingly important role on the company. George junior's son Edgar (died 1950) joined in 1887 and with brother Charles the business was renamed 'and Sons' for a short time from 1892 by which time it was one of the leading general photographic retailers and manufacturers alongside Marion & Co and Fallowfield. The company offered a large range of cameras and accessories under its own name and trade names, principally 'Ensign' which it either made or had made for it and re-badged. It also retailed equipment and sensitised goods from other British manufacturers.

It became a limited company in 1902 and in 1904 Houghtons Ltd when it absorbed four significant photographic manufacturers. By 1908 their Walthamstow factory employed over 700 staff in a floor space of 71,300 square feet and 1000 employees in Great Britain. It was Britain's leading photographic manufacturer. George Houghton junior died in 1913 leaving a significant estate valued at £17,835 10s 9d.

In 1915 it formed British Photographic Industries Ltd with W Butcher and Sons Ltd and in 1926 the two firms merged completely maintaining a manufacturing dominance that was only matched by Kodak Ltd. A selling company Ensign Ltd was set up in 1930 which was absorbed by Johnson and Sons in 1941 when it's premises at 88 and 89 High Holborn took a direct bomb hit. The manufacturing side of the business continued, becoming Barnet-Ensign in 1945 with further mergers taking place until its demise circa 1961.

MICHAEL PRITCHARD

HOUSEWORTH, THOMAS (1828–1915)
American photographer

Thomas Houseworth, sailed from New York City with George S. Lawrence on April 4, 1849, intent on mining for gold in California. As fate would have it, they instead became among the best known early California photographers.

For two years, they worked the mines before settling in San Francisco, where Lawrence opened the first optical shop on the West Coast. Houseworth joined him in 1855.

In 1859, they began selling stereographs, working with local photographers to obtain images of San Francisco, California's boom towns, various mining operations and scenic sites. Soon, they offered the largest collection of stereo views on the West Coast, with more than 1,000 views of California alone.

When Lawrence retired in 1868, the firm became Thomas Houseworth & Company. Houseworth became embroiled in a public squabble with another local photographic firm, Bradley & Rulofson, after commissioning photographer Eadweard Muybridge to make a set of mammoth plate images of Yosemite, only to see his competitors publish them. The controversy left Houseworth in debt and damaged his reputation. His financial troubles mounted in the 1870s and he eventually was forced to turn to other vocations to make a living, such as optometry and accounting.

One of the Library of Congress's earliest photographic acquisitions, in 1867, was a set of more then 900 Lawrence & Houseworth half stereo prints.

BOB ZELLER

HOW, LOUISA ELIZABETH (1821–1893)
Australian amateur women photographer

Louisa Elizabeth How was born in England in 1821 and was married to James How (c. 1818–1868), a labourer from Melvern, Cambridgeshire with whom she had two sons. The How's emigrated to Port Philip, Australia in November 1849 perhaps encouraged by the financial success of a relative, Robert How (c. 1790s–1859). Robert How initially employed James in his thriving merchant and shipping company in Sydney and, by 1857, he had become a principal director of his own company. In line with their new status, the How family lived at 'Woodlands,' Kirribilli Point—a prime location on Sydney Harbour. It was whilst here that Louisa began to photograph, placing her salted paper photographs in a carefully constructed album that she titled and signed. The album (which is now owned by the National Gallery of Australia, Canberra) is significant as the earliest extant work by an Australian woman photographer. Louisa How's choice of subjects largely centred around

her home and she took many informally but artfully posed portraits of her husband and his male friends in a simply constructed 'studio' on her veranda. In 1866 the How's left their home following a downturn in business and little more is known of their lives. Louisa does not appear to have continued with photography and died in 1893 at the age of seventy-two.

ISOBEL CROMBIE

HOWLETT, ROBERT (1830–1858)

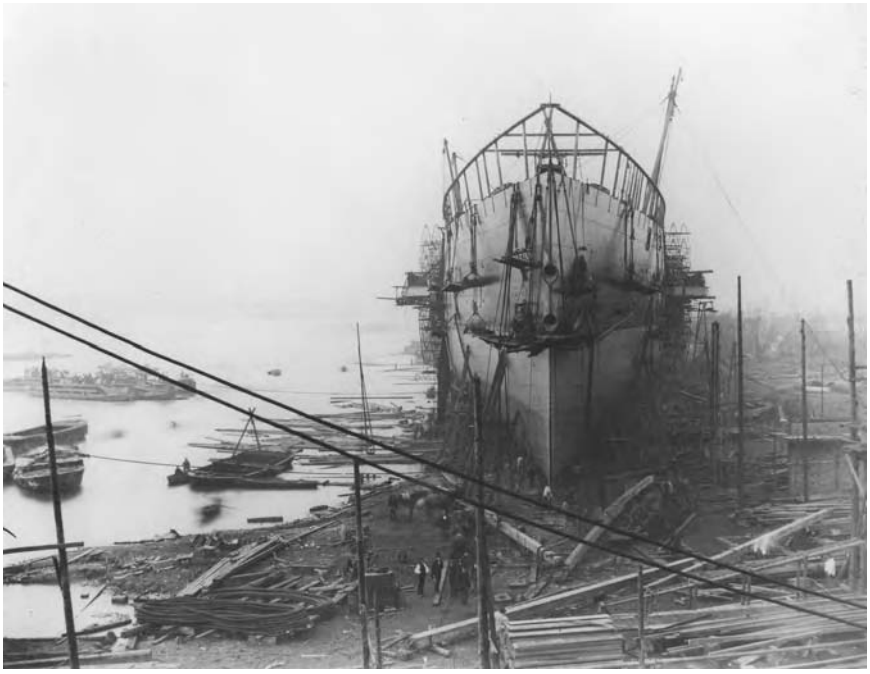
British photographer

Robert Howlett's tragically short life and brief career nevertheless yielded some of the most significant photographs of the 19th century. In particular, his image of *Isambard Kingdom Brunel and the Launching Chains of the Great Eastern* (1857) has become one of the icons of an era and is one of the first and finest examples of environmental portraiture. Despite the fame of his images however, Howlett's origins remain illusive. His father was a clergyman, Reverend Robert Howlett, of Longham, Norfolk. Nothing has been traced to date about his mother, education or early life.

Unlike many of the early gentleman-amateur photographers of his time Howlett is not recorded as having any other activity and can therefore be considered to be one of the first to have taken up photography as a profession exclusively from the start. It is known that he began making photographs in 1852 and very soon thereafter was employed at the Photographic Institution, 168 New Bond Street, London, a centre for the commercial promotion of photography, established in 1853 by Joseph Cundall and Phillip Delamotte. The Institution was active in exhibitions, publications and commissions and also housed a studio for portraiture. Howlett's name first appears in the photographic press in 1856. This and the following year were an incredibly busy and productive period in which he came into professional contact—no doubt through the well-connected Photographic Institution—with eminent artists, royalty and distinguished war heroes.

W.P. Frith commissioned Howlett to photograph crowd scenes from the roof of a cab at the 1856 Derby horse race at Epsom. The photographs were used by Frith in preparation for his painting *Derby Day* (1858). At the same period Howlett undertook the first of a number of commissions for Queen Victoria and Prince Albert that included copying the works of Raphael. Under Royal patronage he also made a series of portraits of soldiers of the Crimean War that were shown at the 1857 Photographic Society of London's annual exhibition under the title *Crimean Heroes*.

Howlett also contributed to the literature on photographic technique with, *On the various methods of printing photographic pictures upon paper with suggestions for their preservation* (London: S. Low, 1856). This publication addressed the fear at the time about the permanence of photographic prints, many of which had begun to show signs of fading. Howlett is known to have used W.H.F. Talbot's calotype process though most of his work was made using wet collodion on glass negatives printed on albumen paper. Alongside the commercial applications of the medium Howlett also produced landscape photographs such as *In the Valley of the Mole, Mickleham* and *Box Hill, Surrey,* 1855. These, among others, he submitted to the annual exhibitions



Howlett, Robert. The Bow of the *Great Eastern*.

of photographic societies in London, Manchester and Norwich in 1856. At the Art Treasures Exhibition, Manchester, 1857, Howlett exhibited his portraits of W.P. Frith and other noted painters such as F.R. Pickersgill, J.C. Horsley and Thomas Webster along with examples of photographic copies of paintings. His architectural views of Rouen, France were exhibited posthumously at the Photographic Society of London in 1859.

Howlett's major work was to document the construction of the massive steamship *Leviathan*, later re-named *The Great Eastern.* At the time of its launching it was the largest ship in the world. It was constructed in London on the banks of the river Thames (at present day Millwall) and Howlett's photographs of the event date from November 1857. His images (along with some by Joseph Cundall) were translated into engravings for *The Illustrated Times* (16 January 1858, vol. 6, no. 146, 45–69) and thus achieved wide circulation. Some of the photographic prints were exhibited at the Photographic Society of London annual exhibition of 1858. He also produced stereographs of the ship with George Downs for the London Stereoscopic Company. Howlett's views of the gigantic hull surrounded by scaffolding in the shipyard, and of the deck peopled with foremen and labourers, reflected and stimulated the widespread interest in this feat of engineering. The best known of all his images is the portrait of the ship's creator and engineer, Isambard Kingdom Brunel (1806–59). Brunel's stovepipe hat, and the stacked heels of his boots, gives him height and presence. His formal clothes are dishevelled and muddied from the site while the cheroot he is smoking lends a jaunty air. The powerful backdrop is simply formed by the chains of the stern checking drum. As the ship was too large to be "free launched" these chains were essential in controlling the rate of slide down the ways to the water's edge where it was halted and left for the spring tide to lift it from its cradles. The portrait by Howlett represents the archetypal Victorian, driven by ambition and confidence, and celebrates the enterprise of an era.

Barely one year after this image was made, Howlett died at his residence in Bedford Place, Kensington, London, on 2 December 1858, aged twenty-eight. A combination of causes of death were reported ranging from a specific "attack of typhus fever which followed a severe cold caught by working in a new and damp operating room" (*Photographic Notes*, 15 December 1858, vol. III, 290) to a more general "excess of zeal … imprudence and overwork" (*Journal of the Photographic Society*, 21 December 1858, 112). However, Mr. Hardwich, the correspondent to the *Journal of the Photographic Society*, continued in his *Remarks on the Death of Mr. Howlett*, with his own speculations about the cause of death: "Collodion photography, in the way that an amateur would practise it, is quite harmless; but the professional operator must be upon his guard; for, unless he is a very strong man, he will certainly suffer in the end by continually shutting himself up in small rooms half full of the vapour of ether." Howlett's early death clearly did not help to allay fears among the growing ranks of professional photographers that working with the noxious chemicals then required for their work could be severely harmful to their health.

Martin Barnes

Biography

Robert Howlett was born in 1830, the son of a clergyman, Reverend Robert Howlett, of Longham, Norfolk. Nothing has been traced about his mother, education or early life. Howlett is not recorded as having any other activity and can therefore be considered to be one of the first to have taken up photography as a profession exclusively from the start. He began making photographs in 1852 and soon thereafter was employed at the Photographic Institution, London. Throughout 1856 and 1857 he was extremely active taking photographs for the artist W.P. Frith, working under royal patronage to photograph works by Raphael and to make a series of portraits of Crimean War heroes, and publishing a book on the printing and preservation of photographs. He made portraits and reproductions of works of art as well as landscape photographs which he showed at the annual exhibitions of photographic societies in London, Manchester and Norwich. Howlett's major work was to document the construction of the steamship *Leviathan*, later re-named *The Great Eastern.* His images were translated into engravings for *The Illustrated Times* in 1858. In particular, his image of *Isambard Kingdom Brunel and the Launching Chains of the Great Eastern* (1857) has become one of the icons of an era and is one of the first and finest examples of environmental portraiture. Howlett died in London, on 2 December 1858, aged twenty-eight. His early death was perhaps hastened by overwork and prolonged exposure to noxious photographic chemicals.

HUEBL, ARTHUR FREIHERR VON (1853–1932)

Photographer and inventor

Arthur Freiherr von (Baron of) Huebl was born on Mar. 20, 1853, in Grosswardein (Nagyvárad, today Oradea, Romania), received higher military training between 1877 and 1879, and studied chemistry in Vienna from 1879 to 1882, finishing with a doctorate. From 1884 to 1918, he worked at the Institute of Military Geography at Vienna, from 1916 to 1918 as its commander general. Starting with a joint publication on the platinotype with Giuseppe Pizzighelli in 1882, Huebl produced a long line of technical books and articles on many subjects in photography, ranging from reproduction techniques over printing methods to his most prominent field, colour photography. His book on theory and practice of colour photography, first published in 1908, saw six issues until 1933 remaining the most comprehensive volume in the field up to this time.

In 1887, A.v.H. helped to found the first Club of Amateur Photographers in Vienna which was the nucleus of the fine art photography movement in Austria. In 1894, Huebl developed a panoramic camera, in 1898 he invented a photographic theodolite. From 1920 to 1924, Huebl installed and presided the Institute of Military Geography in Rio de Janeiro; after his return to Vienna he had his own laboratory at the Cartographic Institute. Arthur von Huebl died in Vienna on April 7, 1932.

ROLF SACHSSE

HUGHES, CORNELIUS JABEZ (1819–1884)

British photographer, writer, and lecturer

As a young man, Hughes developed an interest in debating societies and similar associations. As a lecturer and teacher on memory ("phrenology and subjects cognate thereto" according to the *Photographic Times and American Photographer*) he met John Jabez Edwin Mayall, then working in the Strand as a daguerreotypist, whose secretary he became. In 1849, Hughes established himself as a daguerreotypist in Glasgow. In 1855 he returned to London as a photographer in the Strand, but as this venture not successful, in 1859 he opened a warehouse in Oxford Street. Being a dealer proved uncongenial, so he sought a new opening as a photographer. This presented itself towards the end of 1861, when the Ryde photographer W.G. Lacy died in his Oxford Street sitting room, and Hughes subsequently purchased that business, being succeeded in London by his friend and previous manager, John Werge. He rebuilt the studio and reception rooms in the Arcade at Ryde, later transferring to the purpose-built Regina House in Union Street nearby. His proximity to Osborne and high-class productions secured the patronage of the Queen, for whom he executed a large amount of work. Ever an innovator, he adopted the carbon process to the almost entire exclusion of silver printing.

The death of his only son, who had assisted in Ryde, was a great blow. Alfred Wright Hughes (married with three children) died in London on 1 February 1878. This was reported in two Ryde newspapers and attributed to apoplexy, but that was not the whole story. A death certificate reveals he had died in St. James's Park, the cause being "Prussic acid. Suicide when insane a few minutes." An inquest was held before the Westminster coroner, though this was not reported in the London press, and went unnoticed in the photographic journals. However, documents concerning the inquest, at which both Jabez Hughes and John Werge gave evidence, are preserved in Westminster Abbey. Although Werge knew all about Alfred's suicide, it is never mentioned in his book *The Evolution of Photography*, neither does it feature in any Hughes obituary, so was certainly not common knowledge at the time.

Jabez Hughes never abandoned London, retaining his connection with various photographic societies. He was elected a member of the Photographic Society of London in 1858. He served on the committee of the North London Photographic Association, was also a vice-president of the South London Photographic Society, and, though not an officer of the Photographic Club, presided at its inaugural meeting. He was, in addition, one of the oldest members of the Solar Club.

An obituary in Ryde's *Isle of Wight Observer* noted that as a townsman Hughes was much liked and universally respected, though he refused to have anything to do with local politics. He was a prominent member of the Philosophical Society, and frequently lectured upon scientific topics with a fluency and ease which showed how deeply he had studied and how greatly he delighted in such researches. He also presided over the Ryde Literary Society for several years. Hughes frequently attended social gatherings, and had a turn for verse making, occasionally delighting friends with a topical song to some well-known tune.

In the 1860s he played an important part in raising and administering a fund to support John Frederick Goddard. When the latter's reduced circumstances were brought to his attention, Hughes with characteristic energy and generosity at once proposed a general appeal, issuing upwards of two thousand circulars, and many hundreds of personally written letters to photographers

all over the world, in addition to articles printed in the photographic press.

The *British Journal of Photography* noted that the chief work by which Hughes would be remembered was his photographic manual. This is listed in Gernsheim's *Incunabula of British Photographic Literature*, where there is some confusion over titles and editions. English editions of this work were published as *The Principles and Practice of Photography Familiarly Explained*, by Jabez Hughes, the first dating from 1861. At the same time, a virtually identical book appeared (probably only in the USA) under the title *How to Learn Photography*, by Jabez Hughes and John Werge. Trifling differences suggest that the latter was printed first, allowing time for copies to reach America before the English edition came out. At the time of publication, John Werge was in the USA—he had visited America before, and was possibly better known over there. Also, the less highfalutin title, *How to Learn Photography*, might have been deemed more appropriate for the American market. The latter seems never to have gone beyond its first edition; whereas *The Principles and Practice of Photography Familiarly Explained* was into a second edition within a few months, and had reached a 14th by 1887, those from the 12th (1880) onwards being edited by J. Werge.

Nuggets of practical advice lie buried in this popular manual. Two chosen from the 9th edition (1870): "Double or treble the exposure in the camera is required during an easterly wind ... Avoid the use of wide-angle lenses when the ordinary ones will do. They are dangerous tools to use." Some recommendations from the 10th edition (1873): "Never be contented with a medium quality of picture if you can obtain a better one; 'I dare say it will do!' will not do at all in good photography ... Never attempt landscapes on windy or misty days ... Wash your plates well; wash your negatives well; wash your prints well; and wash yourself well ... Ventilation is the soul of health. Ventilate your dark room; ventilate your bath, your camera, your tent, and your ideas."

RAYMOND TURLEY

Biography

Cornelius Jabez Hughes, known simply as Jabez Hughes, is presumably "Cornelous Hughs son of David & Elizebth Hughs" born on 20 July in the parish of St. James's, Westminster, and entered in the baptismal register of Hinde Street Wesleyan Chapel, Manchester Square, on 24 October 1819. Curiously enough, he was baptised for a second time on 17 January 1827, at the church of St. James, Westminster. The register records Cornelius Jabez (born on July 20, 1819), child of David Hughes (taylor) and Elizabeth, who lived in Heddon Street, off Regent Street. He married on 19 June 1843, at the parish church of St. Paul, Covent Garden. The bachelor groom was described as a tailor, living in Maiden Lane, the son of David Hughes, tailor. His bride Esther Wright, a spinster also residing in Maiden Lane, was the daughter of Edward Wright, gentleman. Their son Alfred was born on 1 October 1843, the father's occupation still being given as tailor. Jabez Hughes died at Ryde on 11 August 1884. He was buried in London's Abney Park cemetery, near his only son. He had made a will in June of that year, his personal estate being valued at £9402 18s. 5d. An obituary in the *British Journal of Photography* provides many useful details of his career.

HUGO, CHARLES (1826–1871) AND FRANÇOIS-VICTOR (1828–1873)

French photographers and writers

Charles (1826–1871) and François-Victor (1828–1873) were the sons of Adèle Foucher Hugo and Victor Hugo, the French poet and politician. Raised in Parisian cultural and political circles, they soon became involved in journalism. In 1851, for political reasons, they were prosecuted and sentenced to jail. On the 2nd of December 1851, Napoleon's coup capsized the Republic. As a republican deputy to the *Assemblée Nationale*, and opponent to the new regime, Victor Hugo secretly fled to Brussels. But his libel *"Napoleon le petit"* made him *persona non grata* in Belgium, and he was forced to leave once again. On the 5th of August 1852, Victor Hugo, along with his son Charles, his wife and his daughter, both named Adele , and their friend Auguste Vacquerie, took shelter in Jersey Island, a common lo-

cation for French exiles. François-Victor was to come a few months later. The family stayed at Marine Terrace until their final relocationto Guernsey on October 31 1855. The poet lived on this Island close to Jersey until the French empire collapsed and the Republic was proclaimed on September 4th, 1870.

While this upper middle class family had led a busy social life in Paris and Brussels, in Jersey, they had to adapt to a new pace, which largely contrasted with their former life. They had to get along with new kind of distractions. So, plans for a book illustrated with photography shaped up as soon as November 1852: *Jersey et l'Archipel de la Manche*. Made up of two volumes, one rather inexpensive, would have contained the poet's 400 verses, and a more luxurious one with text (pertaining to Jersey's history and institutions) would have been illustrated with the photographs taken by his sons Charles and François-Victor, and Auguste Vacquerie.

The Hugos pictures have to be understood within the context of exile and the framework of this project. This publication, and the photographs as well were aiming to distract the Hugo family. For their father Victor Hugo, it could have served to solve some financial problems. The project was also conceived of a common work between the writer and his sons and friend, and an opportunity to have them busy experimenting with a new medium for which V. Hugo was enthusiastic (photography). For Victor Hugo, taking advantage of his interest in Jersey's nature and history and avoiding any political references, such a book of photography let the French public know that not far away from the French shore, was a small group of opponents to the imperial regime.

In 1853 Jean-Jacques Sabatier, another French exile, apparently taught the Hugo sons daguerreotype, and the very basics about photography using negatives. Though François-Victor apparently kept on using this technique, Charles came back to Caen (France) in March–April 1853, where he learnt the use of glass negative, (collodion and albumen plates), and large size cameras, under a friend of his father, the photograph Edmond Bacot. Compared to François-Victor's daguerreotype, Charles gained the possibility of printing several images from a sole negative, mainly using a salted paper technique which gave softness and a result that resembled a drawing, especially with portraits.

Victor Hugo, though he never was the operator during the photographic sessions, acted as a director during the shootings. The Hugos sons' images, particularly in the case of landscapes, show a close attention to scenery, dramatic grandeur, sublime, strangeness, and above all an incredible admiration for their father. Their photographic images of him emphasized his daring attitude as an exiled republican and militant writer. Through those images, Victor Hugo was eager to attest differently his political commitment by spreading his image widely as a message from the determined handful of men standing up against the regime.

Illustration books presenting picturesque or romantic travels belonged to a well-established tradition in the eighteen fifties. Victor Hugo had been earlier included in a project of an illustrated book on Rhine and *Mont Blanc*. And in this same year 1852, Blanquart-Evrard published "*Voyage en Egypte, Nubie et Palestine*" with Maxime Du Camp's photographs. Yet this project which mingled poems and prose with photographs remained unfinished for several reasons: first, Hetzel, Hugo's usual publisher, proved to be very cautious, fearing the high costs for such a publication. Then the censurship organized by the imperial regime threatened the press; the reviews refused to be partners of the project, even though it were publicized in "*La Lumière*" the Parisian journal specialized in photography (August 6 1853, no. 32, and October 8 1853, no. 41). The pictures made in Jersey were to be circulated separately as single images or albums to be given to close friends. For the texts already written, Auguste Vacquerie was to use part of them in *Profils et Grimaces* (1856), *Les Miettes de l'histoire* (1863), and Victor Hugo would publish his poems in *Les Contemplations* (1855). François-Victor published his texts in *La Normandie inconnue* (1857), while his brother never undertook the part he was supposed to write.

All hopes for publication apparently were dropped by 1856. At that time, the Hugos had moved to Hauteville House in Guernsey, and even if a dark room had been organized there, only four new photographs seemed to have been taken in this island (though some reprints from the Jersey negatives seemed to have been done somewhat later on). With the end of this illustrated book project came little by little for the Hugos sons a fading interest in photography, even though Charles seemed to have perfected his technique in1860, when photographers Leballeur and Auzou stayed with the family. The brothers turned to other activities, such as writing plays or translating Shakespeare in French. The exile was getting tiresome and their sojourns abroad, without their father, longer.

MATHILDE LEDUC-GRIMALDI

Biography

Charles (1826–1871) and François-Victor (1828–1873) were respectively Victor Hugo's second and third children of four, and his only two sons. Both of them were very deeply influenced by their father (1802–1885), his work and interests, artistic as well as political.

In 1848, Charles, after a short term as Lamartine's personal secretary, started a newspaper *l'Evènement*, along with his brother François-Victor, and two close friends, Paul Meurice and Auguste Vacquerie. They all

were prosecuted in 1851 on political grounds. After having been jailed at the Conciergerie, they left France, to meet their father who having been banished by Napoleon the Third, had fled secretly to Brussels. Thence, the road of exile took them to Jersey (1852–1855) and Guernsey after 1855.

During their exile, at least until 1855, the Hugos brothers' main interest was photography. Most of the pictures are kept in Bibliothèque Nationale de France, Maison de Victor Hugo, Musée d'Orsay, (Paris, France), and partly in Musée de Victor Hugo (Villequier, France).

Later, they undertook literary activities. Charles wrote novels (*Le Cochon de Saint-Antoine*, in 1856, *La Bohême dorée* in 1859, in 1860, *La Famille tragique*), plays (*Je vous aime* in 1861), or travel writing (such as *La Liberté*, a journey with his father in 1867). François-Victor, starting with the translation of the Shakespearean Sonnets (1857) and Marlowe's *Doctor Faustus* (1858), devoted himself to the entire work written by Shakespeare from 1859 to 1866.

Charles settled in Brussels in 1861; François-Victor joined him with their mother Adèle, after his fiancée died in Guernsey in 1865. In 1869, the Hugos brothers founded along with Vacquerie, Meurice and Rochefort a new political publication, called *Le Rappel*, clearly fighting the imperial regime and its censorship. As a result, the brothers were fined and sentenced to jail several times. Charles married Alice Lehaene (1865) in Brussels, and fathered the two beloved Victor Hugo's grandchildren, Georges (1868) and Jeanne (1869). He died in Bordeaux, a few months after the collapse of the empire and the proclamation of the French Republic. François-Victor died two years later, in Paris.

HUMBERT DE MOLARD, BARON LOUIS-ADOLPHE (1800–1874)

Photographer

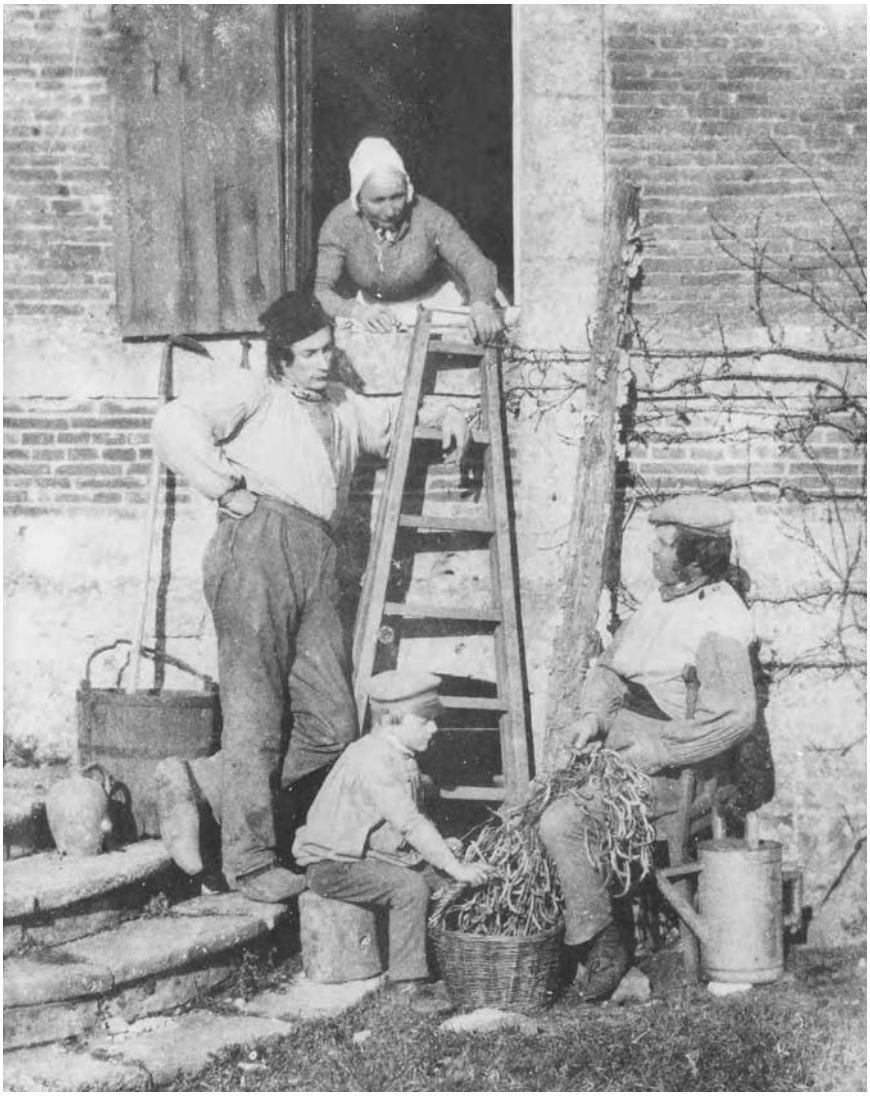
Humbert de Molard was born on 30 October 1800 in Paris, to a family originating from the Calvados region of lower Normandy. His father, Jean-Claude-François Humbert, was a career officer in army who became a baron in 1809, adopting the particle "de Molard" late in life. Very little is known about his mother, Marie-Louise Luce Justine Robillard. Although his parents lived their final days at the *château d'Argentelle*, near Manerbe, it seems that Humbert de Molard's childhood was spent in the environs of Paris.

Few things are known about the first thirty years of Humbert de Molard's life. It appears that he studied law for a time, but it is not known if he finished this course of study or not. He was reputed to be quite a prestidigitator in Parisian circles, impressing people with his command of sleight-of-hand tricks—and perhaps forming a useful background for later photographic practices. He also appears to have been a skilled wood-worker.

In his youth, Humbert de Molard worked for his uncle, Louis-Marc-Antoine Robillard d'Argentelle, a former naval officer who had created a collection colored wax reproductions of tropical plants. Humbert de Molard was charged with maintaining and restoring the wax reproductions, which were exhibited at his uncle's house in what came to be known as the "carporamic museum." Upon his uncle's death in 1828, Humbert de Molard took charge of the collection, giving guided tours to visitors and eventually reestablishing it at his Parisian apartment in 1833. Much later, in 1853, he sold the collection to the Parisian *Muséum d'Histoire Naturelle* [Museum of Natural History], located at the *Jardin des Plantes* [Botanical Gardens].

In 1832, Humbert de Molard married Constance-Clara Saint-Jean de Montfranc. The couple had two children, Louise Marie Julie Humbert de Molard, born in 1832, and Gabriel Charles Claude Adolphe Humbert de Molard, born in 1834, both of whom he would later photograph.

His wife having died in 1841, in 1843, Humbert de Molard married Henriette Renée Patu, a talented miniaturist, lithographer, and landowner from Lagny, in the fertile Aube region east of Paris. He and his children relocated to Lagny, where as a landowner affiliated with his wife's family, he became quite wealthy. His second marriage also coincided with his taking up photography, which was to become a consuming passion for



Humbert de Molard, Baron Louis-Adolphe. Stringing Beans. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Mr. and Mrs. Henry R. Kravis Gift, 2005 (2005.100.263) Image © The Metropolitan Musem of Art.*

the remainder of his life. Here he appears to have been influenced by his friend Hippolyte Bayard, who may have given him his first lessons in photography.

At first, Humbert de Molard practiced the daguerreotype process to a point where he became quite proficient at it. Then, around 1844, he took up the calotype or paper negative process, practicing the two procedures concurrently at first, but eventually becoming more interested in the calotype. He also experimented with the albumen negative process in the late 1840s and the wet-collodion process in the 1850s.

Most of Humbert de Molard's photographs which survive to this day are daguerreotypes and calotypes made during the period 1845–1849. These are either landscapes made in the environs of Lagny or Margne, or photographs of his family, friends, and acquaintances. The landscapes tend to feature sparing, open views of rustic architectural elements, in a similar vein to his contemporary Henri Le Secq. Over and above these, however, he excelled at staged portraits, using props and costumes to artificially recreate an atmosphere of daily life at Lagny, the candid gestures and expressions of his subjects revealing a sense of immediacy that is rare for the period. Many of these being calotypes, they show a concern for detail that is most unusual, as for example, a depiction of a woman seated with ring of playing cards placed upon her lap, or a family portrait, where the text of a sign posted on the wall is also legible. Many of these recall Bayard's self-portraits and anticipate the *tableau vivant* style of Vallou de Villeneuve, with whom Humbert de Molard also seems to have been acquainted.

Throughout his photographic career, Humbert de Molard was very interested in chemical experimentation. Dissatisfied with the way that hypo bleached salt prints, in 1844–1847, he arrived at an alternative fixing bath which avoided the use of hypo entirely. After exposure in a printing frame, the print was rinsed in an ammonia solution. This was followed by a gold chloride toning bath. Once the desired tone was achieved, the print was fixed in a solution containing potassium cyanide and

iodide, then washed. Some of his prints made using this process still survive today and are in very good state, characterized by a reddish-sepia tonality.

Following the work of Claude Félix Abel Niépce de Saint-Victor, Humbert de Molard experimented with albumen on glass in 1848. In 1850, working with Niépce de Saint-Victor, he arrived at an alternative procedure which reduced the exposure time by one-third; however, Humbert de Molard remained unsatisfied with the albumen process's lack of rapidity, as well as the difficulties inherent in obtaining a even coating of albumen.

In 1851, with the help of a chemist named Aubrée, Humbert de Molard published a technique for making paper negatives capable of much shorter exposure times, using ammonium acetate as an accelerator in the developing bath.

In 1854, Humbert de Molard became a founder-member of the Société française de photographie [French Society of Photography]. Through the publication of the society's bulletin, he offered technical advice and comments upon photography's historical interpretation. Concerning technical matters, he suggested a way to render paper negatives translucent using turpentine, advanced an early bellows-style camera design, and made improvements to stereoscopic photography. With regard to the historical interpretation of photography, in 1855, he insisted that French paper negative photography came into full flower in 1847 with the publication of Guillot-Saguez's paper negative procedure, which he viewed as the real break with Talbot's primitive calotype technique, rather than Blanquart-Évrard's more celebrated procedure. Similarly, in 1860, he defended the primacy of Gustave Le Gray's wet-collodion procedure over Scott Archer's, dreading the day when French innovation in the field of making glass negatives should be included under the heading, "archerotypes."

In 1864, Humbert de Molard resigned from the administrative council of the Société française de photography, citing reasons of ill health. He died on 17 March 1874, and was buried in Manerbe.

Alan Greene

Biography

Baron Louis-Adolphe Humbert de Molard was born on 30 October 1800 in Paris. As a young man, he assisted his uncle in the retouching of wax reproductions of tropical flora. From 1843-1849, he practiced both the daguerreotype and calotype with proficiency, making landscapes and portraits. In particular, his portraits were characterized by a theatrical quality in which he was able to obtain relatively candid expressions and poses from his models. Humbert de Molard was also interested in chemistry and introduced a number of innovations to the calotype process, including fixing without the use of hypo and adding a mild alkali to the developing solution in order to accelerate development. In 1854, he was a founding member of the *Société française de photographie*, which counted among its members several other notable French photographers from the period. Humbert de Molard died on 17 March 1874 and was buried in Manerbe, France.

HUMOUR

With amazing speed, photography reached the four corners of the world, and began to make its presence felt in every branch of human endeavour. It recorded the milestones of private life, from birth to burial. It celebrated, or satirized, great figures on the public stage. It could be used to report a war, to further research, to launch a business or to advertize a product. Something of this range and versatility was foreseen in the first notable cartoon about photography, "La Daguerréotypomanie," by Théodore Maurisset, which appeared in December 1839.

Although the photographer soon became a familiar figure in the social landscape, the photographic process itself remained a puzzle. The baffling mystery of how, from a wooden box, a black cloth, a collection of chemicals and one man with a stop-watch, an uncannily lifelike image could be produced formed the subject of several early cartoons, like one by Gérard Fontallard, published in 1842. The travails of the amateur enthusiast, loaded with equipment, lashed by rain, scorched by sun and mocked by self-appointed critics at every turn , was

another favourite theme on which many variations were played, by such artists as Cuthbert Bede (1855).

The most fruitful source of humour, though, was found in the studio world of the professional portrait photographer. Self-delusion is the stuff of comedy, and the pretensions of photographers and clients alike offered tempting targets. Lip-service was invariably paid by both parties at the altar of truth. The photographer's proud claim was that the camera could not lie. The client's firm demand was for a faithful likeness. Unvarnished truth, however, proved very hard to live with. What everybody really wanted was an idealized portrait, and photographers were more than happy to oblige. The magic art of retouching was used to bring out the best and blot out the worst in the client's appearance, while paper flowers, cardboard trees and ballroom backdrops added glamour and dignity to the dingiest provincial studio. Through this gap between rhetoric and reality there ran a vein of comedy, ready to be tapped by countless happy miners.

Soon after it had arrived on the scene, photography became a stock theme for cartoonists, both sophisticated and crude, from Daumier, Nadar, and Cuthbert Bede in the 1840s–1860s, to W.S.Gilbert and Linley Sambourne in the 1890s. Their work was carried by such popular illustrated journals as *Punch* and its many imitators, which flourished all over the world in the same sixty-year period. Cartoonists, always in search of fresh copy, seized their chance whenever photography was in the news, whether as hero or as villain. There were jokes about the camera helping the police to catch wily criminals, and jokes about the camera helping its master to catch unwary customers with "spirit" photographs. Even certain technical developments in photography itself proved to be promising material. The invention of the x-ray photograph in 1896 prompted some uneasy laughter in the months which followed the announcement.

The comic aspects of photography were explored not only in cartoons but in essays, stories and light verse. Edward Bradley, under his pen-name "Cuthbert Bede," wrote the first, mildly funny book about photography in English, *Photographic Pleasures*, which was published in January 1855. This was illustrated with his own cartoons, some of which had already appeared in *Punch* during the two previous years. Lewis Carroll, in "Hiawatha's Photographing" (1857) and "A Photographer's Day Out" (1860), produced charming accounts, in both verse and prose, of the amateur's frustrations in the making of a family group portrait and of an artistic landscape view. Frederick Locker , in his witty verses on "Our Photographs" (1872), described the part played by a photograph in an ill-fated courtship. Jerome K. Jerome, in *Three Men in a Boat* (1889), had fun with the problems of photographing a friend while at the same time trying to steer a boat on a crowded river Thames. For his *Utopia, Limited* (1893), W.S. Gilbert composed a song, a deft variation on the Kodak slogan of the day, "You Press the Button, We Do the Rest."

The photographer was usually the butt of all the jokes, but sometimes the tables were turned and he became the creator of the comedy. In the fantasy world of the studio he could make his own stage-sets and direct his own dramas. At the turn of the century, in the 1890s and the early 1900s, whether as forerunners or imitators of the fledgling movie industry, sets of cabinet cards were issued by many photographic companies. These cards, when arranged in the right order, told farcical tales of office romance and domestic discord, or showed that threat to family tranquillity, a gigantic stork, delivering one bundle of joy after another to a doomed, forever housebound father. Optical distortions, frowned on as flaws in serious photography, came into their own in farce. Gigantic feet, or beards, or noses, on puny little bodies, guaranteed an easy laugh or two on many a comic card.

In the darkroom it was possible to mix and match photographs and sketches, to re-assemble the heads and bodies of different figures into strange new hybrid creatures. This method, of combining a realistic, identifiable portrait head with a fantastic, unlikely body, was often used just for fun, to amuse holiday-makers at the seaside or at country fairs, but it could be employed, with deadly effect, in political satire. A *carte-de-visite*, issued in 1865 at the end of the American Civil War, deflates the pretensions of the defeated Confederate commander, Jefferson Davis. His photographed, instantly recognizable head has been set on the sketched body of a woman, and he attempts to escape in the humiliating disguise of skirt and shawl. Composite cartoons of this kind, concocted by a Government sponsored photographer, Eugène Appert, were circulated to demean and ridicule the leaders of the Paris Commune, after that uprising had been crushed in 1871.

Photography and society soon became inextricably entwined, and humour helped to ease the tension of that tight embrace. In cartoons and commentaries, images and captions, the two were made to mock each other and to laugh at themselves.

HUMPHREY, SAMUEL DWIGHT (1823–1883)

When the first issue of *The Daguerrean Journal* appeared on November 1st 1850, American photographers experienced their first specialist journal devoted to the new art, and the world welcomed the first commercially produced photographic magazine.

The editor and publisher was Samuel Dwight Humphrey, born in Hartland Connecticut, himself a daguerreotypist in New York with several years experience, and already by that time, co-author with M. Finley of the 1849 manual on the process, *A System of Photography Containing an Explicit Detail of the Whole Process of Daguerreotype*. For the third edition of that book, 1851, Humphrey became publisher as well as co-author. His other two major books were both self-published—*An American Handbook of the Daguerreotype* (1853) and *A Practical Manual of the Collodion Process* (1856). Both ran to several editions throughout the 1850s.

After two years of successful publication, *The Daguerrean Journal* name was changed to *Humphrey's Journal of the Daguerreotype and Photographic Arts*—usually referred to as *Humphrey's Journal*—a title it retained until 1864.

Throughout his editorship, Humphrey continued to operate a portrait studio in New York. He became a founding member of the New York Heliographic Association in 1851, possibly the first professional photographic union in the world—which later became the American Daguerre Association—and remained an enthusiastic supporter of maintaining fair prices and high quality. A prolific photographer, in 1853, boasted that he had made sixty-one successful daguerreotypes in one day.

Renamed *Humphrey's Journal of Photography* in 1864 Humphrey's magazine continued to enjoy success under the editorship of John Towler.

JOHN HANNAVY

HUNGARY

Throughout Hungarian newspapers were reports on Louis Jacques Mandé Daguerre's invention, the daguerreotype, scarcely but a few weeks after physician and astronomer, Francois Dominique Arago's announcement of it at the French Academy of Sciences.

As early as 2 February 1839 the newspaper "Hasznos Mulatságok" published an article on Daguerre's invention, which "by light and rays reflects a most accurate image of objects and preserves the image true to life." The same newspaper in its September 4-issue revealed the "secret of Daguerreian painting"; that is, based on Arago's August 19-speech, a paitning which provided a detailed and clear description of daguerreotype like production.

In 1839 count Antal Apponyi, the ambassador of Austria-Hungary to Paris was given a daguerreotype by Daguerre himself. This photo is currently in the collection of Országos Müszaki Múzeum (Hungarian Technical Museum) and unfortunately, the picture can be seen only in reproduction.

University teacher József Petzvál constructed a high sensitivity object-glass in 1840 with which he largely contributed to the decrease of exposure-time. The Viennese company Voigtländer manufactured a camera for this lens.

In May 1840 the description of Daguerre's method of "creating images" was published, translaed by Jakab Zimmermann.

The ambitious people in Hungary were producing daguerreotypes that same year, such as Antal Vállas, an arithmetic teacher at the university of Pest, who in August 1840 presented two of his earlier photographs at a meeting of the Hungarian Society of Siences. He later took two daguerreotypes on the spot of the Danube's bank and of the castle of Buda. Like many of the photographs from the early period of photography these daguerreotypes have not survived, and were only mentioned in newspapers. In June 1841, the first photographic studio opened in Pest. It belonged to Jakab Marastoni, who was a painter and daguerreian artist of Italian origin. According to our current udnerstanding, it was he who took the only photograph of Lajos Kossuth, the outstanding politician of Hungary's 19th century, during the period when Kossuth was still in Hungary before being politically exiled. The plate still exists but the picture has completely deteriorated and only a reproduction from the 1930s resembles its former state. In 2002 the Historic Photographic Collection of the Hungarian National Museum managed to purchase a daguerreotype which had been photographed by Jakab Marastoni in 1842. The daguerreotype, depicting a neatly-positioned biedermeier group of eight people, was in good condition. Being the earlier works of one of the first masters of Hungarian photography, it represents an extraordinary value.

After Marastoni a number of Hungarian daguerreotype-photographers started to run their own businesses from 1842 onwards. The first ones in Pest were located in the cultural centre of the country.Amongst other were Ferenc Tarsch and (N) Khogler (1842), about whom we know only from newspapers. Lipót Strelisky, immigrated from Galicia, and opened his

studio in 1843, and Lajos Kawalky who had come from Danzig in 1838 set up a studio in 1844. József Heller, opened his studio in 1847 while Ádám Gola, a former arificial flower maker, established his studio in 1845 in Buda, and Lajos Mezey—having finished his training in Pest—started his own business 1845 in Nagyvárad (Oradea, Rumania). Unfortunately the locations and circumstances of Móric Zsák's work are unknown, and only two of his daguerreotypes have survived, which can be found at Magyar Fotográfiai Múzeum (Hungarian Museum of Photography). Strelisky and Kawalky were originally goldsmiths by profession. Though Strelisky took daguerreotypes of many leaders of the Hungarian Revolution and War of Independence (1848–49), his photos became lost, and only drawn copies are known from later newspapers. What survived of him was a daguerreotype-copy of a lithograph showing the opening ceremony of the revolutionary general assembly of June 1848. A stereo daguerreotype of Lipót Strelisky's also survived, together with the diffusing-viewer built in its case. Lajos Mezey, who changed from painting to photography took excellent shots of his wife and of himself with his daughter in 1852. A photographer in Buda, Ádám Gola recorded, in 18 daguerreotypes, the statue models of István Ferenczy in the courtyard of the sculptor's studio, before they were destroyed by a desperate and bored sculptor who lacked orders.

Photohistorians had long been puzzled by the identity of the author of the daguerreotype-portrait depicting Sándor Petöfi, one of the most outstanding poets of Hungarian literature. The latest research attributes the shot to actor and amateur photographer Gábor Egressy. The daguerreotype, which can now be found in Petöfi Irodalmi Múzeum (Petöfi Museum of Literature), has deteriorated significantly over the past 150 years but fortunately a reproduction of very good quality was taken 30 years after the poet's death (in 1879). This photo by György Klösz still reflects the poet's true to form traits.

Commonly regarding the Transylvanian region, it can be stated that in the first years that characteristically landlords, and venturesome amateurs pursued photography. Additionally they made photographic experiments. Such people were Senior Miklós Zeyk, Elek Buda, count Zsigmond Kornis, baron Károly Apor and count Imre Mikó. The appearance of professional studio photographers occured later than with the middle or western part of the country.

In the second half of the 1840s more photographers were producing talbotypes. Alajos Kramolin used this method in 1847 to take a photograph of Ernö Kiss, a general of the Hungarian War of Independence who was executed among others in 1849. Antal Kramolin, a relative of Alajos Kramolin took a shot of landlord Vince Perczel, a photograph which attested a good portrayal. Lajos Kawalky produced coloured talbotypes of the famous goldsmith József Szentpétery. Amazingly, a number of heavily retouched photographs by Kawalky copied onto chloride paper still existence today. Also notable, 249 talbotype-positives and 3 talbotype-negatives have been preserved from József Skopáll's studio opened in 1848 in Györ, these photos show the portraits of the town's inhabitants and include some shots of townscapes as well.

Ferenc Veress' talbotype-negatives, one of which depicts the photographer himself, experimented with various techniques of photography. János Tiedge left Mihály Vörösmarty's portrait to posterity (one of the most famous poets of the century) and several prints of these superbly-produced talbotypes have survived.

Károly Pap Szathmári, born in Transylvania, carried out his renowned life's work in the Principality of Rumania; his outstanding acheivement was that he photographed the Crimean War. Another Transylvanian, Iván Szabó from Marosvásárhely (the present Tîrgu Mureş in Rumania) received recognition abroad, in Edinburgh, for his photogrpahy.

In 1857–58 Pál Rosti visited Central and South America, and recorded his experiences on waxpaper-negatives. Four albums survived of his photos: one can be found at the National Széchényi Library of Hungary; another at the Hungarain Museum of Photography; while the third one is in the possession of Loránd Eötvös Geophysical Institute. Rosti gave the fourth one to Alexander von Humboldt, which is now in the possession of Deutsches Museum in München.

In 1859 Ede Heidenhaus recorded the sights of Pest and Buda on large negatives which were later published in an album too.

In the 1860s photographic studios opened one after the other, and became an integral part of services both in the capital and in the bigger towns of the country. The very first criminal photos are attributed to György Mayer, a photographer in Pest, who took stereo photographs of count László Teleki in 1861. Count László Teleki had committed suicide for political reasons. Antal Simonyi put together two albums of the Members of Parliament in 1861, Ignác Schrecker made several albums of the members of the Hungarian Academy of Sciences in 1865. Emperor Francis Joseph I was crowned Hungarian King in 1867, and for this occasion Ágoston Bülch produced full-sized, coloured photographs of the participants of the ceremonial procession in Pest, and later sent his album to the royal couple as a homage present. An attempt was made by József Heller to record the open-air events of the coronation ceremony but for technical reasons he couldn't get a good enough image.

Ferenc Veress, ran his business in the Transylvanian town of Kolozsvár (currently named Cluj- Napoca in Rumania), and put together albums of the town in 1859

and then photographed famous scenes and settlements of Transylvania. He formulated an experimental method of producing photoceramics, and from then on, he made several hundreds of them in his studio. He experimented with colour photography for decades, from 1866 until his death in 1916, and left behind hundreds of coloured paper-prints, also called heliochroms.

Two very important studios were established during the decade of the 1860s: the first was of Ede Kozics' in Pozsony, which is presently Bratislava in Slovakia, and the other was Gondy and Egey's in Debrecen. Photographic dynasties evolved all over the country. In addition to the Strelisky studio in Pest (founded in 1843) was the Knebel family's studio located in Szombathely, Langsfelds' was in Kaposvár, and the Divald family's studios were in located throughout towns in Upper Northern Hungary (Felvidék) and appeared later in the capital as well.

György Klösz is considered to be one of the most significant photographers of the 19th century. His pictures depict Budapest's last third of the century and its evolution into a metropolis. Also interresting are his photographs which illustrate the conditions preceding these changes. In the last years of the century Klösz systematically photographed the castles of the aristocracy, and took shots of the exterior of the buildings. He also photographed scenes of representation and more intimate, private life in addition to the well-kept and diverse castle parks, thus leaving exceptional treasures and unique documents of aristocratic ways-of-life for posterity. In 1879, he recorded the catastrophy of Szeged, which was destroyed by the flood of the river Tisza. Klösz took shots from a boat using large collodion glass plates to document this tragedy.

Károly Divald faced dangerous situations on the mountain paths of Tatra when he photographed the beautiful views of the mountain between 1860 and 1880. He too worked with collodion wet plates.

Balázs Orbán wandered all over Székely Land (Eastern Transylvania) between 1862 and 1868, taking photographs of the scenery and the inhabitants.

Chromotypes were treasured and were rare photographs. Only the well-equipped studios were able to produce them. Amonst the qulifies studios were that of Lipót Strelisky, Ignác Schrecker, Doctor and Kozmata, Ede Ellinger and his brother, István Goszleth, József Heller, Emil Keglovich, Károly Koller, Ferenc Kozmata, Ede Kozics, and László Naschitz.

The works of Hungarian photographers have won a number of honourable mentions and awards at foreign exhibitions, for example Lipót Strelisky received Mention Honorable for his chromotype at the 1867 World Exhibition in Paris. Also, at the 1900 World Exhibition in Paris his son, Sándor won the Grand Prix for his composit photograph titled "Csárdás," which was put together from photographs of significant actors of the time. Jakab Marastoni was the first to present his daguerreotypes at a Hungarian exhibition, which consisted of 20 photographs in 1842. Lipót Strelisky displayed two daguerreotypes at the exhibition of Pesti Müegylet (Society for Supporting Art) in 1846. Photography however, was met with really great success at the Hungarian General Exhibition of Budapest in 1885 and at the Millennial Exhibition in 1896.

In 1890 an exhibition of amateur photographers' works was organised in Budapest. Amongst those amateurs were some aristocratic photographers as well, like count Mihály Esterházy. Hungary's most famous aristocratic amateur photographer however, was archducess Isabelle who was of Belgian decent, but through her marriage she became member of the Hapsburg family and of the Hungarian aristocracy. Her photographs depict her family-members, their forms of entertainment, the agricultural works on their vast estates, the people of these lands, and the beautiful natural environment too. In her legacy both large (21 × 27 cm) glass negatives and contact copies of the period platinotypes are found.

Several Hungarian expeditions reached exotic places of the world and took photographs of rare occurences. After Pál Rosti, János Xantus travelled to Southeast Asia and Japan in 1869. An expedition led by Sámuel Teleki travelled to Africa between 1886 and 1889, during which the leader and one of the members, Lajos Höhner took photographs. The expeditions of Jenö Zichy in 1895, 1896 and 1898, sought traces of Hungarian prehistory, photographing the regions and the peoples of Caucasus and Central Asia. Mór Déchy chose the Himalayas (1877) and Caucasus (1884–1902), and count Rudolf Festetics targeted the islands of Oceania for scientific study and photography. The untiring globe-trotter and art collector Ferenc Hopp, while travelling round the world five times between 1882 and 1913, also photographed exotic spots.

Many of the photographers dealt with photomechanical duplication, the first if which was Károly Divald, then Ferenc Kozmata, Antal Weinwurm and last György Klösz.

At the end of the 19th century, photography was drawn into public administration, in the form of photo identification papers, and in criminal records—particularly in 1898 when photo albums were compiled of pictures of 'subversive elements' who were banned from Budapestand, and given to major police stations for idintification. Photography also became important to the sciences, equally used for ethnography, medicine and astronomy (in the latter field the names of Jenö Gothard and Miklós Konkoly-Thege should be noted).

From the 1890s a new group of private photographers joined the professional and amateur photographers. These new phtoographers were emplyed by the intelligentsia

and the bourgeois class of society. These people photographed those moments of life which did not interest or rather escaped the attention of the "old" photographers. The shots of private photographers have grown to be the primary sources in the research of everyday life of the old days and as such, their numbers rocketed at the beginning of the 20th century.

HUNT, LEAVITT (1831–1907) AND BAKER, NATHAN FLINT (c. 1822–1891)

American photographers

Leavitt Hunt and Nathan Flint Baker were the first Americans to photograph in the Middle East. Traveling together on a Grand Tour that took them to Egypt, the Holy Land, Lebanon, Turkey, and Greece during the winter of 1851/52, Hunt and Baker planned from the outset to exploit both the novelty of photography and Europe's and America's intense fascination with the Orient by selling the prints made from the negatives they would take. They used the waxed paper process to make what they believed would be the first photographs brought back from the Middle East, and returned with approximately sixty good paper negatives—the majority from Egypt, but including views from Petra in Jordan, Jerusalem, Baalbek in Lebanon, and Athens. However, the demand for their photographs they anticipated never materialized and relatively few prints were made, most of which remained in family hands until they were deposited in institutional collections. Only a handful of Hunt's and Baker's prints have ever appeared on the market, and they are among the rarest and most desirable early American paper print photographs.

The partnership of Leavitt Hunt and Nathan Flint Baker was based on family connections and opportunity. Leavitt Hunt was the youngest and most scholarly of the four talented sons of Jonathan Hunt, a wealthy

Vermont judge, banker, and Congressman—both William Morris Hunt, one of the most talented American artists of his generation, and Richard Morris Hunt, the great architect were Leavitt Hunt's brothers. After her husband's death in 1832, Mrs. Hunt moved the family to Paris so her children could receive European educations. While his brothers studied art, architecture and medicine in Paris, Hunt attended boarding school in Switzerland, then took a law degree from the University of Heidelberg in Germany, and in 1851, was enrolled in the Swiss Military Academy in Thun. He was fluent in French, German, Italian, Latin, Greek, and Hebrew and could read Farsi and Sanskrit, and he had traveled throughout Europe, including Scandinavia and Russia. Baker, an independently wealthy amateur sculptor from Cincinnati, had been a student of Hiram Powers in Florence, and had been living in and traveling throughout Europe since the early 1840s. He was an old friend the Hunts, and when he told them of his plans to make an extensive tour of the Orient in the winter of 1851/52, Leavitt Hunt expressed an interest in joining him. They rendezvoused in Florence, Italy, in late September/early October 1851, spent the first two weeks in November in Rome practicing photography, then sailed from Naples to Malta en route to Alexandria. For the next six months Hunt and Baker traveled together in a journey that took them up the Nile and into the Sinai; to Petra; to Jerusalem; to present-day Lebanon; to Constantinople; and to Athens, before they returned to Paris in May 1852.

Hunt and Baker's photographs are mostly of the major architectural monuments they encountered on this tour: the Sphinx and pyramids at Giza; general views and details of the temple complex at Karnak; elements of the Ramesseum at Thebes; structures on the Island of Philae (where they ended their trip up the Nile); buildings of the Monastery of St. Catherine's at Mt. Sinai; rock-cut temples and tombs at Petra; the Church of the Holy Sepulcher in Jerusalem; ruins at Baalbek; and the buildings on the Acropolis in Athens. The photographs, unfortunately, do not offer a comprehensive record of their journey: there are no images from Constantinople, for example, although Baker wrote his sister that they made a number of photographs there.

Hunt and Baker's negatives measured approximately 18 × 24 cm and were made by the waxed-paper process. Some of the images were made as personal works, but most appear to have been collaborations. In making their views, Hunt and Baker did not typically position a human figure in the image to give a sense of scale, but their photographs are carefully composed to balance description with aesthetic appeal, and are of a consistent technical quality that is indicative of a comfortable familiarity with their materials. Among the sixty-odd known images by them that survive, two are especially noteworthy: a photograph of a *ghawázi* (a woman belonging to a caste of female dancers who performed unveiled in public and could therefore be photographed) that is signed in the negative by Hunt and is perhaps the earliest camera portrait of a Middle Eastern woman; and a view of the Parthenon that is notable simply because it is of the less noble, therefore less photographed, rear façade of this well-known classic building.

Hunt and Baker printed their negatives in Paris in June and July 1852, making enough prints to assemble two complete sets of images, with extra prints left over. Hunt assembled one set into an album, which he kept. Baker returned to the United States with the other set and left it with an unidentified print dealer in New York to test the market. The negatives and remaining prints were divided between Hunt and Baker, with Hunt apparently keeping most of the prints. After showing his album to the King of Prussia and presenting a portfolio of eleven prints to Karl Richard Lepsius, the preeminent German Egyptologist of the19th century, Hunt appears to have lost further interest in promoting his and Baker's achievement.

Neither Leavitt Hunt nor Nathan Flint Baker showed any interest in photography after this. Baker returned to Cincinnatti and pursued the life of an independently wealthy gentleman. Leavitt Hunt completed his studies at the Swiss Military Academy, and returned to the United States in 1855 to take a second law degree from Harvard. He practiced law in New York until the Civil War broke out, when he enlisted as a lieutenant in a New York regiment; he served on General Heintzelman's staff, and was brevetted to the rank of Lieutenant Colonel for gallantry at the Battle of Malvern Hill. Invalided out of the service in 1862, Hunt returned to his law practice in New York, but retired to Weatherfield, Vermont in 1867, after his wife inherited her father's estate there. Hunt spent the remainder of his life as a gentleman farmer, living in a house filled with the exotic souvenirs of his travels.

Hunt and Baker's photographs are both extremely rare and seldom seen. Hunt's personal album is now in the collection of the Bennington Art Museum, Bennington, Vermont. The set of prints Baker left in New York is unaccounted for and presumed lost; however, some of the negatives he kept recently surfaced and are now in a private collection. The portfolio Hunt sent to Lepsius is now in the collection of the Museum Ludwig/Agfa Foto-Historama in Cologne, Germany. Any negatives that Leavitt Hunt may have had are lost, but most the prints he kept became the property of his brother Richard Morris Hunt and most of them are now preserved in the Richard Morris Hunt Papers, the American Architectural Foundation, Washington, D.C. Any prints kept by Hunt's family were donated to the Library of Congress years ago. Outside these holdings, the single prints in the Hallmark Collection and at George Eastman House, and the six prints in the Harrison D. Horblit Collection

of Early Photography at Harvard University are the only other known examples of this very rare work.

HUNT, ROBERT (1807–1887)

Robert Hunt was a representative figure among the 'men of science' who played a prominent role in British photography during the first two decades of its existence. Hunt produced some photographs (chiefly nature prints of leaves, etc.) and developed a direct positive paper that he marketed, but his principle contribution to photography came from his pen and his role as an organiser. He became interested in photography soon after its announcement: experimenting with processes, and publishing his findings. The manuals he wrote stemmed from this work. In 1841 he authored, what is usually seen as the first book on photography in English: *A Popular Treatise on the Art of Photography*, following this in 1844 with *Researches on Light*. During the 1840s and 1850s he wrote a series of influential articles on the photography in *The Art-Union* and its successor *The Art Journal*. In 1847, Hunt was a founding member of the Calotype Club. As a member of the group charged with negotiating with William Henry Fox Talbot he also played an important role in Talbot's partial abandonment of his patent claim on photography; in 1853 he seconded the motion calling for the foundation of the Photographic Society; and, in 1854, he served as Vice President when the organisation was formed.

Hunt, described by the editor of the *Art Journal* as a 'self-raised man,' trained with a London surgeon and ran a medical dispensary before making his rise through the scientific establishment to become Keeper at the Mining Records Office, and Professor of Mechanical Science at the Royal School of Mines. Intellectually, Hunt was a Utilitarian; an advocate of Natural Theology and a partisan of the particle, or 'corpuscular,' theory of light. He maintained, until the mid-1870s, that the sun's force was composed of three distinct elements: heat, light and photographic power or "Energia," a view he propounded in his *Researches on Light*. This cluster of commitments puts him at some distance from the dominant Cambridge network (Talbot, Herschel etc.) and finds the closest parallel in the work of Sir David Brewster; indeed, there are many common themes in the photographic writings of the two savants.

Hunt's writing is, in one sense, typical of the period: his early manuals mixed the most prosaic technical descriptions of processes and banal history of inductive discovery with wild figural passages (in one instance peoples are attributed racial characteristics according to their exposure to the sun's rays). Nevertheless, it is possible to draw out some structuring assumptions from his writing. Hunt—in line with other prominent men of science—viewed photographs as 'light-drawn pictures' that were 'geometrically true' (*Researches on Light*, 34). "Wherever a shadow falls," he argued, "a picture is impressed' that demonstrates 'unerring fidelity" (278). In his account photographs are characterised by "extreme fidelity," and 'minuteness' and the active agent is not the photographer—they were untouched by "human handling"—but the sun or nature who "impresses herself." It was the absence of 'mind' or intellect in photographs that made them valuable as copies. This approach constitutes, what historians of science would see as, an "objective" vision in which a seemingly automatic apparatus supplies the detached scientific observer with unerring documents.

Hunt's vision of photography shares two key features with the account put forward by Brewster. Firstly, he inflected the standard figuration of the sun as the principle agent involved in the creation of photographs in an industrial direction. For him, the sun appeared as a natural power (like steam) that could be harnessed by modern science in the service of industry. The "Talbotype" was, he said, "an instrument of new power placed at the disposal of ingenuity and of Art, and which, as in the case of the electrical machine and galvanic trough, may be expected to suggest countless new applications and developments of its principle" ("The Application of the Talbotype," 195). By "Art"he meant the mechanical arts or trades. Secondly, Hunt (like Brewster) differed from Talbot and the Cambridge men in their estimation of photography's relation to the Fine Artist. Talbot was, at best, ambiguous on this matter: largely unconcerned with art he wanted an apparatus that would mechanically substitute for skill with a pencil. Talbot's

primary impetus was to free men of science from their reliance on artists in the production of records or documents, but he does not appear to have been particularly bothered about the effect this project might have on wider conceptions of Fine Art. Hunt, in contrast, was careful to restrict the employment of the automatic copy in a way that would leave Fine Art untouched. In his account, the photograph appears as an aid to the artist (a faithful assistant) and not a replacement for "genius" or "the play of fancy." "The absence of mind," which was so efficacious in the production of documents, undermined any claim to rival Fine Art. "The Sun," he said, "will continue to be a very bad painter, too literal in his details' and could not therefore 'supersede the labours of the artist" ("The Application of the Talbotype," 195). This is a familiar Academic argument. In the same vein, he suggested the real problem was that: "men will be led to copy from the photographic picture rather than study from it..." ("Photography: Considered in Relation to its Educational and Practical Value," 261). He also opposed attempts by photographers to rival "the historical painter"; composition photographs, he thought, "have a tendency to lower the appreciation of Art in the eyes of the public" (Photographic Exhibitions, *Art-Journal*, February 1856, 49–50). Hunt, then, set photography in distinction to art. At the same time he employed the terminology of Academic art theory to describe the photographic image: "littleness," "breadth of effect," "mind" contrasted to copying, and so forth. It would take a great deal of work on the part of the next generation to generate an account that could speak of art and photography together; even then it would not prove entirely possible to reconcile these terms.

STEVE EDWARDS

Biography

Robert Hunt was born in Plymouth Dock (now Devonport) in 1807. The posthumous son of a ship's carpenter, or a navel officer (probably one and the same), he became one of the key scientific popularizers of the time, writing a series of introductory books and publishing articles in *Art Journal* and *Athenaeum*. His most important posts were held at the Mining Records Office where he was Keeper, and the Royal School of Mines where he held the chair of Mechanical Science, from these institutions he pursued a conception of science geared to needs of Britain's mine owners. In 1854, as a result of this work, he was elected Fellow of the Royal Society, and in the following year to Fellow of the Statistical Society. He also authored the *Hand-book to the Official Catalogues of the Exhibition of 1851* (2 vols., Spicer Brothers & W. Clowes, 1851). In addition to these scientific works, Hunt also wrote romantic poetry and Cornish folklore. After Andrew Ure's death, he became the editor of *The Dictionary of Arts, Manufactures and Mines*, producing three editions. His mission to popularise science also resulted in an odd novel *Panthea: the Spirit of Nature (A Sketch)*, (Reeve and Benham,1849). Hunt's involvement with photography was confined to the 1840s and 1850s; he died in 1887.

HURTER, FERDINAND (1844–1898) AND DRIFFIELD, VERO CHARLES (1848–1915)

In 1863, at the age of 15, Vero Charles Driffield became interested in photography. Ten years later, he worked at Gaskell Deacon and Company in Widnes, Cheshire, England, and formed a lifelong friendship with the works' chemist, Dr Ferdinand Hurter, through mutual interests in music and Switzerland. In 1876, Driffield encouraged his friend to take an interest in pictorial photography, but unreliable exposures, and the lack of knowledge relating to the action of light on photographic plates, frustrated Hurter. To determine the strength of daylight, he designed and patented the Hurter Actinometer, but found lighting conditions were liable to change whilst making the necessary calculations.

Hurter's scientific approach impressed Driffield and the men modified the actinometer to produce permanent images of daylight on sensitised paper. For twelve months, between 1885 and 1886, Driffield collected the "daily diagrams of light," which were compressed into a set of monthly charts. In a further refinement, they transferred the information from twelve charts onto

one sheet, which became the database for a patented exposure calculator, the Actinograph. From 1888 to 1892, Driffield sold the device from Widnes until the photographic specialists, Marion and Company, London, took responsibility for marketing it.

The Actinograph's instructions explained how to find the rapidity of photographic plates, and make use of it as an actinograph number. The procedures had evolved from theoretical work carried out by Hurter, and corroborated in practical experiments by Driffield. Hurter reasoned that a photographic plate was inert to the action of light until sufficient energy overcame its *inertia* and by converting this parameter to a number, it indicated rapidity, or the film speed. Because it was feasible to measure all commercially available gelatino-bromide plates, Hurter and Driffield advocated the merits of accurate camera exposure and decried the prevalent rule-of-thumb approaches.

During 1888 and 1889, the two men collaborated in a further series of experiments and presented the results of their investigations to the Society of Chemical Industry in May 1890. It had been necessary to build equipment to give controlled exposures to photographic plates and to design apparatus to measure the photographic deposits of silver, for which they introduced the term "density." By plotting their test results as a diagram (the H & D curve), they characterised the parameters of different plates, and determined their speeds. Hurter and Driffield also examined the effects of exposure, variations in development, the behaviour of developers, and the criteria for the theoretically perfect negative.

The photographic community welcomed the comprehensive nature of Hurter and Driffield's investigations, but one important conclusion contradicted the perceived wisdom of the time. They claimed errors in exposure could not be corrected during development, and this assertion outraged many contemporary commentators. Hurter and Driffield were later criticised for using the government-approved standard candle for testing plates intended for use in daylight, and for selecting ferrous oxalate as the standard developer, instead of a pyrogallol-based type. Because their resources were committed to defending a controversial doctrine, the potential benefits of the Actinograph, and actinograph speeds, were overlooked.

Twelve months after Hurter and Driffield had announced their conclusions, an enthusiastic amateur photographer, John Sterry, alerted Marion and Company to the merits of Hurter and Driffield's technique for determining the sensitiveness of photographic plates. In September 1891, he disclosed to Driffield that "the partners are now thoroughly interested in adopting the test methodology." Ten years earlier, the Editor of *The British Journal of Photography*, had encouraged Alexander Cowan, (the manager of Marion and Company's Southgate works), to establish a reliable standard of sensitiveness. Despite the initiative failing, Cowan had continued to seek a test method for quality control in the manufacture of plates.

The manager of Marion and Company's London office, Frank Bishop, also identified the marketing benefit in providing numerical values to indicate the rapidities of each of the company's four brands of plates. With Driffield's help, Sterry convinced Messrs Bishop and Cowan, and Marion and Company announced the initiative would commence in 1892. Advertisements by the company in *The British Journal Almanac* for 1893 explained that after "more than twelve month's experience in testing by the Hurter and Driffield method, we are in a position to state its absolute correctness." At the time, the speeds continued to be expressed in actinograph numbers.

Within two years, as plate making techniques improved, other manufacturers showed interest in the methodology, which was now being used by Marion and Company to determine H & D numbers. James Cadett (principal of Cadett and Neall) also recognised its worth, but he and Alexander Cowan realised a limitation was the reliance on the standard candle as the exposing source. Driffield had selected it on grounds of economy and because it had been approved by Act of Parliament in 1860 (for monitoring the quality of coal gas).

Hurter and Driffield agreed to replace the candle with gas-powered lamps, which were a better match for daylight and better suited to the examination of orthochromatic and panchromatic emulsions. During 1896 and 1897, Driffield also resisted arguments that the ferrous oxalate developer should be replaced by a pyro-based one. In a lecture to The Royal Photographic Society in January 1898, during which they received the Progress Medal, Hurter and Driffield announced important concessions and thus consolidated the acceptance of the H&D Speed System.

Hurter died eight weeks later, and his partner declined to undertake any further research in photography. Driffield applied himself to his career in the alkali industry but devoted his leisure time to practical photography and Widnes Photographic Society, of which he was a founder member. At the start of the 20th century, the H&D Speed System was a recognised guide to film speeds, and retained a currency in parts of Europe until the outbreak of the Second World War.

Following Driffield's death in November 1915, The Royal Photographic Society acquired his experimental notebooks, letters and papers, which included those of his late partner, Ferdinand Hurter. The material was sorted and arranged by William Bates Ferguson as The Driffield Bequest.

Ron Callender

Biography

Driffield, Vero Charles 1848–1915

Engineer and amateur photographer

Vero Charles Driffield was born in Prescot, Lancashire, England on 7th May 1848. His childhood was spent in London, prior to education at Liverpool Collegiate Institution, Sandbach Grammar School, and a private school in Southport, Lancashire. Driffield's interest in photography began in 1863, and at the age of 17, he enjoyed six months' work experience in the Southport studio of Henry Sampson, where he received grounding in the wet-plate process and emulsion making.

Following an apprenticeship, Driffield joined Gaskell Deacon and Company of Widnes, Cheshire, as works' engineer in 1871. During a lifetime in the alkali industry, he worked on manufacturing processes. When the company amalgamated as part of the United Alkali Company in 1890, the new board appointed Driffield works' manager, until he retired in September 1915. He died at home six weeks later.

In 1877, Driffield married Ethel Bowles Fripp, who died whilst giving birth to a daughter the following year. His daughter, May, survived and was the subject for many attractive portraits and experimental photographs by her father for the next thirty years.

At Gaskell Deacon and Company, Driffield met Dr Ferdinand Hurter, and the two men collaborated in photographic research until Hurter's death in 1898.

Hurter, Dr. Ferdinand 1844–1898

Industrial chemist and part-time photographic investigator

Ferdinand Hurter was born in Schaffhausen, Switzerland, in March 1844 and educated at the Gymnasium. At the age of 19, he worked for a silk dyer and successfully completed a course in chemistry at Zurich Polytechnic. In 1865, his tutor arranged for him to read at Heidelberg University and under a system of continuous assessment, he studied modules of meteorology, stoichiometry, climatology, analytical and organic chemistry.

In 1865, he graduated with the highest honours and came to Manchester. Henry Deacon of Gaskell Deacon and Company engaged him as a personal assistant, but promotion to works' chemist soon followed. When the company amalgamated to form the United Alkali Company in 1890, the board of directors appointed Hurter as Chief Scientist, with a commission to create a central research laboratory.

Until his sudden death in 1898, he worked on improvements to many processes to meet a need for efficiencies within the alkali industry. He was a founder-member of The Society of Chemical Industry, and served on committee for many years as well as contributing important lectures.

In 1871, he married Hannah Garnett, and had four children. In his leisure time, he undertook photographic research in conjunction with his colleague, Vero Charles Driffield.

I

ICELAND

Photography was one of the very few technical innovations which the people of Iceland were able to adopt in the 19th century. The country was a Danish colony, its social structure undeveloped, and its population sparse: in 1840 there were only 57,000 inhabitants in an island with an area of 103,000 square kilometres. Daguerre's method became universally known in 1839, and just a few years later this technology was brought to Iceland by Icelanders who had learned it in Scandinavia and also by foreign travellers, especially the French and the British, who visited Iceland on research expeditions or pleasure trips.

The oldest photographs of Iceland which have been preserved are two daguerreotypes taken by the French mineralogist Alfred Des Cloiseaux (1817–1897) in Reykjavík in 1845. The early stages of photography in Iceland were rather protracted. Three things in particular account for the length of time it took for photography to put down roots there. Most of the inhabitants lived very simple lives; the country was in its very first stages of urbanisation; and the art of portraiture had not become established among the people even though there were a few local artists who had studied at the Academy of Art in Copenhagen.

Photography in Iceland, therefore, differs from photography in other places in Europe because it fell to the lot of photography to create a tradition of portraiture and so it was in fact the precursor of the painted picture. From 1845 until after 1860, a few people tried their hand at photography but they practised it only for a short time. Two of them took photographs using the daguerreotype, but none of their images have survived. Customers were slow in coming forward, technical difficulties took their toll on production and photographers had to depend for their photographic materials on the infrequent arrivals of ships from abroad.

The turning-point occurred when the photographer Sigfús Eymundsson (1837–1809) started working in the country's burgeoning capital city, Reykjavík, in 1866. He became the first photographer in Iceland to succeed in making a living at photography, although he was engaged in many other activities over the course of time. He pioneered various innovations in photography, such as the multiple reproduction of portraits of prominent Icelanders, imitations of sterescopes featuring identical photographs side by side but without the three-dimensional effect and, starting in 1874, he took the first scenic photographs in large format, which he sold to foreign visitors. A considerable selection of original photographs by Sigfús has been preserved, and his collection of plates is in the Þjóðminjasafn Íslands (the National Museum of Iceland).

As urban areas developed and the population density increased, so did the number of photographers, and as soon as villages such as Djúpivogur, Ísafjörður and Akureyri had the capacity to support them, they acquired their own photographers. Among them was Nicoline Weywadt (1848–1921), the first woman photographer, who did her training in Copenhagen, Denmark (as did the majority of Icelandic photographers up until 1890) and who began working in 1872 in Djúpivogur in Eastern Iceland. In the year 1890 there were 10 photographers working in eight places and by 1900 this had increased to 23 in 16 places.

As the number of photographers grew, basic training in the subject was shifted to Iceland, but most photographers still got their advanced training in Denmark as before. Photography was closely related to handicrafts and trade and those who worked at it were generally working in other branches of the craft industry, or as tradesmen, or were the daughters of shop managers or civil servants. Their product was principally portrait photographs. As settlements were far-flung, the

photographers had to travel around the rural areas of the country or to other villages in order to come into contact with sufficient customers. Two kinds of portrayal other than the traditional portrait rapidly became firm favourites in Icelandic photography: pictures of people in front of their farmhouses, and pictures of people on horseback. Photographs taken by overseas visitors may have started this trend, since the foreigners were intrigued by the fact that, until well into the 20th century, farmhouses were usually turf houses and horses were the main method of transportation in Iceland. As very few photographs from Iceland dating from the 19th century have been preserved, the photographs taken by foreign travellers have great historical value.

The first publication of Icelandic photographs was produced for the Tourist Board of Iceland in 1896 and was intended for foreign visitors. The photographs showed the main tourist attractions of the country such as Gullfoss and Geysir (still the most frequently visited sites in Iceland) and most of the scenes were photographed by Sigfús Eymundsson. Ever since, landscape photography has been the dominant branch, apart from portraiture, in Icelandic photography, and its key mission has been to promote Iceland internationally and also to preserve Icelandic national identity.

ILLUSTRATED LONDON NEWS

Publication

The *Illustrated London News*, which commenced publication on 14 May 1842, was the first newspaper to regularly illustrate its topical news stories with woodcuts, drawings and photographs. This popular weekly was a forerunner of similar publications such as *L'Illustration* and *Harper's Weekly*. Its founder Herbert Ingram was born in Boston, Lincolnshire, England on 27 May 1811. Whilst working in the London printing industry he noticed that newspapers sold more copies when they contained woodcut illustrations. This encouraged him to launch the *Illustrated London News*, with Mark Lemon, the editor of *Punch*, as his chief adviser. Ingram hired skilled engravers and illustrators and the first edition sold over 26,000 copies and within a few months was selling 65,000 copies per week.

He recognised that photography could be used to enhance the publication. He hired the renowned portrait photographer Antoine François Jean Claudet to photograph a panoramic view from the top of the Duke of York's Column, Pall Mall, London. Claudet used a specially designed camera for the commission. An artist, C.F. Sargent drew the details of Claudet's daguerreotypes onto sixty wood blocks. The engraving was then undertaken by the firm of Ebenezer Landell. The resulting print was circulated to subscribers and proved to be a hugely successful boost to sales. Until the development of Scott Archer's collodion process, daguerreotypes had to be traced and stencilled onto wood blocks. In 1857, George N. Barnard invented a process whereby the collodion negative could be printed directly onto the block. This method was used until the advent of the halftone and line processes in the 1880s which allowed for the rapid production of illustrations.

The newspaper's images were often accompanied by first-hand accounts of notable events. In response to negative reports in the *London Times*, Roger Fenton was commissioned to photograph the Crimean War in 1855. He travelled with a horse-drawn photographic van and used the newly developed wet collodion plate. Fenton returned with over three hundred war scenes and military portraits, some of which were reproduced by the *Illustrated London News*. James Robertson also reported from the Crimea and engravings based on his photographs appeared in the newspaper. Other major events which were featured by the *Illustrated London News* include the Irish Famine in 1847; the Great Exhibition of 1851 and the outbreak of the American Civil War in 1861. Over 150,000 copies were sold of the edition that reported the funeral of the Duke of Wellington.

Ingram was a staunch Liberal who favoured social reform and this is reflected to a certain extent within the *Illustrated London News*, for example, he used the paper to further his campaign against child labour. Yet the newspaper generally reflected the interests and preoccupations of its middle-class readership and the concerns of the British Empire. Ingram was to die tragically when the steamship *Lady Elgin* sank on Lake Michigan in 1860. His widow Anne continued to run the business with the assistance of Mason Jackson, the paper's Art Editor. The newspaper's success continued into the twentieth century when it hired some of England's top

artists including Frank Reynolds and Henry Brock. It ceased publication in 1993.

IMPRESSIONIST PHOTOGRAPHY

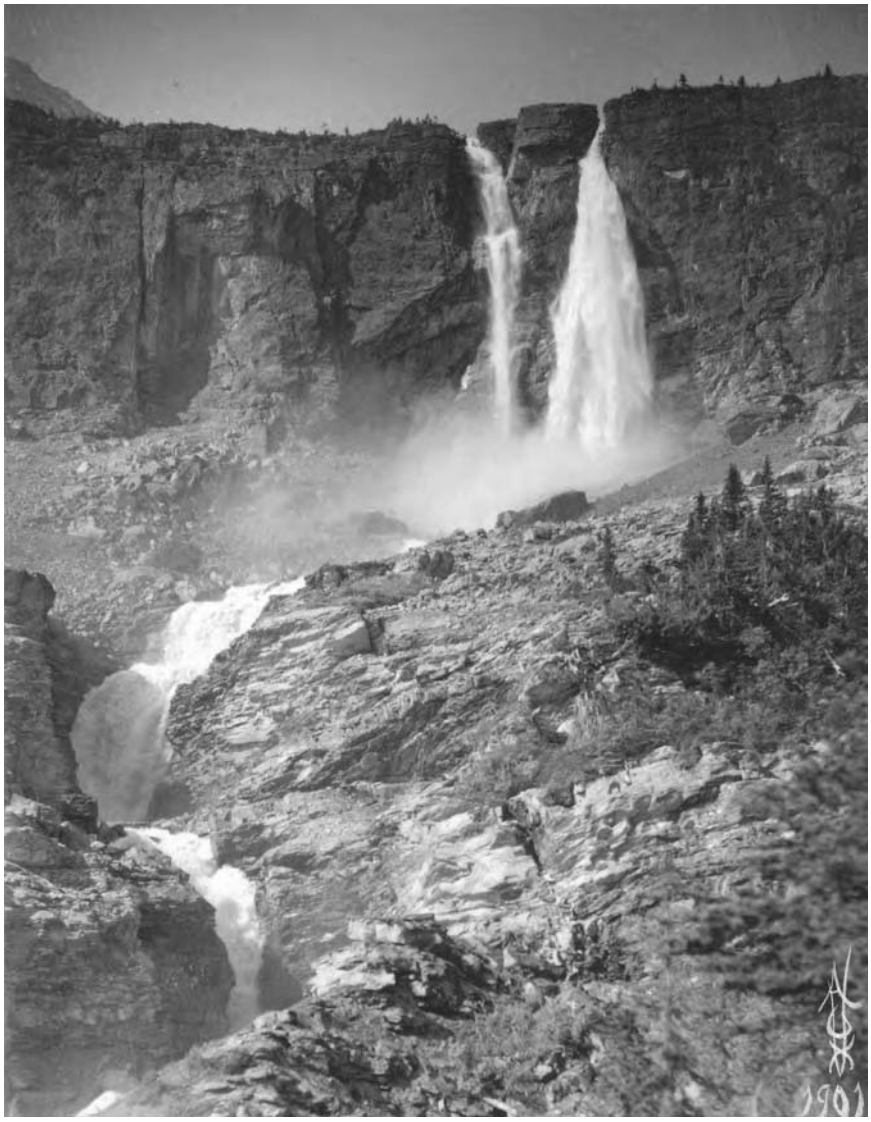
In the fall of 1890, George Davison gave a paper at the Royal Society of Arts called "Impressionism in Photography." He aimed to connect modern photography with modern art, explaining that the "newer school of photographers" and "the body of painters known as impressionists" embraced the same principles: "Our impressions are made up of light and light values in relation to one another—colour, form, binocular vision effect, focus, perspective." Davison rejected what he saw as the idealism of much photographic art, and argued instead for "a close observation of natural appearances under the materialistic tendency of the age" (Davison 1890, 823, 821). He distinguished between representations predicated on verisimilitude, and those arrived at through the personal interpretation of an artist, citing French and British texts such as Ernest Chesneau's *The Education of the Artist* (1886) and Francis Bate's *The Naturalistic School of Painting* (1887).

Davison provided a coherent reading of key formal and philosophical elements of the aesthetic, yet impressionism was a slippery notion. The very name was speculative; of the eight exhibitions of 'impressionist' painting in Paris, none used that appellation, which first appeared in Louis Leroy's satirical 1874 review of the first exhibition (partly inspired by Claude Monet's painting, *Impression; Sunrise*). Émile Zola called the new painters 'naturalistes,' and quite correctly, for the tenets of impressionism overlapped with naturalism and realism. This also pertained to photography; Peter Henry Emerson argued that while "Impressionism means the same thing as naturalism," he preferred the latter, in which the work of art "can always be referred to a standard—Nature" (Emerson 1889, 22). Indeed, early 'impressionist' photographs are nearly indistinguishable from their 'naturalistic' counterparts. Both embraced the iconography of landscape and rural genre, and even the practitioners, such as Alexander Keighley and Lyonel Clark (see, the Linked Ring), were much the same.

In an 1891 article on art photography, James von Falke presented three definitions of impressionism. The first two accorded with the acknowledged perceptual basis, being "the reproduction of the impression made on the artist's eye," and the impression "which a landscape produces on the spectator's eye by virtue of its inherent character." The third version was that "understood in artistic circles, namely, the dissolving and indefiniteness of the forms and tones" (von Falke 1891, 393). This tallied with Leroy's criticism of the indefinition in *Impression; Sunrise*, and it conformed to the explanation given by Alfred Brothers in 1892. Defining the "attempt to produce by photographic means an imitation of what is called the 'Impressionist' school of art," he identified the principal "effect" as the production of an image being "what is called 'out of focus" (Brothers 1892, 302).

In part, this simply extended the popular equation of naturalistic photography and diffusion. A more direct provocation came from Davison's use of pinhole photography, first linked to impressionism at the 1889 Photographic Society exhibition, when the *Daily Telegraph* described Davison's "soft, impressionist work caught through a pinhole." Pinhole apertures originally had a scientific application, and only became practical for imaging once fast dry plate negatives shortened the exposure time. From 1888, they were used for a soft-focus effect, as were single lenses and slit apertures. Whereas naturalistic photography's analytic approach to vision and representation utilised selective focus, the uniform diffusion of pinhole photography accorded with the more synthetic experience of the 'impression.' All of this was incorporated in a long-standing argument about focus and diffusion (see art photography and aesthetics). Indeed, both impressionist painting and photography adopted established pictorial models; Monet based *Impression; Sunrise* on the traditional 'ébauche,' or painted sketch.

In 1888, the British photographer Graham Balfour suggested diffused focus as a photographic version of the summary execution practised by impressionist painters. A similar intention encouraged the adoption of manipulative processes such as direct carbon printing on Artigue paper (Charles Constant Puyo), brush-developed platinum printing (Joseph T. Keiley and Gertrude Käsebier), and additive marking on negatives (Frank Eugene), while in 1898, Fritz Matthies-Masuren recommended gum prints for "simple, painterly



George B. Jr., and Mary M. Vaux, William Sansom Vaux, Jr. Twin Falls, Yoho Valley, 100 ft. High, Mark Field, British Columbia.
The J. Paul Getty Museum, Los Angeles

effects." The inflected surfaces of such photographs were thought to further authenticate photography as fine art, in opposition to the machine-made perfection of manufactured printing papers. However, manipulated photographs were not acceptable to all. Both Emerson and Davison saw retouching as an adulteration or idealisation of natural, photographic truth, a view upheld by proponents of the 'straight print,' such as Frederick Hollyer and Frederick H. Evans.

The advocates of impressionist painting defended rapid brush work as the means of recording transitory phenomena. The photographer could hardly argue this necessity, for the camera could instantaneously capture a scene with detail and precision. The painters themselves were ambivalent about instantaneity. In 1872, Edgar Degas complained of the tendency among young painters to begin work without thought or premeditation: "The instantaneous is photography, nothing more" (Degas 1872, 220). This view was echoed by many photographers and attributed to the unconsidered work arising from snapshot photography. Yet instantaneity brought artistic benefits: practical exposure times could be obtained with low light levels, which suited the naturalistic and impressionist interest in atmospheric effects of light and weather (also see under night photography). In the 1890s, photography was credited with inspiring new compositional structures in art, as discussed by the editor of *The Studio*, Gleeson White, and the German art historian, Richard Muther. They identified aesthetic crosscurrents between snapshot photography, impressionism, and Japanese art; asymmetric and seemingly arbitrary framing, the compression of space, and an emphasis on foreground objects, presented as close-ups and functioning as dynamic compositional devices. Such elements appear in stereoscopic photography as early as the 1860s, and recur in later, 'pictorialist' photographs by Alvin Langdon Coburn, Theodor and Oskar Hofmeister, and Heinrich Kühn.

'Impressionist' characteristics of soft focus, restricted tonal range, and manipulative technique persisted in pictorialism, and in twentieth century processes such as bromoil and three-colour Fresson printing and commercially manufactured imitations of non-standard papers. Impressionism has been accused of being an ill-conceived imitation of painting, untrue to the essence of photography. Yet its diffused and expressive effects looked ahead to abstraction, and those most dismissive of the aesthetic championed a modernist photography that prioritised an objective vision—to see things as they are, without conventionalism—the very ethos of naturalism and impressionism.

INDONESIA (NETHERLANDS, EAST INDIES)

The colonial government in the Netherlands East Indies, now the Republic of Indonesia, quickly saw how photography could be employed to record Javanese antiquities and natural history. Only a year after Louis-Jacques-Mandé Daguerre's (1787–1851) invention had been announced in France in August 1839, the Dutch Ministry of Colonies commissioned Jurriaan Munnich (1817–1865), a medical officer to travel to Java to "test and employ photography in our tropical regions" and to collect photographic representations of the "principle views, etc. and also of plants and other natural objects." He was the first known daguerreotypist to have worked in the country. Largely due to technical difficulties, compounded by the climate, the 64 photographs he took were not very satisfactory; even his most successful image had an exposure time of 26 minutes.

In 1843 the Dutch government accepted a request from Adolph Schaefer, a German-born Daguerreotypist then working in The Hague, for permission to travel to the Netherlands East Indies in return for photographic work. Schaefer arrived there in June 1844 and first worked in Buitenzorg (now Bonger). In September 1844 he established what was probably the first portrait studio in the colony in the capital Batavia (Jakarta). Besides portraits he also made copies of paintings, etc. Evaluating the new technique, the Dutch-language newspaper the *Javasche Courant* (22 February 1845) stated: 'Those who like to be flattered should never long for a daguerreotype portrait; here there is no flattery, it is a mirror that reflects back both the imperfections and the beauties.' In April 1845 Schaefer was ordered to make Daguerreotypes of some of the collections of the Batavian Society of Arts and Sciences in Batavia and later in the same year he was sent to Central Java to make Daguerreotypes of the bas-reliefs of the Borobudur temple. He produced at least 58 successful images, many of which have survived. He later worked as an independent photographer in Semarang.

While the 1840s were dominated by government sponsorship of photography, in the 1850s the growing popularity of studio portraits created a market for a larg-

er number of itinerant photographers to visit the Colony. In early 1853 the itinerate photographer L. Saurman, who had earlier worked in Singapore, visited Batavia and operated 'Saurman's Daguerrian Gallery' from the Marine Hotel for a short time before travelling on. Later in the same year another itinerate photographer C. Duben, earlier active in Shanghai, Macao, Manila and Hong Kong, visited Batavia for the first time. The first photographer in Batavia who produced photographs on glass and paper was Antoine Francois Lecouteux. Starting in 1854, by mid-1855 he had teamed up with the Belgian-born portrait painter and theatre personality Isadore van Kinsbergen (1821–1905). Lecouteux took the photographs and Van Kinsbergen then colored or retouched these. Lecouteux was probably the first photographer to successfully operate a semi-permanent studio as distinct from the many itinerate photographers who traveled from one place to another in search of new clients, mainly rich European colonial officials, merchants and planters and to a lesser extent the Chinese upper class. Except for the local rulers, the indigenous peoples were in no way able to afford the prices asked.

In 1862 Isodore van Kinsbergen, by now a skilled photographer, acted as official photographer on a diplomatic mission to Siam and later that year accompanied the Governor-General on a tour of Java and Bali. His views of Bali were especially well received (he was also allowed to to take portraits of the captured leader of the Balinese resistance during his detention in Batavia in 1868). This led to another government commission to make a large-scale photographic documentation of Javanese antiquities which occupied Van Kinsbergen from 1863–1867, resulting in portfolios of some 350 prints entitled *Oudheden van Java* (Antiquities of Java). He then was commissioned to photograph the sculptures and reliefs of Borobudur. In the 1870s Van Kinsbergen established a portrait studio in Batavia in partnership with H. Salzwedel, who later operated a successful studio in Surabaya. Van Kinsbergen continued to operate a studio under his own name for the rest of the century and like most of his contemporaries specialized in portraiture.

In May 1857 two British photographers arrived in the Colony from Australia. Walter Bentley Woodbury (1834–1885) and James Page (1833–1865) had planned to stay in Java for only a short time before travelling on to other European colonies in the region. "Woodbury & Page" was immediately successful and continued to exist for nearly fifty years, long after their departure. First operating a portrait studio in Batavia, they quickly started to travel around Java in search of more clients. On these journeys they also took large plate topographical views of the towns and countryside they visited, and Walter Woodbury also produced stereo views. Some of the latter were marketed by Negretti & Zambra, London, in the early 1860s. Traveling beyond the main island of Java representatives of the firm produced an increasingly large selection of landscape views. Sold individually or in albums these were extremely popular as souvenirs or as gifts for family and friends back home. No other firm was to have such a large selection. Similarly they produced hundreds of different native 'types' of the whole archipelago, often published as cartes de visite. Mainly produced for the commercial market, these pictures were not so much a record of the lives of the inhabitants of the Netherlands East Indies than a record of how European photographers intended to depict them.

By the late 1870s all the larger towns and cities boosted a number a competent photographers and even in the smaller places studios were being established. By the end of the century the firm of "Woodbury & Page" was in decline, succeeded in popularity by larger, more efficient firms such as "Charls & van Es," established in the 1880s, with branches in Surabaya and Batavia. Returning to England in 1863, W.B. Woodbury went on to become a noted photographic inventor, while J. Page died a few months after his arrival from a tropical disease he contracted in the Indies.

Although many photographers, including "Woodbury & Page," had visited Sumatra the photographic firm of "G.R. Lambert and Co.," in Singapore was among the first to establish a permanent studio on the island in the 1880s. Some of the company's leading photographers such as C.J. Kleingrothe (Medan) and H. Ernst (Bindjai) were to remain on the island as independent photographers. Not coincidentally, this interest occurred at the same time when the Dutch authorities were expanding their presence into Atjeh in the north of the island by military force. While the official government Topographical Dienst operated their own photography division (established already in the 1860s using mainly military personnel), many photographers, both amateur and professional took photographs of these military campaigns, as well as of later campaigns on Lombak and Bali.

In the last decades of the nineteenth century also non-European photographers became active, a trend that would continue in the twentieth century. They were generally less expensive that their European colleagues. One of the few native born photographers was Kassian Cephas (1845–1912). Working in Jogyakarta, the Christian Javanese Cephas, later assisted by his sons, began his career as court photographer to the local ruler. Later he also received many government commissions and provided illustrations for scientific publications. Amongst the non-European photographers, the Chinese, often from Singapore and Hong Kong, were probably the largest group. One of the most successful was Tan Tjie Lan in Batavia. Other important groups were the

Japanese, such as Mazaraki in Medan, and the Armenians. Of the latter Onnes Kurkdjian (1851–1903), with a studio in Surabaya, was extremely successful. In 1904 his successors formed a limited liability company, a trend common amongst many of the larger firms at the time. In addition to studio work, they also sold photographic supplies, developed photographs and operated galleries to promote the art of photography amongst the rapidly growing market of amateurs. Already in the 1850 travelling photographers had offered lessons in photography. Later in the century most of the established studios as well as many stores offered cameras and other photographic supplies and developed the negatives of their clients who could also use their darkroom facilities. In 1902 there was even a magazine called the *Indisch Lux* published especially for this increasingly important amateur market.

INDUSTRIAL PHOTOGRAPHY

While extensive research has been carried out into the more populist fields of photography—portraiture, landscape, architecture and documentary—remarkably little has been written about the emergence and importance of industrial photography in the nineteenth century. Arguably, as in so many other areas of photographic endeavors, the pioneering vision of William Henry Fox Talbot can be seen as the genesis of the industrial photograph. Albeit staged and posed—a manufactured image rather than an observed one– the two-part panorama of the printing establishment at Reading, England, showing photographers and photo-printers at work, can be labelled as the world's first industrial photograph.

Industrial photography as a discipline—as distinctly separate from the documentation of life and place as it is from the pursuit of the picturesque—is almost as old as photography itself. Industrial photography is the application of the medium to serve the needs of industry, of engineers, of manufacturers and of those whose role it was to promote industrial innovation throughout the world. If the legacy of Victorian portrait studios informs us of what our ancestors looked like, then the legacy of nineteenth century industrial photographers makes us so much more aware of how their world worked.

Photography was still in its infancy when its future potential value to industry was first recognised. Early in the 1840s, the eminent and forward-looking Scottish civil engineer, Alexander Gorton, proposed to the Institution of Civil Engineers that photography could soon serve industry well as a means of recording progress and change, enabling "views of building works, or even of machinery when not in motion, to be taken with perfect accuracy in a very short space of time and with comparatively small expense." That value to industry was already being exploited before the end of the 1840s, with the daguerreotype process being used to photograph machinery, the resulting images being used as sales aid by travelling salesmen. A number of these remarkable early images survive in both public and private collections in the United States. Rare daguerreotypes survive of examples of early machinery and of manufactured artefacts. Additionally, early occupational daguerreotypes survive, showing everything from blacksmiths at work to chemists in their laboratories, but these must be classed as occupational portraits rather than industrial images *per se.*

Before 1850, photography was, however, being used to record progress on major civil engineering projects. Contained within the Getty Collection, dramatic industrial daguerreotypes include whole and half plate views of a canal lock under construction (c. 1849), although in the absence of a full understanding of the context which surrounded their creation, it remains unclear if

these were taken to fulfil an industrial or simply pictorial remit.

The immense value of the easily duplicable paper print was ably demonstrated in the very early 1850s, and the illustrations produced for the *The Reports of the Juries* produced after the Great Exhibition of 1851 at London's Crystal Palace stand as one of the first commissioned uses of the medium to record, preserve and celebrate industrial achievements. Indeed, amongst the first images produced in Britain which might be classified as 'industrial' Mayall's dramatic views of the interior of the Crystal Palace at its original Hyde Park location might be included. Numbered within the one hundred and fifty four calotypes printed for the *Reports by the Juries*—of which one hundred and thirty copies were printed—are detailed studies of the latest designs and inventions in agricultural machinery, railway locomotives, philosophical instruments, equipment for sugar refineries and other manufacturing processes, the latest designs for massive ship's anchors, and other products of the world's industry.

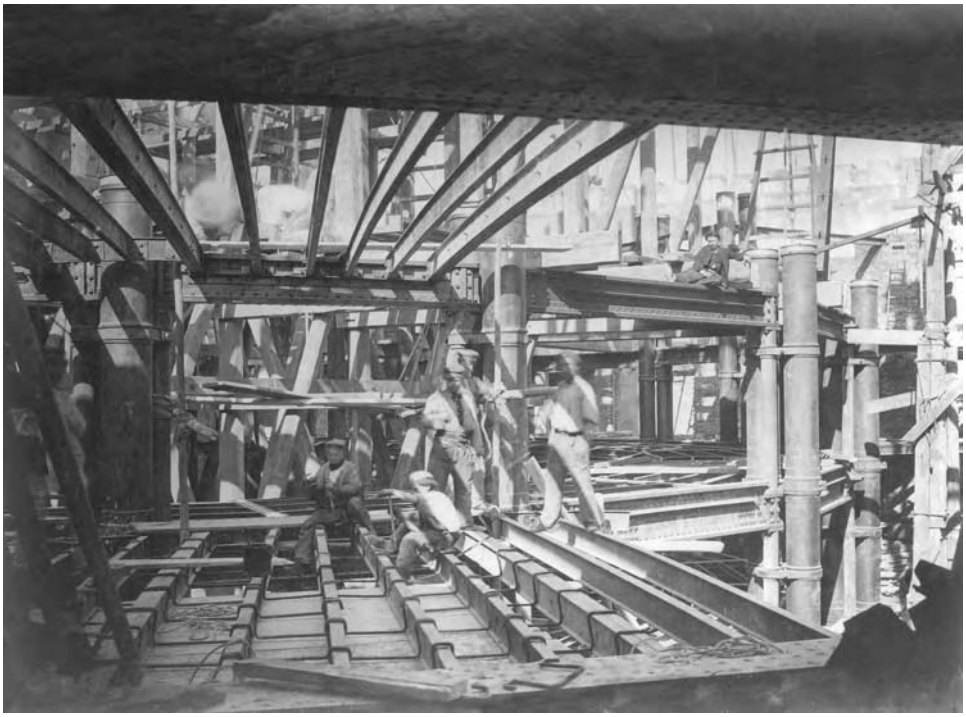
But it was a year earlier, in Philadelphia in June 1850, that the brothers William (1807–1874) and Frederick (1809–1879) Langenheim produced their first industrial photographs—presented as mounted salted paper prints of an eight-wheel steam locomotive built by the Norris Brothers of Philadelphia. Apparently taken as part of their, largely unsuccessful, attempt to promote the value of the 'Patent Talbotype' process in the USA, these images also served to demonstrate the value of photography in helping market engineering products.

In England a few years later, James Mudd (1821–1906) would fully exploit that market, when he embarked upon his long working relationship with the Beyer-Peacock locomotive engineering company in Gorton, Manchester. Starting initially with Gustave le Gray's waxed paper process in 1855, and later migrating to collodion, Mudd produced a priceless visual archive of the company's engineering output over a quarter of a century which survives to this day. Alexander Gorton's prophecy concerning photography's value to engineering proved correct when the engineer Charles Blacker Vignoles undertook the construction of the first permanent bridge over the River Dneiper at Kiev. While Vignoles was able to spend some of each year on site, his other commitments made it vital that he return to Britain for at least some of the year. He voiced his appreciation of the value of photography in helping him keep abreast of progress at the first ordinary meeting of the Photographic Society of London on 3 February 1853, and his comments were reported in the *Journal of the Photographic Society* a month later

> 'Mr Vignoles made a few remarks in illustration of the great services which the new art would be likely to render to engineers and others having to superintend important works which they could only occasionally visit, or having to make intelligible to foreign employers speaking a different language, with whom they could interchange ideas only imperfectly in conversation, the details of blocks and ropes, and complicated constructions. He instanced the pictures taken of the works now going on at Kieff for the suspension bridge he was erecting for the Emperor of Russia, over the Dneiper, on which photographic views had been taken weekly during the whole time of its construction, and especially of the method of raising the chains from the first tightening of the ropes to final elevation of the whole to its proper position, which have been shown with the greatest accuracy and detail.'

Some of those photographs were taken by Roger Fenton during his single visit to the site in October 1852, but the majority of the pictures, taken throughout the three years of the bridge's construction (1851–1853), were, as far as can be ascertained, the only major professional photographic commission undertaken by the engraver and railway illustrator John Cooke Bourne (1814–1896). Bourne, Fenton and Vignoles were not unique in the mid 1850s. Contemporary with their endeavors in Kiev, the value of 'progress photography' was also ably demonstrated in London by Philip Henry Delamotte, whose remarkable photographic account of the dismantling of the Crystal Palace in Hyde Park, and its subsequent rebuilding in Sydenham, 1852-54, was eventually published in 1855 by the Photographic Institution, London, as *Photographic Views of the Progress of the Crystal Palace, Sydenham. Taken during the Progress of the Works, by Desire of the Directors*. The one hundred and sixty albumen prints from collodion negatives contained in these two volumes comprise the first comprehensive photographic document of a civil engineering project ever to be published.

The Exposition Universelle in Paris in 1855 was one of the undoubted spurs which moved French industry to recognise the value of the photograph. Macauley (1994) recounts the part played in this awareness-raising by the entrepreneurial photographer André Adolphe Eugène Disdéri who, after establishing a company specifically to market photographs during the exhibition, circulated letters to potential exhibitors drawing their attention to the potential sales growth which might accompany the use of photography in the promotion of their products. In describing his photography as 'artistique et industrielle' Disdéri may well have been the first to recognise industrial photography as a specifically focused discipline. By 1856, in France, according to Macauley, 'the term 'industrial photography' referred not only to the recording of architectural and engineering constructions but also to the cataloguing of manufactured goods for use by travelling salesmen or for general publicity.' Thereafter, the progress of almost every major con-



Durandelle, Edouard Charles Marville. Nouvel Opera, Details et Modeles Artistiques. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 [2005.100.377.1 (14)] Image © The Metropolitan Museum of Art.*

struction project throughout Europe was chronicled with the camera.

While the majority of industrial photography at this time was produced by generalists rather than specialists, and was the result of infrequent specific commissions, some people began to use photography on such a scale that employing outsiders no longer made any economic sense. Thus, the idea of the 'in-house' photographer was pioneered, with photographers on the company payroll carrying out the wide range of assignments, including industrial ones formerly contracted out. One of the first so to do may have been the Krupps steel-making company in Essen, Germany, who reportedly employed their own photographers from the later 1860s, and in the decades which followed, built up an archive of several hundred thousand images reflecting every aspect of the company's business.

In America, while the real expansion of industrial photography came during the nation's recovery after the Civil War, many photographs which fit within an industrial context survive from earlier dates. The extensive coverage of the California Gold Rush does offer a unique view of a young industry at a time when entrepreneurship rather than large corporate organisations still held sway. It is unlikely, however, that any of these pictures were taken within commissions which we would today recognise as industrial. More likely they were taken simply as records of the activities going on, or as the basis for wood or steel engravings to be reproduced in news periodicals.

In the 1860s, photographers crossed America with the teams of naval and civil engineers to build huge railroads, which produced pictures that were often as much about the grandeur of the scenery as they were about the engineering itself—and in so doing, they produced images which placed the engineering firmly within the context of the landscape. Amongst the photographers who chronicled these great unifying projects were Alexander Gardner, Captain A. J. Russel, John Carbutt and many others. In a fascinating image taken on 10 May 1869 by Andrew J. Russell and Charles Roscoe Savage at Promontory Point, Utah, the role of the industrial photographer and news photographer become one, and are themselves set in context, as the tracks from east and west met, and two huge locomotives stood head to head and a few feet apart. In the foreground, the photographer's second camera stands in one corner of the image.

The photography of mammoth ship-building projects, like the construction of Brunel's 22,000 ton *Great Eastern*, then the largest ship in the world by quite a margin, resulted in iconic images. Robert Howlett's pictures of the huge ship under construction at John Scott Russell's shipyard on the Thames at Millwall demonstrate that, as early as 1857, industrial photographers recognised the importance of camera position. Howlett placed his camera in such a way that the magnitude of the construction was emphasised, creating images which could hardly be bettered a century and a half later. Yet it is the iconic portrait of Brunel himself—the classic *industrial*

portrait—which is the most memorable, more memorable than the huge ship herself. The juxtaposition of the engineer and the massive anchor chains of the monster he has created produced a unique combination of man and machine, emphasising the apparently limitless scale of man's visionx—that one small man could envisage and then realise something so large.

As the century progressed, and photography's capability advanced, industrial photographers were able to take their cameras into ever aspect of manufacture and construction. With advances in transportation, the progress of huge bridge projects was captured on glass plates, and some remarkable photographers came to the fore as a result. One such, Evelyn Carey (1858–1932), had the advantage of having been trained as an engineer, and epitomises a new breed of industrial photographer—one for whom engineering held little mystery. While many of the earliest photographers to turn their attention to industry had come from an art background, the emergence of the engineer-photographer gave the genre a greater sense of purpose.

Carey was an assistant engineer on the Forth Bridge project in Scotland, and was appointed in 1883, to record and chronicle every step in the construction of what was destined at the time to be the longest bridge in the world. Carey's understanding of engineering, married to his innate compositional skills, produced a body of work which is, in the annals of industrial photography, unrivalled to this day. Working with large format cameras and glass plates, often from the most precarious of camera positions either on girders high above the river or on caissons well below the water level, his stunning pictures still evoke a sense of awe. His use of workmen, as tiny ant-like figures seen in silhouette on the huge metal structure, initiated an approach to industrial and construction photography which would dominate the twentieth century. Like Delamotte decades before him, Carey had the task of recording every aspect of the project from start to finish. Like Delamotte before him, and generations of photographers after him, he created a body of industrial imagery that significantly enhances our understanding of our past.

INHA, INTO KONDRAD (1865–1930)

Finnish photographer, writer, and reporter

When K E Ståhlberg opened his photographic studio in Helsinki, Finland, in February 1889, he identified a potential market for selling pictures and engaged a few people to photograph the landscapes of Finland. The scheme was successful and one of his photographers, Into Kondrad Inha, not only contributed the best images but subsequently earned an international reputation because of his pictorial abilities.

Whilst working as a journalist, Inha had studied photography in Germany and Austria for a year, where he excelled in producing landscapes of the mountains and the rivers. When he returned to Finland in 1890, he had already decided to apply his new-found skills to his native country and a commission from Ståhlberg suited his aspirations perfectly. Inha consciously avoided adopting a sentimental approach to his work, and soon established an independent identity of his own—"He saw with his own eyes, in his personal way."

Inha was committed to capturing the technically perfect picture and would go to endless trouble. Although he was able to travel by train to some destinations, he frequently used his bicycle. To reach other locations, he paddled on the rivers and sailed the lakes; depending on the season, he would use skis, or simply walk through the forests with his photographic equipment.

To Inha, photography was an important means of expressing his feelings for Finland and he would search out the best composition, and then wait for the appropriate lighting. His writing abilities aided his photography by stimulating ideas for the way he could interpret and record a scene. It was important to document the landscape so that it fulfilled the commercial requirement but, in addition, Inha was anxious to capture the essence of a contemporary movement of national pride known as "Finnish-ness."

By careful composition, he found he could portray the vast landscapes, which are typical of the country. In the summer, he had long days with hours of sunshine, but the available daylight was reduced in winter and he had no guarantee of sunshine or weather that was suitable for pictorial photography. This was a characteristic of Finland, but Inha always made the most of the circumstances.

Inha experimented with cameras to secure the best equipment, and generally preferred a plate size of 18cm × 24cm, which was ideal for the subsequent albumen prints he favoured. Specialising in panoramas, he would often use several plates to record all the subject matter. Lacking the mountainous features of Germany, where he had trained, Inha concentrated on the expansive forests, the many lakes and rivers, and the deserted areas of wilderness in the north. Unless the sky was bright, and filled with attractive cloud formations, Inha's compositions would often concentrate on foregrounds in order to eliminate drab expanses of space above the horizon. Doing so allowed him to determine his exposure calculations for the important features of his photograph.

His coverage of the country was extensive, and like most Finns, he had a respect for exploring the wilderness. His wanderings on foot took him to otherwise inaccessible places beyond the Arctic Circle, and yet the trips which he undertook on the rivers of Kemi, Oulanka, Oulu and Kajaani provided the challenge of positioning his camera to capture dramatic waterfalls and fast-flowing white water. In wintertime, he composed his views so as to incorporate the ever-present snow—snow drifts, snow-capped trees, melting snow, and snow obliterating foreground rocks and other features.

He travelled to the northern cape of Hanko to photograph ice-breaking ships, and frozen rivers. He coaxed seal hunters into formal poses, and also documented them working on the ice. In western Finland, he secured images of wooden farmsteads and cabins, children at play, and fields of harvests. A summertime visit to Helsinki produced a portfolio showing fine architecture, urban life, the harbours, and the parks.

In following the tranquil lakes, waterways and canals of Eastern Finland, Inha took care to position human figures in his compositions, but also concentrated on the rural lifestyle—the sauna bath, women in the fields, travellers, and boatmen. He produced portraits by making the most of limited facilities—arranging small groups on a single bench to catch side lighting that enhanced their rugged features … even at the expense of shadow detail.

His personality was suited to the task. He had an artistic gift that was successful in photographing children and country people going about their daily lives. In the summer of 1894, he travelled to Karelia and produced a portfolio of over two hundred photographs that empathise with the subject matter. He managed to portray the poverty of the region by combining skilful selection and composition, which retained the dignity that was the essence of the people. He frequently adapted his style to improve his interpretation and because the coverage was so thorough, these plate negatives remain a national asset in the Finnish Museum of Photography, Helsinki.

He continued to modify his ideas and within two years he published *Pictorial Finland,* which was a definitive portfolio comprising nearly two hundred photographs. He took all the pictures for the specific purpose, and ever the perfectionist, Inha had the illustrations printed in Austria to reproduce the quality of the originals. During the summer of 1899, he continued to concentrate on rural scenery and received a commission to illustrate the distinctively Finnish aspects of agriculture for the Finnish Pavilion at the 1900 Paris Exposition.

He did a good technical job, but as his brief was to illustrate the emerging new styles of farming and to emphasise the increase in commercial forestry, it opened his eyes to the way in which Finland was changing. The rural ideal was disappearing and with it, a way of life. Finland was also experiencing political change and after an illness, Inha gave up newspaper work in 1908 and became a recluse. He continued to use his many cameras to good effect and found satisfaction by concentrating on some of details, rather than the full panorama, of the landscapes he cherished.

RON CALLENDER

Biography

Into Kondrad Inha was born on 12 November 1865. His father was a civil servant with the family name of Nyström, but a passion for all things Finnish probably encouraged Inha to change his surname some years later. Inha attended a Finnish-speaking primary school, and at home, his parents encouraged the creative activities of music, story-telling and painting.

In 1885, Inha enrolled at Helsinki University for geography, literature and studies in the appreciation of beauty, but a part-time job appealed to him so much that he abandoned university in preference for permanent employment in journalism.

Inha was a competent journalist and specialised in popular scientific texts and children's stories for over twenty years. For recreation, he cycled throughout Finland and parts of Europe, and his appreciation for the countryside provided inspiration for newspaper articles. After appropriate training, his strongpoint became pictorial photography, which he practised until he died in 1930.

INNES, COSMO NELSON (1798–1874)

English photographer and professor

Cosmo Nelson Innes was born at Deeside in Aberdeenshire, Scotland, on 9 September 1798, the youngest of sixteen children. He attended the Royal High School, Edinburgh and the Universities of Aberdeen, Glasgow and Balliol College, Oxford. He was a member of the Edinburgh Calotype Club (c 1841–1856) and learned his photography in association with the other members of the Club. Photographs by him are in each of the extant albums of the Club: one in the Central Library of Edinburgh and the other in the National Library of Scotland. As well as the caloype process he is reported as also using the waxed paper process. His main subject matter was historic buildings. Lord Henry Cockburn, the judge, records in his Circuit Journeys that he was with Innes while he spent several hours "calotyping" the ruins of Pluscarden Abbey, near Elgin. He was one of the founders of the Photographic Society of Scotland in 1856 and his photographs were included in the Society's exhibitions. He served on its Council and as Vice-President and was still a member when the Society was disbanded in 1873. He became an advocate in 1822 and was Sheriff of Moray from 1840 until 1852. He had antiquarian interest outside the law, reflected in his choice of photographic subjects, and had a great knowledge of ancient, Scottish documents and was responsible for numerous publications. From 1846 until his death he was Professor of History at the University of Edinburgh. He died at Killin, Stirlingshire, on 31 July 1874 while on a tour of the Scottish Highlands. In 1826 he married Isabella Rose and had nine children.

RODDY SIMPSON

INSLEY, LAWSON (1851–1862)

Insley was an enigmatic daguerreian photographer active chiefly in the Pacific Region. He was probably the photographer Insley active in New Zealand from 1851–1853. The diary of Rev. Richard Taylor states Insley had traveled through India, America, New Holland, Van Diemen's Land and New Zealand. In 1851 he advertised plain or coloured daguerreotypes at Lambton Quay, Wellington. He is said to have taken portraits of Maori chiefs in Auckland. By 1853 he was working at 408 George St, Sydney, offering the only coloured daguerreotypes in Australia. He travelled through Goulburn, Braidwood and Queanbeyan during 1854 and 1855, marrying Margaret Cameron in Goulburn on 26 July 1855. He worked at a succession of Sydney addresses from 1856 and set up in 1859 in George St, Brisbane claiming to be the oldest established photographer in the colonies (this cannot be substantiated). He worked in Nicholas St, Ipswich in 1860, declaring insolvency in December but was back working in Brisbane from late 1861, then he went to Maryborough and Rockhampton in 1862. No trace is found of him after this although a son lived in Forbes, NSW and two daughters lived in Sydney. No definite connection with New York daguerreian Henry Insley has been established.

MARCEL SAFIER

Holdings: No original photographs located. An albumin print copy of a daguerreotype by Insley of Edward Hutchison and family in Queanbeyan is in the hands of descendants.

INSTANTANEOUS PHOTOGRAPHY

An instantaneous photograph is one in which the length of exposure is short enough to freeze action. Instantaneity in photography is a relative term, the meaning of which changed repeatedly throughout the nineteenth century as a result of technological improvements. Initially, photographic emulsions were so insensitive that exposure times were seconds and even minutes long. At that speed, moving objects register only as a blur, or fail to register at all. Instantaneous photographs are ones in which the operator was able to accelerate exposure enough so that movement is captured. Although no precise definition of instantaneity exists, from the 1870s it came to mean pictures made more quickly than the naked eye can see. The term was widely used in the nineteenth century, but is now obsolete. It should not be confused with 'instantaneous' dye-sublimation processes (such as those manufactured by Polaroid), which are distinguished by the rapid creation of prints.

Instantaneity in photography was considered highly desirable in the nineteenth century. Many operators boasted of their ability to make 'instantaneous views' in advertisements and on their studio's printed mounts. In addition, instantaneous photography was a common category of competition in salon exhibitions. Nevertheless, early photographers were limited to only modest achievements. In an 1841 report before the French Academy of Science, the mathematician François Arago listed trees blowing in the wind, flowing water, the sea, storms, sailing ships, clouds, and jostling crowds as worthy instantaneous subjects. In the three decades that followed, other writers catalogued faster moving sub-

jects, including waterfalls, moving carriages, speeding trains, rising smoke and flames, flying birds, flapping flags, and galloping horses. Portraits were said to be instantaneous when the sitter was photographed without having to hold his or her pose for an uncomfortable period of time. Photographers renowned for their skill in instantaneous photography include some of the most celebrated praticioners of the medium, but also include many anonymous and little-known figures.

Photographers used a variety of techniques to achieve instantaneity in their pictures. The insensitivity of photographic emulsions was arguably the main obstacle to making instantaneous photographs. Consequently, improvements in chemical sensitivity and chemical accelerants were highly prized, and photographers sometimes jealously guarded successful formulas. Exposure times can also be shortened by increasing the amount of light entering the camera. Consequently, prior to the invention of electric lighting, portraitists designed their studios with large windows, reflectors, and skylights to make the most of ambient light. Outdoor subjects were chosen with careful attention to season, time of day, and the amount of light they reflected back at the camera. In one notable example, Eadweard Muybridge was known to have scattered white lime on the ground in order to increase illumination. Waves and clouds can be particularly bright subjects, and this is one reason many early instantaneous photographs depict them. Optics was another important consideration in making instantaneous pictures. Lenses with wide aperture were well suited to instantaneous photography. Short focal lengths were also successful because they transmit more light than longer lenses of similar manufacture. Accordingly, many of the best-known early instantaneous pictures were made with stereo cameras because these were usually equipped with simple, short lenses. In addition, this preference for short lenses meant that early instantaneous views tend toward a wide-angle, or 'fish-eye' appearance. The quality of lens was also important. Lenses made by the English firm J. H. Dallmeyer Ltd**.** were considered among the best for instantaneous photography. The rapidity with which the operator could cap and uncap the lens was another critical element. George Washington Wilson famously used his cap to control exposure; Captain Stuart Wortley used his bare hand. When these simple methods could not keep up, mechanical and electro-mechanical shutters were devised.

Techniques of less obvious merit were also used. Some instantaneous photographers shot scenes at a distance, as this caused the subjects they wished to capture to move less distance across the picture plane than they would have if taken close-up. This is why early street scenes are often made from considerable remove. Angle of view also had an effect, so that aerial perspective was frequently employed to increase the illusion of arrested motion. Photographers could also pan their cameras to try to keep the relationship between camera and subject constant. And, when all else failed, instantaneity was often faked. Many so-called instantaneous photographs were actually simulations, made using composite printing, creative posing of the subject, and manual retouching to give the appearance of an action shot.

Concern with instantaneity in photography is evident since the time of its invention. In correspondence between Louis Daguerre and Nicéphore Niépce in 1830, the two discuss their inability to create an instantaneous process, a quality they referred to as 'promptitude.' In his seminal *Pencil of Nature,* William Henry Fox Talbot cited his interest in capturing evanescent activity as one of his motivations for inventing the paper negative process. He described photographs of such subjects as 'fairy pictures, creations of a moment.' Writing in the *Photographic News* in 1860, John Herschel suggested that photography might one day be used to record 'the vivid and lifelike reproduction and handing down to the latest posterity of any transaction of real life—a battle, a debate, a public solemnity, a pugilistic conflict, a harvest home, a launch—anything in short, where any matter of interest is enacted within a reasonably short period of time.'

Given their positions as centers of technical innovation, instantaneous photography flourished in Britain and France. Photographers in these countries excelled in the production of seascapes, which were among the first widely admired instantaneous subjects. Gustave le Gray's photographs of the sea near the Mediterranean port of Sète in the late 1850s were praised for their effectiveness in showing rippling and crashing waves, sailboats moving at speed, and clouds. Eugène Collau was also highly regarded for his photographs of racing sailboats, and Jean Victor Warnod was lauded for images of travelling steamships with columns of smoke rising from their smokestacks. Edmond Bacot's apparently unique photograph of waves crashing behind a row of bathing huts in Boulogne (Société Française de Photographie), taken in 1850, has become one of the icons of early instantaneous photography. In Wales, John Dillwyn Llewelyn photographed turbulent seas in the early 1850s, with the noteworthy inclusion of standing figures at the shore. George Washington Wilson's 1859 views of the Loch of Park, in Scotland, were ahead of their time, capturing rowers plying their craft at sunset. Other notable British seascapists were Charles Breese**,** who made collodion on glass stereo slides in the early 1860s of moonlight effects at sea, and Captain Stuart Wortley**,** who made sumptuous images featuring intricate renderings of clouds.

French photographers excelled in the arena of instantaneous family portraits and genre scenes. Jean

Baptiste Frenet's unusual collodion transfer process seems to have been particularly effective in capturing motion, enabling him to portray natural behaviors such as a child's yawn in the mid 1850s. Working just a few years later, Charles Nègre photographed workers and inmates at the Imperial Asylum at Vincennes. His precocious photographs of people and events on the streets of Paris foreshadow reportage images of the 1920s. Louis-Jean Delton's photographs of clowns in the 1860s convey the spontaneity of a circus act, while Adrien Tournachon's contemporaneous tableaux of street performers, and particularly of the Mime Debureau in the role of Pierrot, depict the nuances of gesture and facial expression.

Scotsmen John Adamson and the duo of David Octavius Hill and Robert Adamson anticipated instantaneous genre photography in their well-posed pictures of soldiers and fishwives made in the early 1840s. Using a collodion on glass negative process, compatriot Charles Piazzi Smyth made a remarkably personal series of photographs of Russian soldiers in the squares of Novgorod around 1857. Geoffrey Bevington managed to produce convincing photographic illustrations of workers engaged in their occupations in the 1860s. However, it was in street photography that British photographers were best known. A friendly transatlantic rivalry emerged between George Washington Wilson and the American Edward Anthony**.** Unknowingly at first, the two echoed each other's work in street scenes made in their respective cities of Edinburgh and New York City. The market for instantaneous stereo cards blossomed in the 1850s and 60s. In England, Valentine Blanchard and William England developed large catalogues of instantaneous stereo views. Their efforts were echoed modestly by Giorgio Sommer in Naples and Carleton Watkins in San Francisco, while Ernest Lamy**,** Gustave Laverdet**,** and Auguste-Adolphe Bertsch recorded bustling foot traffic on the streets of Paris.

Instantaneity was particularly important in the field of animal and zoological photography. The unpredictability of animal subjects made apparently simple photographs of animals difficult to execute: pictures of birds such as those made in nature by John Dilwynn Llewelyn and those made at the London Zoo by Count de Montizon in the 1850s were largely confined to species with stalking behaviors such as herons, cranes and egrets. Numerous photographers specialized in animal subjects, notably Louis-Jean Delton, Léon Crémière, and Frank Haes. However, technological limitations affected what could be photographed naturally, so that in some cases animals were actually stuffed and arranged in dynamic poses. Louis-Pierre-Théophile Dubois de Nehaut's unparalleled photographs of the elephant Betsy taken in 1854 at the Brussels Zoo are one notable exception.

By the 1870s, interest in producing truly instantaneous photographs of animals in motion resulted in landmark experiments in the United States and Europe to photograph a horse while galloping. These proved decisive in the history of instantaneous photography. In France, the physiologist Etienne-Jules Marey initially used non-photographic means to attempt to determine the gait of a running horse. This met with only modest success; the results were difficult to verify because the human eye cannot see fast enough to judge the position of all four legs of a running horse. In California, expatriate English photographer Eadweard Muybridge was hired by former Governor Leland Stanford to analyze the gaits of horses at his ranch in Palo Alto California in 1872. The purpose of Muybridge's work was to determine whether a horse ever has all its hooves simultaneously off the ground at some point in its stride. Although he reported modest success using photography to settle the question in 1873, the pictures he produced then were never published and are not preserved. Muybridge's project was interrupted by unfortunate developments in his personal life, but resumed with Stanford's financial backing in 1877. At that time, using a specially designed track and a battery of cameras with automatic shutters, Muybridge produced sequential instantaneous photographs of unprecedented speed. When published, they inspired Marey to dedicate himself to his own equine experiments using photography. Using Muybridge's accomplishments as a point of departure, Marey developed numerous innovative methods for making a sequence of instantaneous photographs on a single photographic plate, and extended his experiments to other animals, notably humans and birds. Muybridge, too, photographed a range of animals including dogs, goats, deer, and oxen.

The advent of gelatin dry plate photography in 1878 greatly facilitated the production of instantaneous photographs. Ottomar Anschütz in Prussia, mindful of the photographs of his contemporaries, produced stunningly detailed individual instantaneous pictures in the 1880s, some of which he assembled into grid-like sequences reflecting Muybridge's sequential method. His work, together with that of others, such as the Hungarian Bertalan Székely and the Frenchman Albert Londe**,** transformed the instantaneous photography movement, bringing metric precision and scientific protocol to bear on photographic picture making. This new generation of photographers created a distinct but loosely organized movement known as chronophotography.

Instantaneous photography effectively ended with the rise of chronophotography, but its legacy was long lasting. The desire to make instantaneous photographs greatly influenced composition and subject matter in photography's first four decades. Perhaps more importantly, the notion that photography could see what the human eye could not closely paralleled the medium's

acceptance as an objective tool. As photography became capable of recording increasingly narrow slices of time, it grew in versatility and status. Ultimately audiences came to understand that photography was capable of making pictures far more penetrating than traditional media such as drawing, painting, and printmaking. Instantaneous photography—and with it, the ability to make images of fleeting and ephemeral subjects—became a central element of photographic aesthetics.

INTENSIFYING

In 1867, *Photographic News* deplored the practice of intensifying under-exposed negatives. "We disapprove … we consider it bad practice …," stated an editorial which argued that correct exposure produced the perfect negative, and "all those harsh black and white specimens" would be eliminated. Nevertheless, uncertainty in exposure encouraged a search for treatments to retrieve thin negatives. Intensification increased the effective sensitivity of the camera material, and was applied to daguerreotypes, collodion plates and dry plates.

The Becquerel effect was found to be suitable for improving underexposed daguerreotype plates. In 1840, after re-exposing plates to yellow and red light, Edmond Becquerel had found that he could strengthen the original image by development with mercury, although Claudet found that the benefit was restricted to plates of silver iodide.

Frederick Scott Archer favoured a bleaching method whereby the silver image of a processed collodion negative was treated with mercuric chloride, which formed a white precipitate and strengthened the image-forming deposit.

Adjusting the colour of the negative would often improve its actinic properties in printing. In 1865, Herman Selle mixed potassium ferricyanide and uranium nitrate to produce a brown colouration and although effective, no further research was done for ten years, when a precipitate (of silver ferrocyanide and lead ferrocyanide) was "blackened" in a dilute solution of ammonium sulphate. Because such treatments were often applied out of necessity, the ensuing print quality was poor and of excessive contrast.

By 1861, intensifying was better understood, allowing the developed image to be modified after drying. The formulas claimed to have influences on tonality and contrast, with preferential action in the shadows, and some, such as chromium intensifier, also darkened prints.

With gelatine emulsions, intensification remained a darkroom procedure when developing plates with insufficient density. There were different methods, each with a "printing value." For example, chromium would bleach the negative for re-development to a value of 1.5, whereas a mercuric chloride bleach, followed by redevelopment in ferrous oxalate, improved the printing value 2 times. Solutions containing mercuric iodide, lead, uranium, copper bromide were widely used, but the most popular were the mercurial processes, with values of 3.

Once dry plates were established, two non-chemical ways of intensifying the latent image emerged. William Blair had proposed a technique in 1869 which ensured "acceleration of exposures" by demonstrating that, before development, the latent image could be re-exposed to diffuse light, to give "these first and weak impressions just that addition which is necessary to let the developer get hold of them, and carry them forward to a visible impression." Blair was aware that

most means of improving "sensitiveness" had already "been pushed to the limit," but as latensification, the strategy remained popular in the 20th century. Inspired by favourable comments, Blair later proposed a variant whereby a controlled amount of light was admitted to the plate before the camera exposure; that is "hypersensitisation." Blair reported increased "acceleration," but with prescience, he warned his results only applied to "comparatively short exposures. With long exposures, other changes take place."

IRELAND

Photography in Ireland developed quite rapidly due to the fact that although Richard Beard did take steps to patent the daguerreotype in Ireland (Irish Patent, No 229, April 1841), he seems never to have enforced his rights. On September 20th 1839 the *Belfast Newsletter* published a letter by the engraver Francis Stewart Beatty (1806–1891) describing specimens of his successful attempts to replicate Daguerre's invention. Beatty's letter is the first published account of photography in Ireland and he went on to work as an operator in Richard Beard's London Polytechnic Institution in 1841 before returning to Belfast to establish a portrait studio in Castle St. in 1842. Beatty continued to have a long association with photography designing his own collodion wet plate field camera in 1858 and along with Dr. Thomas Alexander taking out a patent for photo-lithography in 1860.

In 1840 instruction in the use of the daguerreotype was offered by the Dublin Mechanical Institute and the Natural Philosophy Committee of the Royal Dublin Society purchased a camera for taking daguerreotypes in the same year. A studio established in the Rotunda on Dublin's Sackville St. (O'Connell St.) in 1841 is likely to have been opened by Beard in an attempt to protect his licence purchased from Daguerre. In April of 1842 this studio was taken over by Le Chevalier Doussin Dubreuil and throughout the decade a number of commercial studios appeared throughout Dublin including one opened in 1845 by the self proclaimed Professor of Natural Philosophy, Leone Gluckman. Although there was less commercial activity in other Irish cities during the 1840s a number of studios opened in Belfast including one by a photographer with the surname of Cherry and in Londonderry Robert McGee operated a studio until 1843. In the late 1840s Edward Harding opened a studio in Cork city and in Athlone a self-proclaimed professor of the Daguerreotype, D. Lewis Davis opened a studio in 1847. Although commercial photography continued to expand during the 1850s with studios opened in Belfast, Dublin and Cork it wasn't until the 1860s that commercial photography became fully established throughout Ireland. The longest surviving commercial company was established in 1853 by the Lauder Brothers on Dublin's Capel St. In 1880 James Stack Lauder established the Lafayette studios on Westmoreland St. in the city before opening other Lafayette studios across the rest of Britain. The Lafayette name still exists as photographic studio in Dublin today.

Photography was also quickly taken up by Ireland's professional and landowning classes, many of whom were introduced to photography through scientific and educational connections with Britain. William Holland Furlong from Dublin was introduced to photography at the University of St. Andrews in 1840–41 as was William Despard Hemphill from Clonmel Co. Tipperary who studied medicine there before returning to Ireland in the mid 1840s. Hemphill went on to win a number of prizes for his photographs at exhibitions in Britain and France and published stereoscopic books in 1857 and 1860 of subjects in and around the town of Clonmel. Louisa and Edward King Tension of Kilronan Castle Co. Roscommon purchased a licence from William Henry Fox Talbot and produced many calotypes of topographical subjects throughout the 1850s and Hugh Annesley, a junior officer in the British Army from Castlewellan Co. Down produced photographs of subjects in Ireland and South Africa from 1851–1880. Other early Irish amateur photographers travelled abroad to take photographs, most notably the wealthy Cork landowner John Shaw Smith who produced over three hundred calotypes during a Grand Tour of Italy, Greece and Egypt in 1850–51. A number of Irish soldiers established themselves as commercial photographers in the colonies, including a young private in the Royal Artillery from Co. Wicklow John Burke who opened a studio with William Baker in Peshawar, India in 1861.

Photography was popular amongst the residents of Ireland's big country houses throughout the nineteenth century. Of particular note are Mary Parsons and her husband William, 3rd Earl of Rosse, Birr, Co. Offaly. Lord Rosse, President of the Royal Society was closely associated with William Lake Price who together per-

suaded Fox Talbot relinquish his patent rights of the calotype process. Lord Rosse experimented with the daguerreotype as early as 1842, and in 1853 corresponded with Talbot regarding his attempts to produce calotypes of the moon through The Great Leviathan then Europe's largest telescope. However, it is his wife Countess Rosse (1813–1885) who became the more celebrated amateur photographer becoming a member of the Royal Photographic Society in 1853, the Dublin Photographic Society on the 3rd December 1856 and was elected a member of the Amateur Photographic Association on the 13th March 1863. The Dublin Photographic Society, which changed its name to the Photographic Society of Ireland in 1858, held its first meeting at Leinster House on November 8th 1854 and organised the photographic sections of the Royal Dublin Society's annual Arts and Manufacturers exhibition. At this exhibition in 1859, Countess Rosse was awarded a silver medal for best paper negative by the Dublin Photographic Society and exhibited her photographs at the Dublin International Exhibition of 1865. Other significant amateurs are Sir Joscelyn Coghill (1826–1905) who won a prize for photography at the Paris Exhibition of 1863 and Gerald Dillon and his wife Augusta Crofton Dillon of Clonbrock House Co. Galway.

Inventions relating to photographic processes also appeared throughout the century in Ireland. Dr. Thomas Woods presented a paper on his 'catalystype process' on May 12th 1845 to the Royal Irish Academy, resulting in correspondence between RIA and Fox Talbot who claimed there was little difference between the process and his patented calotype. The miniature portraitist Bernard Mulrenin (1803–68) presented a paper in April 1859 to the Royal Dublin Society and the Photographic Society of Ireland claiming to have devised a process of transferring the image-bearing emulsion of the wet plate negative onto marble or ivory rendering the image similar to miniature paintings. Ireland's most significant contribution to the science of photography came from the Trinity professor John Joly (1857–1903) who patented the first single-image colour photography process in 1894.

During the closing decades of the century, much commercial photography was geared towards tourism, with firms such William Lawrence's *Great Bazaar and Photographic Galleries,* opened on March 20th 1865 at 5–7 Upper Sackville St. in Dublin and destroyed during the 1916 Easter Rebellion, producing stereoscopic views, postcards and picture books for the tourist market. Portraits of political figures involved in Irish nationalism such as the Fenians were also popular as *carte-de-visite* and cabinet card series as were photographs of other political events.

During the last years of the century many amateur societies involved with ethnography, antiquities, archaeology and natural history established photographic clubs to document their activities. Commercial photographer Robert John Welch (1859–1936) from Belfast was an active member of the Belfast Naturalists Field Club and photographed many botanical, topographical and ethnographic subjects during their field work. Many of these organisations used photography to document aspects of Irish culture as part of the Gaelic Revival and the county's leading antiquarians, folklorists and ethnographers were also keen amateur photographers at the turn of the century.

ISENRING, JOHANN BAPTIST (1796–1860)

Swiss daguerreotypist

An artist, engraver and early daguerreotypist—both amateur and professional—Johann Baptist Isenring introduced several early developments in photography. Born in Sankt Gallen, Switzerland, in 1796, he became interested in the daguerreotype almost as soon as the process was announced, ordering his first outfit direct from Paris before the end of 1839, and had produced photographs of his home town by the end of that year. In the following year he took portraits of his family and friends, enjoying relatively short exposures due to the clarity of the mountain air, and the enhanced levels of ultra-violet light at altitude.

Isenring opened a portrait studio in Munich in 1841, pioneering his own process for the colouring of daguerreotype portraits, with a technique for applying pigment and gum acacia to the surface of the plate. Either introducing colour with a brush, or dusting it on to the surface through cut-out masks, his technique involved the adhesion of the gum and pigment mixture by breathing on the plate surface.

British Patent No.9292 issued to Richard Beard in 1842, and entitled 'Colouring Daguerreotype Pictures' was based on Isenring's method, the Swiss photographer's process being acknowledged only indirectly as 'communicated to me by a certain Foreigner residing abroad.'

JOHN HANNAVY

ITALY

After François Arago's report to the Académie des Sciences in Paris on 7 January 1839, that Jacques Louis Mandé Daguerre (1787–1851) had succeeded in fixing camera obscura images, the news of his discovery was received immediately and spread in the capitals of the various Italian states by the most important journals and scientific publications. In the centres in which cultural matters were most hotly debated—Milan, Turin, Venice, Bologna, Genoa, Naples, Rome—both experimental and professional photography was enthusiastically taken up by operators from the most diverse backgrounds like optics, chemistry, painting and engraving. Publications like "La Gazzetta privilegiata di Milano," "Il Politecnico," "Messaggere Torinese," "Gazzetta Piemontese," "Lucifero" and "Poliorama pittoresco," described and discussed the discovery of the daguerreotype process well before 19 August 1839, the date when, at Daguerre's side, Arago (1786–1853) finally revealed the formula of the new invention at the joint meeting of Academy of Sciences and the Academy of Arts in Paris. In the capitals of the pre-union Italian states, Daguerre's manual (Paris: Alphonse Giroux, 1839) was published in

French and Italian (Genoa: A. Beuf, 1839; Bologna: tip. Nobili e c., 1839; Rome: A. Monaldi, 1840). Moreover, the first experiments were carried out: on 2 September in Florence; on 8 October in Turin; in Pisa at the First Congress of Italian Scientists from 1–15 October, thanks to the physicist Tito Puliti**,** in Milan on 30 November; in Naples on 28 November and 15 December. The daguerreotype process immediately found favour among the bourgeois, who were attracted by the possibility of producing images which were faster and less costly than painting and engraving. At first, there were many foreigners who travelled around Italy doing daguerreotypes, in particular, the Frenchmen Alphonse Bernoud, active from 1840 to 1872 ca. in Genoa, Florence and Naples and Perraud, active from 1840 to 1846 ca. in Lombardy—Veneto, Turin and Rome. There was the Parisian Adolphe, active in the 1840s; Meissner, Stenzel, Joseph Renaud (1809–1860 ca.) and Fortin were mainly active in Turin. Very soon, the Italians were working side by side with the French in using the daguerreotype process: Ferdinando Brosy in Lombardy—Veneto, Trento and Trieste; Enrico Federico Jest in Turin; Alessandro Duroni (1807–1870) in Milan; Antonio Sorgato in Venice; Lorenzo Suscipj, Angelo (1793–1858) and Giacomo (1819–1891) Luswergh in Rome.

The daguerreotype process captured the imagination of the artistic and scientific world, and raised a far-reaching debate on its characteristics and potential. The bourgeois *élite*—culturally speaking, the most vital and committed protagonists of the Italian Risorgimento—were the ones to pick up on the significance of photography as a new, extraordinary means of communicating and learning. It is sufficient to mention Macedonio Melloni's passionate report: *Relazione intorno al dagherrotipo, letta alla Regia Accademia delle Scienze di Napoli nella tornata del 12 Novembre 1839*. This physicist and patriot went into exile in Paris after the tumult in 1831. His report was one of the most important scientific announcements published in Italy in the early days of photography. The debate on Italian scientific developments held at the Congress of Scientists in Pisa in October 1839 was also important and significant. Among the main themes addressed by the four hundred delegates at the Congress were the liberalization of trade among the different Italian states and the development of the railway network, indispensable premises for the development of a common market. In this context, photography was presented through experiments that aroused wonder and interest in onlookers, and this confirms how rapidly the novelty of the invention was received, with its way of meeting the demands of representation and self-representation of the rising middle classes.

The "genres" that the daguerreotype process inherited from its predecessors in the visual arts were the view and the portrait. Views respected the linguistic codes of painting and engraving, and were clearly derived from the rules of Renaissance perspective in the symmetrical layout and central positioning of the image. Among the most important collections of Italian daguerreotype views are the 159 daguerreotypes housed in the Science Museum in London. They were commissioned by the English philologist Alexander John Ellis (1814–1890) from different photographers, among whom were Lorenzo Suscipj and Achille Morelli. The collection of John Ruskin, now in Lancaster University, is also significant. Of course, favourite subjects were the most typical monuments in Italian cities, arranged in a visual itinerary that isolated and exalted these works as *topoi* of cultural and artistic identity.

There were many attempts to turn daguerreotype plates into plates for engraving. The best results were obtained not so much by engraving the daguerreotypes as by transferring the design manually to the plates, as in the well-known series of Italian views in *Excursions daguerriennes, vues et monuments les plus remarquables du Globe,* published by Lerebours in Paris in 1842, and the series of aquatints entitled *Vues d'Italie d'après le daguerréotype*, published in Milan between 1840 and 1842 by Ferdinando Artaria (1781–1843). These initiatives in the world of publishing, a prelude to the modern illustrated guide, were aimed at educated bourgeois tourists, who, in fact, preferred this type of product because it was less expensive than traditional engravings. It was also easier to carry because of its small format.

After 1842 it was possible to do portraits in the daguerreotype process since, thanks to the introduction of new lenses and faster chemical processes, posing times were reduced. Portraits done in this way had these unquestionable advantages: clear, precise details (as in the views); a work that was as precious and unique as a portrait in oil or a miniature, but definitely at a much lower cost. Among the Italian daguerreotypists who are worth mentioning: Alessandro Manzoni's stepson Stefano Stampa (1819–1907), who did beautiful portraits of the members of his family; Antonio Sorgato, author of numerous refined portraits; Alessandro Duroni, optician and founder of one of the first *ateliers* of photography. From this period onwards, photography studios began to be organized according to different professional fields, among which was portrait retouching, often carried out by ex-miniaturists.

In the first years of the 1840s, the calotype process began to spread throughout Italy, but with less success than the daguerreotype process. The technique introduced by W. H. Fox Talbot (1800–1877) had resolved the problem of doing images in series with the introduction of a printing process from a single negative. With respect to the daguerreotype, however, the calotype was thought to have less definition, mainly because of the graininess

and opacity of the paper used for the negatives. With the improvements introduced by L. D. Blanquart-Evrard (1802–1872) and Gustave Le Gray (1820–1882), it was possible to produce paper negatives with more precise details while maintaining the half tones, which painter-photographers liked so much. This technique was widely used for views, in particular, monuments, archaeological sites and landscapes. Above all, travellers appreciated the technique because the materials it required was light and easy to carry; they could also be prepared many months beforehand. Among non-Italians worth mentioning are Calvert Richard Jones (1804–1877), George Wilson Bridges (1788–1863), William Robert Baker (1810–1896) and Edouard Delessert (active in Sardinia in 1854). The photographers of the "Roman School of Photography," in particular Giacomo Caneva (1813–1865, from Padua), Frederic Flachéron (1813–1883 ca.) and Eugéne Costant excelled in the calotype process. Together with Giron des Anglonnes and Alfred—Nicolas Normand (1822–1902), they were among the first Roman calotypists who, integrated into the cultural milieu of the 1850s, made Rome an international capital. The Caffè Greco or the French Academy in the Villa Medici were among the places where photographers, artists and intellectuals most frequently met to exchange opinions, news and experiences. This special climate encouraged the development of photography; in fact, there was an extraordinary production of views and monuments of the papal capital and the vicinity. The first systematic campaigns to photograph works of art were undertaken: it is enough to cite Giacomo Caneva's shots of the statues in the Capitoline and Vatican Museums, among which are the famous images of the *Laocoonte* and the *Torso del Belvedere*. In Rome, we should also mention the work of Stefano Lecchi (1805–1860 ca.), author of numerous views of monuments and the first reportage of a war event, the clashes in Rome for the defence of the Republic in 1849. Lecchi, from Lombardy, took shots on site and then printed them as salted papers. He went to all the scenes of conflict, and often had soldiers pose in them for greater effect. His views, recently rediscovered and studied, constitute one of the first examples of a series of photographs dedicated to current events, and came before the series Roger Fenton did in 1855 on the Crimean war. However, the people involved in the action could not yet be photographed as it was happening, but only later, and so the images are full of an expressive force, often retouched by hand in the foreground with the insertion of figures to make up for the lack of action.

In the Lombard–Veneto area, the work of Luigi Sacchi (1805–1861), painter, engraver and then photographer, deserves special mention. After a period of training in the Accademia di Belle Arti di Brera in Milan and experience as a lithographer and wood engraver (he got a prestigious commission as editor in chief of the illustrated edition of Alessandro Manzoni's *The Betrothed* which came out between 1840 and 1842), he chose the calotype process. He depicted the most famous monuments which represented the many centuries of Italy's artistic tradition. His views, part of which were collected in the *Monumenti, vedute e costumi d'Italia* series published between 1852 and 1855, are the work of a passionate photographer, driven by the intention to do a true visual catalogue of Italy's artistic and natural beauty. His intellectual vitality also came out in the journal *L'Artista. Rivista enciclopedica di belle arti, di scienze applicate all'industria, di fotografia, di archeologia e di viaggi scientifici*, of which he was editor and publisher in 1859.

In the fifties, important technical texts on photography were published in Italy. Apart from the treatise Giacomo Caneva's *Della fotografia* (1855), which focused on the calotype process, *Il Plico del fotografo* by the multifaceted, cosmopolitan Giuseppe Venanzio Sella (1823–1876) from Biella came out the following year. A chemist and wool manufacturer, Sella dedicated himself to photography after a period in Paris, and rapidly achieved remarkably high quality results. He experimented with the new wet collodion technique, and became one of the most distinguished figures in the sector.

The daguerreotype and calotype processes co-existed in the photographer's daily routing until around 1860. At the same time, together with the collodion process, the albumen print became widespread in Italy, until the first years after the First World War. From about 1860 onwards, along with the economical, political and social evolution of the bourgeois at the threshold of the unification of Italy, photography became more and more widespread as mean of representation. This success became even more pronounced once unification had come about, encouraged as it was by the cultural context of the second half of the XIX century. The rise of positivism had in fact had deposited fertile terrain for scientific and technological development. All scientific innovations, and hence, photography, were received as signs of humanity's unrestrainable progress. In this period the first Italian journal entirely dedicated to photography, *La Camera Oscura* was founded in 1863 in Milan by Ottavio Baratti. After various ups and downs, publication was stopped after 1894.

The great photography *ateliers* were born, either from previous firms founded by the pioneers of photography at its origins, or on the initiative of new professionals—photographers who had acquired the technical, expressive, cultural and managerial know-how thanks to their travels abroad. The training of this new group was no longer linked to particular, restricted fields like optics or miniatures, but to vaster sectors, above all, engrav-

ing. The advantages of this new technique that brought together the positive aspects of the daguerreotype and calotype processes made it possible for the first time for photography to become a viable alternative to other techniques of reproduction. Engraving, of course, was the medium that paid most dearly when photography became more widely diffused. Photography was already in great demand by tourists and travellers because it cost less and was easier to transport, as is evident from the numerous documents issued by the Calcografia Camerale, the Roman institute which was in charge of the production and sale of engravings when the papal state still existed.

Photography studios in different Italian cities developed different specialities, and were especially oriented towards the three genres of portraiture, views and art reproductions. Among the most important professional photographers were: in Rome, the D'Alessandri brothers, Antonio (1818–1893) and Paolo Francesco, Gioacchino Altobelli (active from 1847 to 1878 ca.), Pompeo Molins (1827–1893 ca.), Tommaso Cuccioni (active from 1830 ca. to 1864), James (1813–1877) and Domenico (1854–1938) Anderson, Robert Mac Pherson (1811–1872), Romualdo Moscioni; in Florence, the Alinaris (active from 1854 to the present day), Giacomo Brogi (1822–1881), Pietro Semplicini; in Turin, Michele Schemboche (active from 1860 to 1906 ca.), Luigi Montabone (active from 1860 to 1877), Henri Le Lieure (1831–1914); in Milan, Pompeo Pozzi (1817–1880), Giulio Rossi (1824–1884), Alessandro Duroni, Giovan Battista Ganzini (1838–1878); in Bologna, Pietro Poppi (1833–1914); in Trento and in Trieste, Giovan Battista Unterverger (1834–1912); in Venice, Carlo Naya (1816–1882), Carlo Ponti (1822 ca.–1869), Domenico Bresolin (1813–1899), Antonio Perini (1830–1879); in Naples, Giorgio Sommer (1834–1914), Robert Rive; in Genoa, Alfred Noack (1833–1896); in Palermo, Eugenio Interguglielmi (active from 1860 to 1900 ca.) and Giuseppe Incorpora (active from 1860 to 1898 ca.); in Verona, Moritz Lotze (1809–1890).

Among the activities of the most renowned firms cited above, there was ample space for the reproduction of works of art and monuments most representative of the art historical tradition and natural beauty of Italy. Nature was not only seen as such, but as an integral part of the landscape, and essential element of a whole in which nature and history, culture and nature harmoniously balanced and completed each other. The wide range of production in this field was conditioned by the requests of the patrons, most of whom were upper middle class and aristocratic tourists from the different parts of Europe. Views of archaeological sites like Pompeii, Paestum and Herculaneum, of the classical ruins of Magna Grecia and ancient Rome, of medieval and Renaissance cities or of the *palazzi* and *calli* of Venice—to cite only a few places—were included in the catalogues of the major photography studios of the period. These images contributed to the creation of true visual *topoi* as well as to the diffusion of a certain image of Italy throughout the world, an Italy that could be identified by its treasures and incontestable art historical supremacy. The language through which photography more or less consciously expressed itself shows multiple influences from previous artistic traditions. This is especially evident in the adoption of the same perspective and compositional schemes from the historic-stylistic legacy of engraving. The main Italian museums (the Uffizi in Florence, the "Pinacoteca di Brera" in Milan, the "Galleria dell'Accademia" in Venice, to cite a few) began to be interested in extensive campaigns to photograph the works they owned. Thus, the collections at the base of future museum photo archives were created; series of different artistic objects came out in special rare editions. In the view genre, the large format prevailed. In editorial production for the public at large, the small stereoscopic format, especially for views, architecture and statuary was popular. Since this format was created to be viewed in three-dimensions, the stereoscopic photograph preferred the subjects that best suited it, thus enhancing its spectacular effect.

Florence witnessed the rise of what would become the main Italian photography firm specializing in the reproduction of works of art, Alinari, founded in 1854 by the brothers Leopoldo, Giuseppe and Romualdo. Leopoldo Alinari, (1832–1865) who had had his earliest experience in the field of engraving, defined the cultural and economical strategies of the agency, which soon carried out systematic photographic campaigns throughout the national territory. In the course of their long career, the Alinaris published numerous catalogues of views divided by region and place, thus showing how they wanted to produce a true visual "catalogue" of the whole of Italy. Among their first images were those published by Eugène Piot in the work *L'Italie monumentale* (1851), a milestone in publishing in France and the entire world, as well as one of the first cases in which the illustrated part is made up of photographs and not of engravings. The Alinaris were called to all the most important exhibits of the age. They got prestigious commissions, among which are the works they did to reproduce the drawings of Raphael in Florence, Venice and Vienna, his frescoes in the Vatican Apartments and the frescoes in the Sistine Chapel in Vatican. The Alinari views were shot using the central, symmetrical layout typical of Renaissance perspective, thus offering a view in which the monument was generally isolated, as a unique, exclusive testimonial to artistic creation. The Alinari images played a fundamental role in the perception and knowledge of the Italian work of art. This became especially clear at the end of the nineteenth

century, when great art historians like Adolfo Venturi introduced the use of photography in the study of art and when the fundamental texts in this sector were illustrated with photos that mainly came from the Alinari studios. Knowledge of the great works of painting and sculpture also became widespread through the carbon print, chosen by Alinari in the 1860s because of the stability of the image, the refined rendering of the tones and shades and the possibility of using coloured pigments to adapt to the different media of the artistic works represented. An Alinari 'style' thus came to be recognized in the monument view genre, and had a great influence on the other contemporary photographers who were working in the same genre.

Another firm working in Florence was the one founded by Giacomo Brogi, who specialized in portraits as well as views and works of art. Brogi's views always showed the monument within the urban and social fabric, thus capturing it in its context and historical dimension, not separated from time and space. Brogi's portraiture adopted the formulas of the *atelier* portrait in the painstaking choice of furnishings, in the studied composition of the poses and gestures of the sitters. Above all, with Carlo (1850–1925), Giacomo's son, the portrait evolved towards more refined forms in keeping with the taste of the period, according to the principles Carlo himself wrote in his treatise *Il ritratto in fotografia: appunti pratici per chi posa*, published in Florence in 1895. Among his most famous portraits are those of the royal family, as well as numerous portraits of the most disparate professions: industrialists, artisans, men of letters, travelling salesmen.

The Alinaris and Carlo Brogi played a fundamental role in the Società Fotografica Italiana, founded in 1889 and soon the main point of reference for anything that had to do with photography in all regions of Italy, mainly through its periodical *Bullettino*. In particular, Carlo Brogi was concerned with questions of copyright and the legal protection of photographs, and thus became an unflagging promoter of initiatives in defence of the profession.

After ca. 1860, the development of portraiture made great strides. It was a period when, through photography, the emerging bourgeoisie was trying to transmit and consolidate an image of its own status and rise to power. Next to the more widely diffused portraits in *carte-de-visite* format, there were portraits in larger formats, starting with the *cabinet* format, which corresponded to the economic resources and prestige of the sitter. The reduction of posing times made new compositions and a more careful interpretation of the subject possible. Among the most important photographers: in northern Italy, the studios of Luigi Montabone, Henry Le Lieure, Giulio Rossi, Alessandro Duroni, Giovan Battista Ganzini, Giovan Battista Sciutto (1827–1900 ca.); in central Italy, the Felici firm and the D'Alessandri brothers in Rome, who were also among the pope's photographers; the Brogi firm, Ugo Bettini in Livorno; in the South, the Interguglielmi studio.

"Genre scenes" were the main concern of some Italian photographers, in particular the Venetian Carlo Naya, the Roman Filippo Belli, Michele Amodio, Alphonse Bernoud, Giorgio Conrad, Giorgio Sommer in Naples. Sommer photographed local customs, the work of craftsmen, the humble but dignified condition of common people of Naples. His images, done in the studio or on the street, represent a varied, picturesque humanity, but without emplaning the problem of social differences; however, they never lacked respect for the subjects portrayed. They were mainly done as souvenirs for tourists.

The events of the Risorgimento served as a catalyst for many photographers. After Lecchi's shots in 1849, Eugène Sevaistre photographed the barricades in Palermo and the fort of Gaeta in 1860. Alessandro Pavia did an entire album of the thousand participants in Garibaldi's enterprise of 1860, thus accomplishing a colossal work single-handed. Other photographers did thousands of portraits, especially in *carte-de-visite* format, of the leading figures of the Risorgimento. Garibaldi, Vittorio Emanuele II and Cavour are among the most recurrent subjects, followed by hundreds of protagonists of the different phases of the war. Gioacchino Altobelli and Ludovico Tuminello (1824–1907) shot the breach that had been opened in the Porta Pia in Rome in September 1870.

After 1880 the new gelatine silver—bromide process technique opened up a whole new range of expression in photographic language. Next to the traditional *ateliers* and professional photographers, the so-called "irregular" photographers appeared. These were amateurs who, thanks to their up-to-date cultural and technical training, had an intuition of the great potential of the tool, and used it as a function of a new language. Existing conventions were abandoned, especially those derived from the rules of perspective, in order to search for new modes of representation. Next to the traditional genres discussed above, the doors were opened to true documentary work. By then, it was possible to reproduce motion and events as they were happening, exposure times could be reduced to a fraction of a second. And so the main characteristic of photography was revealed: it could see beyond our field of vision, and show what our synthetic way of seeing could not take in.

Among the main protagonists of this season: Luigi (1858–1925) and Giuseppe Primoli (1851–1927) in Rome, Giuseppe Beltrami and Luca Comerio (1878–1940) in Milan, Vittorio Sella (1859–1943). The Primoli brothers, whose snapshots showed the life of the *belle époque* of the Roman nobility (the landscape, the horse

races), as well as some episodes of the life of the people with their processions, festivals, and customs. Their special language showed their friendship with painters and artists of the Parisian milieu: think of the use of photography in Degas, or the studies of motion carried out by Marey and Muybridge, who certainly influenced the two brothers' technique.

Around 1890, Giuseppe Beltrami captured different aspects of *fin de siècle* Milan by shooting every sort of character in the streets of the city: humble *clochards*, travelling salesmen, ladies with their wet-nurses and children, business men with cigars and waistcoats. Beltrami worked with a Kodak n.1, the first apparatus for taking snapshots that used film on a roll. He would stop at a certain point in the centre of Milan, between piazza Duomo and piazza della Scala, and from there he would shoot whatever happened to pass by the camera's lens. His images, which were also collected in albums, were an enormous success and were presented at the most important exhibits of the period.

Luca Comerio, photographer and film industry professional, was the author of important photography on the Milanese turmoil of May 1898. The demonstrators, the barricades, the military troops at work putting down the fighting, were all documented in his photographs and then published in *L'Illustrazione Italiana* with the first photomechanical processes. He also did other important documentaries, including coverage of the War with Libia in 1912.

Vittorio Sella deserves mention among the Italian photographers of snapshots. This great photographer of the mountains was the author of documentaries on the Alps, the Caucasus, and the Arctic Circle between 1887 and 1904.

The photographic industry witnessed a phase of remarkable expansion, especially in Milan, a city rooted in industrial development. Here, the following firms sprang up: Oscar Pettazzi, who sold camera obscura, light-sensitive materials and treatises on photography; Salmoiraghi, Lamperti and Garbagnati, Koristka (famous for his lenses); Cappelli (famous for his plates).

The spread of amateurism encouraged the first associations of photographers and the proliferation of journals. In Rome in 1888 the Amateur Photographers Association was born; in 1889, the Italian Photographic Society and the Lombard Photographic Circle were created in Florence and Milan respectively; in 1896 the Bolognese Photographic Circle was founded in Bologna, as was the Camera Club in Naples; in 1899 the Subalpine Photographic Society was founded in Turin, and it incorporated the older Italian Photographic Union, founded in Turin in 1879. In the publishing field, apart from the aforementioned *Camera Oscura* and *Bullettino*, new journals appeared: *Amatori fotografi* in Rome, in Milan *Il Dilettante di fotografia* in 1890, the *Rivista scientifico-artistica di fotografia*, a periodical of the Lombard Photographic Circle, in 1892, and *Il Progresso Fotografico* in 1894.

The exhibits and conferences in this period show that there were different trends in Italian photography. Next to the traditional photography of the professional *atelier*, the work of learned amateurs was making headway. These photographers worked outside the studio and put forward new forms of language which barely exploited the characteristic techniques of photography. Amateurs and professionals alike were involved in the progressive rise of pictorialism, a trend that first appeared in Italy at the Exhibition in Turin in 1898. Here, artistic photography was first separated from technical and commercial photography, thus claiming its cultural role. Optics, chemistry and mechanics were subordinated to artistic creation. Influenced by the theories of Peter Henry Emerson, photographers like Guido Rey (1860–1935), Cesare Schiapparelli, Enrico Grosso, Wilhem von Gloeden, Luigi Cavadini (1878–1962) and Mario Nunes Vais (1856–1932) came to the fore. Experimentation with a new artistic language led to the use of new printing techniques like bromoil and gum bichromate. The Turin Exhibition took place at the same time as 1st Italian Congress on Photography, which confronted the problem of the social role and recognition of the photographer. At the National and International Exhibition in Florence in 1899, there was also the 2nd Congress on Italian photography, and photographers saw the work of Alfred Stieglitz, Robert Demachy, H. P. Robinson, and the Camera Club of Vienna. At the Exhibition of Artistic Photography, promoted within the First International Exposition of Modern Decorative Arts held in Turin in 1902, more non-Italian photographers were present, in particular, members of the Photo Club of Paris. The Italian photographers on exhibit were of high quality, and clearly showed, together with the triumph of the art nouveau style, that Italian artistic photography had reached a fully mature phase.

ITIER, ALPHONSE-EUGÈNE-JULES (1802–1877)

French photographer

Jules Itier was born in Paris on 8th April 1802, the son of a military commandant, and entered the French Customs Service at the age of seventeen. Before he was thirty, he had achieved the rank of Inspector.

His interest in photography dates from 1840 when he was introduced to the daguerreotype, and over the following years, his work and his enthusiasm for travel took him and his camera to many parts of the world. His surviving oeuvre includes daguerreotypes made in Senegal (1842), India (1844), Ceylon (1844), Guadaloupe (1843) and Guyana (1843). He arrived in China as part of a French delegation to sign a trade agreement

in 1844, producing many fine images in Canton, Macau and elsewhere in 1844 and 1845. Those images survive as the earliest photographs ever taken in that country.

In 1845 he travelled to the Phillipines and Borneo—he reportedly bought supplies of plates and chemicals in Manilla—and later that year arrived in Egypt. A number of fine images of the antiquities of Egypt survive from his journeys in 1845 and 1846.

Returning to France in 1846, he continued to pursue his interests in photography until the late 1850s. His images were rediscovered in the late 1970s.

JOHN HANNAVY

ITINERANT PHOTOGRAPHY

From the day the invention of photography was announced to the world, innovative photographers knew that if patrons would not come to studios, then the studio would have to come to them, and as such the birth of the itinerant photographer occured.

Before the advent of the itinerant photographer, several excursion were attempted where camera manufacturers sent employees laden with supplies to "capture" exotic locations of the world. Among this exclusive community of patrons were to wealthy tourists, writers and artists to which these photographers were later "contracted." Horace Vernet, Romantic painter, traveled to Egypt in 1839 under the sponsorship of supplier Lerebour to capture images that later sold as the famous *Excursions Daguerriennes* aquatints. "We kept daguerreotyping like lions," he enthusiastically remembered. In 1855, Roger Fenton and his "Photographic Van" recorded ersatz camp life during the Crimean War, and while in North America the earliest travelling photographers were components of government expeditionary, geologic, boundary and railway surveys. Many itinerant photographers followed or branched away from the growing networks of paths, roads and railway systems. During the American Civil War, portraiture was important as never before in family life, and itinerant photographers in particular enjoyed a boom equal to that of when photography was first introduced. Lowly soldiers seeing for the first time itinerants travelling into war theatres often dubbed the horse drawn studios as "What-Is-It?" wagons.

The definition of an "itinerant photographer" or "itinerant" remains one where a person 'travels with photographic supplies with the purpose of purveying their trade and the intent of selling (and even bartering) their photographic results to a hopeful populace.' Itinerant photographers, whether previous apprentices or self-taught, came from all walks of life and were of both genders.

Some found that life on the road provided a good income. Studio owners sometimes closed their city business for the summer and traveled to resorts and small towns, setting up portable studios and darkrooms on the outskirts of towns and villages. Others hired temporary assistants to cover studio operations while they traveled, or else sent the employee on the road to do predetermined circuits—some with considerable distance and need of time. Such travels however would not successfully happen until the existence of a viable portability of the technology and its convenient use.

In 1851 the Englishman Fredrick Scott Archer invented the wet plate collodion process. This quickly supplanted both the daguerreotype and the calotype, as photographers were now able to make infinitely *reproducible* negatives. Unfortunately cumbersome, the wet collodion process required not only camera, tripod and glass plates, but also chemicals, and a portable dark tent practical enough to travel even by canoe, dog cariole or elephant, as examplified respectively in Canada, Scandinavia and India. On location it was necessary to have at least a barrel of "clean" water, as almost invisible amounts of foreign matter in the silver nitrate bath would invariably result in a blank plate. Frederick Hardwich's indispensable *A Manual of Photographic Chemistry Including the Practice of the Collodion Processes* was a common manual among English speaking itinerants.

The collodion's light sensitivity—or lack thereof, and the need for immediate preparation and use; as well as existing optical properties of the camera, did deter its early usage. In later years the reasonably fast exposure times spurred many to promote "good expressions" and encouraged patrons to "bring their children and babies to be photographed." Few itinerant photographers used the wet collodion process other than for the making of ambrotypes or more often the ferrotype also known as "tintype."

By the 1870s more light-sensitive gelatin dry plates traveled throughout many parts of the world. Itinerant photographers ceased to work with the old wet-plate technology and thus reduced the bulk of necessary paraphernalia. The pre-sensitized dry plates eliminated the need for awkward chemical procedures and the new sensitized papers all but ended the old chemical technology.

Ironically, even with advancements in technology, the photographers were often unaware of then-unknown consequences of their craft. It is well recorded that early photographers, and itinerants in particular, mentioned "recouperating from unknown" illnesses or "afflicted with very sore eyes"—a result of extended exposure to chemicals under light-tight portable tents and other housing contraptions with poor ventilation.

The practicality of transporting supplies on a travelling circuit posed various problems. Most itinerant photographers did not buy their supplies along the way and few are known to have had depots along their

routes. The very nature of early unreliable or inconsistent chemistry and supplies made this perilously obvious—not to mention potential pilfering or outright theft of stock in distant centres. No less important: weighty supplies carried either by horse or donkey or pulled on spring-wagons were prone to accidents—thus the need for an all-encompassing secure method of supply and transport. The results reflected the photographer's initiative to provide functional practicality due to prevailing geographic and economic concerns—and the success of their vocation.

Depending on their situation, some peddled their bicycles across the land carting assorted ingeniously collapsible darkrooms, and slept in tents; others had private railway cars.

Possibly the most ingenious portable self-contained photography darkroom was the "fitted" or "collapsible dark tent." This was literally a slightly oversized suitcase that, sequentially unfolded and set up, formed a table with insert trays, chemistry holders and shelves, and provided for equipment storage. It was covered over and fastened with a light-tight rubberized fabric bag or "tent" allowing the photographer to hide under while they performed the necessary tasks of preparing wet collodion plates like inserting glass negatives into dark slide holders, developing and fixing images or endless other tasks that required total darkness. To prevent insects or dust from spoiling any particular task, the tapered bag fit over the operator and often tightened around the waist. While this was an amazing bit of technology, one had to be hardy and proficient—especially on hot days as temperatures under the tent often became intolerable. Itinerants quickly learned to trust their sense of touch and smell to monitor their progression during the preparation of chemicals or subsequent developing stage.

Certainly during the formative years many itinerants used compact, very portable horse drawn wagons. Exceptionally there were those on sleighs or on riverboats. From the proliferation of images extant we know that itinerant photographers used several ingenious versions of drawn or train-ferried studio-darkrooms. Many included the basics: light-free storage area for chemicals and supplies; special windows glassed to provide pre- and post-development needs as required; and repair and equipment storage area. Considerably fancier vehicles included a studio complete with skylight and indoor props. Purportedly there existed American wagons that could be transferred from track to wheels where and when required. Mid range studios might photograph patrons outside but had collapsible chairs or benches for those waiting.

Presence probably awed the potential customer but only the final photographic results conveyed the true richness of their talents. Indeed, not all itinerant photographers were successful at their trade. Early prairie newspapers mentioned itinerant photographers were not above bartering for wheat, flour, wood or other method of payment for "likenesses." Many had secondary employment as well. The 1850s directories suggested that "photographists" and "ambrotypists" fell back on other professions including civil engineering and draughtsmenship. One was even known as a hypnotist. This level of 'confidence' was more or less consistent in directories published thirty years later. Some photographers plied their trade and sold pianos in the same ad. Some sold real estate and others were insurance salesmen. In North America there were several interesting examples of photographers becoming fur trappers. A Methodist priest-turned-photographer plied his itinerant trade for only two years before his "conversion" to blacksmith. Several met tragic deaths in various parts of the world, including being found purposefully severed in two on railroad tracks.

To promote their trade most itinerant photographers made repeated use of advertisement. The purchase in advance of a spot in newspapers or on broadsheets from towns and hamlets along their travelling route notified prospective patrons of the opportunity to be photographed at set dates and locations. Some advertisements were brief or generic; others touted in great details the photographer's talent and resourcefulness. It was not uncommon to see boastful advertisements such as: "Now is your chance to get good work—better than ever turned out in this town before." Some ads were even purloined from other unsuspecting itinerants. Newspaper publishers printed submitted ads rather indiscriminately under "Business Card," "Artistry," "Photographs," "Photography," "Town," "Local" and "General" or "Miscellaneous" news. Few photographers were moved to advertise with impending seasonal holidays or visiting dignitaries—possibly a function of how slow news traveled. Retractions, "pending" notices, or apologies for changed schedules were common and regrettably often posted after the fact.

Advertisements signaled trends; such as procuring images of sick and, in particular, deceased family members. Since the advent of daguerreotypy and continuing much until the early years of the twentieth century, people brought their deceased to photographers. Itinerants could be counted on to make a keepsake of patrons' dearly deceased—often children. Europeans favoured very much an image transferred to ceramic and then secured onto the tomb of their loved one. Itinerants were adept at producing or transposing, images onto leather, ferrotyped metal, milk glass, silk, porcelain and assorted other materials. However in some cases (most notably the glazed ceramic) work would be carried out later in

a major centre and the patron would receive the finished item upon the itinerant's next visit. Newspaper articles often pointed out that several months passed before receiving a "favourable likeness of one's deceased." Some itinerants managed to have their darkroom work done at a studio in the region they visited but local operators often resented them because they naturally competed for business. Itinerants paid no rent or utility costs, and could undercut prices charged by established studios. Thus most chose to set up at the town's edge, in the open air. Grass became the studio floor and carpet. The image often "captured" patterned fabric or painted backdrops, were often blurred by breezes. The intent was to quickly take a picture and produce several copies thus reducing labour and increasing profit. For pennies more, patrons could have images housed in cheap, white-metal, clasped jewelry or encased.

So as not to be burden with extra weight, itinerant photographs cleverly made use of materials at visiting sites. Carded or framed tintypes were often backed with cuttings from local newspapers. Photographs were mounted on a card support imprinted with the photographer's particular trade design, locale, etc. Some were intricately printed and embossed; others were simply rubber-stamped onto the cards. These individualistic markings or 'imprints' provided clues to the photographers work. One photographer promoted his work as the "soldier's headquarter" as he traveled closest to war torn areas; others heralded themselves as the "ranchman's photographer" thus indicating their expertise. Sure to please was the notation "Photographer to the People." Itinerant photographers, compared to studios, often chose not to protect their work. There were however, examples of subtle symbols or disguised words found on certain Canadian itinerant photography which can be traced to later copied works by other itinerant and studio photographers.

With the advent of truly portable and affordable cameras, the growing interests of travelling camera clubs, and of "snapshooters," the itinerant photographer became a dwindling reality by the early 1900s. Many would fashion themselves into street photographers, where it was the 'itinerant' customer who would approach the photographer and pose for a souvenir image. Possibly the last vestige of itinerant photography was a 1907 patent and detailed drawing, by Frankfort, Germany, photographer Jean Schmidt, of a travelling electric studio car. Unfortunately his travels were dictated by that city's and neighbouring communities' limited overhead trolley lines.

IVES, FREDERIC(K) EUGENE (1856–1937)

American scientist and physicist

Ives was born in 1856 and is known for his pioneering work in photo-mechanical reproduction in both black-and-white and color as well as his early three-color additive photography. Ives is the inventor of photoengraving (halftone block engraving) as we know it today. In 1878 he started to commercially produce screens for the halftone printing process in Philadelphia. Earlier it was not possible to print different gray levels, only black and white could be printed. When working at Cornell University, Ives invented a screen that would convert a photograph or drawing into a pattern of tiny dots—large dots forming where the image was dark and tiny dots where the image was light—giving the illusion of shades of gray. An original photograph to be printed had to be re-photographed through Ives' screen. In this way a halftone was obtained which was then engraved onto a metal plate from which the image could be cheaply and quickly printed on paper. Ives' first halftone process, patented in 1878, consisted of a gelatin relief which was cast in pure white alabaster plaster and brought in contact with an indiarubber sheet covered with pyramidale raised points or lines which had been inked. According to the amount of relief on the cast the rubber points were more or less spread out and

thus gave dots of ink of varying size on the surface of the cast. The light and shade of the image was reproduced and the cast photographed.

Ives invented also the first cross-line halftone screen, composed of two plates with finely ruled parallel lines cemented face-to-face, with the rule patterns running at right angles to one another. The resulting dot pattern could capture finer image details than the inks, papers and the printing pressures at that time could reproduce.

Ives got interested in color photography and by 1892 he had developed an additive three-color photographic technique (composite heliochromy). By the aid of a special photochromoscope camera, fitted with an arrangement of mirrors, prisms and light filters, three images of the object or scene were recorded in succession on three sensitized plates. On image was recorded through a red filter, a second image through a green filter and the third one, through a blue filter. After the negatives have been developed, three positive plates are recorded by contact printing the three negatives. These three transparencies, though themselves of no color, contain information about the color content of the recorded object or scene. The positive plates are mounted and inserted in the viewing device, the *Chromoscope*, in which the plate containing the red information is illuminated with red-filtered light, the green plate, with green-filtered light, and the blue one with blue-filtered light. When the three plates are correctly superimposed in the instrument, a color image is visible. Ives chose the name *KRÕMSKÕP* for his various additive color systems and his type of color photographs is known as *Kromograms*.

In 1893, Ives was also able to make a stereo KRÕMSKÕP, in which pairs of red, green and blue negatives were recorded through color filters in the same way as for the two-dimensional color images. In the viewing instrument, the color photographs were observed with both eyes, and the color picture consequently seen in 3D.

In 1895 Ives constructed a projector, the Projection KRÕMSKÕP, in which the three transparencies could be illuminated with filtered light and projected superimposed on a screen. Ives made both a Diffraction Chromoscope as well as a camera which could record the three color-separated plates in one shot. Louis Ducos du Huron in France had also introduced a similar one-shot color photochromscope camera, the Mélanochromoscope.

The color images recorded with Ives' technique are of high archival stability and the colors will never fade since the color information is encoded in the three black-and-white transparencies. Only when correctly illuminated and superimposed, the color image is synthesized and possible to see.

In Ives' company in Philadelphia, educational Kromograms were produced, such as prepared medical specimens. Beginning in 1898, the KRÕMSKÕP and Kromograms, including also stereo pairs, could be obtain from the Photochromoscope Syndicate Ltd, 121 Shaftesbury Avenue, in London.

In the 1920s, Ives was working on ideas for the subtractive synthesis of color, trying to find dyes and suitable materials for the process. During the 1930s, Ives experimented with the Hi-Pro color process and the two-color Polychrome process, but the results could not equal those achieved with three-color photographic materials or four-color photomechanical reproduction.

Among some other of Ives' inventions is the *parallax panoramagram* patented in 1903. This was a concept for a look-around multiview 3D image based on the raster-barrier principle. Ives invented also, for example, a single objective binocular microscope.

The Optical Society of America (OSA) highest award is the *Frederic Ives Medal*. It was endowed in 1928 by Ives' son Herbert E. Ives to honor his father and his important contributions to photoengraving and color photography.

Some of Ives' early prints are preserved in the Smithsonian Institution.

HANS I. BJELKHAGEN

Biography

Frederic(k) Eugene Ives was born in Litchfield, Connecticut, 1856, the son of a farmer. At thirteen, he left the family farm to become a printer's apprentice at the *Litchfield Enquirer* newspaper and later an apprentice at the Itacha printer Andrus & McChain. In 1874, at the age of eighteen, he applied for a position of photographic technician at Cornell University. Professor W. A. Anthony reluctantly hired him thinking he was too young and inexperienced. The next year he became the director of the university's first photographic laboratory. He remained at Cornell until 1878. During his four years at Cornell he invented the halftone printing process.

By twenty-five, he moved to Philadelphia where he accepted a contract with the wood-engraving firm Crosscup & West, to further develop and commercially produce his halftone screens. Already in 1884 he was able to make high-quality orthochromatic plates for photomechanical applications. In 1887 he moved to Philadelphia and started a photogravure printing company there. The same year Ives was granted a patent for halftone printing. Ives invented also a halftone screening process In the late 1880's he started his work on three-color photography. In 1892 he made his first Chromographoscope, the KRÕMSKÕP, with an improved version introduced in 1895. In 1898 Ives started a company called the Photochromoscope Syndicate Ltd in London.

During his lifetime he received a total of 70 patents. Ives' son Herbert E. Ives (1882–1951) was also a recognized photo scientist, working on color photography and a pioneer of photo-transmission of images. Frederic(k)

Ives continued to work on color photography until he died in 1937.

J

JACKSON, WILLIAM HENRY (1843–1942)

The photographs which earned William Henry Jackson an important place in photographic and American history were made in the last quarter of the nineteenth century, but he continued an active life well into the next century with his images reaching an ever wider audience through color post cards, publications, and exhibitions. Unlike other pioneer photographers of the West, Jackson became a living legend.

Born in Keeseville, New York, on April 4, 1843, Jackson credited his mother with providing watercolor instruction and with introducing him to Chapman's *American Drawing Book.* Following school graduation in 1858, he became a retoucher and colorist for a Troy photographic studio, and two years later he was similarly employed in Rutland, Vermont.

With the onset of the Civil War, Jackson enlisted in a Vermont regiment and served as a staff artist. Honorably discharged in 1863, he returned to the Rutland studio, but the following year he became a studio artist in Styles'Gailery in Burlington, Vermont. Here, his cultural horizons broadened, but a broken engagement resulted in an abrupt departure for New York, where he and two buddies then headed westward toward Montana silver mines. He drove oxen, worked as a farm hand in Utah, and unsuccessfully sought work in California before abandoning the mining quest to head eastward. After driving wild horses to Julesburg, Wyoming, and boarding them on a freight train to Omaha, Nebraska, he found a job in that city as a colorist in the Hamilton Gallery. With help from his father, he bought out this photographic studio along with the competitor in 1867, and the next year he formed Jackson Brothers, Photographers, with his brother Ed.

Realizing that studio work was not his forte, Jackson photographed both landscapes and Native Americans as he followed the route of the yet unfinished Union Pacific Railroad in 1868. He used the cumbersome wet plate process.

The Union Pacific and the Central Pacific tracks finally met at Promontory Point, Utah, on May 10, 1869, but Jackson was in Omaha that day marrying Mollie Greer. Dr. Ferdinand V. Hayden, Director of the U. S. Geological and Geographical Survey saw Jackson's work, and the following year included him, without salary, on the 1870 expedition along the Old Oregon Trail through Wyoming.

Hayden, like fellow surveyor and geologist Clarence King, followed John Ruskin's aesthetics, so he viewed Jackson's detailed work as both scientific document and artistic statement. Painter Sanford Gifford was also with the Survey. For the 1870 Wyoming expedition, Jackson used a whole plate (6½" × 8½") camera, and photographed both views and Native Americans, as Hayden wanted records of what was wrongly believed to be a vanishing people. Jackson usually photographed Indians in a straight-forward manner, though sometimes with studio props. His later photographs of the Moquis pueblo show the native people in their environment.

Some of Jackson's most memorable photographs were made on the 1871 expedition to Yellowstone. Accompanying the party was the painter Thomas Moran, who like Gifford, influenced Jackson's photography. Jackson photographed the geysers and hot springs with a stereoscopic camera and with an 11" × 14" camera (imperial plate size). One of the legends surrounding Jackson was that the Yellowstone photographs swayed legislators to vote in favor of making this area the first National Park. Howard Bossen, however, has effectively demonstrated that Jackson's photographs were but one factor in a powerful lobbying effort to preserve these lands.

Salaried since 1871, Jackson remained with the Hayden projects until the Survey was disbanded in

Jackson, William Henry. Mammoth Hot Springs, Pulpit Terraces. *The Metropolitan Museum of Art, Rogers Fund, 1874 (1974.530) Image © The Metropolitan Museum of Art.*

1879. During this time he made Mountain of the Holy Cross, in1873, a photograph which Moran used for a painting. For the Philadelphia Centennial Exposition of 1876, Hayden placed Jackson in charge of the Survey's exhibition, which included his photographs and his clay models of cliff dwellings based on his exploration the previous year in the Mancos Canyon and Canyon de Chelly.

With the end of the Survey, Jackson left Washington, D.C. in 1879, and moved to Denver, Colorado, where he formed the Jackson Photographic Company. Meanwhile, western railroads sought tourists and settlers on their routes and recognized the persuasive power of dramatic landscape photographs. Beginning in 1881, Jackson worked for numerous lines as an "official railroad photographer," and depicted landscape and trains in picturesque and sublime settings. He now used the new dry plate process, and much of his work involved mammoth plates (18" × 22").

This western railroad photography led to the Baltimore & Ohio railroad's P. G. Pangborn hiring Jackson in 1892, to photographs along that company's route. The photographs were shown at the World's Columbian Exposition in Chicago in 1893, where Jackson was commissioned to photograph the architecture.

Pangborn then organized The World Transportation Commission and hired Jackson to photograph a tour that included Egypt, India, China, and Russia. Jackson was away from his business and family for 17 months, during which time he also supplied *Harper's Weekly* with photographs and articles.

Returning from the arduous tour, Jackson found his business foundering, and he sold out to the Photochrom Company in 1897, to become a salaried director and part owner of the parent company, The Detroit Publishing Company. Jackson continued to actively photograph until 1903, when managerial duties precluded extensive travel. The Photochrom Company failed in 1924, and Jackson retired.

In 1936, Jackson painted murals for the U. S. Department of the Interior in Washington, D. C. That same year Henry Ford acquired 40,000 of his negatives for the Edison Institute in Dearborn, Michigan. By this time Jackson's camera of choice had shifted from the 20" × 24" plate camera used on the 1875 expedition to a 35 mm Leica. By 1939, he was using Kodachrome film.

Jackson also produced a series of romanticized watercolor paintings based on his original sketches, photographs, and recollections. When 97, he published an autobiography, *Time Exposure,* which Peter Hales found "heavily embellished," but which Douglas Waitley claimed had "a scrupulous regard for accuracy..."

Shortly after a fall, Jackson died on 30 June 1942, in New York City at age 99.

JOHN FULLER

Biography

Born, Keeseville, New York, 1843. Retoucher and artist in Troy, New York studio, 1857; similar job in Rutland, Vermont, 1860. Civil War volunteer 1861–63; returned to Rutland studio. Artist in Burlington, Vermont studio, 1 864. Left New York City l 866, for West; various jobs including builwhacking. Formed Jackson Brothers, Photographers, 1867. Married Mollie Greer in 1869, and photographed Wyoming. "Official Photographer," for F. V. Hayden and U.S. Geological and Geographical Survey, 1870–1879. Moved to Washington in 1872, wife died in childbirth. Married Emilie Painter, 1873. Photographed members of Ute tribe, 1874. Organized Survey's exhibit, Philadelphia Centennial, 1876. Founded The Jackson Photographic Co., Denver, Colorado, 1879,' work began as "official railroad photographer." Incorporated as W. H. Jackson Photograph and Publishing Co., 1883. Exhibited and photographed World's Columbia Exposition, Chicago, 1893. World Transportation Commission tour with *Harper's Weekly* assignments, 1894–1896. Part owner, The Detroit Publishing Go. Photographed actively until 1903-, retired from the Detroit Publishing Co., 1924. Mural commission from Department of the Interior, 1936, paintings for National Park Service in 1937. Honorary Fellow, Royal Photographic Society, 1938. Watercolors completed for Oregon Trail Association., 1939. Published autobiography, *Time Exposure,* 1940. Honorary degree from University of Wyoming (Laramie), 1941. Died, New York City, 30 June 1942.

Group Exhibitions

1876 Centennial Exposition, Philadelphia, Pennsylvania. Awarded several medals 1889 Jubilee Exhibition, Berlin, Germany. Highest Honors.
1895 Calcutta (India) Photographic Exhibition. Bronze Medal 1902 Traveling exhibition in Santa Fe Railway private car.
1936 Exhibition of Jackson Collection, Denver Public Library.
1942 "Photographs of the Civil War and the American Frontier," Museum of Modern Art, New York City.

Selected Works

"156 Mountain of the Holy Cross," 1875.
"Cañon of the Rio Las Animas," ca. 1882.
"1068 Grand Cañon of the Colorado," ca. 1892.
"573 The Choonbatty Loop on the East Bengal Railway in the Himalayas," 1895, "1091 Mammoth Hot Springs on Gardiner's River (Wyoming), after 1880 "296 View from Tequa Towards Moqui," 1875.

JAMES, HENRY (1803–1877)

English, patron, officer of the Royal Engineers (Lieutenant 1831, Captain 1846, Colonel 1857, Director General Ordnance Survey 1854–75)

Throughout his career, Colonel Sir Henry James was a proponent of photography as an adjunct to the mission of the Royal Engineers and the Ordnance Survey Office, both in the work of surveying and mapping and resultant publications. He pioneered the use of photography as a method for reproducing maps and plans and established a studio at the Ordnance Survey offices in Southampton where maps, plans, and documents were photographically reproduced. In 1859 he published *Account of Methods Employed for the Reduction of Plans by Photography.* Later he claimed the invention of a photo-mechanical technique, photo-zincography, which was developed by two men under his command at the Ordnance Survey Office in Southampton, England, and at first, starting in 1859, simply a method of preparing a photo-lithographic transfer and applying it to a zinc plate, afterwards printed from. Direct prints from negatives were then made on the zinc plates. Photozincography may refer to a line or a half-tone process. His first successful photozincograph was a reproduction of an etching in 1859. Sir Henry James read a paper to the British Association "On photozincography" in September 1861.

James also saw the utility of photography in field work and ordered the inclusion of photographic documentation in many of the Office's surveys: *Ordnance*

Survey of Jerusalem (1864); *Ordnance Survey of Sinai Peninsula* (1869); *Plans and Photographs of Stonehenge and of Turusachan in the Island of Lewis* (1867); and *Notes on the Great Pyramid of Egypt and the Cubits Used in Its Design* (1869). In addition he oversaw the production of a photographic facsimile of the *Domesday Book* or ancient record of the Survey of English lands, ordered in 1086 by William the Conqueror. This was the first systematic geographic record in England. Under his leadership, photography was an integral component of mapping and surveying accomplished by one of the nineteenth century's most influential forces for exploration.

KATHLEEN HOWE

JANSSEN, PIERRE JULES CÉSAR (1824–1907)

French astronomer, inventor, and photographer

Janssen studied the solar spectrum and developed a spectrohelioscope in 1868. In 1867 he concluded that water vapor was present in the atmosphere of Mars. He also discovered an unknown spectral line in the Sun in 1868 and later shared that information with Norman Lockyer, who was credited with the discovery of helium. Janssen was the first to note the granular appearance of the Sun, and published a monumental solar atlas in 1904. Janssen taught Mathematics and Physics and was appointed as correspondent to India to observe the total eclipse of the Sun in 1868. His first contribution to scientific photography was proof, using a spectroscope, that the solar prominences are gaseous. He also discovered the chromospheres, a type of gaseous envelope of the Sun. The French government appointed him director of the Astrophysics Observatory in Meudon, France, where he resided for about 30 years. Janssen studied mainly the Sun, publishing an atlas with almost 6000 pictures of its surface.

The convention of photography confronts Janssen with the given world, with what one can find in the real world and what the camera may register in its fragmentary vision of time and space. The photographer merely decides when, where and how to do it, which seriously limits the author in the possibilities of creation based on some direct way of shaping the image. In a certain sense, the images had always been there—the task of Janssen is only to spot and register it, which does not seem much. But the history of photography proves that one can perform enormous tasks in this seemingly narrow field. For Janssen himself as a player in the history of photography is photography a creative tool that is composed of repeatedly undertaken attempts at transgression, attempts of going beyond the urely documentary relation between the image and its object. Transgressing this basic feature of photography was for Janssen a fascinating challenge.

Janssen was born in Paris, in 22 February 1824. He became handicapped by a childhood. Pierre Jules César Janssen studied mathematics and physics at the faculty of sciences at the university of Paris. He taught at the lyceum Charlemagne in 1853, and in the school of architecture 1865-71, but his energies were mainly devoted to various scientific missions entrusted to him He became very quickly fascinated with the spectroscopic work of Gustav Kirchhoff and Robert Bunsen. Under their influence, the young man began his search on the solar spectrum in 1862 and showed in particular that certain lines of the spectrum are due to the steam of the Earth's atmosphere. He studied the work of John William Draper, who took a photograph of the moon in 1840. His son, Henry Draper, later became the first person to photograph the Orion Nebula in 1880, which was essentially the first deep sky photograph.

In 1857–58, he worked in Peru on the determination of the magnetic equator and in 1861–62 and 1864, he studied telluric absorption in the solar spectrum in Italy and Switzerland.

In 1867 he conducted optical and magnetic experiments at the Azores, successfully observing both transits of Venus, the first in 1874 in Japan, and the second of the 1882 transit at Oran in Algeria. He took part in a long series of solar eclipse expeditions, e.g., to Trani (1867), Guntoor (1868), Algiers (1870), Siam (1875), the Caroline Islands (1883), and to Alcosebre in Spain (1905).

At the Azores (1867) he examined magnetic and topographical conditions. In 1868 Janssen went to India to observe a total eclipse of the Sun. He was unable to correlate certain lines in the solar spectrum with wavelengths of any known elements. English scientist Norman Lockyer made the same discovery of a new, unknown element and reported it simultaneously to the French Academy of Sciences.

An intrepid traveler in spite of his infirmity, Janssen traveled to Peru, Italy, Switzerland, Algeria (which he reached in a balloon from Paris besieged by the Prussian army in 1870) and finally to Guntur, India.

At this great Indian eclipse of 1868 he demonstrated the gaseous nature of red prominence, and devised a method of observing it under ordinary daylight conditions. One main purpose of his spectroscopic inquiries was to answer the question whether the Sun contained oxygen or not. An indispensable preliminary was the virtual elimination of oxygen-absorption in the Earth's atmosphere, and his bold project of establishing an observatory on the top of Mont Blanc was prompted by a perception of the advantages to be gained by re-

ducing the thickness of air through which observations would be made. This observatory, the foundations of which were fixed in the snow that covers the summit to a depth of ten meters, was built in September 1893, and Janssen, in spite of his sixty-nine years, made the ascent and spent four days taking observations. On August 18 1868 of that same year, while observing an eclipse of the Sun in India, he noticed a bright yellow line with a wavelength of 587.49 nm in the spectrum of the chromospheres of the Sun. Janssen was at first ridiculed since no element had ever been detected in space before being found on Earth. On October 20 of the same year, English astronomer Norman Lockyer also observed the same yellow line in the solar spectrum and concluded that it was caused by an unknown element after unsuccessfully testing to see if it were some new type of hydrogen. Since it was near the Fraunhofer D line he later named the new line D3, distinguishing it from the nearby D1 and D2 doublet lines of sodium. He and English chemist Edward Frankland named the element after the Greek word for the Sun god, Helios, and, assuming it was a metal, gave it an -ium ending (a mistake that was never corrected).

Janssen belonged to this group of photographers for whom even considering the respect they have for the medium nd their awareness of tit limits a purely technical relation is not enough. Janssen created his world for registration himself, subordinating its images to certain manual manipulations because of the need to manifest his own creativity.

In 1874, the French government proposed Janssen is the director of a new observatory intended for astronomical physics. He accepted the offer and chose the site of Meudon for observatory and in 1876, he collected the remarkable series of solar photographs for his great Atlas de photographies solaires (1904). The first volume of the Annales de l'observatoire de Meudon was published by him in 1896. Astrophotography is a specialized type of photography that entails making photographs of astronomical objects in the night sky such as planets, stars, and deep sky objects such as star clusters and galaxies. Astrophotography was used to reveal objects that are too faint to observe with the naked eye, as both film and digital cameras can accumulate and sun photons over long periods of time. Astrophotography posed challenges that were distinct from normal photography, because most subjects were usually quite faint and often small in angular size.

Janssen later became director of the observatory on Mont Blanc. His photographer's of the mountains has interested for the way in which it has involved two main paradigms of historical method, whose results have come together in a very fruitful and complementary manner.

I refer on the one hand, to the concept of the photograph as in effect a container for data from which evidence may be deduced, a classic approach to photographic history; and on the other, to a view of the photograph which owes more to archeology, and pays attention tot the nature of what is to be found with it, irrespective of whether or not there is any primarily photographic connection. However, it depends on each perceiver's sensibility and imagination how broad and interesting the visual world of Janssen might seem. He died at Meudon by Paris on the 23rd of December 1907.

JAPAN

When Daguerre made his historic announcement to the French Academy of Sciences in 1839, Japan had been officially closed to the outside world for two hundred years and was not to be opened to foreign trade for another twenty. News of scientific progress in the West only came to Japan as a result of the exclusive trading privileges that the Kingdom of the Netherlands enjoyed with the Shogun's government, and it is a striking testimony to the persistence and dedication of contemporary Japanese scholars of Western learning—or *rangaku* ('Dutch Learning')—that the first camera was imported into Japan in 1843. This was in response to an order made through the Dutch trading post in Nagasaki by a local merchant, Ueno Toshinojô, and it is typical of the numerous false starts that bedeviled the advent of photography in Japan that the daguerrian apparatus was unaccountably sent back and Ueno was not to see his purchase again until it was finally returned to

Nagasaki in 1848. Various new words were minted by Japanese scholars and lexicographers to describe the new technology, ranging from the direct transliterations into Japanese syllabic script such as *dageriyoteipu* to more elegant coinages employing Chinese characters, such as *ineikyô* ('Shadow-printing Mirror'). By the mid-1860s, however, the classical expression *shashin* (literally 'Copying Truth'), which had hitherto been used to describe a genre of Chinese-influenced painting, gained the widest currency, and to this day remains the Japanese word for photograph and photography.

The first Japanese photographers operated for the most part in a theoretical vacuum, and although many were able to acquire the necessary equipment and supplies, all of them had to struggle to apply the hard-won book knowledge they acquired through translations of Dutch textbooks to compensate for their lack of practical experience. Early researches into photography also required the support of those feudal lords who had a profound interest in Western Learning. Ueno's camera was acquired in 1848 by Shimazu Nariakira, lord of the powerful Satsuma domain, who duly commanded two of his clan scholars, Kawamoto Kômin and Matsuki Kôan, to experiment with the apparatus. Although Kawamoto studied enough Western writings on the daguerreotype process to publish the first Japanese photographic manual in 1854, success evaded the Satsuma scholars for many years, and it was only in 1857 that two other retainers of the clan, Ichiki Shirô and Ujuku Hikoemon, succeeded in taking a daguerreotype likeness of their lord, thus achieving the joint distinction of being the first Japanese to take a photograph. Other domains also conducted research into photography, such as Mito, Fukuoka and Kaga. Even after the arrival of foreign photographers in Japan after 1859, daimyo patronage was of great help to many Japanese photographers, the most famous being Ueno Hikoma, son of Toshinojô, who after learning the wet-collodion from a Western photographer visiting Nagasaki, persuaded the daimyo of the Tsu domain to sponsor his further photographic studies in Edo during 1860–61. In 1862 Ueno published the first guide in Japanese to the wet-collodion process and returned to Nagasaki to open the first commercial studio in the port.

It was through the agency of a Western photographer, however, that the first known photographs were taken in Japan. In 1854, Eliphalet Brown Jnr., a daguerriean from New York, arrived in Japan as part of Commodore Perry's mission to open up the country to foreign trade, and his contribution to the visual record of the mission was later incorporated in lithographic form into the official account published by order of the United States Congress. Less fortunate was Lieutenant Aleksandr Feodorovich Mozhaiskii, who also took daguerreotypes during a parallel Russian expedition to Japan, but whose work was lost before he even left Japan when his ship was destroyed in a tidal wave in 1855. Brown and Mozhaiskii were the first of a wave of foreign photographers who came to Japan over the following decade. Most were amateur photographers who were usually more preoccupied with the business which had brought them to Japan, whether as members of early diplomatic missions, officers serving on the naval vessels which provided them with transport and protection, merchants, or missionaries. Those who came to Japan before 1860 with the specific object of photographing the country and its people were in a minority, such as the American artist Edward Meyer Kern, who visited Japan as part of a hydrographic survey of the North Pacific undertaken by the United States Navy between 1853 and 1856, and the Swiss photographer Pierre Joseph Rossier, who visited Japan on at least two occasions in 1859 and 1860 to take photographs for the London photographic firm Negretti and Zambra.

The first professional photographer who actually took up residence in Japan was the American Orrin Eratus Freeman (1830–1866), who appears to have arrived in Yokohama early in 1860, followed by William Saunders in 1862 and Charles Parker and Felice Beato in 1863. Freeman, who had previously operated an ambrotype studio in Shangahi, taught photography to one Ukai Gyokusen, who later bought his teacher's camera and photographic equipment and went on to establish his own studio in Edo in 1861, thus becoming the first Japanese commercial photographer. Several Japanese photographers served an apprenticeship of sorts with foreign photographers. The most famous was perhaps Kusakabe Kimbei, who worked as an assistant to Felice Beato and possibly Baron von Stillfried as well. By 1881, Kusakabe was operating his own studio in Yokohama and quickly emerged as a major producer of photographs of landscapes and costume studies for the souvenir trade. This route was not always easy. Stillfried, who also taught Usui Shûsaburô and Futami Asakura, soon realized that he was training up future business rivals and sought to limit the extent of his instruction accordingly.

Others preferred to study abroad in order to master techniques not yet current in Japan. Okamoto Keizô, who later succeeded to the name of Suzuki Shinichi II, went to San Francisco in 1879 to study photographic retouching at the studio of Isaac West Taber, and after his return to Japan in 1880 enjoyed considerable success as the first practitioner of the technique. Ogawa Kazumasa spent the years 1882–83 in Boston intensively studying dry-plate photography, carbon printing and collotype printing, and by 1890 had established himself as the foremost photographic publisher in Japan.

Technologically, most of the nineteenth century was taken up with catching up with photographic developments in the West, and the five decades between the

Brady, Mathew and Alexander Gardner. Members of the First Japanese Mission to the United States. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

first documented use of a camera by a Japanese in 1848 and the election of Ogawa Kazumasa as a Fellow of the Royal Photographic Society in 1895 were characterized by the steady closing of the time lag between photographic innovation in the West and its adoption in Japan. Many of the first Japanese students of photography in the 1850s struggled to master the daguerreotype process at a time when it was being rendered obsolescent in Europe and the United States by the collodion wet plate process. As contact with foreign photographers became more frequent following the opening of selected Japanese ports for trade in 1859, up-to-date technical instruction became available and the wet-collodion process enjoyed widespread usage in Japan until the end of the nineteenth century. Even as late as 1896, ambrotypes, encased in distinctive paulownia wooden boxes, remained popular as a cheap method of securing a portrait, and its American equivalent, the tintype, was never adopted. Similarly, many photographers continued to use wet-collodion negatives even after dry-plates began to be imported into Japan in the early 1880s. Indeed, the arrival of the first dry-plates in Japan proved to be something of a false start. In March 1879, little over one year after the British inventor Joseph Swan had perfected his process of manufacturing pre-sensitized negatives, free samples from the Mawson and Swan works were being circulated among selected Japanese commercial photographers. The new technology did not catch on, and most photographers, after experimenting unsuccessfully with the unfamiliar plates, continued as before. The first successful application of the process in Japan—by a Japanese photographer at least—did not occur until May 1883, when the Tokyo photographer Esaki Reiji photographed the controlled explosion of a torpedo during a naval review in the Sumida River. This memorable image served as both an advertisement for Esaki's self-claimed status as a *hayatori shashinshi*, and an encouragement to other photographers. One immediate benefit to the Esaki studio was a sudden increase in demand from parents for portraits of their children, who could now be photographed with greater ease, and by his own estimate in the following three years Esaki produced over 3,000 negatives of infants aged under 15 months old. Nevertheless, Japanese adherence to the wet-collodion process remained widespread for the remainder of the 1880s, partly as a result of the irregular quality of imported dry plates and partly of habit, and for a time even those photographers who used the new plates made a habit of taking second exposures with wet-plates as a form of insurance policy. Eventually, in 1888, the photographic supplier Konishi began to import Marion dry-plates on a regular basis and their reliability ensured

the final acceptance of the dry-plate process in Japan. Several attempts were made by domestic manufacturers to produce dry plates, but by the end of the nineteenth century most Japanese photographers still preferred to use imported plates.

In other respects, Japanese photography made quick progress following the overthrow of the Tokugawa shogunate and the establishment of a new government in the name of the Meiji Emperor (the so-called 'Meiji Restoration') in 1868.

Several branches of the new Japanese government showed an interest in the medium of photography. The Imperial Household Office commissioned Uchida Kuichi in January 1872 to take the first official photographic portrait of the Emperor Meiji (the resulting portrait, which showed the Emperor in traditional Japanese court dress, was subsequently deemed inappropriate to the image of Japan as a modern country and a second sitting had to be arranged with Uchida in October 1873, this time with the Emperor wearing a Western-style uniform). Uchida's favored position with the imperial household was further confirmed in May 1872 when he was ordered to accompany the Emperor on his seven-week tour of Western Japan, and photograph the places visited by the imperial party. By the time of Uchida's untimely death in February 1875, the court's patronage of photography had declined and remained low-key for the remainder of the Meiji Era, and although later photographers such as Maruki Riyô received occasional commissions from the imperial household, none were able to repeat Uchida's success, and the Emperor Meiji was never officially photographed again.

The official patronage of photography was more conspicuous and consistent among those departments most closely connected with Japan's modernization during the nineteenth century. The *Kaitakushi*, or Hokkaidô Colonization Office, began employing photographers after 1871 to document the development of Japan's northernmost island, and the first to benefit from this government largesse were Tamoto Kenzô, who had opened a studio in the treaty port of Hakodate in 1866, and the Yokohama-based photographer Baron Raimund von Stillfried, whose portfolio of photographs taken in Hokkaidô in the fall of 1872 was included among the exhibits sent to Austria in the following year as part of Japan's official contribution to the Vienna International Exposition. The Kaitakushi continued to allocate a large part of its budget to photographic commissions until its affairs were wound up in 1882 following a financial scandal.

After a slow start, the Army Ministry also took a regular interest in photography. In 1874, the Tokyo photographers Matsuzaki Shinji and Kumagai Shin were permitted to accompany the army on its first overseas expedition to Taiwan, and in 1876, Yokoyama Matsusaburo was appointed lecturer in photography at the Military Academy in Tokyo. Initially, the army used photography mainly as an adjunct to map-making and the documentation of Japan's nineteenth century conflicts was entrusted instead to civilian photographers who had either been specifically contracted for the purpose, such as Ueno Hikoma and Tomishige Rihei during the Satsuma Rebellion of 1877, or who had volunteered for the task, as was the case with Matsuzaki and Kumagai during the Taiwan Expedition of 1874 and Count Kamei Koreaki at the outbreak of war with China in 1894. This latter conflict gave rise to a proposal within the General Staff for the creation of a dedicated unit of army photographers, and both the Sino-Japanese War (1894–95) and Russo-Japanese War (1904–05) were documented by a combination of an army photographic unit and teams of civilian photographers authorized by the General Staff.

Although officially supported documentary photography served largely to record Japan's present, the Ministry of Education showed itself to be just as concerned in recording the past. In 1872, Yokoyama Matsusaburô conducted a survey across western Japan, photographing temples and their treasures.

A significant step towards the creation of a photography community in Japan took place in June 1889 when the first Japanese photographic association, the Nihon Shashinkai ('Photographic Society of Japan') was established in Tokyo, with the *Shashin Shimpô* functioning as its official organ. Within four years, its membership had grown from its original 56 founding members to 171 professional and amateur photographers. In May 1893 the Society hosted the first international photographic exhibition in Japan. The exhibition, at which 296 art photographs by members of the London Camera Club were displayed, was organized by William K. Burton, a professor of sanitary engineering at the Imperial University in Tokyo, who was serving as the Society's secretary and was himself a member of the Club. The exhibition attracted numerous visitors, including the Empress Haruko, and had enormous impact, introducing both Japanese photographers and the Japanese public at large to the best amateur photographic work being produced in the West at that time, and some historians date the beginning of *geijutsu shashin*, the Japanese equivalent of Pictorialism, from this event. Despite its role in popularizing photography, the *Nihon Shashinkai* by no means monopolized the subsequent wave of amateur interest. In June 1893, disagreements within the *Nihon Shashinkai,* fueled by the excitement generated by the exhibition, led a trio of photographers consisting of Ogura Kenji, Aritô Kintarô and the flamboyant Kajima Seibei to establish a rival association, the *Dai Nihon Shashin Himpyôkai* ('Greater Japan Photographic Critique Society'). The organization held regular bimonthly meetings, at which

photographs were judged by secret ballot, and quickly established an extensive regional network and its own journal in June 1894. Nevertheless, the Society, which changed its name in May 1897 to the *Dai Nihon Shashin Kyôkai* (Greater Japan Photography Association), never quite lost its elitist tone, the social composition of its membership, which was dominated by members of the upper class as much as professional photographers, serves as a reminder that by the end of the nineteenth century photography was still not yet within the reach of ordinary Japanese. Both associations appear to have ceased their activities at the end of the 1890s, when their financial backer Kajima went bankrupt, although at the same time other amateur photographic associations were being established on a local level across Japan and its growing empire, and by 1902, photographers in Tokyo, Osaka, Kyoto, Kobe and even Taiwan had formed their own organizations.

It was the rise of the amateur photographer in the 1890s that gave permanence to the photographic journals that had begun springing up sporadically in Japan two decades before. Japan's first photographic journal, the elegantly named *Datsuei Yawa* ('Night Conversations Fleeing from the Shadows') was published in 1874 by the Tokyo-based photographer Kitaniwa Tsukuba but lasted for only three issues. It fell into limbo for six years until another Tokyo publisher took up the baton in April 1880 and reissued it under the new name of *Shashin Zasshi* ('Photographic Magazine'). Despite extending its circulation beyond the Tokyo area, the new journal lasted for only seven issues and ceased publication in 1881. In the following year, another Tokyo photographer, Futami Asakuma, established the *Shashin Shimpô* ('Photographic News'), which lasted for 18 issues and almost two years until it folded in July 1884. In February 1889, the title was resurrected by Ogawa Kazumasa and proved more lasting under his custodianship. By the fall of September 1896, no fewer than four photographic journals were in existence, including the *Shashin Shimpô* and the *Shashin Geppô* ('Monthly Photographic Journal'), which had been established in February 1894 by Konishi Rokuhei, a prominent photographic supplier (the present-day Konica). Both journals would continue publication until December 1940.

By 1900, Japanese photography had not only closed the technological gap with the West but had also established itself as part of Japan's modernisation. There is perhaps no better contemporary statement of where Japanese photography stood on the eve of the twentieth century than William K. Burton's assessment delivered to the readers of *The Practical Photographer* in September 1896:

'It is not too much to say that, till about eight years ago, the technical difficulties that the Japanese photographer had to contend against were so great, that his attention was taken up with these alone, and that he had no superfluous mind or energy left to grapple with the artistic side of the subject… It will probably not be generally granted that the photography of the Japanese of the present day is up to the level of the best Occidental photography, so far as artistic merit is concerned, but if the present rate of improvement be maintained, what is to be looked for twenty years hence, or it may be fifty, or even a hundred? I for one would not be surprised to see Japan excel all other countries in the matter of photography as an art.'

JENNINGS, WILLIAM NICHOLSON (1860–1946)

American photographer

William Nicholson Jennings, a Philadelphia commercial photographer, was born on 16 November 1860 in Yorkshire, England to wool merchants William Jennings and Sara Ann Palmer Nicholson. An aerial and progress photographer, an active member of the Franklin Institute, and one of the founders of the American Museum of Photography, Jennings took up photography as a hobby, using his camera as a scientific tool to capture the world's first picture of lightning on 2 September 1882. From 1885–1896 he worked as a Pennsylvania Railroad photographer, documenting construction sites and damaged infrastructure, including the wreckage

caused by the Johnstown Flood of 1889. In 1893 Jennings successfully shot the first four panoramic, aerial photographs of Philadelphia from a free floating balloon. In 1896 he assisted inventor and photographer, Frederick E. Ives, with the development of Kromskop color photography and opened a Kromskop sales studio in Philadelphia in 1899. After the failure of the business in the early 1900s, Jennings operated a commercial studio taking post card pictures and high-angle progress photographs of Philadelphia buildings. In the 1910s Jennings was appointed official photographer during World War I by the U.S. government to document military camps and railroad construction. Actively working as a photographer until retirement from his studio in 1936, Jennings died on 9 September 1946.

LINDA WISNIEWSKI

JEUFFRAIN, PAUL (1809–1896)

French photographer

One knows few things about Paul Jeuffrain, and the biographical material available to draw a clear portrait of him is very short.

Paul Jeuffrain, son of Augustin Jean Jeuffrain and of Marie Crémière, was born in Tours (France) on 5 March 1809. He was 9 years old when his family settled in Louviers. In 1818, Jeuffrain mad his début in the local textile industry. Indeed, the father immediately began to work as a cloth's manufacturer and mill owner for the Poitevin et Thévin factory, which took later, in 1828, the name of Viollet-Jeuffrain, and later on, in 1858, became Jeuffrain and Co. In 1829, Paul had not joined the family industry yet, as the military archives prove it, mentioning his presence in Paris as a proofreader. Though many sources allocate to him a career of naval officer, some others maintain on the contrary that he would have been exempted from military service for frailty of constitution. As Michel Nattier has noted, Jeuffrain has probably travelled for a while in the merchant navy. This is particularly interesting in that it reveals already the young man's taste for exotism and travelling, taste that has not failed afterwards, and was closely connected in his practising of photography.

But, in 1834, Paul Jeuffrain, aged 25, had come back to Louviers, as mentionned in the trade register, where he is marked as being a cloth manufacturer. Associated to his own brother Augustin and married to his cousin Aurélie Crélière, he took the family business over, which, quite flourishing, ensured a comfortable life for him.

One does not know much more about his professional or private life, because remarkably little information about this period has survived. On the other hand, he has passed on to posterity some splendid calotypes, realised during two journeys, one in Italy in 1852, the other in Algeria in 1856.

But how did he arrive to calotype? In spite of any certainty, it is possible however to make some assumptions, for instance in concern with the role played by his career in the textile industry. Because the fact of being part of this milieu, in full expansion, in full technical revolution, has for an evidence made him sensitive to the notions of progress, invention, to the world's unfolding industrialization, and particularly to the increasing part of machines and modern technical devices.The nascent photography was completely in such dynamics; during those first years, it was still especially of the concern of inventors keen on science and art, rich enough to engage in the long and expensive operations required by the photographic protocol. Jeuffrain is one of those, bourgeois half artist, half inventor, his comfortable social position seeming to have allowed him to venture to the pleasures and experimentations of the new born invention. New born indeed, since Jeuffrain's first photos date back to 1849, as revealed by the album conserved in Paris by the *Société française de photographie* (all the images, that is to say this album and the travel negatives had been given to the Société by Jeuffrain's son. The only genuine positives are those of the album), album he made all by himself, combining his own images with those of others great users of the new medium: prints from Hippolyte Bayard, among which some of Louviers dated 1851, proofs of a probable meeting between the two men before 1855; also prints from Roger Fenton, member of the Photographic Society (1853). This album, like those realized at the same period by Hippolyte Bayard or Victor Regnault, clearly attests the climate of emulation, of exchanges, of friendly and fruitful meetings between photographers. It is all the same difficult to understand the kind of relationships Jeuffrain might have had with others amateur calotypists before 1855, even if this album's existence tends to prove he had already met or been in touch with some of them, french and british (Fenton, who was a student in the painter Delaroche's studio between 1841 and 1843, by the side of Charles Nègre, Henri Le Secq and Gustave Le Gray, could have met Jeuffrain during his stay in Paris in winter 1851–1852). In 1852 he took his first travelling photographs, in Naples (his second "photographic journey," in Algeria, dates, as for it, from 1856), but he was not a member of the *Société Héliographique* at that time. It is only in 1855 that he became a member of the *Société française de photographie*, created on 15 november 1854 after the dissolution of the *Société héliographique*, and remained untill he died in 1896. However, he joined on the invitation of the new society itself, since it proposed him in 1855 becoming a founder member, which testifies that his works were known and appreciated in the closed circle of photography's

pionneers. Besides, while he was tooking photographs in Naples in 1852, others were practising elsewhere in Italy. Indeed, the Cafè Greco in Rome was since 1850 a place for meetings and exchanges between French, English and Italian calotypists. Maybe Jeuffrain had met some of them while travelling.

Jeuffrain's place in the history of primitive photography is difficult to understand since informations are rare, and one can only conjecture. He seems to have stayed in the background—his photos for instance have never been shown in the numerous exhibitions of the Société française de photographie—and in the same time, to have really shared the desires and research of the period, the dreams of improving and testing the possibilities of the new invention.

To take an active part in this history implied an experimental standpoint, standpoint that Jeuffrain seemed to have adopted from a technical point of view as well as iconographic or aesthetic. His various experiments of processes, on different papers, on glass, as his few publications concerning technical points prove well such an investment. But the aesthetic concerns appear to have got the upper hand, since he quickly chose the exclusive use of calotype. Paper gives images a finish close to drawing, a *sfumato* effect, which make photography a fine art object. As some of his contemporary calotypists, Jeuffrain seems to have been very early conscient of a specificity of the medium, and thus, of photographic images themselves. His calotypes from Italy and Algeria reveal a new approach of reality, a more analytic vision of the world, and in the same time, a taste for the picturesque, for compositions tinged with nostalgic poetry, where the slightness of light and the silence of desert spaces sometimes border on oddness. So has he photographed italian squares and Algerian streets without any human presence, dramatized by the chiaroscuro plays and the hazy halo peculiar to calotype. Jeuffrain's attitude fits in perfectly with a climate of craze for exotism, travelling, linked to a renewed interest in past and archeology.

He has otherwise taken some beautiful portraits, men and women, alone or in group. But above all what is perhaps the most striking in all these images, is the recurrence of a nearly spectral motif: many of them indeed record the trace of a movement—that of a body moving too fast for the long exposure of calotype, or of boats in a bay—imposing a ghostly dimension, which can not only be attributed to the hazards of the shot, but is rather the sign of a curiosity for a peculiar photographic effect, and a peculiar aesthetic.

Jeuffrain died in 1896, leaving his son caretaker of his posterity. As far as one can judge, all his production is contained in those few hundred photographs; as for the rest—private life or others works—it stays a complete mystery, the same which radiates from some of his images, as the sign or signature of a secret personnality.

Amélie Lavin

Biography

Paul Jeuffrain was born in Tours (France) on 5 March 1809. He might have been travelling for a while in the merchant navy, then in 1834, he came back to Louviers to work as a cloth manufacturer. Associated to his own brother Augustin, he took the direction of the cloth' family factory, "les Etablissements Jeuffrain." He married his cousin Aurélie Crémière in 1834, but she died a few month after the wedding. He married again twice, once with Elisa Alphonsine Lefort, then in 1856 with Victorine Anna Thenon. He began with photography around 1849, and made then two journeys in Italy and Algeria in 1852 and 1856, from which he took back some beautiful calotypes. Founding member of the *Société française de photographie*, created in 1854, he has never been part of the numerous exhibitions organized there. Nevertheless remained he a member of the society until his death in 1896, society which conserves all his calotypes and his *Album* since 1914.

JOCELYN, LADY FRANCES (1820–1880)

Aristocratic British woman photographer

Lady Frances Elizabeth Cowper was born in England in 1820, the youngest daughter of Earl and Lady Emelia Cowper. The Earl died in 1837 when Frances was 17 and two years later her mother married Viscount Palmerston who was to become Prime Minister of England. The Palmerston residences of Broadlands, Panshanger and Cambridge House became the setting for major social

and political gatherings that also served, as Lady Palmerston noted, "to amuse Fanny [Lady Frances]."

Queen Victoria took considerable interest in the Palmerston family and invited Lady Frances to be one of twelve young women to carry her wedding train in 1840. The following year Lady Frances herself was married to Viscount Jocelyn, the eldest son of the 3rd Earl of Roden, who had recently returned from military service in India and China. After their marriage, Viscountess Jocelyn continued to be associated with the Royal Court and was appointed an Extra Woman of the Bedchamber in 1842. Four years later the Jocelyns moved to Northern Ireland to Viscount Jocelyn's ancestral estate. They had six children before the Viscount contracted cholera in 1854 when stationed at the Tower of London and died. Following his death Viscountess Jocelyn and her children returned to England to live with her mother.

In 1858 Viscountess Jocelyn began to take photographs. It is possibly that she learnt the skill from Lord Dudley de Ros, a member of the Royal Court and amateur photographer who took portraits of the Royal Family and court circle, including Viscountess Jocelyn. Other photographers of her acquaintance included Dr Ernst Becker, who had instructed the Royal Family on photography in the 1850s, and Graham Vivian, a family friend who was a member of the Photographic Society and visited and photographed the Palmerstons in 1858. By 1861 Jocelyn had joined the Photographic Society of London and accompanied the Queen and Prince Albert to a view an exhibition there that same year. In 1862 she had developed enough confidence in her own work to submit several landscape photographs of the grounds of Broadlands to the International Exhibition, London where she received a honourable mention for "artistic effect." She continued her involvement with photographic associations until the late 1860s with one of her works included in a group Amateur Photographic Association album in 1867.

However, the main outlet for Jocelyn's talents was in the private not public arena. In common with other aristocratic amateur women photographers, such as Lady Milles and Lady Filmer, Jocelyn carefully assembled photographic albums with her own and commercially bought photographs. The impetus to create such albums may have come, at least in part, from the enthusiasm of Queen Victoria who had a well-known passion for assembling and viewing albums of photographs. A few of the aristocratic women of the Royal circle, Jocelyn included, extended this practice to include inventive photographic montages often incorporating watercolour and drawing. As the audience for these albums was presumably limited to friends and family considerable creative freedom existed when constructing and manipulating family and personal narratives. Their work also differs from mainstream nineteenth century practice in its lack of concern for the 'integrity' of the photographic image which is cut up and over-painted where desired and for their disruption of conventional notions of authorship with the frequent use of commercial photographs as the raw material for their own designs.

In the 1860s and 1870s, Jocelyn created at least six large photographic albums that operate at the nexus of creative expression, personal biography and social history. In one of her major albums (held by the National Gallery of Australia, Canberra), Jocelyn's arrangement of photographs of her family and their homes establishes the continuity and solidity of aristocratic family life. This view is established, in part, through the placement of photographic portraits of family members in hand drawn designs that emphasise permanence and interconnectedness—such as diamond and honeycomb shapes. Jocelyn also frequently includes flowers carefully selected for their symbolic language such as filial devotion and love.

While these portrait montages are largely assembled from commercial photographs, Jocelyn's albums also include her own photographs. The NGA album contains a discrete section titled, "Bygone Hours by the Viscountess Jocelyn," in which Jocelyn and her children pose on the terrace and enclosed courtyard of her house at St Leonards. There is little spontaneity about these images with the participants adopting carefully rehearsed postures as they read, embroider or spin wool. The sense of stasis in these domestic tableaux is reminiscent of the work of her contemporary, Viscountess Hawarden, who similarly created scenes within enclosed domestic spaces.

Jocelyn also created inventive and, at times, whimsical montages constructed from her own and others photographs. In one image she place photographs of babies and young children in a hand-drawn tree, complete with nests, thus playing on the notion of the family tree. Other album pages are more formal and show her inventive design sense with motifs including jewellery, Japanese screens, letters with photographic 'stamps,' and a stained glass window design comprising portraits of men in naval uniform and small head of women mimicking carved gargoyles. Often these album pages are only partially completed suggesting that the process of assembling albums was a lengthy and thoughtful one.

Writer Eugenia Parry Janis has noted "the psychological directness" of collage work produced by aristocratic women photographers and a number of Jocelyn's photographs appear to refer to her own life. In the 1870s her family was dogged by tragedy with all six of Jocelyn's children eventually dying of tuberculosis. A sense of personal vulnerability is apparent from one of her most intriguing collages, a hand-drawn archery

target in which Jocelyn has positioned herself as the "bulls-eye" surrounded but not hit by arrows.

By the mid 1870s, Jocelyn's interest in photography seems to have diminished and she spent much of this time travelling to various English and French seaside resorts with her children in search of health. However, all of her children were to die before Jocelyn's own death in Cannes, France on 24 March 1880.

ISOBEL CROMBIE

Biography

Viscountess Jocelyn (nee Cowper) was born in England in 1820. After the death of her father in 1837 her mother married Viscount Palmerston, one of Queen Victoria's closest advisers. Lady Frances was a bridesmaid at the Queen's wedding in 1840 and was appointed Extra Woman of the Bedchamber in 1842. Lady Frances married Viscount Jocelyn in 1841 and they moved to his family estate in Northern Ireland. They had six children before the Viscounts' death in 1854. Viscountess Jocelyn began to photograph in 1858. She became a member of the Photographic Society of London in 1861 and the Amateur Photographic Association in the 1860s. In 1862 she received an honourable mention for her landscape photographs from the International Exhibition, London. However the main arena for her photographic work was her private albums, where she placed her own and commercially produced photographs. Jocelyn frequently constructed montages of these photographs, hand decorating them with watercolour and drawings. She died in France in 1880.

JOCELYN, WILLIAM NASSAU (1832–92)

British amateur photographer

William Nassau Jocelyn took the first dateable photographs in Tokyo and the first wet plate collodian photographs in Japan. In 1857, Lord Elgin had been appointed to head a British mission to China. During a break in negotiations, Elgin headed over to Japan and spent most of August, 1858 concluding a Treaty with that country, before returning to China. Jocelyn, an amateur photographer and member of the British aristocracy, joined the Mission in Shanghai on July 28th, 1858, just three days before it left for Japan. His appointment was as assistant secretary and official photographer; he succeeded a Robert Morrison who had held the position since April 1857. Jocelyn took photographs of the Japanese Commissioners who had negotiated the Treaty in Edo (Tokyo) in August 1858. He also used the Government's photographic apparatus when the Mission returned to China. Around ten of Jocelyn's photos from the Mission have survived, seven of China and three of Japan. They can be found in the print room of the Victoria & Albert Museum, London. All are in poor condition with significant fading and/or defects. No research appears to have been done on Jocelyn's life and details are very sketchy.

TERRY BENNETT

JOHNSON, WALTER ROGERS (1794–1852)

Walter Rogers Johnson was Professor of Physics and Chemistry in the Medical College at the University of Pennsylvania when he returned to America from Europe having acquired a complete daguerreotype apparatus—probably from Giroux in Paris.

The newspaper *United States Gazette* carried a report of his acquisition on October 22, 1839, and he had begun experiments with the apparatus by early November, marking him as one of America's first daguerreotypists. Recent research suggests he may have successfully made portraits before the end of 1839. By January 1840 he was giving public lectures on the process in Philadelphia, illustrated with his own daguerreotypes of local landmarks. In the *United States* Gazette, on January 31, 1840, Johnson announced that he would exhibit "various samples of the art produced in this city [Philadelphia], including landscapes, interior views, statuary and objects in natural history." A fine whole plate daguerreotype by Johnson, from February 1840, survives in the Smithsonian Collection, showing a laterally reversed view of the Merchants' Exchange in the city, the construction of which had been completed only four years earlier.

Surprisingly, given his initial enthusiasm for the medium, Johnson appears to have abandoned photography completely before 1843, devoting the remainder of his life to his scientific interests.

He died in Philadelphia in 1852.

JOHN HANNAVY

JOHNSTON, FRANCES BENJAMIN (1864–1952)

In her Obituary in *Time* magazine in 1952, Frances Benjamin Johnston was remembered as a 'onetime news photographer who had an inside track to the White House because of her friendships with Presidents Harrison, McKinley, and Theodore Roosevelt… With a box-like camera given to her by George Eastman in 1887, she snapped such shots as McKinley on the eve of his assassination.' McKinley died in 1901 actually only 17 minutes after she had taken the photograph, and by that time Johnston, already widely recognised as an accomplished photographer, would have been using much more sophisticated equipment.

Born in Grafton, West Virginia, on 15th January 1864, she studied art in Paris in 1883 to 1884 before returning to America to continue her studies in Washington.

Her photographic output throughout the late 19th and early 20th centuries was wide ranging and embraced portraiture and documentary, architectural, and even subterranean photography in the caves of Kentucky.

An accomplished writer as well as a photographer, she produced many influential articles about architecture, photography, and photographers, over a career lasting more than fifty years. Amongst those, a series on the foremost women photographers of the period in America, published in the *Ladies Home Journal* in 1901–1902, included essays on Gertrude Käsebier, Eva Watson-Schultz, and others.

John Hannavy

JOHNSTON, JOHN DUDLEY (1868–1955)

John Dudley Johnston is remembered both for his influence on the sesssionist movement in Britain and as architect of the Royal Photographic Society collection. Revered during the first years of the 20th century for subtle depths of his gum platinum prints—such as the minimalist *Valley of the Dragon* (1909), Johnston was an influential member of the Linked Ring and associated with foremost photographers of the period in both the USA and Europe.
