Johnston was born on 23 April 1868 at 42 Arnold Street, Toxteth Park, Liverpool. He was the son of John Glynn Johnston, a general merchant and his wife Laura Dudley, by whose former surname he was known. Dudley Johnston was the eldest of six children. The family stayed briefly in central Liverpool before moving on to Seaforth and in 1877 to "Inglewood," Sandon Park, Wavertree—on the outskirts of Liverpool. Johnston left school in 1883 to become a company clerk in Liverpool and by 1901 he was established as a merchant in India Rubber with Messrs Heilbut, Symons & Co at 9 Rumford Street. He married Edith Maud Barker in 1897 and set up home at 76 Huskisson Street in central Liverpool, where he lived for 14 years. Before his marriage, Johnston, an able clarinet player, was very active in the Liverpool Orchestral Society and later played with the Halle orchestra. He was the Liverpool correspondent for *London Musical Courier* through which he developed many contacts in other parts of the country. He resigned as correspondent in 1897—much to the regret of the Editor. Johnston was becoming deeply interested in photography inspired particularly by a trip to Norway in 1893, which he recorded with a camera.

Already a giant of the northern photography movement before he moved to London, Johnston exhibited at the Northern Photographic Exhibition at the Walker Art Gallery in 1904. The first Northern Exhibition had been held in 1901 and subsequently exhibitions were held every three years in Liverpool, Manchester or Leeds. With its rotating venues, trade display and evening lantern lectures, the Northern was considered the most comprehensive of the pre-First World War exhibitions. It was to become a national beacon for pictorial photographers with exhibitors such as Horsley Hinton, Charles Job, Chas Inston, Alex Keighley, F.J. Mortimer and Frederick Evans and, latterly, Hoppe and Dührkoop.

Johnston became increasingly active in the Northern exhibitions and with the instigating institution, the Liverpool Amateur Photographic Association—one of the oldest photographic organisations in Britain. Johnston's own work was revered not only for its impressionistic technique and exploitation of innovative photographic process, but also for his vision in capturing the solid monumentality, civic pride and industry of the north. For example, in *Liverpool an Impression* (1911), a horse drawn carriage disappears into the fog at the side of the Royal Insurance Company's building—contemporarily considered the most important example of commercial architecture in Liverpool, while *Manchester—an Impression* (1906) reveals a sublime beauty in a canalised river closed in by waterside mills and scaffolding. At the tiem of the 1907 exhibition, Johnston was a member of the Exhibition Committee and Vice President of Liverpool Amateur Photographic Association, by 1911, he had risen to become President and also Chair of the Northern Exhibition Committee. He was elected to the Linked Ring in 1907 in which he rapidly became active and influential. As with music, he networked beyond the three cities of the Northern Exhibition and not just to London: George Good, photographer and author of *A History of the Liverpool Amateur Photographic Association* (1953) recalled how Johnston took a party of Liverpool photographers south to meet a group of Birmingham photographers and observed 'a memorable collection of photographic talent indeed'.

In 1911 Johnston made a career move to London. On his arrival, he immediately involved himself with

the Royal Photographic Society of which he had been a member since 1907. He participated actively in exhibitions and the organisation of the society—he was twice president from 1923–25 and 1929–31. Exhibition labels on the reverse of some of his prints in the RPS collection evidence the breadth of his work and also provide an itinerary of early 20th century exhibitions. His sensitively lit nudes and portraits of the late 1920s recall the meeting with his second wife Florence and a move from process to pattern. The role of pattern is particularly noticeable in *Snow Roofs* (1923) and in other snow scenes of the same period and, later, in scenes such as *Arabesque* (1940), a dappled, sunlight, open market made from an elevated viewpoint.

Of equal, if not greater importance, is Johnston's role in revolutionising the collecting policy of the RPS. He believed that it was vital to the study of photography to be aware of what had gone before. In 1923, as President of the RPS, he initiated the role of curator. By his own account, he built up the collection of photographs from about 100 prints to 1500 prints. The strengths of the collection are based on his personal contacts, his search for knowledge of the process of photography, his dedication to the society and his continued involvement in collecting. His vision for the collection was to dominate the next 50 years: his collecting policy and stewardship of the collection was continued into the 1970s by Florence Johnston.

After his retirement from business, Johnston embarked on a history of the RPS. *Story of the Royal Photographic Society* was not just an account of the Society, it was a history of photography—an exploration of the fifteen years before his own birth. Johnston continued to maintain a high profile through his ongoing enlargement and care of the RPS collection and because of his popular lectures—Switzerland, Bavaria and Italy, a lecture tour on the Grand Canyon- always illustrated by his own, widely admired series of slides.

Dudley Johnston died in Paddington, London in 1955.

JOLY DE LOTBINIÈRE, PIERRE-GUSTAVE GASPARD (1798–1865)

Pierre-Gustave Gaspard Joly de Lotbinière was a merchant, landowner, traveller, daguerreotypist; born Geneva, Switzerland, 1798; died, Paris, France, 1865. In 1828, Swiss-born Pierre-Gustave Gaspard Joly, a wine merchant from the Epernay region of France, married Julie-Christine Chartier, heiress of the seigneury of Lotbinière, on the south shore of the St. Lawrence, not far from Quebec City. In August 1839, he was in Paris about to embark on the Grand Tour, and like others was caught up in the "daguerreotypomania" that followed the disclosure of Daguerre's process. Equipped by Paris optician N.-M.P. Lerebours to take daguerreotypes on his travels, Joly de Lotbinière became the first to photograph the Parthenon in early October 1839. He then continued to Egypt where he travelled from Alexandria as far as the First Cataract in company with fellow traveller-daguerreotypists Horace Vernet, the Orientalist painter and Director of the French Academy in Rome, and Frédéric Goupil-Fesquet, his nephew. His journal and an annotated list of daguerreotypes taken on his travels indicates he took more than forty daguerreotypes in Egypt and another twenty-six in Jaffa, Jerusalem, Damascus, and Baalbek before returning to Paris by way of Rhodes and Turkey. His original plates are not known to have survived; however, five of his daguerreotype views of Greece, Egypt, and Syria were published as engravings in Lerebours' *Excursions daguerriennes* which appeared in instalments between 1840 and 1844; others were engraved for Hector Horeau's *Panorama d'Égypte et de Nubie*, published in Paris in 1841.

JOAN M. SCHWARTZ

JOLY, JOHN (1857–1933)

Inventor

John Joly was born in Bracknagh, Offaly, Ireland on 1 November 1857. His father John Plunket Joly was Rector of Clonsat (Offaly) and came from an influential family of French descent. His mother Julia, Comtesse de Lusi was born in Castlejordan, Meath. After his father's death in 1858 Joly's family moved to Dublin where his education was entrusted to a tutor, John Charles Mahon. His formal education began at the Protestant Rathmines School in 1872. He spent a year in France for health reasons prior to his entrance into Trinity College Dublin in 1876. He was conferred a Bachelor of Engineering in 1882. After graduation he was appointed to the College's Engineering Department where he was to gain a reputation as an inventor of scientific instruments.

In the late 1880s he became interested in the application of photography to the various sciences and to astronomy in particular. He was a member of the

Photographic Society of Ireland from 1890. Joly was commissioned by Arthur Rimbaud, Director, Dunsink Observatory, County Dublin, to design camera shutters which would overcome the difficulties associated with stellar photography. On 18 November 1891 his findings in this area were read to the foremost scientific research body in Ireland, the Royal Dublin Society, of which he was a Fellow and later President. His other early publications on photography included an examination of the effect of temperature upon the sensitiveness of photographic plates.

Yet it was within the field of colour photography that he was to produce his most innovative work. Joly's process followed on from earlier research undertaken by James Clerk Maxwell, André Louis Ducos du Hauron, Charles Cros and Frederick Ives. Maxwell and others had already experimented with additive processes based upon the principle that all the colours of light can be made by combining different proportions of the three primary colours. However, none of the previous solutions had resulted in a colour image which could be observed without the assistance of a viewing apparatus. Joly announced his process in the *Photographic Times* of 23 November 1894 and patented it in the same year. His method required only a single filter and was the first screen plate process to be made commercially available. Essentially, it involved the scoring of a series of fine coloured lines onto a single glass plate through which the image could then be taken. After development and reversal of the photographic plate it was viewed through a similar filter and resulted "in vivid colour with all the realism and relief conferred by colour and colour perspective."

Joly gave a more detailed account of his discovery in a paper read to the Royal Dublin Society on 26 June 1895. In it, he referred to Hermann W. Vogel's work on the sensitising of photographic emulsions to the green and yellow portions of the spectrum and to Ives's images which consisted of three superimposed colours. Lithographic reproductions of Joly's process appeared alongside the published paper. An additional note refers to the early work of du Hauron and the fact that in 1869 he had suggested the use of a lined screen similar to that used by Joly. The note infers that du Hauron's suggestions were not acted upon as his theory of colour was flawed. In 1894, Joly's process received coverage in the French periodical *Les Inventions nouvelles* and was noted and acknowledged by du Hauron in the *Photo-Revue Africaine* on 1 April and 15 May 1895. In the same year Joly was to exhibit his colour photographs at the Royal Dublin Society whilst a group of American businessmen established the *Natural Colour Photo Co.* in Great Brunswick Street, Dublin, with a view to producing the screens commercially.

Unfortunately Joly was to encounter legal difficulties as an American, James W. McDonough, of Chicago, had arrived upon a similar process which involved the coating of a plate with coloured particles of powdered glass. As a result of these legal problems Joly was required to visit the United States in September 1895 and again in March and July of 1896. McDonough whose process was patented in England in 1892 also manufactured his plates commercially. However, his method was expensive to produce and his firm the *International Color Photo Company* went bankrupt.

Likewise, Joly's process did not achieve the widespread acceptance which he had hoped for. He encountered technical difficulties which hampered commercial production of the screens and the failure to produce colour prints on paper limited their appeal. The first truly successful commercial colour process, the Autochrome, did not appear until 1907. It was invented by August and Louis Lumière in 1903 and was also a three colour additive process. The mosaic screen was made of minute grains of starch which had been dyed and strewn onto a plate. Its success was partly due to the commercial strategies employed by the brothers and the excellent results which were achieved by their factory produced plates.

Joly did not lose interest in photography and was to apply for over 40 photography related patents in Britain, the United States and France during the period 1868–1903. He was President of the Photographic Society of Ireland from 1902–1903. On 11 February 1896 he exhibited his X-ray photographs, the first such taken in Ireland, to the Dublin University Experimental Association. This interest was the foundation of his work on radiation. In 1897 he was appointed Professor of Geology and Mineralogy in Trinity College, Dublin a post which he was to hold for 36 years. In 1914 he developed a method of radium therapy which was subsequently used for cancer treatment around the world. He continued to publish widely in the fields of botany, mineralogy, geology and experimental physics. He also worked to improve conditions for the students to whom he gave weekly lantern slide shows until his death on 8 December 1933.

The National Library of Ireland holds over half of the extant Joly slides in its Photographic Archive. Many of the 306 slides depict botanical specimens but other subjects include landscapes, printed advertisements and portraits. Joly material is also held by the Science Museum, London; the Physics Department, Trinity College, Dublin and the Kodak Museum, Harrow, London.

ORLA FITZPATRICK

Biography

Joly the scientist, educator and photographer was born in Bracknagh, County Offaly, Ireland in 1857. His father John Plunket Joly, Rector of Clonsat (Offaly) came from

an influential family of French origins whilst his mother Julia, Comtesse de Lusi was born in Castlejordan, Meath of German extraction. His relations included the Royal Astronomer, Charles Jasper Joly and Jasper Robert Joly, a founder of the National Library of Ireland. He was educated in Trinity College, Dublin from 1876 to 1882 where he was to remain as a lecturer, professor and fellow for the rest of his life. He became interested in the application of photography to the various sciences and to astronomy in particular in the late 1880s. However, he was to make his greatest contribution to the field of colour photography. His additive process which was patented in 1894 was the first successful method of producing colour from a single plate. Although his method was supplanted by the Lumière Brothers Autochrome process he was to retain an interest in photography. He continued to publish widely in the fields of botany, mineralogy, geology and experimental physics making a considerable contribution to the field of radiation treatment. He died in Dublin on 8 December 1933 and is buried in Mount Jerome Cemetery, Dublin.

JONES, CALVERT RICHARD (1804–1877)

British painter and photographer

Calvert Richard Jones was born in Swansea, South Wales on 4 December 1802 the eldest of five children. He had two brothers and two sisters. His father, also named Calvert Richard Jones, and mother, Prudence, lived at Veranda, a house in Singleton Park, Swansea. About 1813 the family moved to the nearby Heathfield House. As part of the landed gentry of South Wales, Jones's father was active in civic affairs. The young Jones was educated at Oriel College, Oxford where he gained a first class degree in mathematics in 1823. While at Oxford he became a close friend of Christopher (Kit) Rice Mansel Talbot, first cousin of William Henry Fox Talbot. In 1824 Jones and Kit travelled to the Mediterranean to purchase works of art. In 1829 Jones took holy orders to take up position as rector of Loughor, a small town near Penllergaer, Wales and as lay rector of St Mary's Swansea. As a rector he performed the marriage ceremony of his friend Kit and Lady Charlotte Butler in 1835. Jones abandoned his ecclesiastical profession at the time of his first marriage on 25 July 1837 to Anne Harriet who bore their only child, Christina Henrietta Victoria Games.

Jones became a talented musician as well as a skilled draughtsman and painter in watercolour and oils. It is believed that the artist Samuel Prout gave him instruction and that he was acquainted with the marine painters John Wichelo and George Chambers and members of the Old Watercolour Society. Jones' drawings and paintings dating from the 1830s show landscapes and figures but he favoured marine subjects made around Swansea, especially ships beached or in dry harbour. The controlled and precise nature of these works suggests the use of an optical drawing aid such as a *camera lucida* or *camera obscura* though there is no evidence to prove this. However, it is clear that Jones later applied to photography the artistic methods of composition, and some of the same subject matter, that he had dealt with as a draftsman.

In February 1839 Jones learned of the photogenic drawing and calotype process through Fox Talbot's correspondence with his cousin Emma and her husband John Dillwyn Llewelynwho were friends and neighbours of Jones in South Wales. Writing to Talbot, his cousin Charlotte Traherne noted, "Mr Calvert Jones is quite wild about it and I dare say by this time is making experiments in Swansea himself." (Buckman, 21). Notwithstanding his enthusiasm for Talbot's discovery, Jones was also quick to respond to the announcement of the daguerreotype process that he also learned between 1840 and 1841. The only known example by him is a fine view of Margam castle (1841), built in 1830 by Kit Talbot (National Library of Wales). However, Jones was keen to use calotypes on his travels since the paper used was lighter than the copper daguerreotype plates and easier to prepare in advance. Talbot's patent had become available in February 1841 and by May Jones had written to Talbot wanting details. By June, Jones was practising it Italy but with limited success due to technical difficulties.

Sometime between 1841 and 1843 Jones met and photographed in Paris with Hippolyte Bayard who had independently discovered a method of forming a positive image on paper (through Jones, Bayard and Talbot were eventually introduced to each other and their respective pioneering processes). Jones persevered independently with Talbot's process until 1845 when he renewed regular correspondence with him in which Jones asked for tuition. Talbot responded by asking him on a photographic excursion to York. Jones followed up with a trip just outside London making views of Hampton Court taken on his own. The same year, he was also invited to Talbot's Reading Establishment. With renewed enthusiasm and improved technical expertise he planned an extensive photographic tour of the Mediterranean in the company of Kit Talbot and Kit's ailing wife, Lady Charlotte. Talbot hoped to gain a stock of foreign views through Jones's excursion. Paper was prepared for him at the Reading Establishment. In November 1845 he travelled to France and Malta where he experienced difficulty in obtaining essential photographic supplies locally and on order from Britain. While in Malta he was visited by the Reverend George Bridges whom he instructed in the calotype process. The trip was suddenly disrupted by the death of Lady Charlotte. However, Jones continued in 1846 to Sicily, Naples, Pompeii, Rome and Florence, returning to Britain by early June with numerous negatives.

Jones was by this time encountering financial difficulty and was anxious to sell his new negatives to Talbot. Many of his prints were made available through Talbot's Reading Establishment. However, by 1846 the venture was becoming unprofitable. Impressed by Jones's skills, Talbot asked him to manage premises in London in the hope of making a new start in a more prominent location. Jones refused but the business was eventually taken on by Talbot's assistant Nicolaas Henneman to become the Regent Street Studios. Talbot and Jones remained on good terms and his prints continued to be sold at Regent Street. Despite his hopes—and Talbot's endorsement of his work—none of Jones's pictures appeared in *The Pencil of Nature*. He continued to make photographs while travelling and views survive from France, Belgium, Italy and Ireland and in numerous British locations especially Ilfracombe, Bath, Bristol, Cardiff and Swansea.

Jones's interest in the technical advancement of calotype photography is evidenced in his correspondence with Talbot that shows how the process was refined through Jones's observations. Jones's prints reveal his experimentation with varnishing (to prevent fading), retouching and hand colouring. He was also one of the first photographers to make use of the panoramic format or 'joiners' and 'double or treble views' as he called them. In 1853 he presented a paper *On a Binocular Camera* (*Journal of the Photographic Society*, Volume 1, 1854, pp. 60-61) to the Photographic Society of London of which he was one of the first members. By the early 1850s, the calotype had been largely superseded by the introduction of glass negatives and albumen prints. Jones's last known correspondence with Talbot is from 1853.

After his father's death in 1847 Jones had gained financial independence, took ownership of Heathfield House and become involved in related business affairs and local politics largely to the exclusion of photography. He also took up a household in Brussels where his wife died in 1856. He is not known to have made any photographs after that time though he continued to paint. Jones' second marriage was to Portia Jane Smith in 1858. They had two daughters. Thereafter the family lived at Bath with frequent visits to the continent. Jones' first daughter died on 29 June 1877 shortly before her father who died at Lansdown Crescent, Bath on 7 November 1877. He was buried in Swansea at St. Mary's church.

Calvert Jones's important contribution to the development of photography is now being realised after many years of neglect following his death. He was one of the few Britons to have produced a substantial body of calotypes in Britain and abroad. His marine studies were made at a time of major transition in shipping from sail to steam and are of significant historic worth. Similar historical value can be placed upon his variety of architectural studies taken from his preferred oblique angle or as a detailed partial view. His figure studies within architectural settings and environmental portraits are unique to Jones as a photographer during the period in which he was working (and it may be noted that Jones himself likely appears in many of his own photographs). However, his most significant contribution to the early development of photography lay in his ability to fuse technical skill with artistic training, intentions and results. Jones revealed his understanding of both the simplicity and challenge of photography as an artistic medium, when he wrote to Talbot: "The best artists, to whom I have shown specimens, have been perfectly enchanted, especially with details and foregrounds and as nature is infinite, so is the supply which I could furnish: the great point being to select the proper subjects from a proper position." (Letter to W.H.F Talbot, June 9, 1846, quoted in Buckman, 29).

Martin Barnes

Biography

Calvert Richard Jones was born in Swansea, South Wales on 4 December 1802, the eldest of five children. The family were part of the landed gentry of the area. The young Jones was attended Oriel College, Oxford

where he gained a first class degree in mathematics in 1823. In 1829 he took holy orders to take up positions as a rector in Wales. He abandoned his ecclesiastical profession at the time of his first marriage in 1837 to Anne Harriet who bore their only child. Jones became a skilled draughtsman and painter in watercolour and oils. In 1839 he learned of the calotype process through Fox Talbot's correspondence with his relatives who were friends and neighbours of Jones in South Wales. Between 1840 and 1841 he also learned the daguerreotype process. However, Jones extensively used the calotype on his travels from 1841 to 1845 photographing locally in Wales and other parts of Britain and in Italy, France, Belgium and Malta. He corresponded regularly with Talbot who sold Jones's prints through his Reading Establishment. Jones took ownership of the family estates after his father's death in 1847 and became involved in business and local affairs largely to the exclusion of photography. He also took up a household in Brussels where his wife died in 1856. He is not known to have made any photographs after that time. Jones's second marriage was to Portia Jane Smith in 1858. They had two daughters. Thereafter, the family lived at Bath with frequent visits to the continent. Jones's first daughter died on 29 June 1877 shortly before her father who died at Lansdown Crescent, Bath on 7 November 1877. He was buried in Swansea at St. Mary's church.

JONES, GEORGE FOWLER (1819–1905)
English photographer and architect

Being both an architect and a photographer is not uncommon but Fowler Jones remains exceptional and he notably encompasses every process from paper, glass and nitrate between the 1840s and 1900.

Born in Aberdeen and trained under William Wilkins and Sydney Smirke he practised in York from 1846: his views of the city were among the first but he continued another 50 years [using the ceroline paper negative process] frequently revisiting Scotland.

2100 well documented negatives at the National Media Museum cover domestic and ecclesiastic structures across northern England, Scotland and Ireland. His amateur eye is professionally informed by an architectural vision so his work is distinctive compared with commercial, picturesque or quick progress work. He unusually includes new as well as old buildings with singular well documented devotion—yet his only exhibition was posthumous. Neither did he publish yet his son did produce a series of drawings of York clearly deriving from photographic originals. Architectural commissions and views in Ireland prove he was active there as early as 1845 so his travels need investigation.

English Victorian architect-photographers usually fall into the amateur or dilettante categories and by the 1870s most architects utilized professional architectural photographers like Bedford Lemere so Fowler Jones stands outside the norm.

Ian Leith

JONES, HENRY CHAPMAN (1854–1932)
English chemist and author

The scientist Henry Chapman Jones was engaged in wide-ranging studies concerned with the chemistry of photography, and for many years was a regular contributor of informed scientific opinion on the emerging study of the workings of the photographic process.

He was born in London and later studied at the Royal School of Mines. In 1879, he was elected a Fellow of the Royal College of Chemistry.

Amongst his many contributions to the photographic press was a memorial lecture delivered to the Royal Photographic Society in 1920 on the work of Sir William de Wiveleslie Abney, whom he had known during his lifetime.

He was in regular correspondence with Hurter and

Driffield throughout the period of their important research into the understanding of the relationships between sensitivity, exposure and development.

Of significance is an article published in *Photography* in 1890, disputing several assertions made by H&D in their 1890 paper. This led to a heated debate with Driffield, culminating in a rift between the two men, and the publication in *The Photographic Journal* of Jones's paper 'Density ratios as affected by development,' which sought to disprove a central canon of H&D's work.

An Introduction to the Science & Practice of Photography by Henry Chapman Jones was published by Iliffe & Sons in 1888, and had reach a third edition by 1900.

JOHN HANNAVY

JUHL, ERNST (1850–1915)
Collector and curator

Ernst Wilhelm Juhl, born on December 10, 1850, one of five children, in Hamburg, Germany was to have a significant influence as collector and supporter of experiments in photography in the late nineteenth and early twentieth centuries. Juhl attended high school in Hamburg and then went on to study engineering at the Technische Hochschule in Hannover. A sketchbook with technical drawings from those student years is in the collection of the Hamburg Museum für Kunst and Gewerbe.

Following his studies, Juhl returned to Hamburg and tried without too much success to found two companies. With independent income, however, Juhl was able to marry Johanna Julie Auguste Jacoby, (Henny), the grandniece of the composer Richard Wagner. The couple had three children, a son Ernst Carl, and two daughters, Hertha and Isle.

Being well-educated, Juhl spoke several languages, enjoyed traveling and entertaining a variety of people at his home. A number of artists came to gatherings at the Juhl home, and Juhl began collecting paintings and drawings from Hamburg artists who were experimenting in modernist styles. Among those works he collected early were those of Ernst Eitner and Arthur Illies.

From the late 1890s onward, Juhl expanded his personal library to include a number of valuable art books catalogues, and portfolios. Of particular interest was a 1903 portfolio, "*Heliogravuren nach Gummidrucken von Mitgliedern der Gesellschaft*." Unfortunately many of Juhl's books and graphic works were destroyed during World War II when a bomb hit Juhl's son's house.

Through Juhl's influence and interests, Hamburg became one of the most important cities in Europe to foster the growth and development of photography. It is ironic that Juhl took very few photographs himself, but felt the medium to be a powerful and significant one for the nineteenth and twentieth centuries. He promoted the founding of the "Amateurphotographen-Vereins" and then the "Gesellschaft zur Förderung der Amateur-Photographie" (Society for the Promotion of the Art Photography).

From 1893 to 1903 with the Society for the Promotion of Art Photography, Juhl organized ten international-photographic exhibitions at the Hamburg Kunsthalle. These exhibits honored photography as an art, and had a strong influence on the photography of the Art Nouveau or *Jugendstil* period.

In 1903 the tenth, and last Annual International Exhibition of Art Photography at the Hamburg Kunsthalle, made Hamburg a focal point for experiments in Jugendstil photography. Juhl, as President of the Art Association and the Society for the Promotion of Art Photography, invited amateur and professional photographers from throughout the globe. Among them was the well-known professional photographer Nicola Perscheid from Leipzig. (Perscheid moved to Berlin in 1965.) Perscheid exhibited two large-scale allegorical wall images, entitled "Mower" and "Shepherd," as well as eight portraits.The large scale portraits are still preserved in Dresden.) Among the portraits were those such as *Portraits of His Majesty the Emperor in Hunting Dress, H.M. King George of Saxony* and *Professor Max Klinger.* (Max Klinger had recently completed the large-scale sculpture of a Zeus-like Beethoven for the opening of the Vienna Secession building in 1902.)

Not only did Juhl help organize significant art and photographic exhibitions, but he also served as a juror or commissioner for various exhibits in other major European cities: in Amsterdam (1895), Haarlem (1896), Berlin (1896), Oxford (1901), Turin (1902), Lille (1903), and Dresden (1909). He was also made an honorable member at a number of the new emerging photography clubs that sponsored photography as a valid art from—i.e., The Photo Club of Paris, the Camera Club of Vienna, and the Belgian Photography Association.

Further, Juhl, as a well respected Hamburg citizen, was able to encourage museums and private individuals to collect contemporary photography. Juhl also exerted influence by writing various articles on the new photography and serving as art director of the *Photographische Rundschau*, a position which he had to give up in 1902, because he had so enthusiastically supported the new Impressionist work of the young photographer, Edward Steichen, whose photographs had begun to look much like paintings. For some, who expected, and wished photography to retain its documentary status, Juhl's attitude and support for such experiments, was inappropriate and unacceptable.

Juhl's artist judgment, however, was largely respected and in 1908 he was commissioned to direct the organiza-

tion and planning of a "State Photographic Collection" by the Senate of Hamburg. Many of the pictures for the collection were taken by Minya Diéz-Dührkoop, the daughter of the well-known photographer, Rudolph Dührkoop (1848–1918), and Anton Joachim Christian Bruhn, who was initially a carpenter but made photography his primary profession about 1900. Bruhn's photographs of Hamburg are strong atmospheric images, many of which depict the working class of a major port city. From 1908 to 1912 over one thousand 18x24 cm. photographs were taken under Juhl's direction.

Ninety of these were put together in a portfolio in 1912. The mayor of Hamburg at the time, Dr. Johann Heinrich Burchard, was also very supportive of this project. Burchard unfortunately died a month before the project's completion. The bound portfolio, however, was dedicated to Burchard's memory. The collection was titled, "Ernst Juhl, Hamburg and the Hamburg Landscape," photographed by the Commission of the Free and Hanseatic City of Hamburg. Copies were made of the portfolio in two different editions, one bound in parchment, the other bound in a half-linen binding. Copies were for sale and used as gifts for Hamburg citizens who contributed special services to the city. The photographs taken for this project, in general, emphasized the pictorial and artistic, rather than pure documentary qualities.

Juhl's own private photography collection began in earnest, probably about 1893. His collection began to particularly expand in 1899 after he purchased a number of calotypes from James Craig Arman and work from David Octavius Hill, Robert Adamson, and Julia Margaret Cameron. A special exhibit of Juhl's collection was held in Berlin from May 8-June 30, 1910 at the Kunstgewerbe Museum. Juhl's collection, now in Hamburg's *Museum für Kunst and Gewerbe,* and Berlin contains examples of quality work from photographers working throughout the world at the turn of the century. Major names, such as Stieglitz, Steichen, Käsebier, Hofmeister, Kühn, etc. who were experimenting with various photographic techniques and content imagery, fighting for the role of photography as a significant art form, are to be seen in the collection. Due to financial difficulties for Juhl's widow, Henny, the collection was sold after Juhl's death.

Ernst Juhl died on August 16, 1915. In a commemorative statement, Dr. Willi Warstatt wrote, "Er war seiner der bedeutendesten Freunde und Forderer der Kunstlerischen Photographie, und sein Tod wird nicht nur in Deutschland, sondern auch über die Grenzen unseres Vaterlandes hinaus Anteilnahme und Trauer erregen." ("He was one of the most meaningful friends and supporters of art photography, and his death will evoke sympathy and grief not only in Germany, but far past the borders of our fatherland.")—Quoted in Rudiger Joppien, *Eine Schöne und auf dem Kontinent wohl einzige Sammlung*; *Die Sammlung Ernst Juhl* (Hanburg, Museum für Kunst und Gewerbe, 1989, 21.)

KATHERINE HOFFMAN

Biography

Ernst Juhl was born on December 10, 1850, one of five children in Hamburg, Germany. He attended the Gymnasium in Hamburg and the Technische Hochschule in Hannover, studying engineering. His attempts to work in business were somewhat unsuccessful, and following marriage to Johanna Julie Auguste Jacoby (Henny) and starting a family, Juhl became much more interested in the arts and photography. From 1893–1903 he, with the Society for the Promotion of Art Photography, which he had started, organized ten international art photography exhibitions at the Hamburg Kunsthalle. In 1902 he was forced to give up the art direction of the "Photographische Rundschau." From 1908–1912 Juhl directed the planning and organization of a State Photographic Collection by the Senate of Hamburg. He died on August 16, 1915.

JÚNIOR, CHRISTIANO (1832–1902)

José Christiano de Freitas Henriques Júnior was born in Portugal, in the small island of Flores, Azores archipelago, in 1832. He is known for his work in Brazil, Argentina and other South American countries. Nothing is known about his first years in Portugal where he remains unknown, he is not even mentioned in the only *Portuguese History of Photography*, written by a fellow Azorean. Even on his small island, his memory seems to be lost. Following the path of many of his fellow countrymen, he migrated to Brazil in 1855. His photographic activities started in Maceio, northeast Brazil, in the early 1860's. He went to Rio de Janeiro in 1863, where as a partner of several photographic studios, he

made some of his best known work: The *carte-de-visite* of negro slaves. These were sold as a souvenir mainly to the visiting or returning Europeans. These were a complement of a successful business as a portrait photographer. His next step led him to establish his business in Mercedes, Uruguay, and in 1867 in Buenos Aires. At that time he managed studios in three South American countries. In his Buenos Aires studio in Florida Street of Buenos Aires he photographed landowners, politicians, diplomats, the core of the Argentinean society, including the presidents: Pelegrini; Mitre, Sarmiento. In the 1870s he established a studio run by his son, José Virginio Freitas Henriques for photographing children, a difficult task in the wet collodium time. He earned a gold medal in the Cordoba National exhibition in 1871. In Argentina, as in Brazil he completed his successful portrait work with photographs of the growing city of Buenos Aires, the local costumes and other Argentinean cities. His children's studio was destroyed by a fire in 1875. He sold his studio to Witcomb in 1878, and a year latter started touring Argentina publishing photographic albums of Argentinean provinces. He retired from his photographic activity in 1883. He died in Asunción Paraguay in 1902.

K

KARELIN, ANDREY OSIPOVICH (1837–1906)

Professional photographer, artist

Andrey Osipovich Karelin was born in 1837 in the Tambov region. He was the illegitimate child of a peasant woman and a landlord. During his childhood Karelin demonstrated an inclination for painting, and at the age of ten wanted to be a master of iconic painting. The local landlord recognized his talent and in 1857, sent him to St. Petersburg Academy of Art. At the Academy, he studied with future famous artists such as I. Kramskoy, K. Makovsky and others. In the course of his studying, Karelin received two silver medals for his works.

Karelin began as a retoucher in a photographic studio and later chose to experiment with photography. Upon graduating the Academy in 1864 and receiving the qualification of an "independent artist," Karelin left St. Petersburg. In the summer he went to Nizhny Novgorod's fair and chose to stay there to work in the studio of M. Nastjukov, one of the first photo-chronographer in the Volga area.

In 1869 Karelin opened a studio of his own in Nizhny Novgorod. The photographer made portraits and multi-figured genre scenes. At first he used wet collodion, but then switched to bromgelatine plates with dimensions of 50 × 60 cm. The more perfect optical shape of the lens allowed him to achieve considerable depth of focus in his multi-figured compositions. The decisive factor affecting the scene was the light and the layout of his photos which were derived from the laws of academic painting that he studied in the Academy of Arts.

In 1870 the gentlefolks' leader of Nizhny Novgorod requested that Karelin and the well-known Russian landscape painter I. Shishkin create an album comprised of images within Nizhny Novgorod, its neighborhood, and photos of the nationalities inhabiting the region. The prints were water-colored by Shishkin and Karelin themselves. The exemplary album was presented to the Emperor Alexander II.

From 1870 to 1880, Karelin created a most interesting "Art Album of Photos from Life," which contained his studio genre pictures. The photographer photographed idyllic family life where everyone in his pictures were preoccupied with something appropriate. Some were depicted playing musical instruments while others read. Karelin was in constant search for a more effective means of expression. He experimented with sitters, costumes, and worked on composition by taking several pictures of the same scene. His primary concern in arranging the scene was to make all the elements of the composition interactive. Karelin loved to use windows as the background for his photos, thus demonstrating his mastery in lighting, making the sitters' features and the photographs' details visible through exemplifying the light and shadow of the photograph. Karelin experimented with the role of property by photographing unique objects from everyday life that he had in his varied collection, which he had been gathering for quite a while.

All the works in the album were in accordance with the laws of academic painting. Even the scenes donated to charity bore no pathos of exposure of social inequity and characteristics of injustice, which were often found in the works by peredvizhniks. Karelin tried to make photo-images less documentary by employing the method suggested by Russian photographer A. Denier. Karelin made a wide use of this technique especially in the works of considerable size, thus obtaining a soft image without needing to retouch it. M. Dmitriev, a photographer, wrote of Karelin's works: "He was the first to show how to photo groups of sitters in a studio so as to fix marvelous effects of sunlight and make the poses of sitters dainty and noble. His works were always

Karelin, Andrey Osipovich.
Conversation in the Salon.
From the Art Album of Photos from Life 1870–1880s. Private Collection: Alexei Loginov.

marked by high artistry and more to it by elaborate and subtle technical efficiency." In 1876 Karelin was given the honorary title of photographer of the Emperor's Academy of Arts. In the 1870s he worked the Nizhny Novgorod fair from his studio. Karelin successfully exhibited his works at photo-exhibitions at home and abroad. In 1873, he took part in the sixth International exhibition of pictorial photography in Vena, and in 1876 he won the silver medal at a Special exhibition of the French photography society in Paris. He also won a bronze medal at the centennial Exhibition held in Philadelphia in 1876 to mark the centenary of the foundation of the United States of America. The photograhs that he exhibited at the Edinburgh Photographic Society's Exhibition in 1876 and 1877 were very well received, and Karelin was awarded a gold medal and a diploma. In 1878 Karelin became a member of the French national academy of arts and was given a diploma from the French photography society and a gold medal at the eighth World exhibition in Paris.

Even though Karelin was very successful with photography, he never stopped painting. For more then 30 years he worked as the head and teacher of a drawing and painting school that, since pedagogy was of great importance to Karelin, gave free lessons for all students. The school had 30 to 40 students of all ages. In 1886 he, along with other local artists, organized a provincial art exhibition in Nizhny Novgorod. Some of his students such as M. Dmitriev, S. Solovjev and his son A. Karelin later became famous. Karelin's activities were not just confined to Nizhny Novgorod. In fact, he created portraits for and was friendly with people from all over

Russia. He was acquainted with scientists, musicians, writers, and artists such as D. Mendeleev, I. Kramskoy, I. Repin, and many more.

In 1886 Karelin issued his album "Views of Nizhny Novgorod." In this ablum he returned to landscape photography. The most remarkable of them were his panoramic views of the city and the Volga River. These photos were done by means of a landscape objective from the top of the highest bank of the river. The depth of space is, as a rule, highlighted by placing something in the foreground, the effect of which is strengthened by an aerial perspective. The album also comprised landscapes of city streets, monuments of architecture, separate buildings and fragments of buildings. And again Karelin built the composition of these photographs in accordance to the norms and rules of academic painting. His choice of positioning is the reason why his photographs came out so elaborately.

Karelin's creative works were widely acknowledged not only by specialists in photography, but also by the intelligentsia. His works immensely influenced the process of development of photography in Russia. In 1895 Karelin became a fellow member of the Russian photography society in Moscow, and in 1896 he became its honored member. In 1897 he was elected as a fellow member of the Emperor society of natural science, anthropology and ethnography. Finally, in 1903 at an International photography exhibition in St. Petersburg, his last ever, he won a silver medal.

In the course of his life, Karelin never stopped his altruistic activities. He died in 1906 in Nizhny Novgorod. His obituary ran as follows: "He was the first to prove by all his numerous photo sketches that art and photography are very closely connected. He proved that the fantasy of a photo-artist, his dainty taste in choosing the plot for his works might be realized through photography."

In the USSR the photo report became the main trend of the official photography, causing Karelin's work to be forgotten. Many contemporary photographers, including the commercial photographers, are more often using and developing Karelin's methods to achieve the maximum expression of the image by arranging the composition and the artificial lighting.

ALEXEI LOGINOV

Biography

Andrey Osipovich Karelin was born on July 4, 1837, in the village of Selezny in the Tambov region. He studied at the St. Petersburg Academy of Arts from 1857 to 1864. In 1869 he opened his studio in Nizhny Novgorod. He made photo–portraits and views of the city. In 1870 together with landscape painter Shishkin he created the album "Nizhny Novgorod." From 1870 to 1880 he created his "Art Album of Photos from Life" which comprised studio genre scenes of idyllic family life. He took part in and won prizes at numerous exhibitions. He taught painting in Nizhny Novgorod for everyone and he took an active part in the Artistic culture of the city. He created a large gallery of portraits of Russian scientists, writers, musicians, artists and public figures. In 1886 he issued the album "Views of Nizhny Novgorod," and thus returned to landscape photography. Karelin died in 1906 in Nizhny Novgorod.

KARGOPOULO, BASILE (VASILI) (1826–1886)

Ottoman Greek photographer

Basile Kargopoulo opened his studio on Grand' Rue de Péra in the Ottoman capital Istanbul in 1850, and opened a second studio in partnership with E. Foscolo in the city of Edirne, then a major army base.

Kargopoulo was particularly renowned for his panoramas of Istanbul, scenes of the city and the Bosphorus, and photographs of royal palaces. He kept a large wardrobe of costumes in his studio for young men who wanted to dress up for their photographs. He became well known for his series of Istanbul types, including fishermen, greengrocers, and street vendors, such as *simit* (bagel) and sherbet sellers, sold as mounted 6 × 9 cm prints. Today these photographs are important documents recording life in 19th century Istanbul.

Kargopoulo was appointed royal photographer to Sultan Abdulmecid (1823–1861, r. 1839–1861), and was private photographer to Sultan Murad V (1840–1904, r. 1876) When Sultan Abdülhamid II (1842–1918 r. 1876–1909) came to the throne, Kargopoulo's appointment as royal photographer was rescinded because he did not take down the photograph of Murad V on his studio wall, but shortly later, he was reinstated.

ENGIN OZENDES

KÄSEBIER, GERTRUDE (1852–1934)
American photographer

Gertrude Käsebier came to photography relatively late in life and was soon among the most esteemed photographic portraitists of her day, successful both artistically and commercially. From the end of 1897 for the next thirty years, she operated a prominent portrait studio in New York City. Her work was vigorously championed by Alfred Stieglitz following their meeting in 1898, but within a decade, the two had begun to fall out over aesthetic and practical differences. Indeed, throughout her career, she maintained a determined independence, frequently holding what she termed "heretical views" with regard to prevailing commercial and artistic trends.

Married and the mother of three, Käsebier first made photographs using her family as a subject in 1885. In 1889, at the age of thirty-seven, she enrolled in the Pratt Institute in Brooklyn to study painting. Following her course of study she turned to artistic photography and, in early 1894, submitted the winning photograph to a juried contest in the *Quarterly Illustrator*. This prompted criticism from her painting masters for her involvement both with photography and with the illustrated press. In spring of 1894, she traveled to Europe, producing a series of photographs of French peasants, reminiscent of the paintings of Jean-François Millet, which she subsequently published in the *Monthly Illustrator*. In Germany, she undertook a brief apprenticeship with a chemist in order to learn the chemical basis of photography, before returning to New York in 1895.

Käsebier launched herself into professional portrait photography in 1896. After apprenticing with a commercial photographer, she opened her own studio in Manhattan in the winter of 1897–1898. Her style of portraiture dispensed with conventional props, focusing on softly lit heads against dark backgrounds. In addition to her fashionable clientele, she began photographing Plains Indians from Buffalo Bill's Wild West Company in April 1898, producing a series of remarkably intimate character studies.

Käsebier quickly made a name for herself as a pictorial photographer. In June 1898, she introduced herself to Stieglitz, leading figure in the Camera Club of New York. At the 1898 Photographic Salon of Philadelphia, with Stieglitz on the jury, Käsebier exhibited her recent work and gave a lecture on the need for an artistic approach to portraits emphasizing simplicity, naturalness, and directness. She recommended that artistically trained women take up "modern photography" as a "vocation" (Käsebier, 86).

Blurring distinctions between artistic and commercial photography, Käsebier charged a premium for her portraits and favored the fine platinum print over the popular gelatin silver print. Stieglitz enthusiastically exhibited her photographs at the Camera Club in February 1899, and in April featured them in *Camera Notes*. At the 1899 Philadelphia Salon, Käsebier served on the jury, alongside Clarence H. White and Fred Holland Day, and received praise for *The Manger*, a luminous image of a gauze-draped Madonna with child. British actress Ellen Terry would famously buy this picture for $100, an unheard-of sum for a photograph at the time.

At the 1900 Philadelphia Salon, Käsebier achieved critical acclaim for *Blessed Art Thou Among Women* (1899), an allegorical photograph of a young girl crossing a threshold into public life. Also in 1900, her work was exhibited abroad in Paris and London. In October, she and British photographer Carine Cadby became the first women elected into the elite Brotherhood of the Linked Ring. At this time, Käsebier began a series of portraits for the illustrated magazine *World's Work*, photographing such eminent figures as author Mark Twain and educator Booker T. Washington. She was achieving success simultaneously on three fronts: commercially in her portrait practice, artistically in exhibitions and photography journals, and publicly in the illustrated press.

Following a stay with Eduard Steichen in Paris in the summer of 1901, Käsebier became an ardent practitioner of the gum bichromate printing process. Subsequently, she both alternated and combined platinum and gum printing techniques in her work, experimenting with different versions of the same image. Her prints might feature crisp photographic detail or moody handling of the emulsion, depending on the situation.

In 1902, Stieglitz included Käsebier as a founding member of the Photo-Secession, and in January 1903, he devoted the first issue of the Photo-Secession's deluxe journal, *Camera Work*, to her work. In 1905, several pastoral images by Käsebier, among them, *Happy Days* (1903), were featured in *Camera Work* 10 and exhibited at Stieglitz's newly opened Little Galleries of the Photo-Secession.

The theme of women's emotional experience recurs throughout Käsebier's work. In 1902 she produced *Portrait of Miss N.*, a frankly erotic depiction of the young showgirl Evelyn Nesbit poised seductively with an open pitcher tipped toward the viewer, symbolically suggesting the girl's entry into sexual life. Two years later, Käsebier's wrenching portrait of the poet Agnes Lee, entitled *Heritage of Motherhood*, depicted a grieving mother in a bleak landscape.

The emphasis on depth of feeling in Käsebier's photographs led to divergent assessments of her work in 1907. An article by Mary Fanton Roberts (pseudonym Giles Edgerton) in the April issue of *Craftsman* praised Käsebier's investigation of "Photography as an Emotional Art." In response, Charles H. Caffin, previously a strong supporter of Käsebier, wrote a stinging satire,

published in *Camera Work* 20 (October 1907), of the self-indulgent "emotional artist." The privileged role of intuition in pictorial photography was beginning to give way to a more detached, modernist photographic aesthetic.

By 1909, Käsebier's relations with Stieglitz had grown strained over her identification with professionalism and his with non-commercialism (Michaels, 130). In 1910, in the wake of Stieglitz's International Exhibition of Pictorial Photography, tension erupted over financial matters relating to the sale of her works (Michaels, 136). Stieglitz, meanwhile, was turning his attention away from pictorial photography in favor of the machine aesthetic and modern art. In 1911, he asked for a pledge of loyalty to the new direction that the Photo-Secession was taking under his leadership; Käsebier refused. When Clarence H. White, himself an ex-Secessionist, founded the Pictorial Photographers of America in 1916, he made Käsebier honorary vice president

From the start of her career in the mid-1890s, Käsebier's critical fortunes had risen and fallen rather precipitously. What at first seemed bold and daring in her work came, in light of trends away from pictorial photography after 1910, to seem conservative (Tighe, 98). After her death in 1934, decades of relative invisibility followed. In the 1970s, however, concurrent reevaluations of pictorial photography and the neglected history of women artists led to a revival of interest in Käsebier's life and work. Subsequently, in the late 1990s, her innovative portraits of Native Americans drew renewed attention to her exceptional career.

STEPHEN PETERSEN

Biography

Gertrude Käsebier was born Gertrude Stanton in Fort Des Moines, Iowa (now Des Moines, the state capitol), on 18 May 1852, to a family of Quaker heritage. From the age of eight to twelve she, along with her parents, John W. Stanton and Muncy Boone Stanton, and younger brother Charles, lived in the Colorado Territory, where her father sought his fortune in the gold rush. After finding success in mining operations, he and his family moved east in 1864, settling in Brooklyn, New York. Käsebier attended Moravian Seminary for Young Ladies in Bethlehem, Pennsylvania, from 1868 to 1870. In 1874 she married Eduard Käsebier, a German immigrant and shellac importer six years her senior. Living first in Brooklyn and later in New Jersey, the Käsebiers raised three children before Gertrude decided to pursue a career as a painter, returning to Brooklyn to study at the Pratt Institute from 1889 to 1895. Turning in 1896 to a profession in photography, she apprenticed with Brooklyn portrait photographer Samuel H. Lifshey. Following her apprenticeship she operated a highly regarded portrait studio in New York for thirty years, before physical ailments forced her retirement. A member of the Brotherhood of the Linked Ring from 1900–1909 and of the Photo-Secession from 1902–1912, she knew and exhibited with all of the major pictorial photographers. Käsebier died on 13 October 1934 in New York City at the age of 82. Her husband predeceased her by twenty-five years. Early in her career, she published her photographs in many journals and magazines including *The Monthly Illustrator*, *The World's Work*, *Everybody's Magazine*, *Ladies' Home Journal*, and *Harper's Bazaar*. Major exhibitions during Käsebier's lifetime included the Philadelphia Photographic Salon, Pennsylvania Academy of Fine Arts, 1898, 1899, 1900; The New School of American Photography, curated by F. Holland Day, Royal Photographic Society, London, 1900; American Pictorial Photography Organized by the Photo-Secession, National Arts Club, New York, 1902; and the International Exhibition of Pictorial Photography, Albright Art Gallery, Buffalo, 1910.

KEELER, JAMES EDWARD (1857–1900)

The American astronomer James Edward Keeler was born in La Salle, Illinois, and during an extended period of illness in his teens, developed a passion for astronomy. After completing his bachelors degree at John Hopkins University, he studied for two years in Europe—at Berlin and Heidelberg—and subsequently

was appointed to the staff of the Allegheny Observatory in Pittsburgh in 1884.

By 1888 he had been appointed as astronomer at the newly completed Lick Observatory in California, where he stayed for three years conducting a wide range of spectrographic experiments with the observatory's refracting telescope, before returning to the Allegheny to take up the position of Professor of Astronomy and Astrophysics.

He returned to the Lick Observatory as Director in 1898, and set about applying himself to the photography of every nebula listed in Sir William Herschel's catalogues of 1786, 1789 and 1802—two and a half thousand in number. He photographed over half of them, and in the process discovered many more.

For his photographic recordings, he used the Observatory's 36-inch f/5.7 Crossley Reflecting Telescope, imported from England where it had previously been used by A. A. Common in his garden observatory in Ealing, London. The exposure for each plate was between three and four hours.

Keeler died in San Francisco in 1900 at the age of only 42, his photographic project far from complete.

John Hannavy

KEENE, RICHARD (1825–1894)
English

Richard Keene was born in London on May 15th 1825 and his family moved to Derby in 1825 where his father managed a silk mill.

Keene was apprenticed to local printers Thomas Richardson and Sons, later moving to their London offices. He later worked for publishers and booksellers Simpkin Marshall and Co.

He returned to Derby in 1851, married Mary Barrow and set up as a printer, publisher and bookseller at 24 Irongate.

Becoming interested in photography, he started making local views which he sold commercially and exhibited 16 architectural views at the 1862 London International Photographic Exhibition.

He was known for his high quality portrait, landscape and architectural studies which he produced as albumen, gelatin silver and platinum prints. He also specialised in producing photographs on ceramic. Keene published several books about Derbyshire, was official photographer to the Midland Railway Company until 1883 and a member of the local archaeological society.

Keene was a member of the Photographic Society of Great Britain and was elected to membership of The Linked Ring on 26th July 1892 with the pseudonym 'Master Printer,' the link name reflecting the quality of his photographic printing skills.

Keene died at his home in Radbourne Street, Derby in 1894, leaving five sons and three daughters.

Ian Sumner

KEIGHLEY, ALEXANDER (1861–1947)
English photographer

Although the son of a wealthy worsted mill owner, of High Hall, Stretton, Yorkshire, Keighley had to work his way up, from shop floor sweeper to managing director. Interested in oil and watercolour painting, the influence of Henry Peach Robinson allowed him to combine these interests into photography in 1883, then he joined the Bradford Photographic Society. In 1887, with 12 prints, he was awarded first prize by Peter Henry Emerson in the *Amateur Photography* competition (Alfred Stieglitz came second). Yet Emerson lamented Keighley's sharp focus and then later criticised him for becoming a 'gum sploger.' In the end Keighley adopted the manner of soft focus Impressionism and became a leading Pictorialist with many solo exhibitions in London, USA and throughout Europe. Invited member of the Linked Ring Brotherhood 1892, Fellow of the Royal Photographic Society 1912, Honorary Fellow 1924. Often he used a quarter plate camera, without a view finder, permanently set at 10 yards and covered in a bag so that he could surreptitiously photograph people, often on his travels abroad where the majority of his photographs were made. The negatives were then made into full plate positives, then manipulated using combination printing, pencil and dyes, then enlarged onto 16 × 20" or 20 × 24" glass negatives for contact printing with carbon. In his time, his photographs were highly praised as "lyrical," "poetic," the "poetry of romance," but they have not survived well. Now they would be regarded as "sentimental," "unreal," but his reputation suffers, like many of his time, in that only the same few images are ever reproduced.

Alistair Crawford

KEITH, THOMAS (1827–1895)
British surgeon and amateur photographer

Dr. Thomas Keith's appreciation of light, and his ability to recognise its potential for powerful visual statements is evident in his small but significant body of early paper photography. Working only when working pressures permitted, he produced over two hundred architectural and landscape views.

His subject matter embraced the Closes and Wynds of Edinburgh's Old Town, wooded highland landscapes, and the romantic ruins of Iona Abbey and his last dated negatives were taken in September 1856. With his preferred soft or diffuse light, his use of angular shadows

created powerful and dynamic images. At a time when the chemical and technical manipulation of processes occupied the minds of early photographers, Keith was concerned with controlling and exploiting the lighting conditions he found in mid-Victorian Scotland. In a paper presented to the Photographic Society of Scotland in 1856, he said

> If you were to ask me to what circumstance more than another I attribute my success, I should say, not to any peculiarity whatever in my manipulation, or to any particular strength of the solutions I employ, but entirely to this, that I never expose my papers unless the light is first-rate. This I have now made a rule, and nothing ever induces me from it; and I may safely say that since I attended to this I have never had a failure. (Keith, "Dr. Keith's Paper on the Waxed Paper Process" in Photographic Notes vol. 1 no. 8, 17, July 1856, 101–104)

His family had several early associations with photography. As a founder member of the Free Church of Scotland, his father, the Reverend Alexander Keith, had been photographed by David Octavius Hill and Robert Adamson for inclusion in Hill's painting "The Signing of the Deed of Demission at Tanfield." Thomas's brother Alexander, also a clergyman, was also photographed by Hill and Adamson. His older brother George Skene Keith, an amateur daguerreotypist, travelled to the Holy Land in 1844 and 1845 and produced daguerreotype views from which engravings were made for the 1848 edition of his father's book *Evidence of the Truth of the Christian Religion*.

Keith's practical engagement with photography spanned no more than five years. His earliest dated images were taken in 1854, his last in 1856. As some unspecified examples of his salted paper prints were reportedly exhibited in Aberdeen in 1853, it can be assumed that he had first experimented with photography no later than the summer of 1852. He intimated his decision to give up photography in 1857, almost certainly due to increasing pressures on his time as a medical practitioner. There is no evidence that he took any photographs in that year. He did, however, continue to exhibit his work for several years after.

Keith's medium of choice was Gustave le Gray's Waxed Paper Process, a process ideally suited to the constraints placed on his photography by the demands of his profession.

For the practice of photography to be possible, he needed a process which permitted him to prepare his negative materials in advance, and process them some time after exposure. Despite the ascendancy of the Wet Collodion process, Waxed Paper was ideally suited to the time-constrained amateur. With it, Keith pre-waxed and prepared his paper negative materials at least a day in advance, and developed them overnight. Thus freed from collodion's requirements of location processing, Keith could operate with lightweight and easily transportable equipment, and respond quickly to lighting conditions. His reasons for selecting the Waxed Paper Process are all contained and clearly expressed within the text of his 1856 lecture.

That lecture, to the Photographic Society of Scotland on 10th June 1856, is one of the most significant explications of the Waxed Paper Process. In it he underlines the importance of the quality of the prevailing light—the feature which marks Keith's photography out as exceptional. Turning necessity to his advantage, he learned how to exploit the soft long shadows of early morning and late afternoon.

> I am almost always sure of clear mornings soon after sunrise, and most of my negatives have been taken before 7 in the morning or after 4 in the afternoon. The light then is much softer, the shadows are larger and the halftints in your pictures are more perfect, and the lights more agreeable. (Keith, "Dr. Keith's Paper on the Waxed Paper Process" in *Photographic Notes* vol. 1 no. 8, 17 July 1856, 101–104)

By the time of his invitation to deliver that key lecture, Keith's reputation as a photographer was already considerable. The images he displayed at the meeting were "greatly admired, and were considered by the Society to be the finest yet produced."

He was an early member of the Society, serving on its Council from 1856 until 1858, although he seldom attended meetings. He did, however, exhibit regularly, and images of Iona Abbey, taken in early September 1856, were hung in the Society's first Exhibition in 1857, to considerable acclaim. He exhibited in both 1858 and 1859, his last contribution being to an exhibition in Aberdeen where his work was shown alongside photographs by his friend John Forbes White with whom he had collaborated on several of his photographic expeditions.

Since their creation, Keith's photographs have had many admirers, including Alvin Langdon Coburn, who made prints from selected original negatives and exhibited them at the Royal Photographic Society in 1914, almost sixty years after they had been taken. Coburn included Keith as one of the "Old Masters of Photography," describing his work as being "as good as Hill's." He arranged for a selection of prints to be shown in New York's Ehrich Gallery, and again in Buffalo in the following year. He eventually acquired some of the negatives, later bequeathing them to George Eastman House. Miller and art collector, John Forbes White was also included as one of Coburn's "Old Masters."

Keith's reputation was further embedded by Helmut Gernsheim's inclusion of his work in the 1951 exhibition *Masterpieces of Victorian Photography* at the Victoria and Albert Museum in London.

The major holding of his work—predominantly Waxed Paper negatives—is the Hurd Bequest in Edinburgh Central Library.

JOHN HANNAVY

Biography

Thomas Keith was born in St. Cyrus, Aberdeenshire, Scotland, in May 1827, one of seven sons of the Reverend Alexander Keith. He studied art in Aberdeen, before becoming one of the last medical apprentices in Edinburgh, and subsequently serving as a junior member of Sir James Young Simpson's team working on anaesthetics—his brother George Skene Keith was Simpson's assistant. After qualification, and a residency at Edinburgh Infirmary, he moved to Turin as House Surgeon in the British Embassy, returning to Edinburgh in 1851. By the time he took up photography, he was in general practice with his brother George. He later pioneered several important procedures in ovarian surgery, and his hobby always took second place to his career as a doctor, surgeon and gynaecologist. His close and lasting friendship with Joseph Lister was sustained by a shared belief in the importance on cleanliness in the operating theatre, and he was one of the first to introduce Lister's antiseptic techniques in his work. In his obituary, celebrating an eminent career in medicine, the only reference to photography concerned his knowledge of glass—ironic for a master of the paper negative! He died in 1895 as a result of health problems exacerbated by sustained exposure to large quantities of early antiseptics.

KERN, EDWARD MEYER (1823–863)

The youngest of three Philadelphia-born, artistically-minded brothers who all took part in important ventures of American exploration in the mid-19th century, Edward Meyer Kern was probably the boldest, and, although primarily a draughtsman, the only one to practice photography—in the form of daguerreotypes. Indeed, he used a daguerreotype apparatus on several important American naval expeditions to the Far East and thereby helped introduce the process in a number of locations in Asia and the Pacific area.

Though his actual photographic output was still largely unknown or unidentified, and though most holdings of his work consisted exclusively of sketches, drawings and maps of the American West, Edward "Ned" Kern was a significant figure in the development of photography, for at least two reasons. First, he was part of an important cultural and professional transition, which saw the novelty of photography gradually penetrate the tradition of scientific drawing in American exploration, albeit only timidly at first. Second, after 1853 Kern was a pioneer spreading photography to the Far East and, as such, a representative of the process of technological modernization, which in many parts of the world was associated with the advent of photography.

Kern's involvement in photography, however, had been slow in developing. As was the case with most of the artists, draughtsmen and scientists who took part in the ambitious U.S. government program of exploration of the American West before 1860, Kern did not at first seem interested in the daguerreotype process as an adjunct to scientific exploration. From 1845 to 1851, instead, he worked exclusively as a pencil artist and topographer on several surveys of the American West, notably under the leadership of John Charles Frémont, and often in company with his brothers Benjamin and Richard Kern, the latter being regarded as the most gifted artist of the trio.

Frémont, it is true, had experimented with the daguerreotype as early as 1842, and he did hire a daguerreotypist on his 1853 expedition, but this was rather an exception in the U.S.; at any rate, claims that Edward Kern was once employed as daguerreotypist by Frémont are not substantiated by survey records or private archives. Although his sketching style might be regarded as theatrical and almost naive, Kern was in fact a prime example of the American explorers' typically Romantic and highly productive commitment to the hand and the eye; along with the prolonged dominance of the impractical daguerreotype process, this explains why until 1860 photography remained largely alien to the practice of U.S. military engineers, who instead favored tried-and-true methods closely associating topography and draughtsmanship.

After breaking his connection to Frémont on account of the latter's brash methods, Kern indeed continued to work with brush and pencil on various Western surveys until 1851-52, reaching a degree of fame in Philadelphia with several exhibitions of Western sketches and illustrations of botany and Indian subjects. Without a doubt,

through his stays in California and his experiences in exploration, this skilled and adventurous artist-scientist must have learned about the daguerreotype before 1853. In 1853, however, when Kern did take up the process, it was not to go back once again to the American West with the Army's topographical surveys, to which he lost both his brothers between 1849 and 1853—killed by Indians—but to leave American soil and take to the sea.

That year Kern enrolled as artist and daguerreotypist on the U.S. Navy's North Pacific Expedition, and before sailing went to New York especially to gain instruction in the process at the Anthonys' firm. The North Pacific Expedition, which was to remain at sea until 1855, was a large-scale venture, intended to provide a scientific complement to the famous, more strategically-minded expedition of Commodore Matthew Perry, which had just forced the "opening" of Japan to the West and had itself included daguerreotypist Eliphalet Brown. The Ringgold-Rodgers expedition ended up covering a huge area in the South and North Pacific, exploring naval routes and describing coastal areas from Australia to China, along the Japanese coasts, and even north to Kamtchatka and Siberia; it was prolonged by another Navy survey of sea routes between California and China in 1857–1860, on which Kern was also engaged as artist and daguerreotypist.

Although few or none of the many images that he produced on these historic ventures have surfaced so far (one probable exception being a view of the American cemetery at the Gyokusen-Ji Temple in Shimoda, Japan, which is held at the George Eastman House and was exhibited in Tokyo in 1992), it is known from written sources that Kern made daguerreotypes, as well as sketches, on the coasts of China, Japan, Siberia, and on various islands such as Hawaii and Okinawa. Indeed, as historian of American exploration William H. Goetzmann has written, "perhaps even more than Brown of Perry's expedition, Kern introduced photography to the Far East" (*New Lands, New Men*, 350). In Japan especially, it appears that the introduction of photography by Brown, Kern and others heralded made visible, the advent of Western culture, its technology, its particular form of realism, and its commercialism, which were to be adopted quickly and efficiently.

It is certainly worth noting that whereas the U.S. Army's engineers refrained from resorting to a technology that they tended to view as ill-suited to their needs and even tainted with a kind of charlatanism, the U.S. Navy made a point of displaying and exporting this same technology—along with telegraphy, clocks, and railroads—to the potential markets and dominions of the Pacific, as if the daguerreotype had most concretely embodied the supposed superiority of Western culture. In this early episode of globalization, Edward Kern was merely an agent, but in hindsight he appears as a prime illustration of the fundamental link between American expansion, technological modernity, and the appeal of the sun-picture.

François Brunet

Biography

Edward Meyer Kern was born in Philadelphia in 1823, the youngest of a genteel family that also produced an art teacher and two other artist-explorers, Benjamin Jordan (1818–1849) and Richard Hovenden (1821–1853). Having exhibited in Philadelphia as early as 1841, "Ned" Kern participated in several surveys of the American West: in 1845 with John Charles Frémont's third expedition and his "conquest of California"; in 1848, again with Frémont, through the central Rocky Mountains, this time along with Benjamin and Richard (Ben was eventually killed on this expedition); in 1849 on a military raid against the Navajos, and in 1850-1851 for topographical work in New Mexico. From 1853 to 1855 Edward joined, as artist-daguerreotypist, Lieutenant Cadwalader Ringgold's North Pacific Expedition, later commanded by Lieutenant John Rodgers; from 1857 to 1860, he was daguerreotypist to Lieutenant John M. Brooke's survey of sea routes in the Central Pacific. Once back in the U.S., and after another stint with Frémont, Edward Kern returned to Philadelphia and taught art. He died of epilepsy in 1863.

KERRY, CHARLES (1857–1928)

Australian photographer and studio owner

Charles Henry Kerry was born on Bobundra Station, near Bombala, NSW in 1857, the son of grazier Samuel

Kerry and Margaret Blay. As a teenager he accompanied a travelling photographer, then at 17 he worked for Alexander H. Lamartiniere in a studio at 308 George St, Sydney, eventually becoming a partner in the business. Lamartiniere left the business in debt around 1883 but Kerry managed to resurrect it, providing portraiture which he eventually delegated to staff while he photographed an increasing array of landscape views, social events and bush life. In the 1886 he formed a partnership with C. D. Jones that capitalised on the dry plate process. In 1888 Kerry began using magnesium flashlight, put to use inside the Jenolan Caves and 10 years later he used electric flashlight. Kerry and his employed photographers made regular trips throughout New South Wales during the 1890s executing private and government commissions and building a massive stock of landscape views. In 1895 the NSW Government requested Kerry photograph the state's Aborigines. In 1898 new four level premises were opened at 310 George St. In 1903 the firm started producing postcards and it quickly became one of Australia's larger postcard publishers. Kerry left the business in the hands of his nephew in 1913 to pursue mining interests and it closed in 1917. Kerry died in 1928 in North Sydney.

KILBURN, BENJAMIN WEST (1827–1909) AND EDWARD (1830–1884)

Stereoscopic photographers and publishers

Benjamin and Edward Kilburn were the sons of Josiah and Emily Bonney Kilburn. Josiah managed a machine and iron foundry in Littleton, New Hampshire. Benjamin, the oldest child, was born on 10 December 1827. His brother Edward was born on 27 February 1830. In 1843 both children began a three-year apprenticeship at an iron foundry in Fall River, Massachusetts. After their apprenticeship they returned to Littleton to work with their father.

Littleton is located in northern New Hampshire, on the western edge of the White Mountains. Its popularity as a tourist destination dates to the middle of the nineteenth century. The area offered spectacular scenery and hiking, fishing, and hunting opportunities, as well as resort hotels for relaxing and dining.

In the mid-1850s Edward Kilburn learned photography from O.C. Bolton, one of the early White Mountain photographers. Edward pursued photography as a pastime while he established a match factory and later sold Grover and Baker sewing machines. Both brothers enlisted in the Civil War. In 1865 they formed a stereographic view partnership, known as the Kilburn Brothers, which would grow to dominate the field of stereo publishing. Stereo views are two photographs mounted side-by-side that appear three-dimensional when placed in a viewer called a stereoscope. Collecting stereo views was a craze of the middle-class in the mid to late nineteenth century. People acquired stereo views of tourist spots that they had visited as well as exotic locales that they would only experience through the wonder of the stereoscope.

Although Edward was initially the firm's primary photographer, Benjamin quickly took over this important duty. Early views concentrated on the White and Franconia Mountains. In spite of their rural location, Kilburn Brothers's views were sold around the country. In 1866 the *Littleton Gazette* reported that: "... the Kilburn Brothers with their new instrument for taking Sterreoscopic [sic] views ... are being extensively circulated throughout the United States, and are pronounced by the most useful critics to be equal if not superior to any others published in the United States."

After only two years of business the firm was selling views internationally. In 1867 the Kilburn Brothers built a factory on Main Street in Littleton. In addition to the production areas, a sales shop occupied the front room.

The Kilburn Brothers used assembly line techniques in the production of their stereo views. The firm employed predominantly women who were responsible for a variety of duties including sensitizing the albumen paper, and hand cutting and pasting the prints. Men worked as printers, photographers, and in managerial positions. Over the years, the number of employees fluctuated, reaching a peak in 1904 when the company employed more than 100 people. They worked ten hour days from 7 a.m. to 5 p.m.

In December 1873 the Kilburn Brothers moved into a new and bigger factory on Cottage Street in Littleton. This building had a southern exposure along its length, providing more natural light for the printing operation. At this time, the company produced between 1400 and 1800 stereo views a day. A dozen views cost approximately $2.00.

Despite the company's success, Edward retired in February 1875 at the age of forty-five. In retirement he gave a series of magic lantern shows featuring views from the Kilburn Brothers's inventory and planted a large orchard. He died in 1884.

Benjamin continued to run the stereo company, changing its name to the B.W. Kilburn Company. One of the company's specialties was views of the cog railroad run by the Mount Washington Steam Railway Company. Kilburn documented the development of the railroad, and a series of his views appeared in the

21 August 1869 issue of *Harper's Weekly.* By tilting the camera, many of his stereo views exaggerate steep angle of the track making the descent look vertiginous. With other views, Kilburn carefully composed his photographs, often emphasizing the foreground to enhance the three-dimensional qualities of the stereo views. In addition to his views of New England, Benjamin made stereo views in Virginia, Bermuda, Mexico, Canada, and Europe. He photographed events, such as Grover Cleveland's inauguration, and acquired the exclusive rights to produce stereo views of the 1893 World's Columbian Exposition in Chicago and the California Midwinter Exposition. Other popular subjects sold by the firm were the Johnstown, Pennsylvania flood, the Boxer Rebellion, the Boer War, and the Spanish-American War.

One of the company's foremost photographers was Percival Graham. He joined the firm in the 1870s and photographed extensively at the 1901 Pan American Exposition held in Buffalo, New York. James M. Davis also worked as a photographer and distributor for the company.

The firm used several cameras including a Henry Clay stereo view camera and an American Optical Company camera that used a tripod. In an effort to eliminate the use of a tripod, Benjamin designed a "gun camera." The camera was mounted on a gun stock that rested on the photographer's shoulder.

In addition to their own inventory of negatives, Kilburn also bought negatives from other photographers. In 1881 he purchased the negatives and rights to a large collection by Boston stereo manufacturer John Soule, which included views of Niagara and Yosemite.

The studio produced both standard sized stereo views and larger cabinet sized stereos. Most views were pasted to buff mounts. Yellow, orange, and gray mounts were also used. Their stereo views were available for purchase in the company's sales room, and at local stores, hotels, and tourist sites, such as the Mount Washington Railway gift shop. College students were employed in the summer to sell stereo views door-to-door in the Northeastern and Midwestern United States. In the 1870s the company issued catalogs listing their views. Orders could also be placed by mail.

In the United States, the Kilburn firm was both the largest producer of stereo views and in operation for the longest period of time-forty-four years. The exact date of Benjamin Kilburn's retirement is unknown. In 1901 he sustained a stroke which left him disabled until his death in 1909. In 1910 the Kilburn negatives and equipment were sold to their former agent James Davis, and later to one of their main competitors, the Keystone View Company.

Kilburn's negatives and logbooks are in the collection of the California Museum of Photography. The Littleton New Hampshire Public Library holds thousands of Kilburn stereo views.

CAROL JOHNSON

Biography

Benjamin Kilburn (1827–1909) married Caroline Burnham on 16 November 1853. They had one daughter named Elizabeth. On 25 May 1857 Edward Kilburn (1830–1884) married Adaline Owen, a local schoolteacher. Their union produced one child, a daughter named Emily. In 1862 both brothers enlisted in the Civil War, and served through 1864 in New Hampshire's 13th Regiment, Company D. In 1865 the Kilburn Brothers stereo company began operation. It became the most prominent stereo view company in the world. Their views were exhibited at the 1876 Philadelphia Centennial exhibition. In 1909 when the company ceased operations their inventory included nearly 100,000 glass stereo negatives.

KILBURN, WILLIAM EDWARD (1818–1891), AND DOUGLAS THOMAS (c. 1812–1871)

English photographers

The brothers Douglas and William Kilburn were born in London, the sons of Thomas Kilburn and Catherine Ward.

William Kilburn was working as a professional photographer before. 1846 and his photographs of a Chartist Rally in London in 1848 brought his work to the attention of Prince Albert, from whom he later received several commissions, styling himself 'Photographist to Her Majesty and His Royal Highness Prince Albert'.

Kilburn exhibited a series of 'photographic miniatures (daguerreotypes) at the 1851 Great Exhibition, but finest daguerreotypes were produced between 1852 and 1855, at his studio at 234 Regent Street London. His use of light, and skilful tinting was remarkable. From 1856 he exclusively used collodion.

Douglas Kilburn, a watercolorist and photographer, emigrated to Australia before 1847. After having arranged for William to send equipment and materials from England, he was the first to make daguerreotypes of Aboriginal people of the Yarra Yarra tribe in Victoria in 1847 which were used as basis of illustrations in William Westgarth's *Australia Felix* (Edinburgh 1848). He operated a daguerreotype studio in Collins Lane, Melbourne, from May 1848—only the second professional photographic establishment in the city.

He returned briefly to Britain in 1850 where he was married, before returning to Australia and settling in Hobart, Tasmania—where he was the first to demonstrate stereoscopic photography in 1853. He eventually turned his attention to politics and became an MP in the Tasmanian parliament.

JOHN HANNAVY

KIMBEI, KUSAKABE; See KUSAKABE KIMBEI

KINDER, JOHN (1818–1903)
English artist and photographer

The Rev. John Kinder (1818–1903) was ordained in the Anglican Church after attending Cambridge University. He came to Auckland, in 1855 where he took up a teaching post at the Church of England Grammar School. In the tradition of well educated English gentlemen, he made several sketching tours in the North Island during term breaks. Around 1860, after taking lessons in photography from an Auckland professional photography Hartley Webster, he completed a series of stereoscopic views which of Auckland. As he grew in confidence as a photographer, he took to using a large format view camera which yielded a series of topographical views. About this time, his photography became something of an *aide memoir* for his watercolours. He was a brilliant draftsman and was well aware of all the effects that could be obtained by perceptive selection of subject and rendering. His intense commitment to photography ended in 1872 as other matters demanded his attention. Kinder obviously considered photography as being on an equal footing with his watercolours, exhibiting them as he did along with his watercolours at exhibitions staged by the Auckland Arts Society.

WILLIAM MAIN

KING, HENRY (1855–1923)
Austrailian photographer

Henry King was born in 1855 in Swanage, Dorset, the son of William and Eliza King. He arrived in Sydney, Australia as a toddler aboard the *Kate* in 1856. He started in photography in 1873 working for the studio of J. Hubert Newman. King opened a studio at 330 George St., Sydney, in partnership with William Joseph Slade in 1879. They moved to 316 George St the following year then Slade left to set up in Newcastle. King worked by himself thereafter initially producing *carte de visite* portraits, but with time he began to specialise in landscapes, rivalling the work of Charles Kerry. King travelled extensively in New South Wales and Queensland to photograph landscapes and to document the Aboriginal population. In addition to enlargements, King produced many lantern slides and stereoviews including series featuring the Jenolan Caves and views around Sydney and environs. King was active in the NSW Photographic Society and always encouraged amateurs. He worked from a variety of George St addresses until 1920 and died following an operation 23 May 1923. In 1929 bookseller James Tyrrell acquired several thousand of King's glass plate negatives that are now in the Powerhouse Museum, Sydney.

MARCEL SAFIER

KING, HORATIO NELSON (1828–1905)
English photographer

The career of H. N. King spans the first sixty years of photographic history and also encompasses a wide range of formats and subjects. Starting in Bath in the 1850s he ingeniously combined the roles of local theatrical impresario with taking portraits of celebrities visiting this fashionable resort.

Moving to London he inherited more than 1000 negatives taken by the photographer Vernon Heath and by the late 1870s he had transferred his scope and operations to the Goldhawk Road in West London becoming an important topographical and architectural specialist competing with Francis Frith, James Valentine, and George Washington Wilson. This business was underpinned by his longstanding connections with the Royal family: in his reminiscences he mentions visiting Windsor Castle over 250 times to create what must be one of the most extensive records of royal residence including Buckingham Palace, St. James' Palace and other properties.

King claimed to have been the first to introduce photographs in railway carriages having been granted two first class tickets for six months by the Great Western Railway. This must link with his catalogue of over 7000

mainly British views including stereo cards and lantern slides—which also includes over 150 views of India.

IAN LEITH

KINNEAR, CHARLES GEORGE HOOD (1832–1894)

Schottish photographer and inventor

The Honourable C. G. H. Kinnear was active in photographic circles, particularly in Scotland, from the mid-1850s until the early-1890s and was described as 'the inventor of the modern form of camera bellows'.

Kinnear was a founding member of the Photographic Society of Scotland from 1856 until it was wound up in 1873 and held various offices with the Society including Honorary Secretary from 1856–1860 and Vice President. He was also a founder member of the Edinburgh Photographic Exchange Club from 1859 and, later, a member of the Edinburgh Photographic Society. He exhibited widely in Scotland. He published several articles in the photographic press including reports of his photographic travels and exhibited his work between 1856–1864.

His principal contribution was a design of camera which he described in 1857. A report was published in the *Journal of the Photographic Society* in February 1858. Kinnear's camera had tapered bellows which allowed each fold to collapse within the previous larger fold when closed. The design was based on Captain Fowkes' camera which had straight bellows, but Kinnear claimed his design was stronger and more suited to travelling. It also cost about £4 or half the price of the Fowkes camera which it quickly superseded. The original camera was for 12½ × 10½ inch paper negatives and was built for Kinnear by Bell of Potterrow, Edinburgh. The camera was 15½ × 13 × 3½ inches when closed and weighed 13lbs. The design was taken up by the principal London camera makers such as Ottewill, Bland & Co, Rouch and Meagher and Improved Kinnear cameras were advertised from the early 1860s.

Kinnear's original design was a little awkward with the back section needing to be screwed on to the baseboard and the lens board required mounting on to the front standard. Camera makers improved and adapted the basic design while keeping the innovative bellows arrangement. Over time the means of focusing was changed from an endless rod screw from the camera's back to a side-turned rack and pinion and refinements such as swing-backs, rising fronts and reversible and fixed backs were added. The refined design, principally through the work of McKellen in the 1880s, became the *de facto* standard plate camera until the early twentieth century. Kinnear died aged 63 on 5 November 1894.

MICHAEL PRITCHARD

KINSEY, DARIUS REYNOLD (1869–1945)

American photographer

Darius Reynold Kinsey was born on July 23, 1869, in Maryville, Missouri. In 1889 he and his family moved to Snoqualmie, Washington Territory. After learning photography from a Mrs. Spalding in Seattle around 1890, Darius spent five years photographing for the Seattle and Lake Shore Railroad Company. He formed a brief partnership with his brother Clark, but Clark and another brother Clarence moved to the Yukon Territory, Canada, during the Klondike Gold Rush, forming the Kinsey & Kinsey photography business in Grand Forks. Married in 1896, Darius' wife Tabitha (d. 1963) worked in the darkroom. Their first studio, opened in 1897, was in Sedro-Woolley, Washington. In 1906 they relocated to Seattle and Darius gave up portrait work, devoting himself over the next three decades to photographing logging activities in the Pacific Northwest, a passion shared by his brother and competitor Clark between 1913 and 1945. Darius worked with stereoscopic, panoramic, and large format cameras, including a 20 × 24 inch camera. Only an injury at age 71 stopped his career. The Whatcom Museum of History and Art, Bellingham, Washington, acquired the Darius Kinsey collection (over 4,700 negatives and several hundred prints) in January 1979. The University of Washington also holds 151 Darius Kinsey prints, along with his brother Clark's negative collection.

DAVID MATTISON

KIRCHNER, JOHANNA FREDERIKA DORIS (EMMA) (1830–1909)

European photographer and studio owner

Emma Kirchner was one of the few female European photographers of the 19th century. A portrait made around 1855 by the first female daguerreotypist of Germany, Bertha Wehnert-Beckmann (Leipzig 1815–1901), discovered in 2004, showed a young Emma Kirchner. It only proved that they knew each other, but doesn't prove that Kirchner was her pupil. The proof that Kirchner already worked as a photographer in Leipzig, was shown at the back of her oldest picture made after her arrival in Holland which marks "*Emma Kirchner—Zuiderstraat*."

After the death of her father, Emma's mother took care of the tailor shop he left her and Emma, not yet three years old and baby Maria. Mother and daughter Emma ran the shop with very little help.

Kirchner never married but had daughter Dorice with the Leipzig Publisher Rudolph Loës and two daughters (one of whom died after a few days) with Commissionaire Carl August Bretschneider.

Kirchner immigrated 1863 to Delft in the Netherlands with her mother and daughter Dorice. Kirchner started the photographic firm with Frederik Gräfe, husband of her sister Marie, and from there photos where signed "*E. Kirchner & Co-Zuiderstraat 179*." At the firm, Emma Kirchner was the professional photographer and Gräfe still a gunsmith until 1872.

May 9, 1871, Gräfe fired Kirchner and announced that he would work alone at number 136 at the same street, on May19, Kirchner announced that she worked alone in the old studio.

In 1875 her daughter Dorice (1852–1939) married Henri de Louw (1851–1944) with whom Kirchner worked almost a year as '*Henri de Louw & Emma Kirchner.*'

Unfortunaly Kirchner never left any written documents, which makes her life more mysterious.

From 1876 until 1899 Kirchner made her best work, mostly *carte-de-visite* and *cabinet pictures* portraits of Citizens in and around Delft by albumin-style. May 1899 Johan van Doorne took over her studio.

Kirchner moved to The Hague and in 1903 to Amsterdam where she died at the house of composer Bernard Zweers (1854–1924), who was married to her granddaughter Dora (1876–1959).

Kirchner was not only a highly educated emancipated woman, but the only women photographer in Delft until almost the end of the 20th century. She was the only photographer in the Netherlands to work alone for such a long period of time without any pupils, compared to other female photographers, who worked with their husbands or pupils.

PETRA NOTENBOOM

KLIČ, KAREL VÁCLAV (1841–1926)

Perhaps surprisingly, for someone whose contribution to the printed image was so significant, some considerable confusion results from reading the published accounts of Klič's life. He is variously described as being Czech, German and Austrian.

Karel Václav Klič was born in Hostinne, in the foothills of the Krkonose Mountains in the present-day Czech Republic. The town has long been a centre for paper-making. His artistic talents showed early in his life, and he was admitted as a student at the Art Academy in Prague in 1855 when aged only 14. Apparently unwilling to conform, he was expelled after only a few months, only returning to complete his studies some years later.

Klič, also known as Karl Wenzel Klietsch—the German/Austrian version of his name—had a varied career —working as a draughtsman and as a painter for a time, before leaving Prague. He was also an accomplished cartoonist and illustrator, and found outlets for his work in many newspapers. Records show that he worked in Prague and Brno (Moravia) and Budapest before opening a photographic studio in Vienna, Austria.

It was probably Klič's experience in newspaper illustration which led him to revisit the idea of developing a photo-mechanical printing process—an idea first explored and brought to fruition, albeit crudely, by Henry Fox Talbot in the 1850s.

It was while he was working in Vienna that Karl Klič developed the process for which he is remembered —photogravure. His first successful prints were exhibited at the annual exhibition of the Vienna Photographic Society in October 1879 and drew much admiration, although the secretive Klič did not reveal any details of his methodology. Further prints were exhibited at the following year's exhibition in November 1880. With hindsight, much of the credit for the process must go to Talbot whose photoglyphic engraving process had produced a similar if rather less refined result more than twenty years earlier, but Klič's innovations made it work much more effectively. Whereas Talbot's work had largely remained experimental, Klič's process became the first widely used mass-production process for photographic images, offering the permanence of a pigment-based image at a cost which was only a fraction, in both time and money, of that associated with the Woodburytype or with carbon printing.

In 1880 and 1881, several of his prints were reproduced in the Austrian photographic journal *Photographische Korrespondenz*, and also in 1881, a photogravure portrait of Mungo Ponton was published in Britain in *The Yearbook of Photography and Photographic News Almanac.* This portrait, provisionally dated 1870-1879 may have been taken by Klič.

The process was used to great artistic effect by, amongst others, Peter Henry Emerson in the 1880s for publications such as *Pictures of East Anglian Life*, published in 1888.

Alfred Steiglitz started to use the process in the 1880s, ands some of the finest examples of photogravure printing can be found on the pages of *Camera Work* published by Steiglitz in the early years of the twetieth century.

T & R Annan of Glasgow, whose *Old Closes and Streets* had originally been produced in carbon two decades earlier, produced editions in photogravure in 1900. Thomas Annan and his son James Craig Annan had learned the intricacies of gravure printing directly from Klič in Vienna in 1883.

Klič had experimented with zinc etching processes in the 1870s before his quest for the ideal photomechanical printing process led him to what became photogravure. His earliest proposals embraced ideas drawn both from Talbot's experimental process of 1858, and from the carbon printing process, at the height of its popularity in the 1870s.

A copper plate was coated with a resin and then a bichromated gelatin tissue similar to that used in carbon printing. After exposure, the unhardened bichromated gelatin could be removed and the plate etched. The etched plate was then inked—the ink being held within the etched areas to depths dependant upon the tonal density of the image—and printed on a flatbed printing press. No 'screen' was necessary, and the process was capable of rendering a considerable tonal range. This process is now known as 'grain gravure' to distinguish it from the later screen-based process.

But Klič's vision extended well beyond the production of single sheet-fed prints, and in 1895 he and his collaborator Samuel Fawcett developed rotogravure. It would appear that Klič and Fawcett had been working, independently, towards the development of a rotary intaglio printing process, and that their collaboration brought the process to a successful conclusion. Klič was, by the early 1890s, resident in England.

At some point c.1890 Klič made contact with the Storey Brothers in Lancaster, a firm of calico printers where, according to company records, Fawcett was already employed. By 1895 Klič, Fawcett and the Storeys had established the Rembrandt Intaglio Printing Company to exploit the new rotogravure process. Fawcett had been working on a design for a rotary press for textile printing, and Klič's rotary photogravure expertise proved the catalyst. It was at Klič's suggestion that the company moved from printing textiles to printing high quality gravures of paper. Their *Burlington Art Miniatures* were a significant commercial success, and for several years they led the world in high quality gravure printing, still closely guarding the details of their techniques. Eventually, of course, other companies caught up with them, and instigated technical improvements to the process.

By 1897 Klič was technical director of the company, but in that year he left England and returned to Vienna, leaving the operation of the Rembrandt Intaglio Printing Company to Fawcett. He returned briefly in 1906—by which time he had perfected a close-registered three-colour gravure process using a fine half-tone screen—but he spent much of the remainder of his life in Vienna where he died on November 16th 1926.

KLUMB, REVERT HENRY (1837–c. 1886)

Born in Berlin, Germany in 1837, Revert Henry (Henrique) Klumb began working in Brazil in the early 1850s. After running the studio of French photographer and lithographer Paul Theodore Robin, he worked for a painter, François René Moreaux. In 1855, he opened his own studio and pioneered stereoscopy in Rio de Janeiro. Emperor Pedro II appointed him Imperial Photographer on August 24, 1861. Around that time, Klumb opened a studio in Petrópolis, the emperor's mountain retreat. After moving there in 1865, he lectured at the Imperial Academy of Fine Arts and tutored Princess Isabel, the Emperor's daughter. In 1872, he published an illustrated road guide on Brazil's first highway, between Petrópolis and Juiz de Fora, Minas Gerais. Renowned for his landscapes and bold use of close-ups when photographing plants in Princess Isabel's gardens, he exhibited his works at the Petrópolis Horticultural Exposition in 1875. After that, Klumb and his wife, Hermelinda Barreto, went to live in Bahia and had two daughters there. By 1886, they were in Paris, from where he wrote to Empress Teresa Christina begging her to help him and his family return home. His patroness agreed, but he died shortly thereafter, possibly en route to Brazil.

SABRINA GLEDHILL

KNUDSEN, KNUD (1832–1915)

Norwegian landscape photographer

Knud Knudsen was born in Odda, Norway. He came from a family of country merchants, but got interested in photography quite early. He probably worked as an assistant to Marcus Selmer from 1857, before he started his own studio in Bergen in 1864. His business grew to one of the biggest in the country, catering to Norwegians and tourists alike and selling thousands of images.

His motives are mainly landscapes and documentation of the rapidly vanishing rural culture from which he came. Knudsen was the first to systematically photograph the whole of Norway, but with emphasis on the Vest coast. In spite of some composition elements inspired from painting, his images show us a skilled photographer who uses photographic elements to the full. Up to 1882 Knudsen used the wet plate and his darkroom tent is sometimes to be seen in his images. He developed an understanding for the special quality of the collodion process and produced images that are full of contrast and detail in the dark parts. To solve the difficult problem with exposure time for light and dark surfaces

Knudsen often made two exposures. One can therefore find different landscapes with the same sky. Knudsen retired in 1898 and left his business to a relative.

The University of Bergen possesses the biggest collection of images, both negatives and positives, after him.

Hanne Holm-Johnsen

KOCH, ROBERT (1843–1910)

Heinrich Hermann Robert Koch was born on December 11, 1843, in Clausthal, a small mining city in the Harz Mountains of Lower Saxony (Niedersachsen). Robert's father, Herrmann Koch, was a mining administrator who eventually became head of the mine. Robert's mother, Mathilde Biewend, was actually her husband's grandniece. Koch died on 27 May 1910 at Baden–Baden, a victim of a serious heart attack.

From positions as a country doctor, experimenting on microbes in his spare time, he moved to Berlin and eventually went on to become—together with his great French rival Louis Pasteur—the founder of bacteriology.

His articles about bacteriological methods—including culture media, microscopic plate technique, and specimen staining procedures—held great significance for the history of photomicrography.

In 1877 Koch published the first photomicrographs of bacteria ever, producing collotypes of such quality, they set the standard for decades.

To produce the wet collodion negatives K. used state-of-the-art equipment such as the first focus free oil-immersion lenses and the new Abbe condensor, named after its inventor Ernst Abbe, an optical consultant for the Carl Zeiss Company in Jena.

For Koch himself photography was of eminent importance for scientific practice, especially in the field of microbiology, because "(t)he photosensitive plate represents the microscopic image more reliably than the retina of the eye" (Koch 1877, 408). "The photographic picture might be more relevant occasionally than the specimen under the microscope itself" (Koch 1881, 11).

Koch also made extensive use of photography during his several excursions, mainly to Africa, to study tropical medicine between 1883 and 1907. As well as serving as private souvenirs the photographs were made as medical documents, anthropological illustrations, or visual tools in "parasitological" research.

Jan Altmann

KODAK

In 1888, reviewing a new camera that had just come on the market, made by an American company formed just a few years earlier, *The British Journal of Photography* wrote: 'What, in the name of all that is photographic, is the Kodak…? Just over twenty years later, Bernard E. Jones in his *Cyclopaedia of Photography*, published in 1911 knew precisely what "Kodak" was: "A trade name which is so familiar that many suppose it to apply to all hand cameras..." This rapid transformation from unknown novelty to household word is one of the most remarkable episodes not only in the evolution of photography but in modern business history. The success of Kodak was down to the vision, industry, commercial awareness and determination of one man—George Eastman.

George Eastman (1854–1932) was born in Waterville, New York. From a modest family background—his father died when George was eight—he soon learnt the value of industry and thrift. Aged fourteen, he left school to work as an errand boy for a local insurance company, earning three dollars a week. Some idea of his character can be gleaned from the fact that, even as a teenager, he kept meticulous account books, noting every item of income and expenditure. By 1872 he had managed to save over $1,000. In 1874 he joined the Rochester Savings Bank as a bookkeeper. Still only twenty, he now took over all his family's financial responsibilities.

Despite his work and family commitments, young George still found time to pursue leisure interests, in particular, photography. In 1877 his account book reveals that he bought a photographic outfit for $49 and began to take lessons in wet collodion photography with a local photographer, George Monroe. He soon became absorbed in his new hobby, spending all his free time taking photographs or studying photographic magazines to improve his technique and knowledge. In 1878, he came across an article in *The British Journal of Photography* describing Charles Bennett's improved method for making gelatine emulsions by 'ripening' them to greatly improve their sensitivity. Eastman began to experiment with coating his own plates at home, often working through the night. By the end of the year, he was getting consistently successful results and began to consider making plates for sale. In 1879, frustrated by the tedious and slow process of coating plates individually by hand, he devised a plate-coating machine, consisting of a roller and a trough of warmed emulsion, which he patented in England, America and several European countries.

In 1880, just three years after he had first taken up photography, Eastman rented the third floor of a building in Rochester, New York and began the commercial manufacture of dry plates. He invested all his own savings in the enterprise but he also got financial backing from Colonel Henry A. Strong, a well-off whip manufacturer, who, with his wife, lodged with the Eastmans. Strong invested $1,000 and, crucially, gave George the benefit of his long business experience. On 1 January, 1881, the Eastman Dry Plate Company was formed, supplying plates to the leading American photographic

supply house, E. & H.T. Anthony. Later that year, Eastman resigned from his job in the bank and devoted himself full-time to his new enterprise. After surviving some early setbacks, the business prospered.

In 1883, the Company moved to larger premises in State Street, Rochester and the following year the business became a corporation, changing its name to the Eastman Dry Plate and Film Company. The change of name reflected the development of a new product, Eastman Negative Paper, which Eastman had devised in partnership with a camera maker, William H. Walker. Using paper as a negative support revived an idea from the earliest days of photography. Gelatine emulsion coated paper, however, was much more sensitive than earlier paper processes and offered a potentially attractive alternative to heavy and fragile glass plates. At first, special adapters enabled sheets of Eastman Negative Paper to be used in conventional plate holders. However, to fully exploit the possibilities of his negative paper, Eastman and Walker also devised a rollholder which attached to the back of a standard plate camera and contained a roll of negative paper sufficient for twenty four exposures. The paper was advanced after each exposure by turning a key. Rollholders were not a new idea. In 1854, Spencer and Melhuish took out a British patent for a device in which sheets of negative paper were gummed together and wound on rollers and in 1875 Leon Warnecke introduced a more sophisticated version which held a one hundred exposure roll of tissue coated with a dry collodion emulsion. These early rollholders, however, were not commercially successful—mainly because of imperfections of the sensitised paper. The Eastman Walker rollholder combined precision of manufacture with negative paper that was both sensitive and easy to manipulate and enjoyed some popularity.

Soon after the rollholder came on the market in 1885, Eastman announced an improvement on his paper negative film, which he called "American Film." This consisted of a paper base coated with a layer of soluble gelatine, then a layer of collodion and, finally, a gelatine emulsion. After exposure and processing, the film could be soaked in warm water, dissolving the soluble gelatine so that the image-bearing layer could be stripped off and laid on glass for printing. American, or "stripping" film as it was also known, combined the lightness and flexibility of paper with the transparency of glass but it was a comparatively difficult material to use.

To sell his range of plates, rollholders and negative papers, Eastman looked beyond North America to the lucrative European market. In May, 1885 an International Inventions Exhibition was held in London's Albert Hall. William Walker brought over some rollholders and exhibited them under the title "Apparatus for the production of negatives in the photographic camera from continuous rolls of paper." They won a silver medal form the exhibition judges and received favourable reviews in the British photographic press. Encouraged by this success, Walker returned to London later that year to open the company's first foreign office, at 13 Soho Square. European sales were promoted by the appointment of "sole agents"—one of the best-known being Paul Nadar, son of the famous French photographer, "Nadar."

Eastman's next move was to combine the concept of the rollholder and paper negative film with a hand-held or "detective" camera. In 1886 he took out a joint patent with Franklin M. Cossitt for a box-form hand camera designed to be used with either a rollholder or conventional plates. Despite the manufacturing experience gained from production of rollholders, manufacturing a camera proved to be both difficult and costly. By June 1887, only fifty had been completed. Eastman decided to cut his losses and sold them off to a Philadelphia photographic dealer, W. H. Walmsey, for $50 each. Only one example is known to have survived, and is in the Smithsonian Institution in Washington.

Undeterred, Eastman immediately began work another camera, putting into practice the lessons he had learned and devising a camera in which for the first time, the rollholder was an integral part of the design. This time he got it right. In October 1887, he wrote: "I believe I have got the little rollholder breast camera perfected." The "rollholder breast camera" was put on the market in June 1888 under a more succinct and memorable name—"The Kodak." In 1920, Eastman described how he had come up with the name:

> The letter "K" had been a favourite with me—it seems a strong, incisive sort of letter. It became a question of trying out a great number of combinations of letters that made words starting and ending with 'K.' The word 'Kodak' is the result. To the British Patent Office he wrote: 'This is not a foreign name or word; it was constructed by me to serve a definite purpose. It has the following merits as a trade-mark word: First, it is short. Second, it is not capable of mispronunciation. Third, it does not resemble anything in the art and cannot be associated with anything else in the art.

The Kodak camera initiated a revolution in photography that was to quickly transform it into a truly democratic pastime within the range of everyone, regardless of income or technical knowledge. Extremely simple to use, it reduced taking a photograph to three simple actions: 1. Pull the string. 2. Turn the key. 3. Press the button. The camera itself did not embody any great technical advances; it was not even the first camera designed solely to take roll-film. The most revolutionary aspect wasn't in fact the camera, but Eastman's concept of separating the act of picture-*taking* from that of picture-*making*. The Kodak was sold already loaded with film for 100 exposures. After this had been exposed, the entire camera was returned to the factory for the film

to be unloaded, developed and printed. The reloaded camera was then returned to its owner, together with a set of prints. The Kodak system was summed up by Eastman's famous advertising slogan—"You Press the Button, We do the Rest." For the first time, anyone (as long as they could afford the 5 guineas which the Kodak cost) could become a photographer.

Originally, "Kodak" was used only as a name for Eastman's detective camera; only later did it become generally adopted as a designation for the company's products. The success of the Kodak can be gauged from the fact that in May 1892, the company formally changed its American name to the Eastman Kodak Company. In Britain, the Eastman Photographic Materials Company had been set up in 1889 to manufacture and sell Eastman's products outside North and South America. From 1891, at their new factory in Harrow, they manufactured film and paper and developed and printed customers films. In 1898, reflecting the change which had already taken place in America, the British company changed its name to Kodak Limited. By this date, other European companies had been established, wholly owned by the British Company— Kodak Gmbh in Germany in 1896, Eastman Kodak S.A.F. in France in 1897. Belgium, Holland and Austria/Hungary followed in 1899, then Russia and Australia in 1900 and Italy in 1901. By the outbreak of the First World War, Kodak had offices and branches all over the world.

The introduction of a range of Kodak cameras, the successful manufacture of flexible celluloid rollfilm and, later, daylight loading film cartridges, transformed the company's fortunes. What had been a comparatively successful photographic manufacturer now became a worldwide business phenomenon. By the mid-1890s, over one hundred thousand Kodak cameras had been sold and the pace of growth showed no signs of slowing down. The word Kodak entered popular usage as a verb as well as a noun as people carrying Kodaks "Kodaked" everything in sight. As early as 1890, *Photography* magazine had correctly prophesied: "The word will very likely develop verbal, adjectival and adverbial forms as "'I am going to Kodak,' 'This is a Kodak negative,' 'This picture looks Kodakky'." Other manufacturers, too, were eager to seize on the popularity of the Kodak name but Eastman jealously guarded the integrity of his trade name and the company stamped down hard on any perceived misuse. In 1898, for example, the company obtained an injunction against the Kodak Cycle Co Ltd., preventing them from using the name Kodak in connection with any of their products. Similar court cases took place all over the world. As the company's advertisements repeatedly reminded customers: "If it isn't an Eastman, it isn't a Kodak."

The revolution begun in 1888 with the introduction of the Kodak, took another giant step forward in 1900 with the appearance of the Brownie camera. With the Kodak, Eastman had attempted, in his own words to: "...furnish anybody, man, woman or child, who has sufficient intelligence to point a box straight and press a button...with an instrument which altogether removes from the practice of photography the necessity for...any special knowledge of the art." With the Brownie camera, costing just five shillings (one dollar), the financial as well as the technical constraints on photography were finally removed. One hundred thousand Brownies were sold in 1900 alone.

In creating and satisfying a huge, previously untapped, market for popular photography Eastman was to create one of the biggest business empires the world had ever seen. All over the world, the word Kodak became as instantly recognisable as that other great symbol of American commercial imperialism, Coca-Cola. In 1898, *Commerce* magazine predicted: "The year 1888 will rank in the annals of photography as the date of the introduction of the Kodak." The passage of one hundred years has only served to reinforce this prediction.

KOREA

By the mid-nineteenth century the Yi Dynasty had ruled Korea since 1392 and a policy of 'no contact' with foreigners had been adopted. A Russian fleet visited the port of Wonsan in 1856 and tried in vain to open a dialogue with the local officials. In 1866 the still deeply conservative regime became concerned over the increasing number of Christian converts and instituted a wholesale massacre. A number of French priests were also killed and, as a result, seven French warships sailed to Kanghwa Island, close to Seoul. When negotiations broke down, the French looted Kanghwa city but were driven off after suffering significant casualties. The same year an American ship, the USS *General Sherman*, tried to open commercial relations. Misunderstandings arose, and when the ship became grounded in the shallow Taedong River, all on board were massacred and the ship was burnt.

Taking stock: Did any of these events give rise to photographic opportunities? The writer has seen one *carte de visite* portrait, from a Shanghai Chinese stu-

dio, of what appears to be a French priest together with other Koreans—presumably escapees from the 1866 persecution. The writer also has in his collection several *cartes de visite* of French origin, which show portraits of unkempt-looking Koreans probably photographed on board a ship. The 1866 French-Korean conflict strongly suggests itself.

In May, 1871 Admiral Rodgers led a fleet of five ships to Kanghwa with the dual purpose of enquiring about the attack on the *General Sherman* and of opening trade relations. Felix Beato was the expedition's photographer. When the American diplomacy failed, Beato was able to photograph the conflict of the 10th and 11th of June—including the carnage inside the captured forts. Beato had gone across to Shanghai by 28th June, and on the 30th June, with the American fleet still in Korea, Beato advertised in the *Shanghai News Letter* the sale of his photograph albums of the conflict! Beato did not believe in wasting time. Albums of the conflict are exceptionally rare, but one example is held by the Library of Congress, another is in the writer's collection.

In September of the same year, John Thomson was on a photographic tour of China and had reached Peking. There he encountered a few Koreans who were part of a mission to China and were on the point of leaving. Thomson was just in time to secure one portrait of two of the officials which is reproduced in his monumental 1873–1874 work, *Illustrations of China and its Peoples.*

In 1874, the American photographer D.R. Clark was in the Far East to photograph the Transit of Venus. He subsequently published a stereoview series in 1875, *Asiatic and Tropical Views,* and included were five views of Korean interest. Clark had photographed a Korean emigrant community living in Vladivostok and the first view, *Natives of Corea,* which is now in the writer's collection, would appear to be the earliest-known photograph to include Korean women.

In 1876, a Korean embassy in Tokyo was photographed, examples of which are in the writer's collection. A fine group of photographs of an 1880 mission to Japan are held by the *Russian Geographical Society*, St. Petersburg. A photograph of an 1883 mission to the United States is in the *Peabody Essex Museum.*

At this time, photographic activity amongst Koreans themselves started to emerge. The first professional Korean photographer was Kim Yong-Won who was a member of both the 1876 and 1880 embassies to Japan. He was helped by a Japanese photographer, Honda Shunosuke, and Kim set up a studio in Korea in 1883. In 1884, both Ji Un-Young, who had studied photography in Japan, and Hwang Chul opened studios. However, no photographs appear to have survived, and there is precious little documentary evidence concerning the activities of these three pioneers.

All three had to contend with widespread ignorance and suspicion of photography. Rumors persisted that photographic chemicals were the residue from cooked local children! Hwang Chul's studio suffered regular stoning. The new technology was also associated with the unpopular Japanese, and the general hostility resulted in all three studios being closed down and destroyed in 1884.

Not surprisingly, these early photographers had confined themselves to portraiture, which they could practise in relative safety. Kim Kyu-Jin, an artist who went to Japan to study photography around 1895, was appointed the first official photographer at the Korean Court, but none of his photographs have been positively identified.

In the final few years of the nineteenth century, photography was given a boost when the King issued an ordinance banning the wearing of the traditional male topknot. Many Koreans wished to preserve an image of what they looked like before complying and photo studios suddenly experienced unprecedented demand. But Korean sources, so far as the writer understands, have yet to positively identify any photograph, taken by a Korean, prior to 1920.

By the late-1880s, however, a succession of amateur Western photographers had photographed the country. The talented amateur and American diplomat, George Foulk (1856–1893) took a number of photographs, examples of which survive in American institutions. In 1883 the American, Percival Lowell, travelled to Korea and in a book which he published in 1885, included twenty-five of his own photographs. The first professional Japanese photographers in Korea seem to have been Honda Shunosuke, and a Kameya Teijiro who died in Korea in 1885 following the setting up of his studio at around this time. Nothing much is known about either of them.

A large part of the Sino-Japanese War of 1894–1895 was fought on Korean soil and photographs were taken by, amongst others, the French artist and cartoonist Georges Bigot (1860–1927), many of whose photographs can be seen at *Kawasaki City Museum*, Japan and John Alfred Vaughan, an engineer on HMS *Undaunted.* Examples of his work are in the writer's collection.

Because Korean photography was so late in getting started, virtually all surviving work is represented in albumen or silver print. Photographic formats include stereoviews, *cabinet*, *cartes de visite,* and lantern slides. All nineteenth-century photography of Korea is rare, and what there is exists mainly outside Korea.

KOTZSCH, CARL FRIEDRICH AUGUST (1836–1910)

German photographer

Carl Friedrich August Kotzsch was born Sept. 20, 1836, in Loschwitz near Dresden. Working in his father's vineyard he received only a basic formal education. From 1853, the Kotzsch house was host to a colony of artists, mostly students of the well-known graphic artist Ludwig Richter. Around 1860 August Kotzsch began to draw and take photographs. From 1861, August Kotzsch was known as professional photographer in Loschwitz. Around 1870 he began with the production of still life photographs of common fruits like apples, grapes, and quinces, which were placed on simple plates and shelves. Nothing is known about the reasons why he took up these forms of photography hitherto completely alien to the medium except for industrial products. Roughly fifty of these still lifes were produced within a comparatively short time, always using a shadowy daylight—exactly the way Karl Blossfeldt did with his widely acclaimed plant images forty years later. The stunning quality of these still lifes exceed his good quality as a travel and landscape photographer. Curiously enough, these images were recovered from obscurity in the 1980s. After 1895, there is no photograph known from his studio. On October 23, 1910, August Kotzsch died in Loschwitz which he never left farther than walking distance.

ROLF SACHSSE

KRASZNA-KRAUSZ, ANDOR (1904–1989)

The twentieth century career of the photographic publisher Andor Kraszna-Krausz had a decisive impact on the revival of interest in nineteenth century photography, but just how his own interest in the medium came about remains obscure. When setting out in Great Britain in the late 1930s to establish the Focal Press, the imprint that by the 1960s would become the world's largest and most esteemed publishing house for books about photography, film and television, he often reminded people that he had had a long career in Germany working for the Continent's largest specialist photography publisher, Wilhelm Knapp in Leipzig. And this was perfectly true, as far as it went. What remained unsaid was that his experience with Knapp was almost exclusively in Berlin as the film critic and then editor of the leading moving picture trade paper *Die Filmtechnik* from 1925 to 1936. With strong domestic film production dominated by the Universum Film, A. G. (UFA) studios and significant interchange with American producers in Hollywood, Weimar Berlin was, arguably, at the time the leading centre for film criticism and film theory, where Kraszna-Krausz published in parallel with writers like Herbert Ihering, Siegfried Kracauer and Rudolf Arnheim. His lengthy, detailed analyses of films by F. W. Murnau, Fritz Lang, E. A. Dupont, Viktor Sjöström, G. W. Pabst, Charles Chaplin, John Ford, Vslevod Pudovkin, Fred Niblo and others were mixed on Kraszna-Krausz's rich palette with equally incisive notices of documentaries, experimental productions, and animated films. He regularly supplemented his reviews and interviews for *Die Filmtechnik* with intense editorials decrying impersonal commercial productions, the dominance of the star system, and the exorbitant production costs of films, while arguing in other essays on behalf of socially relevant, culturally significant filmmaking and examining the contributions of technicians to the art of filmmaking. But apart from reviews of a few books which included photography, such as Laszlo Moholy-Nagy's *Malerei, Photographie, Film* (Painting, Photography, Film) of 1926, there is little evidence in these years of the passion for photography with which Kraszna-Krausz launched his second career in Britain.

Established in 1938, Kraszna-Krausz's Focal Press at first relied heavily on his former contacts in Germany. Two of Focal's first titles, *Snaps of Children and How to Take Them* along with *A Good Picture Every Time*, both by Alex Strasser, were translations of works published earlier by Knapp in Germany, who also printed the books for the new British publisher. The 1939 title *Phototips on Children: The Psychology, the Technique and the Art of Child Photography* was written by Kraszna-Krausz's longstanding colleague in film criticism, Rudolf Arnheim, together with his wife Mary Arnheim, undoubtedly as they passed through Britain on their way to distinguished new careers in America. One of the earliest books from the press, *The All-in-One Camera Book* by E. Emanuel and F. L. Dash, was a solid success, ultimately running to some 81 editions and remaining in print until the early 1990s. Perhaps encouraged by the

substantive if not yet secure financial platform provided by this book, or perhaps beginning to express the fondness for and sympathy with the culture and history of his adopted country that would become so prominent throughout the remainder of his life, Kraszna-Krausz in the early 1940s began to publish large-format picture books on nineteenth century photography.

Gallery of Immortal Portraits (1940) and *Victorian Photography* (1942) featured works of William Henry Fox Talbot, David Octavius Hill, Julia Margaret Cameron, Roger Fenton, Frank M. Sutcliffe, and others, selected from the permanent collection of the Royal Photographic Society by Alex Strasser and introduced by texts from Kraszna-Krausz. Most importantly, these books reproduced original prints, at a time when 19th century photography was principally known from copy prints that over decades had gradually become more and more "modern" in the sense that they attempted to show the quality of Victorian images through printing them with current techniques. Just how radical these publications were at the time is hard to imagine now given the roll-call of eminent pioneers they brought out of the RPS archive, once-forgotten photographers who are today honoured, studied, collected and many times republished. Comprising volumes 1 and 2 of the *Classics of Photography*, a nascent series cut short by wartime limits on paper supplies, the publications were accompanied by Kraszna-Krausz's own very defensive texts that beg his readers to understand the primitive and awkward photographic technology used in the past, to excuse the photographers' subservience to styles of painting already *passé* when the photographs were made, and to recognise that modern photography had successfully avoided the *cul-de-sac* that trapped the Victorians.

It would seem that Kraszna-Krausz, a committed modernist and advocate of democratic values in both photography and moving pictures, was in these essays beginning to work out for the first time his relationship to the history of photography and to its legacy. After warning his readers that the Victorian photographers had struggled gallantly with crude and undeveloped tools, what Kraszna-Krausz celebrates is their spirit of amateur adventurousness, along with their curiosity and freedom to experiment which in his view saved photography from the habitual and miserly commercialism of the professional studios. Here, Kraszna-Krausz repeats his conviction that honest amateurism was always to be more valued than formulaic professionalism, a view that was also a theme of much of his film criticism in the late 1920s. The idealism that Kraszna-Krausz found in the Victorian photographers was also a fundamental tenet of his new publishing firm, which was committed to providing access for every intelligent reader to modern technical work in filmmaking and photography at the highest level, clearly explained and concisely delivered. By producing unvarnished albums of classic Victorian photography untainted by romantic visions of the past, Andor Kraszna-Krausz allowed a new generation to see their work directly and to recognize the innate qualities which made it a mirror of its period.

DEAC ROSSELL

Biography

Born on 15 January 1904 in Szombathely, Hungary, to Adolf and Irén (Rosenberger) Krausz, Andor Kraszna-Krausz added the unidentified "Kraszna" to his name sometime before 1925, although in that year he experimented with spelling his name in several signed articles as "Kraszna-Krauß," "Kraszna-Kraus," and "Kraszna-Krausz." Little is known about his youth and early education; he was reputed to be an eager photographer from the age of twelve, to have studied law at the University of Budapest, emigrating to Germany in the early 1920s and followed up an intense interest in photography and film at Munich University. By 1925 he was in Berlin, working as a journalist for professional film magazines to which he contributed film reviews, commentary, interviews and occasional book reviews. Appointed in September, 1925, the chief film critic of the trade journal *Die Filmtechnik* published by the specialist photography house of Wilhelm Knapp in Halle, he became the magazine's editor in January 1926 and oversaw every biweekly issue until the summer of 1936, when he left Knapp and Germany, ultimately settling in the United Kingdom. In 1938 Kraszna-Krausz established his own publishing enterprise in London, Focal Press, which became the world's largest photographic publishers, issuing both practical handbooks and books on specialist techniques in photography, film, and television, issuing some 1,500 titles over its first half century. Kraszna-Krausz oversaw every aspect of book production at the Focal Press, which continues today, until he retired in 1978 at the age of seventy-four. He was awarded the Kulturpreis of the German Photographer's Association in 1979, made an honorary fellow of the Royal Photographic Society and the British Kinematograph Society, and established a foundation in 1984 to support research in and award a book prize for photography and film, which upon his death in 1989 received the bulk of his estate.

KRONE, HERMANN (1827–1916)

Hermann Krone lived most of his life in Dresden, and spent it in pursuits that ranged over photographic experimentation; being a photographer for solar eclipse and transit of Venus expeditions; teaching photography, photo printing processes and art in schools and private lessons; portraiture; and travel photography including stereo images (some of which are held at George Eastman House). He made attempts to get copyright for photographers, did extensive public lecturing on a wide range of scientific and photographic subjects, and created publications which most famously includes a unique *Historisches Lehrmuseum fur Photographie* (Historical Didactic Museum of Photography), actually a group of large pages devoted to documenting many of the photo processes that were or became known in his time. This document was recently published in book form (1998), including all the paper pages, but omitting a small number of glass plate color images and about 900 glass negatives. Krone's teaching and production reputation were international.

The color plates are spectra made by Lippmann's process. Krone was one of the early experimenters in this process and was the first to publish trials of it that omitted the mercury mirror (1892). Instead, the light reflected from the emulsion-air interface interferes with the incoming light. The resulting image has color less saturated than that in the original technique, which used a mercury mirror in contact with the emulsion to create a stronger reflection. Krone's work in this area anticipated Rothe's better-known results by about a decade.

KRUGER, JOHAN FRIEDRICH CARL (FRED) (1831–1888)

German landscape photographer and studio owner

Fred Kruger was born on 18 April 1831 in Berlin. He emigrated to Australia in the early 1860s to join his brother's furniture business and later took it over as sole proprietor. In 1866 upon selling the furniture business he became a cabinet maker but also opened a photographic studio in Carlton, Victoria. Kruger was recognised at international exhibitions for his landscape photographs but also photographed the civil progress, scenic views and Botanic Gardens of Geelong, Ballarat and Queenscliff, Victoria extensively. In 1868 he was commissioned to photograph the Aboriginal Cricket Team that toured Australia and which played at Lords. In 1877–1888 he photographed the Aborigines at the Coranderrk Aboriginal Mission Station at the request of the Victorian Board for the Protection of Aborigines; "Badger's Creek, Coranderrk (Aborigines Fishing)" (State Library of Victoria) notably depicts Aboriginal subjects at leisure in the landscape. After settling in Geelong, he received a further commission at Coranderrk in 1883 for physiognomic studies. Kruger's photographs were available individually or presented in albums and were regularly used in the illustrated press. Commissions remained a source of income from property owners and in 1886 the Victorian government requested photographs of the Yan Yean waterworks. Kruger died in Surrey Hills, Melbourne, on 15 February 1888.

JULIA PECK

KÜHN, HEINRICH (1866–1944)

Austrian photographer

(Carl Christian) Heinrich Kühn was born on February 25, 1866, to wealthy parents in Dresden. He studied medicine and natural science in Freiburg in Breisgau. Due to health problems he moved to Innsbruck/Tirol. In the Camera Club Vienna, which he joined in1895, he became acquainted with Hugo Henneberg and Hans Watzek. Kühn is considered an internationally well-known representative of the Austrian Pictorialismus. Numerous personal contacts and connections to the international scene marked his activities. Kühn was friends with Alfred Stieglitz and over three decades lasting exchanges of letters marked their friendship (1899 to 1931). In 1896 he was accepted as a member in the Linked Ring Brotherhood London. The portraits of his children was emphasised in his work. He worked intensively with the technology of the autochrome. After

the loss of his fortune, Kühn operated a private studio in his house. In 1914 he established a photography school in Innsbruck, which had to be closed one year later due to the continuing First World War. The design of a soft-drawing lens named "Imagon," the publication of two photo books about the technology and aesthetics of photography, as well as numerous publications in specialized magazines marked his activity in the 1920s and 1930s. Kühn died on September 14, 1944, in Birgitz/Tirol.

ASTRID LECHNER

KUICHI, UCHIDA; See UCHIDA KUICHI

KUSAKABE KIMBEI (1841–1932)

Japanese photographer and studio owner

Kusakabe Kimbei was one of the most successful photographers in nineteenth-century Japan, operating a studio in Yokohama from where he produced, for foreign residents and tourists, beautifully decorated albums of handcolored albumen prints of both scenery and *genre* subjects. As a result, Kusakabe is better known today in the West than in Japan and usually by his first name, Kimbei, which he used no doubt because it was easier for foreigners to pronounce. Born into a family of textile merchants in Kofu, Yamanashi Prefecture, Kusakabe left home at eighteen to become an artist in Yokohama. Some time in the 1860s he joined Felix Beato**,** initially to assist in the handcoloring of photographs, but than as a studio assistant. He subsequently worked with Baron Raimund Von Stillfried-Ratenicz**.** Kusakabe opened his own Yokohama studio in 1880 and was adept at cultivating foreign patronage—no doubt his time with Beato and Stillfried would have helped in this respect. Becoming a Christian in 1885 would also not have harmed his business and, by the end of the century, he operated the largest studio in Japan. Retiring in 1914 he spent his later years painting. By 1930 his health had worsened and he moved to Ashiya City where he died in 1932.

TERRY BENNET

L

LACAN, ERNEST (1828–1879)
French editor and critic

Although Ernest Lacan never practiced photography, he was a central voice in the international photographic community during the second half of the 19th century. As editor and writer for the two leading French photography journals, *La Lumière* [*The Light*] and *Le Moniteur de la Photographie* [*The Monitor of Photography*], from 1851 to 1879 Lacan helped shape the terms of the debate around photographic practice and theory as he strove to articulate photography's cultural significance.

Lacan was born in Paris, France, in 1828, the son of Auguste Théophile Lacan and Marie Josèphe Monodé Devassaux. He studied painting under the artist Léon Cogniet and apprenticed in his studio in the 1840s. Cogniet was a highly regarded history painter with a strong interest in photography and Lacan later credited Cogniet's enthusiasm for stirring his own interest in the new medium. It was with Cogniet's encouragement that in 1849 Lacan first envisioned creating a photography journal, after having decided to give up painting for writing.

In 1851 it was another painter and member of the Société Héliographique**,** Jules-Claude Ziégler, who helped Lacan start *La Lumière,* which first appeared on 9 February under the photography society's auspices. When the society dissolved several months later, photography supplier Alexis Gaudin bought the weekly and appointed Lacan secretary (i.e., manager), then editor-in-chief.

As Europe's first photography journal, *La Lumière* achieved a significant readership in France and internationally, and throughout the 1850s Lacan used its pages to cover technological advances and historical issues, as well as to promote photography within the greater intellectual and artistic community. Dedicated to "Fine Arts, Heliography and Sciences," it sought a broad audience of artists, scientists and scholars as it centered on photography but also encompassed other, carefully chosen topics like the annual Paris Salon.

In his writings and editorial policy, Lacan fought fiercely to defend photography against what he saw as a common misconception that "imagination and artistic feeling play no part in the results." While he exalted photography's many applications, he sought to downplay its commercial reputation, taking pains to distinguish the medium's "amateurs," "artists," and "savants" from the legions of "simple photographers" who toiled in the portrait trade.

Throughout the first half of the 1850s, Lacan wrote regular photography reviews for the journal, addressing the work of some of the most important photographers of the epoch, including Charles Nègre**,** Roger Fenton**,** Edouard Baldus**,** and Olympe Aguado**.** While Lacan's colleague, the critic Francis Wey**,** wrote more generally for the journal on the aesthetics of photography and art, Lacan's reviews mapped out photography's artistic terrain by analyzing specific works with a scrutiny of form and a depth of commentary previously reserved for the other arts. He was among the first to claim that photography had its own schools and styles, and although he believed these initially derived from the different photographic processes, he was convinced that photography "permits each [artist] to take—according to his tastes and the nature of his talent— a different path."

Lacan was reluctant to situate photography squarely within the fine arts, but he saw it as closely related to them rather than an inferior substitute, and his reviews would contribute to securing the photograph's place as an aesthetic object. Even if he never ventured to incorporate its most obvious characteristics— like its reproducibility or mechanical means—into his assessments,

his criticism was exceptional in challenging the limits of what could be considered artistry by including works beyond the scope of other critics. In reviewing the images of English asylum patients taken by Dr. Hugh Welch Diamond, for example, Lacan boldly declared that they "can be ranked, in their execution, among the most beautiful photographic productions."

Given his links to Parisian art circles, Lacan played host to regular photography salons in his Paris home in the 1850s. These informal gatherings bolstered the French photographic community, especially during the crucial period between the dissolution of the Société héliographique in 1851 and the founding of the Société française de la photographie in 1854. Open to an eclectic mix of photographers, writers and other artists, his salons usually included displays of recent photographs made by guests, thereby helping to reinforce the link between photography and aesthetic discourse.

In 1856 Lacan published *Esquisses Photographiques* [Photographic Sketches], a collection of several of his *La Lumière* reviews as well as articles he had written elsewhere on photography's origins and uses. The book was a turning point in Lacan's career, as he would thereafter concentrate his writing more on technical innovations and business reporting. He also took on numerous outside projects, like contributing introductions to books on photography by Claude-Félix Abel Niepce de Saint-Victor (1855) and Alphonse Louis Poitevin (1862), editing a popular weekly, *Le Moniteur Universel* [The Universal Monitor], becoming scientific editor of *La Vie Moderne* [The Modern Life] (1859) and serving as French correspondent for *The Photographic News* in London.

At the end of 1860, after disagreements with Gaudin, Lacan left *La Lumière* to co-found a competing journal, *Le Moniteur de la Photographie,* with Paul Liesegang**,** German publisher of *Photographisches Archiv* [Photographic Archive]. Subtitled "International Journal of the Progress of the New Art," the fortnightly periodical first appeared on 15 March 1861. Primarily addressed at professional photographers, Lacan augmented the editorial staff by inviting respected commercial photographers and printers like Antoine Claudet, Louis Désiré Blanquart-Evrard and André-Adolphe-Eugène Disdéri to contribute articles. Lacan wrote a regular column, reported on technical matters and detailed new applications of photography in fields like criminal investigation and military strategy.

While he continued to review major photography exhibitions like that held at the Universal Exposition, Lacan was less concerned with individual photographers or styles. Perhaps reflecting his journal's stronger commercial slant, he expounded on aesthetic trends within the medium as a whole and often attributing these to technological innovations rather than personal creativity.

In 1870, Liesegang left *Le Moniteur de la Photographie* and Lacan became sole proprietor. He fell gravely ill in the summer of 1878 but continued writing and editing up to his death the following January. His longtime colleague, Léon Vidal, succeeded him as editor and the journal remained in print under various owners until 1914.

Although the writings of other early critics of photography—like Charles Baudelaire and Lady Elizabeth Eastlake—have received greater attention, Lacan's work as a whole provides a comprehensive view of the evolving attitudes and aims that marked photography's first decades. His versatility and energy, not to mention his enduring faith in photography's benefits to society, were rarely matched in his lifetime.

STEPHEN MONTEIRO

Biography

Emmanuel Ernest Auguste Lacan was born in Paris, France in 1828 to Auguste Théophile Lacan and Marie Josèphe Monodé Devassaux. He studied painting under Léon Cogniet and apprenticed in Cogniet's studio in the 1840s. He worked as a librarian before turning to journalism in 1851, helping found the photography journal, *La Lumière,* where he was editor and a regular contributor until 1860. He published a collection of his photography writings, *Esquisses Photographiques* (1856), and contributed to several books on photography. He also published poetry and fiction, including *Le Mort de l'Archevêque de Paris* [The Death of the Archbishop of Paris] (1849) and *Les Petites Gens* [The Little People] (1870). He edited and wrote for *Le Moniteur Universel* from the 1850s through the 1870s, was scientific editor for *La Vie Moderne* (1859), and contributed to other journals published by the Société des Publications Périodiques. He was also a correspondent for *The Photographic News.* Lacan co-founded the weekly journal *Le Moniteur de la Photographie* in 1861, which he published until his death. He was married to Camille Valentine Salle and died in Paris on 18 January, 1879.

LAFAYETTE, JAMES (JAMES STACK LAUDER) (1853–1923)

James Stack Lauder (1853–1923), photographer, under the name James Lafayette, was born in Dublin on 22 January 1853, the eldest son in the family of six sons and four daughters of Edmund Stanley Lauder (1824–1891), photographer, and his wife Sarah Stack (1828–1913). Edmund was a pioneering and successful photographer who had opened a daguerreotype studio in Dublin in 1853.

In 1880 James Stack Lauder founded his own photography studio, using for the first time the professional name of James Lafayette "late of Paris" and naming his studio variously "Jacques Lafayette," "J. Lafayette," and "Lafayette" as an indication of his artistic training in the City of Lights. He was joined in the new business by his three brothers, all of whom were experienced photographers who had worked in their father's studio. In 1884 he was elected member of the Photographic Society of Great Britain, and thereafter his entries in the multitudinous photographic competitions around Britain and in Europe started winning him medals for "exceptionally fine portraits."

By 1885, the studio's output was praised in print by the Photographic Society of Great Britain as "very beautiful, being distinguished for delicacy of treatment..." and Lafayette's early experiments with hand-colouring produced images that were described as "permanent carbon photographs painted in water-colour on porcelain," and the new specialist photographic press waxed generally lyrical over the fine quality of "Monsieur Lafayette's" portraiture. His work was noted to be of the highest technical excellence. His poses were graceful and good, the flesh was rendered as flesh and the folds of the drapery were rich and effective in the "Rembrandt style." As well as producing a number of faux rustic and cloying images of mother and child in the high Victorian style, Lafayette registered many idylls for copyright at Stationers' Hall. A typical image of this genre, half photograph, half line drawing, made as late as June 1894 has elements of highly sanitised fully-clothed Victorian eroticism depicting, in Lauder's own words, a "group of two figures, girl on ladder gathering apple blossom, man under tree receiving same in his hat, called 'Blossoming Hopes.'"

During the World's Columbian Exposition of 1893, held in Chicago, the foremost German professor of photography, H.W. Vogel, described a portrait of Lafayette's work as the "grandest photographs… He shows great skill in finely arranged single pictures and groups. A suspended angel, almost life-size and taken from life, is remarkable." This floating angel could be considered a rudimentary beginning of special effects photography and it was not until decades later that an employee divulged that the image had been made by photographing the subject lying down on a large sheet of glass over a painted background, so adjusted and so illuminated as to give the proper idea of perspective and the draperies having been arranged on the surface of the glass to give the impression of flight.

In the studio's commercial portraits, Lafayette followed the recipe well-tested from the early days of the daguerreotype when having an image made of oneself suddenly became affordable and no longer the preserve of active patrons of painters. As the subjects of portraits became democratised, the commercial photographer faced the situation of having to make flattering photographs of people who had no experience of sitting for a portrait and Lafayette's art of posing and skill in cropping the prints from his 12" × 15" glass negatives engendered both commercial success and, on 6 March 1887, the grant of a Royal Warrant as "Photographer to Her Majesty at Dublin."

The Royal Warrant, which was subsequently renewed by King Edward VII and George V, conferred enormous prestige, and the style and title of "Photographer Royal" on the studio advertising and promotional literature, proved extremely useful in attracting new clients. The business expanded rapidly in the 1890s. Studios were established in Glasgow (1890), Manchester (1892), and with the expected business bulge in Jubilee year (1897) a branch was opened on London's fashionable Bond Street. Subsequently another studio was established in Belfast (1900). In 1898 all the Lauder family businesses were incorporated and shares in the newly established Lafayette Ltd. were floated on the Stock Exchange.

Lafayette's commercial success coincided with developments in the half-tone printing process, which resulted in the proliferation of illustrated weekly magazines. The firm was one of the first to recognize the opportunities offered by syndicating photographs and portraits of his favourite subjects—"some of the great ladies of the land"—were published in such great numbers as full page covers in *The Queen*, *The Tatler,* and *Chic*, *inter alia*, that *The Lady's Realm* in 1900 stated outright: "It is well-nigh impossible to open any

magazine or paper which contains portraits of present-day celebrities without seeing at least one reproduction of a photograph by the well-known Lafayette house [with its] 'special Lafayette silver process'." By 1897, the fame of his portraits of the great society beauties, such as the Countess of Warwick, Daisy Princess of Pless, and Queen Alexandra, led the critic Levin Carnac (pseudonym of the author George Chetwynd Griffith-Jones) to muse in *Pearson's Magazine* in 1897 that it was "Lafayette's blissful lot to photograph more of the most beautiful and distinguished women of Europe than anyone else." The male was not forgotten and portraits of distinguished men and from society, the stage, and politics appeared prominently in the various new publications, frequently providing the frontispiece and setting the tone for the publication.

The sale of photographic postcards had also become big business, and certain images by Lafayette, such as Queen Alexandra in her Doctor of Music robes, registered for copyright on 28 April 1885, sold over eighty thousand copies by 1900. The Lafayette range of postcards included many images of the British royal family as well as luminaries of the stage, including a seminal series of Sarah Bernhardt as Hamlet from her London season of 1899.

On 2 July 1897, to mark Queen Victoria's Diamond Jubilee, Louisa, Duchess of Devonshire (1832–1911), one of London's foremost political hostesses, held a costume ball with around seven hundred guests ranging from royalty down to aristocracy and a commission went out to Lafayette, who had opened a studio on London's fashionable Bond Street with "patent fog-clearing equipment" earlier that year, to set up a tent in the garden to photograph the guests in costume during the Ball. This would have been a formidable commission for James Stack Lauder, and evidence from the extant negatives shows that he had transported from the Bond Street studio a variety of backdrops and props and, of course, photographic equipment. His remit was to photograph guests who would be in costumes ranging from mythological and ancient Greek down to renaissance and oriental characters. In order to capture the sense of event and location, the studio prepared a new backdrop representing the very lawn and gardens of Devonshire House complete with statuary. Approximately 162 negatives exist from this event, many of which were published by the Duchess of Devonshire in a private album and which represent the studio's largest output from a single photographic session. A copy of this album is held by the National Portrait Gallery, London.

The Lafayette studio, which survived the vicissitudes of World War I and Irish Independence, finally closed in 1952—the Lauder family having been in the business continuously from 1853. A storeroom of negatives, possibly representing the press archive of the studio, was discovered in the attic of a building in Fleet Street in 1968 during building works. The archive was eventually handed to the Victoria & Albert Museum, London, which kept 3,500 glass plate and celluloid negatives dating from 1885 to c 1937. The rest of the collection, consisting of circa forty thousand nitrate negatives from the 1920s to the early 1950s, was given to the National Portrait Gallery.

During the heyday of the Lafayette studio, the ranks of sitters included most of the British royal family, many European royalties, a significant number of maharajas, and official visitors from the Far East. The quality of the studio's portraiture peaked between 1897 and 1920 and was an inspiration to the following generation of photographers, who were more willing to experiment with new styles of lighting and posing. Of the thousands of images credited to Lafayette and which are recognisably portraits in the Lafayette style, only 649 photographs registered for copyright before 1912 bear the signature of James Lauder as author.

James Stack Lauder died at the Hôpital St. Jean, Bruges on 20 August 1923.

LAI AFONG (active 1850s–1890s)

Although almost nothing is known about his personal life, Lai Afong will probably be remembered as the most significant Chinese photographer of the nineteenth century. Afong, as he preferred to be known, opened his first studio in Hong Kong in around 1859 and continued to operate it until ca. 1900. He assiduously cultivated foreign clientele, employing a succession of foreign assistants such as William Lentz and D.K. Griffith to help him do so. John Thomson spoke highly of his work in his 1875 book, *The Straits of Malacca, Indo-China & China*: "…a man of cultivated taste, and imbued with a wonderful appreciation of art…his pictures, besides being extremely well executed, are remarkable for their artistic choice of position." By the 1870s Afong's advertisements proclaimed him as photographer: "By appointment to H.E. Sir Arthur Kennedy, Governor of Hong Kong, and H.I.H. The Grand Duke Alexis of Russia." He accumulated an impressive portfolio of views from all over China claiming, in 1897, to have more than any other Far-Eastern studio. Apart from his excellent portraiture, he is known for his dramatic views of the 1874 Hong Kong Typhoon and for an exquisite album of Foochow scenery, a copy of which is held by the *Scottish National Portrait Gallery*, Edinburgh.

TERRY BENNETT

LAMBERT & CO., G.R. (1867–1918)

German-born, commercial photographers of Singapore and Malaya

The first known mention of Singapore photographers, G.R. Lambert and Company, was an advertisement (dated 10th April 1867) that appeared in a May edition of the *Singapore Daily Times* announcing the opening of a "Photographic Establishment" at 1 High Street.

The island of Singapore, which lies off the Southern tip of the Malay Peninsula, was established by Sir Stamford Raffles and became a trading post under the East India Company in 1819. It was incorporated with Penang and Malacca to form the Straits Settlements in 1826 and came under British colonial rule in 1867, the same year as Lambert's announcement.

Lambert was a German from Dresden and may of been connected with the Lambert Brothers' carriage makers, undertakers, and masons, who were well established in Singapore.

It appears that at some time after his initial advertisement Lambert returned to Europe, it is not clear whether his first studio failed or not, but another announcement ten years later (in May 1877) told of his return to Singapore, with a studio at 30 Orchard Road (opposite Lambert Brothers' Carriage Works). Interestingly, this advertisement stated that photographs [portraits] were taken daily 7a.m.–11am. It was probably too warm for portraiture after this time. The Orchard Road premises had previously been briefly occupied by another German photographer, G.A. Schleeselmann, who, in turn, had purchased the negatives of former occupant and fellow countryman, Henry Schuren.

By 1878 Lambert had moved studio again, this time to 430 Orchard Road, where he advertised a new collection of Singapore 'views and types.' Lambert visited Siam (Thailand) in late 1879 and returned in February 1880 after being appointed official photographer to the King of Siam.

In fact Lambert & Co. were to become the "official" photographers of South East Asia; they recorded major royal and political visits, government buildings, plus social and sporting events, along with formal portraits of ministers and merchants.

Lambert's studio portraits were mainly comprised of commissioned studies depicting European merchants and their families, as well as local dignitaries. However, there was another body of work that showed native or racial types and these more exotic studies were aimed at the tourist market

In the early and mid 1880s much of the Singapore studios' output by was undertaken by manager, J.C. Van Es and assistant Alexander Koch, who became a partner in 1886. Around this time Lambert himself seems to have returned to Europe leaving the running of the business in the trusted hands of Van Es and Koch.

In 1886 the main studio moved again, this time to number 186 Orchard Road, where they stayed until ca.1902. The firm also operated other studios at 1B and 3A Orchard Road and also at Gresham House in Battery Road. By the early 1900's Lambert and Co. had become the leading photographers in South East Asia, with operators creating landscape and portrait photographs in Borneo, Malaya, Sarawak, Sumatra, Thailand, and elsewhere.

As well as several studios in Singapore, Lambert & Co. had bases in other parts of South East Asia. Heinrich Ernst, Charles Blum, H. Kunz (and others) operated the Lambert studios at Deli and Medan in Sumatra. Photographers H. Stafhell and Charles J. Kleingrothe both worked as assistants to Lambert in Sumatra before setting up on their own as Kleingrothe & Stafhell in 1889. There were also other branch offices situated in Kuala Lumpur and Bangkok.

It is not known which photographers made which "Lambert" images, at least forty different managers, assistants, and photographers were known to have worked for Lambert & Co. at one time or another. Furthermore, negatives and prints by other operators were regularly bought and sold when studios closed or photographers moved overseas.

Considering the number and differing experience of staff employed, the work produced by the company was generally of a high standard and always technically competent, which was quite an achievement considering that the location work was invariably undertaken in hot and humid tropical conditions.

The pictures produced were largely aimed at the European market and documented the rapidly changing face of Singapore, which was constantly growing in size and importance during the end of the 19th and early 20th Centuries. The images produced in remoter areas, often showing local inhabitants, are the most interesting and exotic. The groups were carefully chosen and posed but no attempt was made to document poverty-stricken natives, commercial considerations being prerequisite.

Lambert's operators recorded the growth in trade throughout the area; coffee and rubber plantations, tobacco farms, mines and shipping were all well documented and the resulting images helped promote South East Asia as an attractive place in which to invest.

The images produced by the company were initially produced as albumen prints and later gelatin-silver, and were often gold toned, which helped maintain their color. Later still, platinotype prints were offered. Titles and reference numbers were added to the glass negatives in a variety of styles and the later prints were sometimes embossed with an oval company blindstamp.

By the end of the century, the company had started producing postcards, over 250 views were on offer and reportedly a quarter of a million were sold annually.

The market for photographs was changing, visitors were choosing cheaper postcards over larger and expensive studies and Lambert & Co. started catering for the emerging amateur photographic market, offering cameras, film, and processing facilities. By 1902 the studio at 186 Orchard Road was closed and Gresham House succumbed in 1910. By 1911 the operation was in liquidation and the business was confined to premises at 3A Orchard Road. A succession of managers were brought in, the final one being H. Nugent Buckeridge, who later formed his own photographic business, which lasted until the Second World War. By 1918 Lambert & Co. were, briefly, back at 186 Orchard Road, however the business was in trouble and finally closed the same year. Tastes were changing and with the world's economy in decline, the market for high-quality, expensive prints had ended.

IAN CHARLES SUMNER

Biography

G.R. Lambert, born Dresden, Germany (dates unknown). Part of a large German business community in Singapore. Opened photographic studio in Singapore April 1867 (which may have closed shortly after) returned to Europe, returned to Singapore 1877, and created chain of studios throughout South East Asia. Returned to Europe ca.1886, leaving the operation in the hands of managers. Maintained an interest in the business until ca.1910. Firm ceases trading 1918.

LAMPREY, JOHN (active 1860s–1870s)

John Lamprey was Librarian of the Royal Geographical Society and Assistant Secretary of the Ethnological Society of London. Very little is known of him, however his photographic legacy is the system for the production of anthropometric photographs which he published in the *Journal of the Ethnological Society* in 1869. The system was devised for use to both anthropologists and artists for the "comparison of measurement of individuals by some common standard." In poses that refer back to traditional visual modes of mapping the body which had developed since the seventeenth century, the figure was arranged in both full face and in profile poses, with ad-

ditional head studies, in front of the background screen divided into two inch square by means of silk threads. The idea was that the measurements of the body could be read off the scaled photograph so: "the anatomical structure of a good academy figure or a model of six feet can be compared with a Malay of four feet height in height."

Although Lamprey himself is often attributed with the photographs himself, it would appear that he only facilitated them on behalf of the Ethnological Society. Indeed it is not known precisely if he initiated the system or was merely acting on instructions, nor is it clear how subjects were recruited, although a number appear to have been seaman. However the fact the President of the Ethnological Society, the distinguished Darwinian biologist, Thomas Huxley, initiated his own system within months of the publication of Lamprey's system, and with no reference to the latter, suggests that as science the scheme was found wanting in some way. The photographs themselves appear to have been taken for the Ethnological Society by Henry Evans, described as photographer and scientific instrument maker. Evans was prosecuted for the sale of indecent photographs in March 1870, a high-profile case which raised the question of the boarderline between science and pornography. It has often been assumed that the photographs probably commissioned by Lamprey were part of this prosecution. "Men of Science" (probably senior members of the Ethnological Society) petitioned on Evans' behalf, as did artists whom he was supplying with model photographs, including Rossetti and Burne-Jones, but to no avail. Although it was clearly stated that the "scientific" photographs were not those that were the subject of the prosecution, there is another set of photographs in existence, using the same models which are of more questionable intent and are not amongst the sets commonly found in anthropological collections. As Evans' whole stock, including the anthropometric photographs and studies by O. Rejlander, was burned, after his conviction, we shall probably never know.

None the less the system was quite influential, largely because it was one of the few instructions in the field to be published. For instance it resonates through the black and white chequered background used by Portman and Molesworth for their 1894 anthropometric studies of the Andamanese and some Lamprey-system photographs were reproduced in Carl Dammann's *Anthropologisch-Ethnologiches Album in Photographien* (1873–74). The photographs have become iconic of nineteenth century racial beliefs and have been published widely in post-colonial critical studies and art works, for instance Faisal Abdu' Allah' s untitled installation for "The Impossible Science of Being" (Photographers Gallery, London, 1995).

LANCASTER, JAMES & SONS (1830–1955)

English photography studio

James Lancaster established his business in Birmingham as a spectacle maker and optician in 1830. The company became J Lancaster and Son around 1876 and in 1905 it became a limited company. It ceased trading circa 1955.

W. J. Lancaster (died 18 September 1925) was the driving force behind the company's rapid expansion into photographic equipment from the early 1870s leading one obituary to describe him as "the pioneer of amateur photography." This was achieved by the adoption of a system of production reported on by George E. Brown in 1930: "The great output of his apparatus was organised on a system which I do not think has been imitated on a similar scale in the photographic trade. He had no factory in the ordinary sense. In Birmingham there have always been a vast number of individual workshops…and all making for Lancaster."

The system of using out-workers to produce parts and to assemble equipment allowed the company to sell reasonable quality cameras and lenses in very large numbers. In 1887 they claimed 25,000 cameras sold, in 1888 sales of over 15,000 Instantograph cameras, in 1894 sales of over 120,000 cameras and 150,000 lenses in the previous ten years, and, in 1898, they claimed to be the largest makers of photographic apparatus in the world with upwards of 200,000 cameras sold. The firm's success was based on offering attractive goods at popular prices.

W. J. Lancaster was granted eighteen patents between 1885 and 1899 which were incorporated into the firm's products with the rotary and see-saw shutters being particularly successful. The firm's first cameras date from the early 1870s when they also offered ferrotype equipment and chemicals, but it was the period from the early 1880s to early 1900s that was the firm's most successful. Their Le Merveilleux, Le Meritoire, and Instantograph cameras were introduced in 1882 and remained popular into the early twentieth century undergoing numerous revisions. The Instantograph had sold over 100,000 by the end of the century. Their watch camera was patented in 1886 and two versions were produced including a compact ladies version, the Rover (1892) was a popular hand camera and a range of

professional studio cameras and multiple lens cameras was also made. Lancaster produced a range of associated accessories and darkroom equipment.

In common with its major rival, Thornton-Pickard, Lancaster failed to respond to the changing demand for smaller plate cameras and simpler amateur roll film cameras. After the First World War the firm declined rapidly with few new cameras being produced; one of it's more successful products was an enlarger. It gradually declined and ceased around 1955.

MICHAEL PRITCHARD

LANDSCAPE

The evolution of every photographic genre is highly determined by a wide range of technical developments. Some technical factors, however, were particularly relevant for the visualization of landscapes, which are characterized by infinity, capriciousness, changeability, an endless amount of tiny details, and ever-changing light conditions. As a result, more than in any other genre, the landscape photographer is obliged to select some of the available options provided by the technical apparatus. Sharpness, for instance, can determine the mood of an image. Whereas a sharp definition enables the landscape photographer to bring forward little details and texture, the use of a wider aperture can push the unfocused zones to the back, rendering a soft and mysterious atmosphere to it. Confronted with subjects in motion, such as waterfalls or sweeping foliage, the photographer has to use a speed short enough to halt the movement, or, by contrast, he can use a certain blur because it suggests movement. A longer exposure time can do justice to the complexity and variety of the image but, simultaneously, it can render the ripples on a water surface invisible. Adjusting the exposure to the terrain implies an overexposure of the sky—this resulted in the typical uniform white skies of many nineteenth-century landscape photographs. The limited sensitivity of the collodion emulsion (especially for greens) and the intense luminosity of the sky made the recording of clouds almost impossible if the exposure was correct for the tonal values of the landscape. Panchromatic films and yellow and red filters circumvented these difficulties, but wet-plate photographers often avoided glaring white skies by the combination of cloud details from another negative during contact printing in the studio.

Nineteenth-century landscape photography was also in another way highly dependent on technical limitations. Since landscapes have to be photographed on the spot, the photographer had to deal with the relative mobility of his equipment. This included first and foremost the huge size and bulk of the field camera itself since negative size determined finished print size before enlarging became easier and more practical in the 1890s. Furthermore, the tools of a landscape photographer also comprised a tripod, a darkroom, developing gear and attachments, silver-coated metal plates or collodion plates, and a box of chemicals. Certainly after the wet-plate process appeared in the 1850s and prior to the introduction of the silver gelatin dry plate in 1871, the landscape photographer had to carry with him a whole laboratory; specially because collodion plates had to be exposed while still wet—and therefore prepared *in situ*—and developed immediately after the exposure had been made.

Landscape photography, of course, was also highly dependent on the availability and accessibility of its subject. In light of this, the genre is not only a component of the modern invention of photography but also a product of modern urban culture and its attitude *vis-à-vis* natural surroundings. The nineteenth century, after all, was an age characterized by the opening up of all kinds of territories. Within the context of the colonial enterprise, travelers and explorers discovered and charted other continents. Photography unmistakably contributed to both the physical and cultural appropriation of exotic territories and the continuous exploration and settlements of new lands. In its own way, photography was a form of mapping and it allowed the land to be controlled, visually at least. It contributed to the practical and symbolical management of the vast colonial territories which demanded the classifying, recording, census-taking, and mapping of everything in order to render it knowable, imaginable and controllable by means of European systems and on European terms.

At home, the European landscape came within reach through the railways and, at the end of the century, the bicycle. The photography of landscapes and scenery was encouraged by tourism, a modern phenomenon inherently linked with the massive production, distribution, and consumption of (mechanical) images. In the industrializing nations, railroads made formerly isolated regions accessible to new classes of travel consumers. These included middle-class families on a limited budget and schedule, who purchased photographic views as souvenirs. Later, when do-it-yourself mass consumer photography developed shortly before the turn of the century, they took their own pictures.

Furthermore, the genre of landscape photography was not only the product of new kinds of image production and new ways of approaching the lands but also of specific ways of looking at natural surroundings and the countryside. After all, throughout the nineteenth century, landscape and nature were not only important motifs in photography, they were pre-eminent themes and motifs in painting and literature as well. What's more, landscape photography was unmistakably influenced by literary and pictorial conventions. Landscape photographs confirm that the very notion of landscape

Russell, Andrew Joseph.

was connected to picture making and aesthetic conceptualizations from the beginning. According to the *Oxford English Dictionary*, the term "landscape" occurred for the first time in 1603 and stood for "a picture representing natural inland scenery." The word was borrowed from the Dutch *landschap*, probably because of the influence and the prestige of landscape painting of the Netherlands. In most languages, the word has the double meaning of both a "piece of land, region" and an "image" representing such a piece of land. This double meaning is telling. It focuses our attention on the fact that landscape has not exclusively been a piece of the environment or nature, but has been, from the very first, dependent on its structuring by human presence and by the gaze in particular.

The importance of landscape and nature in nineteenth-century literature, painting, and photography was also endorsed by new aesthetic concepts, which originated in the late eighteenth century, on the eve of industrialization and shortly before the inception of photography. New notions, such as the sublime and the picturesque, presented the natural site not only as an ideal setting for beautiful or heroic acts, but rather as a primary source of meaning in itself. Throughout the nineteenth century, many photographers were eager to demonstrate that their new medium was perfectly suitable for visualizing these new sensibilities and to create photographic equivalents of literary and pictorial evocations of nature.

Particularly the concept of the picturesque, the development of which had been closely related to that of the English landscape garden, became a popular guideline for many landscape photographers, both professionals and amateurs. William Gilpin, the pre-eminent theorist of the picturesque, had argued in the late eighteenth century that picturesque views should be irregular, highly textured, and composed of things rugged, rustic, or antique, stripped of their utilitarian associations. Such telling details would provoke in the sensitive viewer poetic reflection on the passage of time, on the brevity of glory, and on the ephemeral nature of human achievement. Preferring the whimsicalness of nature, however, the aesthetics of the picturesque approached nature indirectly, through *pictures*. The term picturesque, consequently, refers both to a certain kind of landscape, which is suited as a subject for a painting, and to a fragment of reality that could be viewed as if it would be part of a painting. On the one hand, the English landscape gardens were designed to be viewed as a Claude Lorrain or a Nicolas Poussin might paint them. On the other, the viewer could discover and recognize picturesque scenes in nature itself. In his *Three Essays* on the picturesque (1794), Gilpin encouraged travelers, for instance, "to frame views, to graduate prospects from foreground to background, and above all to ensure variety of painted, drawn or engraved texture, which minimized similar qualities in the natural world."

A few decades later, this was right up the alley of photographers, who often used their cameras to frame similar views of the landscape. In particular British pioneers, such as John Dillwyn Llewelyn and Benjamin Brecknell Turner, and photographers of the 1850s and

1860s, such as Roger Fenton, George Washington Wilson, Francis Bedford, and William England, followed in the footsteps of the theorists and painters of the picturesque. Fenton even photographed the very same locations that Gilpin had depicted earlier in his watercolours. Other photographers referred explicitly to the concept of the picturesque in their writings. In the *British Journal of Photography* (1864), George Washington Wilson described the picturesque as "a simple viewpoint that the traveler or amateur would easily find for themselves; a convergence point toward which the eye is drawn imperceptibly by a gradation of tones and a dark foreground; a harmony of all the parts, in a closed composition which does not arouse unsatisfied curiosity." In his *Pictorial Effect in Photography* (1869), a true bestseller among photographers in England and abroad, Henry Peach Robinson quoted extensively from eighteenth-century writers on the picturesque. He also noted that the power of the art of photography was limited. "The sublime cannot be reached by it," Robinson wrote, but "picturesqueness had never had so perfect an interpreter" as photography.

In the second half of the nineteenth century, however, the picturesque was often freely interpreted as denoting any landscape endowed with scenic charm. The general and vague notion of what constitutes the picturesque became an inherent part of the Victorian imagination. It also became an imperative for every successful landscape photographer, whose task included searching and framing strategically the right sort of locations, and articulating their physical subtleties through proper exposure of the negative. Furthermore, photography democratized the picturesque, which originally entailed an exclusive capacity of the gentry, who understood both art and touring. Now, the middle classes used photography to enjoy nature. This cult of the picturesque resulted in thousands of photographs of humble landscapes and pastoral scenes that mostly ignored the brutality of urban modernization, labor, and industry. Figures and landscapes were integrated into a harmonious unity evoking a well-balanced social order. The predilection for the countryside and the peaceful village—objects already resonant with English values—transformed the notion of the picturesque into an ideological concept that contributed to the construction of a national identity.

Consequently, the frame of the picturesque turned out to be useful in the photographic survey of the colonies. Exotic landscapes were tamed and domesticated according to established terms of reference reflected in the photograph's composition and treatment of subject. Samuel Bourne's pictures, for instance, of the unwieldy and very often "un-picturesque" topography encountered on his treks in the Himalayas were unmistakably influenced by his earlier search for picturesque scenery in Wales, Scotland, and the Lake District. In many of his pictures taken in Northern India in the 1860s, spaces are contained within enclosures, encirclements, or boundaries. The world arranges itself for the viewer. The struggle with nature gave way for contemplation based on balanced proportions, carefully selected viewpoints, the use of watery reflections, and the harmonious integration of foregrounds and backgrounds—all borrowed from the tradition of the picturesque. Nonetheless, as many pictures by other European photographers working in exotic locations, Bourne's photographs are characterized by an interesting tension caused by his frustrations over trying to frame the vast spectacle of terrain within his camera's field of view and still maintain a balanced composition and containment of suitable picturesque features.

Bourne's vistas of breathtaking landscapes from the peripheries of the British empire also demonstrate that, at the time of the mid-nineteenth century proliferation of photography, the conventions of the picturesque had merged with those of the sublime. The characteristics that Edmund Burke had attributed to the sublime—obscurity, privation, vastness, magnificence, and so on—were clearly evoked in the grandeur of the exotic landscapes in Asia and the Americas that were beyond exact description. At the same time, however, painters and photographers evoked the sublime by means of a repertoire of established compositional formulae. Landscape photography, in a way, helped to domesticate the sublime and to subject it to pictorial conventions—a logic that constitutes the strategy of the picturesque.

The tension between the rough subject matter of the wilderness and the cultivated framings of the gaze was also a challenge to American photographers such as William Henry Jackson, Eadweard Muybridge, Andrew J. Russell, Carleton Watkins, and Timothy O'Sullivan, among others. Many of them worked in the context of government topographical expeditions and geological surveys, which helped to open the vast territories of the West to phenomena such as railroad construction, logging, mining, farming, urbanization, and even tourism. Whereas the 1859 stereographs of the Catskill Mountains and Niagara Falls by William England still could answer to picturesque conventions, the survey photographers working after the Civil War entered completely new kinds of lands. In contrast with the celebration of the newly found harmony between man and nature celebrated in European landscape photography, American photographers faced a frightening wilderness that, from an artistic point of view, could only be interpreted as a chaotic environment unfit for lyrical depictions. The spectacular natural scenery of the Americas lacked the picturesque balance of hills, lakes, and trees. Nonetheless, it was difficult for the painters and photographers of the American wilderness to accept nature in a naked, non-referential condition

and many of their impressive views are characterized by formulas derived from, but not coextensive with, the picturesque and sublime modes of landscape depiction. Comparable with the landscape painting by artists such as Albert Bierstadt, Frederic Edwin Church, Sanford Robinson Gifford, and Thomas Moran, the American survey photographers adopted and reformulated pictorial landscape conventions and merged them with a heretofore unmatched technical virtuosity. Joel Snyder demonstrated that critical literature of the period commended photographers for having achieved pictures faithful to nature that "coincidentally" shared specific compositional and pictorial features with landscapes wrought in other media such as painting and drawing. In other words, photographers were congratulated not for their use of landscape conventions but for their coincidental or mechanical corroboration of them.

Nonetheless, American landscape photography does not show the pastoral harmony so typical of the English interpretation of the picturesque. When pictures allude to a landscape claimed and occupied by man, not classical culture but modern industrialization enters the frame. Carleton Watkins' mining and railroad photographs in particular, for instance, attempted to portray a visual harmony between the land and the new tokens of industrial progress such as tracks of a new rail line.

In contrast with the European picturesque, however, man and civilisation are usually absent in the pictures of the American surveyors. In the spectacular large-format views of the American landscape from the 1860s and 1870s, man is often confronted with a terrifying emptiness and vastness reminiscent of the sublime in the way Edmund Burke had written about it in the eighteenth century. Moreover, compared with most examples of European landscape photography, the pictures of the American West are characterized by a more dispassionate and "placeless" look due to high vantage points, uninterrupted lines of vision, and marginal foregrounds. Miniscule figures frequently give a sense of scale and measure to the landscape but instead of mediating between the viewer and the depicted scene, they are dwarfed by the daunting natural marvels. Men are reduced to indices of the precarious and frightening relationship between man and nature. Unmistakably refering to the then popular theory of Catastrophism, a geological theory which held that the world was shaped by periodic and large-scale disasters, these landscape photographs supported a transcendentalist vision of nature. The American landscape was not only interpreted as an impressive physical reality but it also included an underlying sense of the spiritual. Nature was presented as a stage of a symbolical presence. In some pictures, *chiaroscuro* creates a natural drama. Specific viewpoints and lighting exaggerate the sudden and violent forces required to create certain geological formations. In others, a kind of overwhelming silence results in an unusually modern, austere imagery. This is especially the case in many photographs by Timothy O'Sullivan, who preferred landscapes that seem to resist definition, such as immeasurable and inaccessible deserts. His photographs show landscapes so devoid of human reference, so lacking in the signs of history and culture, that plastic values were the only one at hand. O'Sullivan's landscapes, in consequence, can be considered the point of departure for both the modernist landscape photography of Ansel Adams and the late-twentieth-century predilection for natural and urban wastelands and non-descript areas. O'Sullivan's landscapes deny the possibility of comfortable habitation and an agreeable relation between man and the bleak and godforsaken landscape.

Strikingly, this specific evocation of the American frontier lasted only a few decades. The initial flourishing of American landscape photography passed with the closing of the frontier, to which photography contributed in contradictory ways. On the one hand, American western landscape photographs had opened the West by presenting it as potential real estate and as a site for eastern investment and development. On the other, the photographs of the natural wonders struck a romantic chord among the public and positively influenced legislation to create the first National Parks in the early 1870s. By the 1880s, photography and travel had become easier and the closing of the frontier at the end of the century was confirmed by the more impressionist approaches, which also characterized the European landscape photography of the *fin de siècle*. In the 1890s, Henry Hamilton Bennett, for instance, depicted the Wisconsin landscape as an ideal place for leisure whereas in the early landscapes of American pictorialists, every suggestion of harshness and difficulty was suppressed. The bitter cold, the cruel heat, and the infinite spaces made way for a nature that had become a part of the known habitat and the conventions of art.

Artistic conventions and cultural references also continued to play an important part in the landscape photography of many European countries. Although the picturesque quickly became a component of a kind of "Englishness," the concept was also instructive for the landscape photography practised in other regions. Many photographers with pictorial sensibilities, for instance, directed their cameras at the Italian landscape, which played such an important role in European culture in general. With its ruinous remnants of antiquity, the Italian landscape remained a reference point for artists throughout the nineteenth century. In addition, it had been a major source of inspiration for the aesthetics of the picturesque. Its enjoyment and depiction became obligatory components of the Grand Tour. Right from its inception, photography superseded the eighteenth-century *vedutismo*, the paintings of panoramic views

of places. Daguerreotypes and calotypes offered the traveler excellent "diary" potential and in the second half of the nineteenth century, other photographic processes documented, besides architecture and monuments, the countryside and mountain scenery. The Roman *campagna*, the ultimate landscape considered worthy of pictorial representation since centuries, was photographed abundantly. In the 1850s, Giacomo Caneva made a series of impressive views, some of them intended for French artists staying at the Villa Medici. During the following decades, many others, such as Ludovico Tuminello, Pietro Dovizielli, Pietro Poppi, and Federico Faruffini, made numerous studies of nature, with or without figures. At the end of the century, professional studios, such as that of the Alinari brothers in Florence, a firm specialized in pictures of artworks and architecture, also provided landscapes for the tourist market. Foreign photographers as well, such as Robert MacPherson in the 1850s, made *vedute* for tourists. With an exceptional mastery of technique, MacPherson photographed, mostly in large formats, the Latium countryside and he made many beautifully composed landscapes, such as his pictures of the ruins of Tivoli, which seem to be organically connected with the natural surroundings.

Some specific impressive locations, such as the Vesuvius, which combined classical references with a romantic fascination for the sublime, attracted many photographers such as the pioneer Calvert Richard Jones in the 1840s and Giorgio Sommer in the 1860s and 1870s. From across the bay, Sommer made spectacular photographs of the enormous plume of smoke during the eruption of the volcano in 1872. Others of his photographs, as well as pictures taken by John Buckley Greene earlier, show an exceptionally modernist sensibility for abstract shapes by focusing their attention to the volcanic concretions instead of the broad view of the Naples Gulf.

Another spectacular landscape explored by many European photographers were the Alps, which both had fascinated northern artists on their way to Italy since the renaissance and which had become a *locus classicus* of romanticism and the cult of the sublime in the late eighteenth century. Noël Marie Lerebours included an Alpine view in his famous *Excursions daguerriènnes* (1840–44), John Ruskin commissioned Frederick Crawley to make daguerreotypes of the Mont Blanc in 1854, and William England immortalized the snow-covered tops in a series of stereographs. In addition, Vittorio Sella depicted the Italian Alpine topography with an already modern dedication that evaded the often superficial curiosity of the Grand Tour. Sella even specialized in mountain pictures operating, between 1887 and 1908, in such remote and exotic areas as the Caucasus, the Himalayas, Karakorum, and Alaska. The Italian Alps, however, were his favourite terrain. Here, in 1879, he made his first of several panoramas consisting of four or five adjacent pictures. His photographs became an important reference point for geographical and botanical societies, cartographers, geologists, and, of course, alpinists.

Some prominent French photographers explored the Alps as well. The German but Paris-based pioneer Friedrich Martens made daguerreotypes of the high mountains in 1853–54, Ferrier made a series of stereographs in 1856, and Charles Soulier made a series of views in 1869. The most spectacular examples of Alpine photography, however, were created by the Bisson Brothers and Adolphe Braun. From 1854 onwards, Louis-Auguste and Auguste-Rosalie Bisson made increasingly better shots of the high mountains. In difficult conditions, they not only managed to get the fluid collodion under control, they also produced a series of impressive large prints (as big as 70 × 100 cm) characterized by subtly balanced tonal values—no sinecure in the midst of the high contrasts of the snowy landscapes. Initially, their carefully selected viewpoints, which render a sense of depth to the landscape, were unmistakably indebted to the tradition of the picturesque. Later on, however, their snowscapes were characterized by a more austere approach showing mountaineers dwarfed by the fanciful shapes of the glaciers, and the imposing formations of the terrain and the mountain tops. Together with the seascapes of Le Gray and the architectural photographs by Baldus, the Bisson's Alpine views can be considered one of the highlights of the golden age of French photography around the middle of the century.

Sparkling Alpine scenery was also a favorite subject of Adolphe Braun, who was one of the largest producers of commercial landscape views in France during the second half of the nineteenth century. In 1866, an observer claimed that it was virtually impossible to take a step in Switzerland without stumbling upon a shop selling Braun prints and stereoviews. Based in Mulhouse, Braun turned his attention to scenic photography in 1859 with the publication of his *L'Album de l'Alsace*, a collection of large-plate views of sights, monuments, and landscapes, which were clearly indebted to previously published engravings of Alsatian views, such as Jacques Rothmuller's *Vues pittoresques*. Braun depicted the Alps, especially in Switzerland, Northern Italy, and the then recently acquired Haute-Savoie region, not only by means of large-plate views (sometimes using panoramic techniques) but also by stereographs, which were especially suited to the introduction of figures because of their palpable sensation of depth.

Braun's collection of landscapes also includes scenery in which picturesque ruins have been exchanged for tokens of modernity, such as the construction of the Gotthard Pass rail tunnel in the 1870s. This celebra-

tion of the modernity of the landscape can be found frequently in French nineteenth-century photography. In 1855, Edouard Baldus created this truly separate genre when he photographed the landscape between Boulogne and Paris changed by the construction of the railroad. In contrast with the usual picturesque approach that neglects the traces of industrial modernity, Baldus' photographs strikingly showed how all kinds of new constructions, such as railway tracks, viaducts, and bridges, fitted perfectly into the landscape. During the following decades, the photographers employed by the Ecole des Ponts et Chaussées and many others would depict the spectacle of railroad construction—an indication of the importance railroads had assumed both in the changing landscape and in the public consciousness.

This modern stance in French photography can also be found in the interest in the landscape of the everyday. As in other countries, the development of French landscape photography was unmistakably closely connected to the practise and theory of landscape painting. In France, however, other pictorial codes than those of the picturesque and the sublime were much more relevant. The work of many French landscape photographers shows similarities, for instance, with the new realist and naturalist tendencies in painting that developed in the era of photography's inception. The forest of Fontainebleau, which attracted the painters of the so-called Barbizon circle (Corot, Diaz, Millet, Rousseau) between 1825 and 1860, also became a popular photographic motif during and after the Second Empire. Painters and photographers were not only engaged in documenting a way of life they saw as rapidly slipping away under the pressures of industrialization, they also searched for humble subjects that contrasted heavily with the overworked picturesque formulas and sublime and pompous themes of academic painting.

Averse to classical *vedute* and spectacularly sublime mountain tops, photographers such as Gustave Le Gray, Alfred Briquet, Eugène Cuvelier, Constant-Alexandre Famin, Achile Quinet, Ernest Landrey, John Buckley Greene, Paul Berthier, and Henri Langerock, among others, depicted various locations in the forest that became more accessible by the railways from the 1850s onwards. Some photographers made "Studies from Nature," supplying painters with documentation, such as the *Vues artistiques diverses* by Famin. Others, such as Le Gray and Cuvelier, were painters themselves and made highly personal photographic works that often focuses on a gloomy and melancholy aspect of nature. After 1849, Le Gray made many calotypes of trees and underwood, and he later continued the series using large-size glass negatives. The perfection of his prints and their sensibility for lights and shades answer to a pre-Impressionist naturalism that owed little to traditional pictorial examples. Another photographer closely connected to the circle of Barbizon painters, was Eugène Cuvelier, who particularly explored the rocks and sand dunes of the forest and, in doing so, created pictures reminiscent of the Rousseau's paintings in particular. He remained faithful to the calotype and fully exploited its aesthetic possibilities: the thickness of the paper negative and its grainy texture resulted in the sketchy details and schematic light effects so cherished by the Barbizon painters and the impressionists.

Many works of the Barbizon photographers show a remarkable, "impressionist" interest in the play of light, reaching its climax in Gustave Le Gray's series of large-format seascapes. Some of Le Gray's "marine" studies give an impression of an instantaneity, which can suddenly capture the impetuous movement of the waves. Constructed by means of two separate negatives (one for the sea, the other for the sky), his more tranquil seascapes skilfully capture the ways light moves over the ocean and show backlit skies heavy with clouds or the sky at sunset.

French landscape photography also included other specific motifs from contemporary impressionist painting, which, in its turn, borrowed formal features from the new medium of photography: absence of depth, abstraction through unusual viewpoints, arbitrary framings, and so forth. The impressionist fashion for the outdoors, for instance, resulted in the topographical genre of middle-class pastimes. Comparable to famous scenes by the impressionists, people at leisure were photographed in the outskirts of Paris or in the recently developed seaside resorts. Olympe Aguado, an amateur photographer close to the Emperor, was the leading exponent of this genre that gave evidence of the urbanization and domestication of the landscape. It was no accident that the places painted by the impressionists were the suburban landscapes within several hours' train commute of Paris. As in many impressionist paintings, in French landscape photography, nature is no longer the background of heroic acts (as in classical landscape painting) or of the sublime terror of natural forces (as in Romanticism), but has been translated into the environment of the *bourgeois* on a summer Sunday afternoon. As in the landscapes of the Barbizon painters and the impressionists, a great deal of French landscape photography is characterized by a dichotomy between nostalgia for a vanishing agrarian past and an interest in the emblems of industrial modernity and a specifically modern way of occupying natural surroundings.

Characteristics of Barbizon and impressionist painting would continue to play an important part in the landscape photography of many countries up until the very end of the century. Both an impressionist optics and a preference for landscape and peasant subjects also marked the late nineteenth-century vogue mode of pictorialist photography—yet another indication of the

close connection between pictorial and photographic landscape depictions throughout the nineteenth century. Corot's paintings, for instance, were a major source of inspiration for pictorialist photographers such as Peter Henry Emerson, who applauded Millet and Corot in his book *Naturalistic Photography for Students of the Art* (1893), and Léonard Misonne, who was aptly called the "Corot of photography." Many pictures by George Davidson, Alfred Horsley Hinton, Robert Demachy, James Craig Annan, Hugo Henneberg, Hans Watzek, Theodor and Oskar Hofmeister, the young Edward Steichen, and Alfred Stieglitz, among others, refer unmistakably to an impressionist aesthetics, which translated specific motifs such as people engaged in rural labor or outdoor activities into tonalist studies of transient elements. Paradoxically, pictorialism presented itself as the ultimate style of landscape depiction by both evading and stressing the inherent limitations of landscape photography. It ignored the infinite amount of details and attempted to suggest or to evoke movements and atmospheric effects, which photography cannot represent by definition. Using a selective focusing to restore actual optic sensations and capturing the general effect of landscape, definition of form was sacrificed to a diffused field of tonal landscape. All kinds of ephemeral atmospheric effects, such as smoke, haze, mist, or fog, were rendered in mediating tones. Impressionist motives such as trees, foliage, streams, and clouds became the material upon which the artist's manual influence could be exercised resulting in uniquely crafted gum prints. Furthermore, by abstracting the landscape, pictorialism stressed the idea that the landscape and nature itself possessed an essential character or emotion. No longer a depiction based on objective observation, pictorialism presented landscapes of carriers of personal expressions and feelings. Many pictorialist landscapes evoke a deep melancholy reminiscent of Symbolism. They seem to indicate the existence of a spiritual dimension of nature rather than an Impressionist depiction of the material world in terms of sensory perception. Also the medium of photography was considered capable of depicting landscapes of the mind.

LANGENHEIM, FRIEDRICH (1809–1879) AND WILHELM (1807–1874)

The Langenheim brothers, Ernst Wilhelm, and Friedrich, were born in Braunschweig in Germany, and emigrated to America, Friedrich in the early 1830s—probably around 1834—and Wilhelm probably c.1840. Sometime after arriving in America, they both anglicised their names, becoming known as Frederick and William.

William is known to have studied for a law degree in Gottingen, Germany, before emigrating to America and settling in Texas where he helped establish a settlement near San Antonio. He served in the army during the Texan War of Independence (1835–36) under General Sam Houston, and despite escaping from San Antonio just days before the fall of the Alamo, was captured and imprisoned for eleven months at Matamoras by the Mexicans. After being released, he is believed to

have worked both as a soldier and as an army clerk in Florida and New Orleans before joining his brother in Philadelphia c.1840. Friedrich worked as a journalist for the German language newspaper *Alte und Neue Welde* owned and edited by George Francis Schreiber before joining his brother in their first photographic studio. After acquiring a daguerreotype camera from Von Voigtländer, Friedrich Langenheim and Schreiber were briefly in partnership. Where William learned photography is unknown.

By 1843, the brothers were listed in a Philadelphia trade directory as operating a studio at 26–27 Exchange, Philadelphia. In their partnership, William assumed the role of senior partner.

Unusually, and perhaps reflecting their European background, by the late 1840s they offered their clientele photographs taken using both the daguerreoype and the calotype process. Calotypists were, at that time, relatively uncommon in America. So impressed was William by the calotype that he had Frederick negotiate with Talbot for the American patent rights for the paper negative process—acquired in 1849—and spent some considerable time modifying and perfecting it to suit the conditions in Philadelphia. Three significant letters from Frederick to Talbot survive in the collection of the National Museum of Photography, Film and Television, Bradford, England.

In the first of these letters, dated 10th June 1849 Frederick wrote to Talbot at length, noting

> We had the pleasure to receive a communication from our W. Langenheim, informing us of the effectual arrangement he had succeeded in making with you in regard to the purchase of your Patent. It is our interest, but it will be an especial pleasure to us to promote and perfect your invaluable invention, and in a very short time we hope to be able to send you a few specimens of Talbotypes, which will surpass in sharpness and delicacy of shading even a good Daguerreotype.
>
> The Talbotypes have created a great sensation all over the United States, and most papers of any standing contain favorable articles on the subject, among a great number of which we refer only to the Daily National Intelligencer, Washington, of May 12, which contains a long article on the subject, and which it may perhaps interest you to read.
>
> But the Talbotypes have also created a great deal of envy among our opponents and doubtless attempts will be made to infringe upon our purchased right, against which we have to guard with every possible care, and in which effort we hope you will lend us your aid.

The letters from William Langenheim to Talbot, to which Frederick refers, may yet be discovered. It is known that the Langenheims sent Talbot examples of their calotypes—including views of Philadelphia.

The exact nature of the brothers' partnership remains unclear, and although Frederick wrote to Talbot in 1854 of the failure of W. & F. Langenheim three years earlier, Frederick himself was listed as operating a daguerreotype studio in New York in 1845 and 1846—at 201 Broadway—and from 1846 until 1849 as being in partnership with Alexander Beckers. It may well be that Langenheim established the studio, trained Beckers, and then left him to manage it. As the Langenheims' sister was married to Peter Friedrich Von Voigtländer, it is perhaps not surprising that Langenheim & Beckers advertised themselves in the later 1840s as sole agents for Von Voigtländer's innovative metal-bodied daguerreotype camera and Professor Petzval's fast lens.

While in New York, Frederick travelled to, and photographed, Niagara Falls, one of his images being used as the basis for an engraving published in 1845. In the following year he took out a patent (US Patent 4370 1846) for colouring daguerreotypes, by which time both the Philadelphia and New York studios had earned much praise for the quality of their daguerreotype portraits.

As early as 1846 the brothers had become interested in the idea of projecting photographic images, and had imported episcopes from Vienna and experimented, with some success, at projecting daguerreotypes on to a screen. Recognising that the quality of the projected image from a reflected daguerreotype was not ideal, they experimented from 1848 with the creation of glass diapositives from glass and paper negatives using Niepce de St. Victor's albumen-on glass-process, the resulting process, which they patented in 1850s, becoming known as the Hyalotype. The involvement of a rival claimant to the invention, George Schreiber with whom Frederick had worked in the early 1840s, was described in an essay in *The American Journal of Photography* 13 no.137, in 1892. In that essay, Schreiber is said to have produced the first positive on ground glass c.1848.

The impact of the Hyalotype on the social history of photography was far reaching, turning the magic lantern into an important educational and information tool. Their catalogue of glass stereo diapositives would eventually become extensive.

By 1850, the brothers advertised themselves as "Daguerreotypists and Calotypists," and in that year they produced *Views in North America, Taken from Nature July 1850 by the Patent Talbotype Process* comprising just over one hundred images, but by the following year, despite continuing commercial and critical success, and being awarded medals at the Great Exhibition in London, their partnership had been dissolved. Frederick then left for a three-year sojourn in South America where, as he told Talbot in a letter upon his return in 1854, he had gone "to revive [his] spirits after the failure of the firm W. & F. Langenheim." William continued in business on his own, expanding the company's catalogue of lantern slide views

The brothers' partnership was renewed in 1854 and

by 1861, styling themselves the American Stereoscopic Company, they were producing lantern slides and stereo diapositives in huge numbers.

The brothers remained active in marketing photographs until William's death in 1874, after which Frederick retired and the company was sold.

LANGLOIS, JEAN-CHARLES (1789–1870)

French war photographer

The Crimean War photographs taken by Colonel Jean-Charles Langlois either on his own or with Léon-Eugene Méhédin and Friedrich Martens offer a much more chilling image of the war than Roger Fenton's more celebrated productions.

He was born in Beaumont-sur-Auge, Calvados, in 1879, the year of the French Revolution, and later joined the French army. He served in campaigns up until 1815, when he embarked on a study of painting before returning to his military career, but as an artist not as a soldier.

He developed an interest in panorama painting before 1830, later translated into an interest in panoramic photography. Posted to Algeria in 1833, he made numerous sketches which resulted in his remarkable *Panorama of Algiers* painted three years later. In 1839 another panorama painting, this time of the burning of Moscow in 1812, was opened in a specially constructed building on the Champs-Elysée in Paris.

In 1855 and 1856 Langlois made two journeys to the Crimea to record the scenes there. Working with both Méhédin and Martens, he produced a fine series of photographs, now in the Bibliotheque Nationale, sketches for a huge panorama of the siege of Sevastopol painted from inside the Malakoff Fort. The resulting painting was his first to be based on photographic sketches. It was exhibited in Paris in 1860.

JOHN HANNAVY

LANTERN SLIDES

The magic lantern, the projector which delivered thousands of Victorian slide shows, and which enjoyed renewed popularity with the introduction of the photographic lantern slide, can trace its lineage back, at least, to the middle of the seventeenth century. Some historians place the genesis of the lantern much earlier.

Before 1850, the magic lantern was used to project hand drawn and hand-painted slides as public entertainment, with narrative sequence being created by artists, and some movement being introduced by elaborate optical-mechanical features.

The introduction of the hyalotype, or photographic lantern slide, by Frederick and William Langenheim after 1850, revolutionized magic lantern shows, and creating a huge new market for photographers and photographic publishers.

The lantern slide, as introduced by the Langenheims, gave a new lease of life to the slow but very fine grain albumen-on-glass process which had been introduced a few years earlier, and not very successfully, by Felix Abel Niepce de St Victor. While its low sensitivity made it impractical as a negative medium for all but still life work, or landscape and architecture on the stillest of days, as a printing medium it proved ideal.

Using a camera obscura in reverse, large negative images could be reduced and printed on to the small glass plate for projection in the lantern. The fine grain structure of albumen-on-glass was ideal for this purpose, retaining the finest of detail—essential when the image was subsequently projected on to a large screen.

While it is clear that the Langenheims initially saw the lantern slide as an extension of the entertainment business—they charged admission to their slide shows—it proved to be of much great importance in the second half of the nineteenth century.

With series of slides covering travel, architecture, landscape, exploration, history, biblical themes, and many other subjects, the magic lantern swiftly moved from being an entertainment to being a powerful educational and instructional tool.

Lantern slides, before the advent of photography, came in a variety of sizes. "French Pattern" slides were 3.25" × 4", while "English Pattern" used a square 3.5" × 3.5" format. The European standard size was slightly smaller at 3.25" × 3.25", and it was this format which became the standard for photographic images, although the 3.5" × 4" format endured in France, America, and Japan.

Color, introduced by hand-painting over the photograph, was used for some images, but toning was more usual as, in addition to offering a variety in coloration, it also helped protect the image against premature fading under the intensity of the lantern's illumination.

While today the idea of the projected image is com-

monplace, the novelty of the large projected photographic image in pre-cinema days was considerable, and the popularity of such displays grew exponentially.

While travel themes were probably the most popular—educating an audience about the treasures of places they would never visit—the magic lantern show covered a wide range of subjects. Themes and ideas which had previously been projected using painted slides were given added realism when photographic imagery was used. Thus biblical lantern shows proliferated—the photographic "evidence" of places mentioned in the Bible being used to add authenticity to the stories thus delivered.

Many of the leading travel, architectural and landscape photographers of the second half of the nineteenth century offered their images in lantern slide format as well as traditional paper prints and stereographs. Thus the Langenheim brothers published series of views of their adopted home, Philadelphia, and, wider afield in America.

Edweard Muybridge, a consummate showman, lectured widely throughout the 1870s, 1880s, and 1890s using lantern slides of his landscape and architectural views to delight audiences. When lecturing about his ground-breaking photographic experiments in animal locomotion, in addition to using hyalograph discs in his zoopraxiscope to recreate motion, he illustrated his lectures with selections from several thousand lantern slides of single images. A vast collection of these lantern slides is preserved in Kingston Museum, England.

Aberdeen photographer George Washington Wilson's series on Windsor Castle and the River Thames could be purchased in slide format, as could his delightful 1880s series of view of life on the remote Scottish island of St. Kilda.

The photographs taken by Charles Piazzi Smyth for his *Three Cities in Russia* (1862), best known in two-volume book form, were also available as a series of warm-toned and tinted lantern slides, and lantern slide sets exist of his views of the pyramids of Giza.

The negatives for many subject photographed for the stereoscope could be reprinted as lantern slides and, trimmed down, as *cartes-de-visite* as well, considerably increasing the sales potential of a single negative.

Several manufacturers of magic lanterns offered extensive catalogues of photographic slides to their customers. Amongst these, York and Company of London, and McAllister & Brother in Philadelphia were major players. By the late 1850s, McAllisters had a large photographic department marketing slides of photographs by numerous photographers. As the majority of lanterns they sold by the 1880s were imported from Europe, especially Britain, it can be assumed that their image catalogue contained both the European and American sizes of slides.

The growth of the photographic lantern slide as an education tool has been credited with revolutionising a number of academic disciplines, most notably the sciences and the history of art. Universities throughout the world had, by the end of the century, extensive libraries of lantern slides, and continued to use them until the lantern slide was replaced by the film transparency after the Second World War.

Lantern slides as entertainment developed as a separate but equally important entity, with companies creating elaborate tableaux exploring moral and social issues such as the evils of drink, and producing narrative sets of slides to illustrate their themes—just as they had with stereocards in the 1860s and 1870s.

One such company, Bamforth & Company of Holmfirth, Yorkshire, picked up the "story-telling" idea which had been so successfully exploited in the 1860s and 1870s by the London Stereoscopic Company, and marketed series with resonant titles such as "The Curse of Drink," "The Drink Fiend," "The Road to Heaven," "Strike While the Iron is Hot," and "Deep in the Mine." It was a logical step for Bamforths to progress from the still picture sequence to the moving image, and become, for a view years, pioneers in early cinema.

LAROCHE, MARTIN (WILLIAM HENRY SILVESTER) (1814–1886)

A jeweller turned photographer, Martin Laroche is primarily remembered for the important court case *Talbot v Laroche* in 1854, in which Talbot attempted to claim that the 'new process' of collodion was covered by his 1841 British Patent No.8842.

Talbot had relinquished his patent rights over amateur photographers in 1852, the year after collodion was introduced, but had sought to retain control over the use of negative materials from which positive prints were made for professional portraiture. A situation existed whereby professionals had to pay a licence fee to Talbot to use a process given freely to them by Frederick Scott Archer.

Laroche opened a studio at 65 Oxford Street, London, before 1848—under the name 'Silvester Laroche'—initially making daguerreotypes, examples of which were shown at the Great Exhibition in 1851. He later used the wet collodion process. The studio continued to operate until at least 1862.

In the 1854 court case, Talbot was represented by, amongst others, the eminent scientist William Grove FRS, while Laroche's solicitor was Peter Wickens Fry who had worked with Archer in the development of the collodion method. The verdict confirmed Talbot's pre-eminence as the inventor of negative/positive photography, but also confirmed that collodion was not covered by his patents.

JOHN HANNAVY

LATENT IMAGE

A latent image can be most simply defined as a hidden or invisible image formed by brief exposure to light, which can be revealed to the naked eyed only by the chemical action of a developing agent.

The first steps towards the concept of a photographic latent image are often traced back to W.H.F. Talbot's work in September 1840 that led to the introduction of his Calotype process. However, there can be little doubt that L.J.M. Daguerre, albeit imperfectly, recognised the presence of some invisible pre-image state initiated by light, perhaps as early as 1837. His daguerreotype process required the use of a silvered copper plate made light sensitive by exposure to iodine vapour. Little or no visible image was produced after several minutes of exposure in the camera, but it was found that a distinct image appeared after treatment (development) with heated mercury vapour. Daguerre is reputed to have discovered his developing agent purely by accident when he left a collection of old plates in a cupboard containing an uncovered basin filled with liquid mercury. The term "latent image" was certainly used in 1839 in connection with the daguerreotype process. An account of the official report of Daguerre's technique published in *Le Constitutionnel*, 21 August 1839 states; "After 4 to 10 minutes, according to the period of the day, according to the season, and to the intensity of light, the image of immobile objects from which the lens receives the light, becomes perfectly imprinted on the plate, although this image is yet invisible and only latent ["seulement latente"]…. But this image, that is yet, so to say, in a state of an unformed chrysalis, what consequently comes to reveal it out of its swaddling clothes? It is the vapour of mercury, from mercury heated to 60 Reaumur."

Talbot's concept of the latent image has been more widely recognized, perhaps because of his use of techniques closer to modern practice. The story is well documented. In his original process announced in1839, photogenic drawing, paper coated with silver halide salts was exposed in a camera until an image appeared. The process was very slow. Many minutes, even hours, were required to produce a satisfactory picture. In the late summer of 1840 he recommenced some earlier experiments he had begun using gallic acid. His notebook of September 21 refers to "an exciting liquid" a mixture of silver nitrate, acetic acid and gallic acid. His entry of September 23 records "The same exciting liquid was diluted with an equal bulk of water, and some very remarkable effects were obtained. Half a minute suffices for the Camera the paper when removed is often blank but when kept in the dark the picture begins to appear *spontaneously,* and keeps improving for several minutes. . . ." On the same page in the context of reviving what he called old or faded pictures, he refers to a "kind of *latent* picture…." Talbot had discovered the latent image, which could be revealed using a developer, in his case, gallic acid. He later wrote in a letter to the *Literary Gazette*, 19 February, 1841, "I know few things in the range of science more surprising than the gradual appearance of the picture on a blank sheet, especially the first time the experiment is witnessed."

The mechanism of latent image formation intrigued and baffled the pioneers and continued to be the subject of speculation and dispute throughout the nineteenth century. According to the popular 1850s guide, *A Manual of Photographic Chemistry*, by T. Frederick Hardwich (third edition, 1856), "the ray of light determines a *molecular* change of some kind in the particles of Iodide of Silver forming the sensitive surface." The American authority, M.Carey Lea, offered a different explanation. In *The Photographic News*, (11 August 1865) he claimed "…the production of a developable image in the camera upon an iodo-bromised film is a purely physical phenomenon, that no decomposition of the silver salts takes place, no separation of iodine. By the end of the nineteenth century, most latent image formation theorists were sharply divided in favour of one or the other of the two approaches cited above, the chemical or the physical. The former group suggested the formation of an unknown sub halide salt while those favouring the latter argued that the action of light caused some change in the physical character of the silver salts. It was not until photography became a giant industry supported by systematic scientific research facilities in the 20th century that the mysteries of latent image formation began to be unravelled.

Modern scientific explanations are based on the *concentration speck theory* of R.S. Sheppard and colleagues working at the Kodak Research Laboratories in the 1920s and the mechanism proposed in 1938 by Professors R.W. Gurney and N.F. Mott based at Bristol University. The detailed theories are complex and the supporting experimental evidence requires an

understanding of the nature of ionic mobility, crystal structures and quantum theory. Only a much-simplified explanation is, therefore, possible.

Since the end of the 19th century, most photographic films, plates and papers have been coated with a gelatin emulsion in which are suspended crystals of light sensitive silver halides (chlorides, bromides, and iodides). A brief exposure of light is believed to act on some silver halide crystals in a way that produces an aggregate of metallic silver atoms. This aggregate is the latent image, the invisible building blocks from which the visible image is formed. The number of silver atoms involved may be very small but they render the silver halide crystals susceptible to the action of an appropriate chemical solution, (developer), which when applied causes the invisible aggregate to change and grow into a visible image of black metallic silver. Although understanding of the latent image has greatly progressed since the 19th century, its mechanism remains based on theory and subject to modification and revision. Even with the best modern technology, it remains impossible to detect a latent image by direct physical or chemical means.

LAURENT, JUAN AND COMPANY (1816–before 1892)

Born Jean Laurent in Garchizy, France, in 1816, he moved to Madrid in 1843, where he reportedly registered himself as "Juan" (the Spanish style of "Jean"), and established and operated a successful company manufacturing cardboard packaging. His photographs however, where they are identified, simply bear the legend "J. Laurent" or "J. Laurent y Cia."

His earliest recorded encounter with photography dates from 1856, with the establishment of a studio at Carrera de San Jerónimo in Madrid. Although he lived in Spain for the remainder of his life, he never lost contact with his French roots and, at the height of his success, Laurent opened a gallery in Paris selling prints from his finest Spanish and Portugese architectural and landscape scenes, copies of great paintings, art and architectural treasures. Like the Englishman Charles Clifford, he photographed and sold images of Spain's rush towards the modernisation of its capital city, and the building programmes which dominated the 1860s.

Again like Charles Clifford, he went on to develop a reputation as one of the finest photographers in the city, enjoying, also like Clifford, the patronage of Queen Isabella II. Indeed, for most of the 1860s, he styled himself "Photographer of Her Majesty the Queen."

Laurent's large format camera work is technically more precise than Charles Clifford's—with great attention to details of architectural accuracy—but like Clifford, his love of the Spanish light, architecture, and scenery is apparent. In some of his architectural studies, careful choice of camera position, ideal lighting, and technical excellence combine to produce images which revel in simple geometric patterns, a direct and graphic style which others would adopt only very much later. *Puente de Zura* (Collection of the Metropolitan Museum of Art) dating from c. 1867, is a fine example of this approach.

In 1867 the studio exhibited a number of large *Álbumes de Obras Públicas* at the Exposition Universalle in París, and the production of large albums of views would remain a signature activity for the studio.

Laurent reportedly employed several photographers to create the images for these albums and catalogues, as well as a large number of support staff. One of the photographers was José Martínez-Sánchez who worked with Laurent for many years, and is believed to be responsible for a significant proportion of the studio's considerable output.

In 1866, in collaboration with Martínez-Sánchez, Laurent perfected 'Leptographic' paper ('Leptofotografía'), a collodio-chloride printing paper which was sold ready to use. The light sensitive silver chloride was held in a binding layer of cellulose nitrate, separated from the paper by a layer of barium sulphate (later known as baryta), giving a much whiter base colour to prints than had been previously possible with albumen paper. The baryta layer acted as a barrier, eliminating the spotting from rusting metal particles in the paper which sometimes happened with albumen papers, and at a stroke, the introduction of this paper removed from the photographer all the paraphernalia of having to sensitize the paper before use, as had been needed with albumen. As the manufacturers claimed, it had three times the sensitivity of albumen, and exposure times for contact printing could also be reduced significantly. In the same

year, the Leptographic Company opened a branch in Paris, reported by Marc-Antoine Gaudin in *la Lumière*, August 30, 1866, and offered samples of the new paper to members of the *Société française de photographie* for them to experiment with. For a variety of reasons, it would be a further fifteen years before commercial-scale production of collodio-chloride papers became successful—and in Germany rather than France or Spain.

It is apposite, and perhaps significant, to observe that the majority of the surviving examples of Laurent's work are printed on albumen paper rather than his own invention.

A member of the *Société française de photographie* since 1859, and a regular exhibitor in Paris where his prints and albums found a ready and wealthy clientele, Laurent exhibited only once in London, at the 1858 exhibition of the Photographic Society.

Architectural views of Granada, Toledo, Segovia, Seville, and elsewhere all attest to the quality of his output. And by the mid 1860s, as Laurent y Cia, he was the proprietor of the largest photographic publishing house in Spain, with a growing reputation—and demand for his work—wider afield.

In the 1860s alone, the company produced over twenty catalogues listing their huge archive of images.

His 1866 album of 164 photographs from the collection of the Prado Museum in Madrid, marketed through his own gallery in Paris, was distributed for the British market by Marion & Co. of London.

Laurent y Cia had the exclusive photographic franchise within the Prado from the late 1870s until his death, and produced a huge catalogue of images of the masterpieces contained within the museum. An exceptional panorama, dating from 1882–83 and showing the museum's central gallery, survives in the Prado's own collection of Laurent's work.

Another album depicted the treasures of the Madrid Armoury, and as one of the images is titled, in the negative, *Armeria de Madrid. 337. Trophée formé de diverses armes, oeuvres de Mr. E. de Zuloaga. J. Laurent Madrid*, we can recognize that the published album contained only a very small proportion of the images he had produced.

Uncertainty surrounds the exact date of Laurent's death; certainly no later than 1892, some historians have offered a date as early as 1883, with others suggesting the late 1880s or 1890. The studio was apparently owned, or at least operated, by his step-daughter Catalina and her husband Alfonso Roswag after 1883. Roswag had been employed some years earlier as one of Laurent's team of photographers, and the studio of Laurent y Cia remained in their hands until Alfredo's death in 1899.

LE BLONDEL, ALPHONSE (1814–1875)

Alphonse-Bon Le Blondel, also Leblondel, (both spellings existed until 1862)—was born in Normandy on April 19, 1814. He first trained as a painter but soon turned to photography along with two of his brothers—Alexandre and Théodore (both born in 1822). He learnt the trade in 1840–1841, most probably among a circle of daguerreotypists prevalent in Paris's Palais Royal where he used to sell photographic equipment.

As early as 1842 he made various forays as an itinerant photographer with Alexandre into the North of France (Lille, Douai, Arras), thus playing an important role in the circulation of daguerreotypes among the general public. In 1845 he founded one of the first professional studios in Lille. He rapidly caught the attention of Lille's notables by his exemplary technical expertise and an aggressive commercial strategy (cheaper prices, advertisement in the local press, and exhibitions in shops). Indeed, he managed to compel recognition for 10 years as he found no serious competitor in Lille.

From 1855, the development of the "Le Blondel Brothers" studio, of which Théodore was now a partner, expanded both on a commercial level as well as in terms of recognition among professional photographers. His success and profitability enabled him to persue his trade until 1892.

Le Blondel was one of the first professional daguerreotypists. He also experimented with paper photography as early as 1845 and marketed so-called 'advanced' calotypes at the beginning of September 1846. When studying Lille, one cannot forget to mention Louis-Désiré Blanquart-Évrard who communicated the first results of his research work on the improvement of calotypes to the Academy of Science in Paris on September 28, 1846, the very process being unveiled in

Le Blondel, Alphonse Bon. Postmortem. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundatoin Gift, 2005 (2005.100.31) Image © The Metropolitan Museum of Art.*

January 1847. Despite a few allegations, no connection between the two characters can be traced as they had quite different ambitions.

Le Blondel was attentive to the technical development and ingenious improvements of the already-existing processes. Therefore, he managed to conserve his local pre-eminence by providing constantly renewed services. In 1853 he adopted the process of collodion glass-plate photography, which he used with remarkable expertise in his urban views. He also worked on ambrotypes (1854), stereoscopic photography (1859), photographic enamels (1872) and specialized in enlargements (1874). Last of all, not long before his death, the studio turned to aristotypes and snapshots, showing an interest in the new permanent printing processes—lambertypes, 'encre-grasse' printing and carbon photography. Over the course of his career, Le Blondel had tackled many photographic genres: portrait in all its forms, studies, genre scenes, topographic, and architectural views.

In the second half of nineteenth century, town planning was deeply transformed. Four cities, among the most important Paris, Lyons, Marseilles, and Lille, hired photographers to bear witness to that upheaval—Marville in Paris, Terris in Marseilles, Froissart in Lyons, and Le Blondel in Lille.

In 1870, he was commissioned by the city of Lille to capture shots of the building of Rue de la Gare. The death of their founder in 1875 did not prevent the studio from carrying on with this task and they continued to take part in professional shows. The critic Ernest Lacan admires their 'beautiful reproductions of historical monuments' at the photographic show of Le Havre in 1877. In 1878, under Théodore's management, Le Blondel's studio carried out a prestigious order from the city of Lille for Paris's World Fair: an album entitled "*Photographic Views of the Major Works Made in the Enlarged City from 1860 to 1878"* displays an outstanding survey of Lille's transformation in forty-three large-sized albumen prints: the building of thoroughfares, administrative edifices, schools, hospitals, religious buildings, industries, shops, public gardens, and stately gates. In 1882, the studio was to fulfill an important order from the city of Roubaix to take shots of the recently-built school buildings.

From 1842 onwards Le Blondel regularly displayed his works in the best-known downtown shops in order to keep his fame alive. True recognition however, came from the capital's professional photographers. In 1853 he exhibited framed portraits in Dunkirk. In 1854 he sent daguerreotypes and paper prints to Paris's newspaper *Le Propagateur,* which were then highly praised. He was awarded medals and distinctions as appreciation for his participation in Paris's World Fairs (1855, 1867, and 1878), in the shows organized by the French Society of Photography (1857, 1859, and 1861), in Le Havre's exhibition (1877), in Brussels and Courtrai's international exhibitions (1856, 1857, and 1865). Le Blondel thus gained recognition from critics (Ernest Lacan in the reviews called *La Lumière* and *Le Moniteur de la photographie*, Paul Périer in *Bulletin de la SFP*).

The technical and aesthetic quality of his work particularly asserted itself in the urban views on albumen paper. In these works, horizontal centring was favoured over wide foregrounds, which caught the subject either frontally or obliquely. Sobriety in lines,

subtlety in light and fineness in details characterize his photographs.

Le Blondel's photographs make up a rich and consistent collection of about 700 original works visible in private and public places in France and abroad. The majority can be found in Lille and the North of France with 650 "vintage" works (423 paper prints and negatives, 227 glass plates of 36cm x 26cm size). The most significant collection is that of Lille's public library, which owns 180 salt-paper and albumen prints such as portraits as well as varied views. Most importantly, the collection contains three big albums with views of Lille containing about a hundred albumen original prints—the album made for 1878's World Fair being one of these. The North's Historical Committee is in possession of the glass-plate negatives for these albums, which are now kept in the North's Record Office. The rest is divided between various institutions in Lille (Museums, Diocesan Archives) and Roubaix's public library which holds two albums dating from 1882 (64 print papers). In Paris, the Bibliothèque Nationale and Orsay Museum own a few daguerreotypes and about forty print papers.

So, as to retrace the studio's history; Lille's public Library displayed 170 photographs in Lille's Palace of Fine Arts from September 16th to December 18th 2005 in an exhibition called "Le Blondel—A Photographic View of Lille in the 19th Century," which led to the publication of a scientific catalogue.

ISABELLE DUQUENNE

Biography

Alphonse-Bon Le Blondel was born into a six-child family of clockmakers on April 19, 1814, in Bréhal, a small town in Normandy near Granville. After training as a painter, he learnt photography with Paris's daguerreotypists from 1840–1841. In 1842 he worked as an itinerant photographer in the North of France before he founded one of Lille's first professional studios at twenty-five, Rue de Paris in 1845. From 1855 he developed 'Le Blondel Brothers' company which lasted until 1892. In 1859 the studio grew larger and moved to 1, Pont de Roubaix/Rue du Cirque. With the help of his wife Angélique-Aimée Daviette (1800–1871), a fellow photographer, two branches were successively opened in Lille in 1866 and 1869. Being an excellent portraitist, Le Blondel compelled recognition as a specialist of urban views. He produced a topographical series of Lille and its great transformations in the 1870's.

He died in Lille on May 12, 1875.

LE GRAY, GUSTAVE (1820–1882)

French photographer, artist, inventor, and writer

Like many early photographers, Gustave Le Gray's artistic background was in painting, a fact that, as with his contemporaries, influenced his direction, his vision and the composition of his finest photographs. A student in the Paris ateliers of François-Edouard Picot and Paul Delaroche in the early 1840s, surprisingly only one example of his accomplishment in drawing or painting has so far been identified—a photographic copy dated 1854 of a drawn portrait of the painter Bénédict Masson. This absence of surviving work is despite Le Gray having set himself up as a working painter in Paris before 1847—the year in which he took up the new art of photography—and records up to 1848 which describe his contributions to various exhibitions in the city. He continued to advertise his services as a painter of miniatures well into the 1850s, by which time he was already acknowledged as an authority on photography.

Le Gray became aware of photography in the mid-1840s, and was immediately intrigued by it. By his own recollection, his first engagement with the medium was with the daguerreotype, probably under the guidance of François Arago, and by 1847–48 he was sitting for the camera of Henri le Secq, who was experimenting with a post-waxed paper negative process, probably based on Fox Talbot's calotype. Le Secq's studies of him, casually dressed and posed as the young artist, have a vitality and a confidence which were already becoming characteristics of early French photography. It is likely that Le Gray had met Le Secq and Charles Nègre while studying in Delaroche's studio.

The enthusiasm with which Le Gray embraced the art of photography, and his early grasp of its chemical intricacies, can be gauged by the fact that within a year

Le Gray, Gustave. Brig on the Water.
The Metropolitan Museum of Art, Gift of A. Hyatt Mayor, 1976 (1976.645.1) Image © The Metropolitan Museum of Art.

he was teaching others. A notable student—who took lessons from him in 1849—was Maxime du Camp, probably the first European photographer to travel extensively in Egypt with a camera in 1850.

Le Gray's work appeared in France's first photographic exhibition—within the *Produit de l'Industrie* exhibition in 1849—and those early images, taken in the Forest of Fontainebleu, won him a bronze medal at the exhibition. Nine images submitted to the Paris Salon in the following year were hung in the Graphic Arts section amongst the work of lithographers, but were quickly removed and returned to the artist, apparently being inadmissible.

Le Gray's confidence with the technology and chemistry of early photography manifested itself in a series of treatises, the first of which—*Traité Pratique de Photographie Sur Papier et Sur Verre*,—was published by Germer Ballière in Paris in June 1850. He was, by this time, an ardent promoter of paper negative processes and in that publication wrote

> The future and extensive application of photography will doubtless be confined to the paper process and I cannot too much engage the amateur to direct his attention and study to it. (from the English translation, "A Practical Treatise on Photography upon Paper and Glass" translated by M Cousens, London: T&R Willats, 1850)

Despite his advocacy of paper-based photography, that same treatise offers an intriguing glimpse of Le Gray's enthusiasm for experimentation with a range of processes. In addition to his description of a range of paper processes, he noted in an appendix that "I am now making use of the following process on glass: Fluoride of Potassium or Sodium is dissolved in alcohol of 40° mixed with sulphuric ether and then saturated with collodion," a tantalising suggestion that he was using a wet collodion process before Frederick Scott Archer published his account thereof. Writing in *Plain Directions for Obtaining Photographic Pictures Upon Glass and Albumenised Paper* (Richard Willats, London 1853) Charles Heisch noted that this was undoubtedly the first published account of the method, although such a process had been predicted as early as 1847. Needless to say, Archer dismissed the Frenchman's claim because "he did not give the public the advantage of following him and that in his work of 1850 the subject is dismissed in three or four lines (Heisch quoting Archer, 1853).

Le Gray's acknowledged contribution to the emerging science of photography was not his prediction of wet collodion, however, but his widely practised *papier ciré*—the Waxed Paper Process, the first photographic negative material with a surface-coated light sensitive layer on a flexible support—announced in 1851 and arguably prefacing the materials which would dominate photography throughout the twentieth century. While Le Gray's original formulation was ideally suited to conditions in France, it had to be customised by others—including Roger Fenton, William Crookes and Dr.

Thomas Keith in Britain—to suit different qualities and intensities of light. In its various formulations it became a high-quality and user-friendly process ideally suited to travelling photographers and to amateurs. Pre-waxing the paper restricted the light sensitive chemistry to the paper surfaces, and removed the tendency for a photographic image of the paper fibres to be created in addition to the image of the subject. In its original form, with the waxed paper immersed in the silver bath, a light-sensitive coating was created on both faces of the paper. Later refinements included floating the paper on the sensitising solution, thus restricting the image-bearing layer to a single surface.

From the point of the travelling photographer, waxed paper negatives could, if required, be prepared several days before exposure, and developed several days afterwards. Thus freed from the constraints of transporting a darkroom wherever they went, photographers could concentrate solely on the image.

Le Gray demonstrated the versatility of his process in a remarkable series of landscapes taken between 1849 and 1852 in the densely wooded Forest of Fontainebleau. His understanding of the relationship between the light and the limited spectral sensitivity of his dry waxed paper negatives is manifest in these images, creating in his salt prints an intimacy which at once both draws the viewer into the composition and evokes a strong emotional relationship with the environment. By careful choice of both lighting and location, his images went far beyond simple representation, denoting a clear understanding of the potential of his process, and the unique vision of the camera.

The forest was a subject to which he returned in his later engagement with collodion, further developing his personal relationship with the place.

In parallel with his continuing exploration of Fontainebleau, Le Gray applied his talents and his process to a unique undertaking on behalf of the Commission des Monuments Historiques, an agency of the French government. Recognising the importance of photography as a tool of record, the Comte de Laborde, a curator at the Louvre working on behalf of the Commission, approached a number of founder members of the Société Héliographique in Paris in 1851 to undertake a nationwide photographic survey of historic buildings, many of which were deemed to be under threat. Laborde had long been enthusiastic in his advocacy of photography.

First to be thus commissioned was Edouard Baldus—ironically to photograph buildings around Fontainebleau, an area Le Gray knew so well. Further commissions went to Henri le Secq, and to Hippolyte Bayard, who had contributed his own unique process to the emerging development of photography.

Some months later, Gustave le Gray's name was added to the list, with commissions to photography buildings in and around the Loire valley, Orléans, and as far south as Carcassonne.

All the photographers commissioned were conversant with a range of paper negative processes, and all but Bayard used variants on the calotype or the waxed paper process to produce their images. Bayard is believed to have used albumen on glass, the process pioneered in the late 1840s by Claude Félix Abel Niépce de Saint. Victor. While about three hundred paper negatives are archived in the Musée d'Orsay in Paris, none of Bayard's glass plates is known to have survived.

Le Gray received his commission at the same time as Olivier Mestral, and the two men appear to have pooled their lists and elected to work together. The French journal *La Lumière* reported that "Accompanied by M. Mestral, M. Le Gray is working in the region of the Midi beyond the Loire towards the Mediterranean: he has not yet returned but has sent precious dispatches." While this clearly implies that negatives had been sent back to Paris, the question remains unanswered as to whether or not they were processed in the field, or sent back undeveloped.

Many of the images they created show all the hallmarks of Le Gray's mastery of light and shade. Details of buildings are revealed in bright pools of sunlight, while other areas are allowed to recede into deep shadows. They are however overshadowed by his architectural studies of Paris in the later 1850s, and of Italy and Egypt in the early 1860s.

Just what the Commission initially planned to do with these images is not clear, but in the event it did little except secure their survival. They were not published, and indeed relatively few were even printed. But as many of the buildings photographed were subsequently subjected to ill-informed "restorations" in the years that followed, these images have today acquired an historical importance far beyond any original intentions the Commission might have harboured.

Concurrent with these major undertaking with waxed paper, Le Gray had, according to N. P. Lerebours in *La Lumière* in 1852, also been working with the wet collodion process since 1850. He had also been working with albumen on glass, and Philip Delamotte exhibited two such images amongst five Le Gray titles at Great Britain's first photographic exhibition at the Royal Society of Arts, London in December 1852. Waxed paper, however, still remained his principal and preferred medium well into 1854, at which time it still featured strongly in the fourth edition of his treatise on photography.

Later in 1854, he became one of the founder members of the Société Française de Photographie, and a member of its management committee.

Whilst the dating of many of Le Gray's extant images is problematic, there is scant evidence of his continuing

employment of either waxed paper or albumen on glass into 1855. All his subsequent imagery was produced using collodion on glass.

With collodion, he returned to Fontainebleau and revisited his earlier works on the forest, exploiting the greater sensitivity of the glass plate but still exploring the pools of light which penetrated deep into the woodland. In printing some of these later images he also carried out experiments in combination printing, combining negatives of the forest walks—exposed correctly for the foliage—with separately exposed negatives of sky and cloud. This technique was also exploited in his series of seascapes from 1855, which heightened his profile considerably in the world of French photography.

Le Gray's seascapes are remarkable for a number of reasons, not least of which is the impact they had when first exhibited. They were striking and powerful, taking landscape and pictorial photography to new levels of sophistication both in design and execution. They were also phenomenally popular, selling in very large numbers—with contemporary advertisements claiming sales of over eight hundred prints.

Very little is known of the techniques used in their production, and they represent both a significant leap forward for photography and change of direction for Le Gray. Researchers have determined that they fall into two categories—those which are genuine single instantaneous exposures capturing sea and sky at the same time (but perhaps manipulated in processing and/or printing) and those which are the result of careful and controlled combination printing.

Whilst they met with significant public acclaim, their reception in the photographic press was mixed—several reviews citing the 'unnatural' relationship between cloud and sea. Dark and often overpowering skies, shot directly into the sun, give a moonlight effect to some, and a sense of an approaching storm in others. One British reviewer complained that they did not conform to contemporary expectations that photography would reflect truth in nature

> Measured by the photometer, a cloud, according to the illumination, is from a thousand to a million times more luminous than a terrestrial body. In this picture we doubt if in any part of it a greater contrast could be found than in the proportion of 1 to 30. (William Crookes, editor of The Liverpool & Manchester Photographic Journal 1:6, 15 March 1857.)

Photography's great dichotomy has always been the distance between artistic interpretation and truthful representation. While many of Le Gray's architectural studies do conform to the expectations of those who saw photography's role as being truthful to nature, the images which form his major contribution to photography's history are now rightly recognised as art.

In 1856 Le Gray moved from his studio in Chemin de Ronde de la Barrière de Clichy in Paris, to new premises in the Boulevard de Capucines, premises already partly occupied by the Bisson Frères, and later by the charismatic Nadar (Gaspard-Félix Tournachon).

Given the high profile of Le Gray's architectural, landscape and seascape photography today, it would be easy, but inappropriate, to categorise him simply as a photographer of the outdoors. His interest in portraiture predates his engagement with photography, and the photography of people was a consistent feature of much of his professional life, particularly the period between 1854–55 and his departure from Paris in the early months of 1860.

Fine studio portraits survive of the French Emperor and Empress, and of leading figures from both military and civilian life. A small number of nude studies, photographed on waxed paper, survive from the early 1850s.

In the summer of 1857, Le Gray was commissioned by the French Court to photograph an innovative military development—the creation of a special camp for the Imperial Guard at Châlon sur Marne, presided over by the Emperor and Empress themselves. The series of photographs which resulted from that commission—panoramas, military portraits and theatrically-staged tableaux, have, in their conception and execution, much in common with Roger Fenton's depiction of the war in the Crimea two years earlier. Given that the Imperial Guard had Zouave divisions—as did the British army in the Crimea, there are obvious similarities in some of the group tableaux. Despite the advances made with the wet collodion process since Fenton's commission, the large format of Le Gray's plates, and the cumbersome nature of his camera, clearly imposed limitations on any aspirations he may have had about capturing the bustle and spontaneity of the proceedings.

It is ironic, considering the importance of Le Gray's oeuvre, that by 1859 he was apparently facing financial ruin. Early in the following year, *Le Gray et Cie* ceased trading, and the photographer himself left France and his family for good. He set sail with Alexander Dumas on a Mediterranean journey which took them into the midst of Garibaldi's struggle in Italy—resulting in a remarkable series of images by Le Gray of battle-damaged buildings in Palermo and elsewhere. There is strong evidence that for part of this voyage at least, he reverted to his original preference for waxed paper—sacrificing the enhanced detail of the glass plate, for the advantages of travelling light and preparing and processing at leisure.

Le Gray parted company with Dumas in Malta, and made his way to Lebanon and Egypt, again photographing extensively wherever he went, and again using large waxed paper negatives. He remained in Egypt for the

remainder of his life, living at times in Alexandria and in Cairo.

He became a tutor in drawing and painting, and the last recorded reference to him working in photography is dated 1869. After that time, he slipped off the European photographic stage into relatively obscurity, although well respected in Cairo. He is believed to have died there in 1882.

JOHN HANNAVY

Biography

Jean Baptiste Gustave Le Gray, or Legray as he sometimes styled it, was born on August 20, 1820, the son of Jean Martin Legray and Catherine Gay, at Villiers-le-Bel, France. From about 1839 until 1843, he studied drawing and painting in Paris, before travelling to Switzerland and Italy where he met and married Palmyra Leonardi in 1844. Their first daughter, Elvira born in 1845, lived less than a year, and her name was given to their second born the following year. She died before she was three years of age, probably a victim of cholera. A further daughter and a son were born in the mid 1850s, but by 1865 only one child was apparently still alive, living with Le Gray's estranged and near-destitute wife in Marseilles. In that year, he travelled to Rome to meet with his wife, in the hope that his financial difficulties in France might permit a return, but it was not to be. Hopeful of returning to France to resume his photographic career, he had retained his membership of the Société Française de la Photographie until at least 1863.

Le Gray's death—in Egypt in 1882—was reported by Nadar, but no formal confirmation of the date has yet been discovered. Nadar reported that Le Gray suffered a broken arm after a riding accident, and that "il mourut vers 1882 dans une détresse assurément imméritée."

LE PRINCE, LOUIS AIMÉ AUGUSTIN (1841–c. 1890)

Son of a major in the French artillery, young Le Prince's interest in photography was perhaps spurred by a family friend, L.J.M. Daguerre. A surviving daguerreotype shows him as a young boy, with his parents and brother. After college at Bourges and Paris, Le Prince did postgraduate work in chemistry at Leipzig, Germany. He studied art, and specialised in the painting and firing of art pottery. Invited to Leeds, England, by old school friend John R Whitley, he stayed and joined the firm of Whitley brothers, brass founders, and in 1869 married Miss Lizzie Whitley, who had trained at the famous French pottery at Sevres. During the Franco-Pussian war he survived the Seige of Paris as an officer of volunteers, and on his return to England the Le Princes set up a school of applied art in Park Square, Leeds.

Le Prince carried out photography on metal and pottery, and his portraits of Queen Victoria and Prime Minister Gladstone were placed in the foundation stone of Cleopatra's Needle in London.

In 1888 Le Prince went to the United States on a business venture but this failed. He became manager of a group of artists who made large circular panoramas in New York, Washington, and Chicago. A 10th-scale mock-up sketch of the scene was "squared up" and each square photographed. Lantern slides of the drawings were then projected onto the huge panoramic canvases as a painting guide. These giant vistas were visually impressive but the action scenes they depicted lacked movement, which may have given Le Prince the idea for developing moving "panoramic views." Soon afterwards he started experimental work on moving picture machines in the workshops of the New York Institute for the Deaf, where his wife taught; and in 1886 he applied for an American patent for a machine using one or more

lenses (illustrating the most difficult proposition, incorporating 16 lenses). The patent was granted in January 1888, but the U.S. Patent Office deleted claims for machines with one or two lenses as having been already covered by others. His patents in Britain, France, and elsewhere, however, allowed a one-lens version.

In Paris, in 1887, to demonstrate proof of working he produced a 16-lens machine. Although this was designed to use two picture bands moving alternately, the only surviving sequence is a single set of 16 images, suggesting that the tests may have been made with a fixed plate.

Back in Leeds Le Prince rented a workshop at 160 Woodhouse Lane and engaged woodworker Frederick Mason and J.W. Longley, inventor of an automatic ticket machine, and by the summer of 1888 had constructed a "receiver" (camera), with a single lens and intermittently-moving take-up spool. The patent suggests the use of gelatine coated with bromide emulsion, or "any convenient ready-made acting paper, such as Eastman's paper film," the "stripping film" which had recently been made available in the first Kodak amateur rollfilm camera. A paper negative sequence of the family cavorting for Le Prince's camera was exposed in his father-in-law's garden, apparently as early as October 1888. Scenes of his son Adolphe playing the melodion, and of traffic on Leeds Bridge, were taken at about the same time, at between twelve and twenty pictures per second.

Projection was more of a problem, due to the unsuitability of the paper base and the registration difficulties with unperforated bands. Undeterred, Le Prince built a "deliverer" (projector), having three lenses and three picture belts and apparently using a Maltese cross intermittent movement. This machine probably used belts of glass slides, the fibre belts moving alternately to ensure that an image was always on the screen, thereby reducing flicker. A single-lens projector was also built. These machines did not succeed to Le Prince's satisfaction, and he probably experimented with celluloid which offered a more suitable image base, in 1889/1890.

Also attempting to produce motion pictures in England at about this time were William Friese-Greene, with his associates Mortimer Evans (1889 patent) and later Frederick Varley (1890 patent); and Wordsworth Donisthorpe and William Carr Crofts (1889 patent). They all had some success in shooting sequences of photographs on flexible films, but like Le Prince, had serious problems with projection and were unable to present successful motion pictures to the public. In France, Etienne-Jules Marey had also produced sequence photographs on both paper and celluloid strips, but was mostly concerned with motion analysis—examining the individual images—rather than recreating movement on the screen. (Though he would later build a projector for his unperforated filmstrips, but it was never demonstrated).

While Le Prince was experimenting in Leeds, his wife and family remained in New York, having rented and renovated a mansion in preparation for showing his apparatus and motion pictures. Apparently troubled by financial problems, in the summer of 1890 he packed up his equipment in Leeds ready for the move to New York, and in August went to France with friends. He left them at Bourges to visit his brother Albert at Dijon, where he was last seen boarding the train for Paris on 16 September, and subsequently disappeared. In 2003, an 1890 photograph of a drowned man resembling Le Prince was discovered in the Paris police archives.

STEPHEN HERBERT

Biography

Louis Aimé Augustin Le Prince, was born in Metz, France, on 28 August 1841. His father Louis Le Prince was an army major; his mother was Elizabeth Boulabert. Le Prince spent much of his life in Leeds, England, with occasional business ventures in the United States. He took sequence pictures on paper "film," but was apparently unable to achieve successful projection. According to his employee Frederick Mason, Le Prince—Gus to his family—was most generous and considerate and, although an inventor, of an extremely placid disposition which nothing seemed to ruffle. Seven years after his 1890 disappearance, Le Prince was declared legally assumed dead.

LE SECQ, HENRI (JEAN-LOUIS HENRI LE SECQ DES TOURNELLES) (1818–1882)

French photographer and painter

Henri Le Secq was born in Paris on August 18, 1818 to Auguste-Jean-Catherine Le Secq and Anne-Louise-Françoise "Dolly" Tournaire. Le Secq's father served as the chief clerk at the Prefecture of the Seine and eventually became mayor of the ninth arrondissement (today

Le Secq, Henri. Grandes figures au porche nord, cathédrale de Char.

the fourth). Undoubtedly influenced by his father's service to Paris, Le Secq became a connoisseur of his native city, particularly its architectural treasures, as artist, antiquarian, and most notably, as photographer.

Le Secq began his artistic studies with the sculptor James Pradier in 1835. In 1840, he entered the studio of Paul Delaroche where he began painting genre scenes, and in 1842 he exhibited his first paintings at the Salon. In 1845, Le Secq followed Delaroche to Rome and returned to Paris in 1846. At Delaroche's studio Le Secq met fellow painter Charles Nègre. In 1848, with the instruction of artist/photographer Gustave Le Gray (also a student of Delaroche), Le Secq and Nègre began to experiment with photographic processes. In this year Le Secq married Marguerite-Fanély Palais.

Le Secq was one of many French photographers making calotypes, a paper negative/positive process invented by William Henry Fox Talbot in England in the 1830s. In 1850, Le Secq and Nègre began using Le Gray's waxed paper negative process which improved the translucency of the paper negative by rubbing wax on the paper before it was sensitized and exposed in the camera. Even when his contemporaries began using glass negatives, Le Secq continued making paper negatives. Le Secq's first use of photography was to make quick preparatory sketches of posed figures in genre subjects for paintings but soon he began photographing architecture. By the time Le Secq, along with Nègre, Le Gray and others, helped to found the Société héliographique in 1851, the first photographic society to be established, he was considered one of the best architectural photographers in France.

His fame as an architectural photographer led to Le Secq's inclusion in the Mission Héliographique, the first photographic survey of historical monuments in France. The group was arranged in 1851 by the Commission des Monuments Historiques, a group of French political antiquarians, architects, and archeologists. The Commission felt it urgent to preserve France's architectural heritage by documenting medieval buildings and monuments threatened by deterioration from neglect, as well as industrialization and restoration. The Commission hired five established architectural photographers to document five provincial centers in France. Le Secq was assigned the religious edifices of Champagne, Alsace, and Lorraine. Though the mission was never fully realized (due to difficulties in obtaining permanent prints) and only 300 paper negatives survive, the Mission provided Le Secq with experience in the field and an opportunity to perfect his skills at photographing architecture. Following this first commission, Le Secq documented the sculpture of Strasbourg, Amiens, Reims, Chartres, and various other churches around Paris.

Le Secq's photographs demonstrate both his roots in Salon painting and an interest in using the camera to reach heights and vantage points previously unattainable. To make "Flying Buttresses, Reims Cathedral," 1852, Le Secq climbed to a point where he could photograph the successive arches of the flying buttresses, a vantage point that the ordinary visitor to the cathedral would not be able to reach. By 1852, Le Secq had also turned to landscape photography and photographed stone quarries and woods around Montmirail. These works show the influence of paintings by Corot, Rousseau, Dupré, and Diaz. The landscape photographs were meant to be used as studies for artists. As in the architectural photographs, Le Secq utilized the calotype process's potential for murky, moody effects to an extreme by making long exposures, thus creating dramatic compositions of deep shadow.

Between 1849 and 1853, Le Secq photographed old monuments, buildings, and churches in various states of disintegration, such as "Tour St. Jacques," 1853, as well as demolitions and various public works projects begun by Jean-Jacques Berger, Prefect of the Seine. He also photographed Notre Dame, the old Hotel-Dieu, Amiens, and Chartres. His photographs of demolitions, such as

that of the king's stables in *Place du Carrousel*, 1852, seem to foreshadow Baron Haussmann's renovations of the city in the 1860s when demolitions and construction sites would appear throughout the city. Baron Haussmann was clearing many of Paris's old streets for his renovation of Paris into wide, modern boulevards. Le Secq's intimate knowledge of and love for his native city inspired his excursions with camera and tripod. He was particularly tied to his old neighborhood, the Saint Antoine section, which was being razed for the extension of the rue de Rivoli. Le Secq also captured the old Pont Neuf, Hôtel Dieu, as well as changes taking place around Hôtel de Ville, and assembled them into albums. In 1853 six of Le Secq's negatives, including those of Chartres, Strasbourg, and Beauvais, were used by print publishers such as Lerebours and Lemercier to make lithographs.

From 1851, Le Secq's photographs were included in exhibitions, including the Universal Expositions in London in 1851 and 1855, where he was acknowledged as one of France's greatest artist-photographers, and received a silver medal for work shown in Amsterdam in 1855. In 1856, he made several photographic still lifes, composed of objects, fruit, and vegetables. By this time, Le Secq's photographic career was drawing to a close although as the paper negative went out of use and the collodion on glass negative took its place. However, Le Secq did reprint many of his waxed paper negatives. For the rest of his life, Le Secq returned to painting and regularly exhibited at the Salon and formed his own art collection of contemporary printmakers and painters such as Whistler, and Millet, as well as artists Jongkind and Daubigny and major impressionists.

After the death of his wife and only daughter in 1862, he sold a large group of his own painting and drawing collections and began collecting forged iron, particularly ancient keys, locks, and signs. In 1863 Le Secq published a pamphlet on the reform of the Salon entitled *Les Artistes, les Expositions, le Jury*, edited by A. Cadart and F. Chevalier. The following year he wrote a second pamphlet for the defense of artists entitled *Aux artistes et aux amateurs des Beaux-Arts*. In 1882, Le Secq died in Paris, leaving his art and iron collections to his sons.

KAREN REED HELLMAN

Biography

Henri Le Secq was born in Paris on 18 August 1818. He began his artistic studies with the sculptor James Pradier in 1835. In 1840, he entered the studio of Paul Delaroche where he met fellow painter Charles Nègre. In 1848, with the instruction of artist/photographer Gustave Le Gray (also a student of Delaroche), Le Secq and Nègre began to experiment with photographic processes. In 1850, Le Secq and Nègre began using Le Gray's waxed paper negative process Even when his contemporaries often used glass negatives, Le Secq kept making photographs with paper negatives. Le Secq's first use of photography was to make quick preparatory sketches of posed figures in genre subjects for paintings but soon began photographing architecture. By the time Le Secq, along with Nègre, Le Gray, and others, helped to found the Société Héliographique in 1851, the first photographic society to be established, he was considered one of the best architectural photographers in France. In 1851, Le Secq was included in the Mission Héliographique, arranged by the Commission des Monuments Historiques. Between 1849 and 1853, Le Secq photographed old monuments, buildings, and churches in various states of disintegration, which foreshadow his later photographs of demolitions and architectural documents made during Baron Haussmann's renovations of Paris in the early 1860s. By 1852, Le Secq had also turned to landscape photography and photographed stone quarries and woods around Montmirail. Le Secq published two pamphlets on the reform of the Salon. Le Secq died in Paris in 1882.

LEA, MATTHEW CAREY (1823–1897)

American photographer and author

Matthew Carey Lea, also known, as Carey Lea, son of scientist Isaac Lea and Frances Carey Lea, was born in Philadelphia on 18 August 1823. An acknowledged authority on photochemistry in the late nineteenth century and a member of the Franklin Institute, Lea

began experimenting with the chemical properties of developer in 1864. Educated through tutors and the Philadelphia chemistry laboratory of Booth, Garrett and Blair, Lea particularly studied the function of silver in the development process. His scientific advancements of photographic processes included inventing the first mordant-dye picture in 1865 and increasing the clarity of developed dry plate negatives in 1880. Lea also wrote prolifically about his experiments. In 1864–1866, he assumed the position of American correspondent to the *British Journal of Photography* and became a steady contributor to the *Philadelphia Photographer* and *Photographic Mosaics*. In 1868, he authored *A Manual of Photography*. During the 1870s and 1880s, he continued to experiment with silver halide salts and the color process, including the description of "photo haloids" (i.e., metal compounds that resemble salt) in 1885 and the discovery of "allotropic" forms of silver of various colors between 1889 and 1891. On March 15, 1897, Lea died in Philadelphia, two years after his election to the National Academy of Sciences.

ERIKA PIOLA

LEGEKIAN, G & CO
(dates unknown)

The name "G Legekian" is found on a large number of very fine images of Egypt from the late nineteenth century, but very little is known of the photographer(s) who created them.

Known to have produced dry-plate images from 10"x8" up to 'mammoth' 20" × 16" images, the Cairo-based Legekian studio—next door to the well-known Shepheard's Hotel (misspelled "Shephard's" on his cards)—was at the forefront of the tourist market from c.1880.

Legekian himself is believed to have been Armenian, but personal details are significantly difficult to find.

In 1883 or 1884 the Legekian studio was appointed Photographers to the British Army of Occupation in Sudan, and that appointment signalled a temporary change of language on their photographs—from French to English, and from *G Legekian photographie artistique, atelier special de peinture* to *G. Legekian & Co*. In 1890, some *cartes-de-visite* include both appellations. By 1891, however, their cartes and larger pictures were once again captioned exclusively in French.

Several Legekian images from the late 1890s were included in the book *Celebrities of the Army* published by Newnes in 1902, and the 1906 book *New Egypt* records that Legekian "has, besides some remarkable portraits, a unique collection of views both in large prints and in postcards."

JOHN HANNAVY

LEGGO, WILLIAM AUGUSTUS
(1830–1915)

Inventor, leggotyper, engraver, and publisher

William Augustus Leggo, was born Quebec, Quebec, 25 January 1830; died Lachute, Quebec, 21 July 1915. Trained originally as an engraver, first by his father, William Augustus Leggo Sr., and later by Cyrus A. Swett with whom he completed his apprenticeship in Boston, Leggo had by 1850 established himself as an engraver in Quebec City. From this traditional print background, Leggo, together with George Edward Desbarats (1838–1893) who became Leggo's business partner in 1864, went on in the 1860s and 1870s to pioneer important advances in the graphic arts though the application of photography to early photomechanical printing processes. Indeed in 1869, their efforts contributed towards revolutionizing global communication in terms of how newspapers were illustrated by their publication of the world's first letterpress halftone reproduction of a photograph.

Leggo's and Desbarats' early photomechanical process, named leggotyping, was first identified in 1864 as an improved photoelectrotyping process to provide an inexpensive, rapid means of producing accurate facsimilies of any type of line image via either relief or intaglio plates without assistance of engraving or other hand work. With Desbarats financial backing, Leggo continued to perfect the process and to expand its application to allow halftone images of photographs and other tonal works to be photomechanically reproduced using a type-compatible format. The goal to expand leggotyping to halftone work was achieved in September 1869 when a Canadian patent was granted for "Leggo's granulated photographs." Shortly thereafter, Leggo and Desbarats put their line and halftone photomechanical discoveries to commercial use to illustrate Desbarats' new pictorial weekly the *Canadian Illustrated News.* Launched October 30, 1869, the Montreal based paper featured a cross-lined screen halftone of William Notman's photograph of His Royal Highness Prince Arthur in its inaugural issue. Leggotyped line and halftone images were also used to illustrate *L'Opinion publique*, Desbarats' french language counterpart to the *Canadian Illustrated News,* and the process became a speciality of the two partners' firm, Leggo & Company.

Further advances in halftone reproduction followed in September 1870 when Leggo and Desbarats applied their recently patented process which married lithography and leggotyping to the pages of the *Canadian Illustrated News,* making it the first periodical to have its illustrations printed planographically. The process was also applied to *L'Opinion publique* beginning 1871 and to the partner's illustrated newspaper, the New York *Daily Graphic,* which they launched March 4, 1873.

Within a year of starting their new American venture however, Leggo's and Desbarats close professional ties were severed when Desbarats encountered financial difficulties which left him insolvent. Leggo himself remained with the *Daily* Graphic as publisher and continued his research with photomechanical processes for some years. By 1879 however, Leggo had returned to the Montreal, where he appears to have remained in the area the rest of his life.

Beyond directing his considerable creative talents to the development of new photomechanical processes, Leggo also obtained patents for a variety of other interests, including telegraphy and photographic equipment. For example, in 1869 Leggo developed a camera to photograph architectural subjects which eliminated a problem other cameras then experienced of distorted perpendicular lines in the resulting photograph. A valuable improvement, in general, to outdoor photography, its improved picture taking capabilities were actively demonstrated to all in leggotyped half-tone within the *Canadian Illustrated News* and *L'Opinion publique*.

Terresa McIntosh

LEITZ, ERNST (1843–1920)

Ernst Leitz (I) was the first in the father-son-grandson sequence of men with that name who succeeded one another as leaders of the renowned family-owned German firm of Ernst Leitz Wetzlar GmbH. He was born on the 26 April 1843 in Sulzburg (not Salzburg) in the southwestern German province of Baden. Ernst was the youngest of three children born to Christina Elizabeth Leitz (née Doebelin) and Ernst August Leitz, both of whom were teachers at the high school of Sulzburg. The parents were very religious and wanted young Ernst to study theology, but the latter had a very practical disposition and he was able to persuade his father to let him pursue a career in mechanical craftsmanship. The father arranged for Ernst to embark on an apprenticeship with the instrument maker Christian Ludwig Oechsle in Pforzheim, also in Baden, a town known for its jewelry makers and goldsmiths. Oechsle's establishment had the impressive name "Workshop for Physical and Chemical Instruments and Apparatus and Machines of the Mechanic Oechsle, Gold Controller for the Grand Duke of Baden." The shop produced a great variety of physical equipment, as shown in its 1855 catalog, which had 24 sections with a total of 553 items, including a few optical devices. Under the tutorship of the exceptionally competent Oechsle, Ernst Leitz was able to acquire a wealth of knowledge and skills that would ultimately stand him well as a solid foundation for his trade. But it appears that he realized early on that excessive versatility that did not yield a top performance in any particular field might lead him to become a jack-of-all-trades. This portended his eventual career.

As was the custom at that time, after completing his apprenticeship, Ernst Leitz (I) began traveling as a journeyman. He visited one of his sisters in Vevey in Switzerland and after a brief time in Zurich, he found a job as an assistant to Mathäus Hipp, a prominent manufacturer of electric clocks in Neuchâtel. It is there that he first became acquainted with the process of mass production of precision parts for world-famous Swiss watches that was already routine in Swiss factories. This manufacturing process was of fundamental significance later on when he became the sole owner of a precision manufacturing enterprise. The aforementioned Oechsle also produced precision instruments, but they were made individually, which required more time, so that their prices were significantly higher.

While working for Hipp, Ernst Leitz (I) met Karl Junker from Giessen, a university town north of Frankfurt, Germany. Junker was on his way to Paris after having worked for Friedrich Belthle, who in 1855 had taken over the Optical Institute, a small microscope manufacturing enterprise founded in nearby Wetzlar in 1849 by Carl Kellner (1826–1855). Junker encouraged Ernst Leitz (I) to visit that institute because it was in serious need of competent instrument makers. Heeding that advice, Leitz joined that small firm in Wetzlar in early 1864 and only one year later, on 7 October 1865 he became Belthle's partner. Belthle was not an efficient manager, he was in poor health, and he did not cultivate adequate connections with the world of science, so that the demand for his microscopes was quite limited. When Belthle passed away in 1869, Ernst Leitz (I) became the sole owner of the company and named it "Optisches Institut von Ernst Leitz," a name that prevailed in various mutations for 119 years thereafter.

A memorable event in the career of Ernst Leitz (I) occurred on 21 September 1864 during the 39th Congress of German Natural Scientists and Physicians in Giessen, where Ernst Leitz (I) demonstrated Belthle's microscopes and where Philip Reis (1834–1874) successfully demonstrated a telephone that he had invented. Reis had demonstrated it before, but the construction was faulty until Ernst Leitz (I) became interested in it and helped Reis to build a properly functioning model, based on the knowledge of electricity, electro-magnetism and instrument making that he acquired during his journeyman years. Reis' telephone was acclaimed at that congress, but it was only promoted to institutes of physics and Reis did not possess the foresight and know-how for marketing it to business users and to the public. Only one year after Reis' death of tuberculosis on 14 January 1874, 11 years after his successful demonstration, the American Alexander Graham Bell (1847–1922)

presented an improved model and was generally credited as the inventor of the telephone.

Not yet 30 years old when he took over, Ernst Leitz (I) revitalized the lagging company by implementing the series production methods that he had learned in Switzerland, gradually overcoming the earlier lack of innovations, the growing competition and the slump caused by the outbreak of the Franco-German war in 1870. His new methods enabled him to offer faster delivery times that were quite unusual at that time. This and the participation in nature- and medical congresses with practical demonstrations brought him into closer personal contact with personalities from science and technology from well beyond the nearby universities of Giessen and Marburg. As a result, Leitz microscopes and their accessories began to gain favor in the right circles. It was in 1870 that Leitz published his first price list under the wordy title *Current prices of the achromatic microscopes of the institute founded by C. Kellner in Wetzlar, successor Ernst Leitz (formerly Belthle & Leitz) 1870.*

During these years the fields of medical histology, pathology, and bacteriology were being rapidly developed primarily by German scientists with the aid of affordable, serviceable German microscopes designed with these fields' requirements in mind. The production of Leitz microscopes began to grow vigorously, in spite of increasing but stimulating competition from Carl Zeiss, who had begun producing microscopes in 1858 and who had engaged the services of the brilliant physicist and mathematician Ernst Abbe. Additional competition was rendered by Georg Oberhäuser-Hartnack, a German citizen who had immigrated to Paris, where he produced microscopes that were cheaper and that performed better than the Belthle microscopes. Engelbert & Hensoldt also produced competing microscopes, as did the Wetzlar brothers Wilhelm and Heinrich Seibert in cooperation with a man named Gundlach. All of them had worked with Leitz's predecessors Kellner and/or Belthle at various times before setting out on their own. The statistics show that microscope production improved dramatically after Ernst Leitz (I) took over in 1869**:**

1849–1860	circa	400 microscopes
1861–1870	circa	600 microscopes
1871–1880	circa	2,500 microscopes
1881–1890		13,650 microscopes

The 10,000th microscope was completed in the year 1887.

Ernst Leitz's (I) older son Ludwig had developed a compact and inexpensive photomicrographic apparatus in 1882, which led to the development of three lenses for general photography marketed by Ernst Leitz (I) in 1886 called Summar, Periplan, and Duplex. The initial focal lengths were 24, 42, and 64 mm, with a maximal aperture of f/4.7. The series was later expanded and pages 608 and 609 of the 12 September 1901 issue of the London magazine "Photography" published a highly favorable report on the wide-angle performance of a Periplan No.5 lens with a focal length of approximately 8 inches (203 mm). The awareness of photography already existed during the earliest times of the firm, as evidenced in a letter in which Carl Kellner informed his friend and occasional associate Moritz Hensoldt that he had built a lens for a Daguerreotype camera. The superb quality of Leitz lenses for photography was to become one of the company's most famous attributes.

Competition triggered strong awareness of the need for improvements and innovations, and as early as 1877 Ernst Leitz (I) created a scientific department dedicated to research and development in optics. The man placed in charge was the mathematician Karl Metz, who already had experience in the computation of lenses for telescopes. The initial task was to improve the company's own achromats, building on the pioneering work already performed elsewhere by Gauss, Helmholtz, and Abbe, and later applying the possibilities provided by new types of optical glass supplied by the prominent glass laboratory of Schott & Genossen that was founded in 1886 in Jena with government support.

The growing demand for Leitz microscopes and many related instruments led to several expansions of the manufacturing space that had started in a regular house in Wetzlar that served as both a family residence and a factory, followed by several moves to larger facilities that culminated in a stately group of buildings at the foot of a hill topped by the Kalsmunt castle, where the Leica Microsystems Company buildings still stand today. At one point there were three separate substantial buildings at this location that housed the mechanical shop, the carpentry shop, and the optical shop.

Ernst Leitz (I) was a personable individual who maintained friendly relations with persons from scientific, industrial and academic circles, and this inspired him to tailor his products to their respective needs. He also had a talent for attracting and nurturing the right people for the jobs. In a significant example, he recognized the skills of Oskar Barnack and encouraged him to come to work in Wetzlar, in spite of the fact that Barnack suffered from severe asthma. Leitz offered him all the time he needed for trips to health spas and even accompanied him on some of these trips.

Barnack had worked at Carl Zeiss in Dresden and Jena from 1902 to 1910, where he had approached Director Guido Mengel of ICA, a camera-making subsidiary of Zeiss Ikon, with a prototype of a 35 mm camera that he had built, but Mengel had rejected it. At the suggestion of Emil Mechau, who had left Zeiss earlier to work on motion picture projector design at Leitz, Barnack eventually, albeit reluctantly (for health

reasons), also accepted a position at Leitz, where began working in the newly created experimental department on 2 January 1911. Ernst Leitz (I) was intrigued by Barnack's unconventionally small camera and he took it along on a trip to New York and used it to take quite a few candid pictures. That camera was the so-called "Ur-Leica," an improved version of which was placed in production by Ernst Leitz (II) [the son] in 1924 and introduced at the Leipzig Spring Fair of 1925, eventually becoming the legendary Leica camera whose subsequent models are still in production today!

Ernst Leitz (I) had a trait that was a strong characteristic of the Leitz family for the generations that followed, in that he was genuinely concerned for the welfare of his employees and he knew nearly everyone by name and would chat with them warmly during his regular rounds through the shops. He introduced the eight-hour workday and health care assistance and in 1899 a pension for invalids, widows, and orphans. His equally social-minded wife Anna Leitz visited families in need and she would discreetly slip money into their pockets to help them with their expenses. As a result, "der alte Chef" (the old boss) and his family were affectionately revered by his employees. In recognition of his achievements and his benign social engagement, on 24 December 1910 the University of Marburg bestowed an honorary degree of Doctor of Sciences upon Ernst Leitz (I).

Ernst Leitz (II) remained active until the end of his days. While on a health visit to Solothurn in Switzerland, he passed away on 12 July 1920, having survived his wife by 12 years. Because his first son Ludwig Leitz had died of a riding accident at the prime of his career in 1898, his second son Ernst Leitz (II) took over management of the company, which continued to flourish under his competent guidance.

ROLF FRICKE

LEMERCIER, LEREBOURS AND BARRESWILL

Rose-Joseph Lemercier (Paris, 1803–1887), and Aloïs Senefelder, a pupil from 1817 to 1819, worked in the Senefelder printing house directed by Knecht from 1825 to 1829. Lemercier established a lithographic printing house in 1829 in Paris, 57, rue de Seine. He came to photography in 1839, and produced his first daguerreotypes. At the beginning of the 1850s, he became interested in photomechanic process. During this period, the obstacle was in obtaining stable photographic images. The rapid fading of some silver-based prints initiated a search for a more reliable and commercially viable process. The future of photography depended on it. This issue became the central point of focus for the Société d'encouragement pour l'Industrie nationale. The Society became one of the most important institutional forces for the development of photography. More than any other group, it foresaw the development of photography as an industry and organized competitions to encourage photographers to produce photographic prints that were of high quality, economical to produce and easy to conserve. As early as 1840, the Society concluded that if it were to progress in the industry, photography needed to abandon pre-industrial hand-made means for more modern means geared toward mass production.

From 1852 to 1854, Lemercier linked up with Lerebours, Barreswill and Davanne. Noël Lerebours (1807–1873) was optician, founding member of the Société heliographique and builder of photographic material; Barreswill was a chemistry professor at the Turgot school as was Alphonse Davanne (1824–1912).

Together they developed the lithophotographic process, which was based on the work of Niépce de Saint-Victor. This process consisted of pouring a solution of bitumen of Jude on a lithographic stone. The stone was then exposed under a negative (paper or glass). The bitumen then received the light and hardened in the areas not exposed to light. The image formed was then engraved with acid and washed from its bitumen. The hardened areas remained after the acid wash, and were then covered with printing ink. After pressing the image onto paper, the image was transferred to the paper, providing various shades and tints.

Lemercier and his associates sent sealed letters containing lithophotographic prints to photographers, the prints which were later presented by François Arago in a lecture to the Academy of Sciences on August 16, 1852. They asked for an invention patent of fifteen years on July 3, 1852, the request was accepted on August 25, 1852. Next year, Lemercier established in his lithographic studio, a photographic printing house, where he produced prints from the negatives of Henri Le Secq. Looking for a renaissance in the photographic underworld, six of those prints from Le Secq were published as prototypes of lithophotography in a treatise on the new process entitled *Lithophotographie ou impressions obtenues sur pierre à l'aide de la photographie, 1er cahier*. It was published in notebook at the Academy of Sciences in January 1854.

The prints from Le Secq represented subjects of architecture and architectural sculpture that he photographs for the Missions heliographique. They accurately reproduced old monuments and the printing on paper gave the grain conferring a certain aesthetic. Lemercier certainly tried to find an outlet (and a market) for the production of prints from the Missions heliographique. That commision, the first photographic project initiated by the French government through the Commission des monuments historique, needed printers able to produce stable images in a timely manner and as accurately as

photographic prints. Lithophotography was real progress and it easy to do. It was also less dangerous than the previous processes, and more suitable to industrial production, but because of the grainy stone, details lost their precision. By founding this photographic printing, Lemercier tried to fulfil the wish, announced in 1851, of the Société heliographique. The request was to have a photographic printer in the company itself to produce the images of photographers and commissioned project studies, which had typically been failing because of a lack of means.

In 1855, Alphonse Poitevin (1819–1882) improved the process and utilized it in his studio until 1857. Named photolithography, his process was based on the mix of albumin and bichromate of potassium propriety to retain, after exposure to light, the printing ink. The bichromate gum has been a decisive discovery of Poitevin's and a tremendous progress for photography in that it was easier to prepare and more accurate in results, and so it took the place of the bitumen of Jude in the sensitive processes of the printing plates. On October 27, 1857, for reason of poor management of business, Lemercier bought Poitevin's studio and patent, and used photolithography in his printing house. They created together a society in collective name for the utilization of the process. The profits were split down the middle. The society was later divided in February 1867. Corine Bouquin and Sylvie Aubenas showed that the use of the patent would unfortunately reveal itself barely profitable, the stress of which put the two men at odds with each other. In 1859, Poitevin began legal proceedings against Lemercier for not having put the complete title "Procédé Poitevin" on the bottom of the plates, instead putting only "P. Poitevin," and for paying less than the full cost of the patent. The judge ruled in January 1860, in favour of Poitevin.

Several photographers gave their negatives to Lemercier to print their images, like Bisson brothers, and Julien Vallou de Villeneuve, but this production stayed experimental or limited. Lemercier never really exploited his process. However, he developed the photolithography to illustrate scientific and artistic books. Two albums were published thanks to this technique: *Le Sérapéum de Memphis* by Auguste Mariette in 1857, created from Charles Marville's and Paul Berthier's negatives (30 plates); the book of Jules Labarte *Histoire des Arts Industriels* (1864–1866) about decorative arts, created from the negatives of Marville and Berthier (150 plates).

Lemercier also printed images which were not lithophotography but photographic prints. The Bisson brothers made *L'œuvre de Rembrandt reproduit par la photographie, décrit et commenté par Charles Blanc* (60 plates) and *Choix d'ornements arabes de l'Alhambra offrant dans leur ensemble une synthèse de l'ornementation mauresque en Espagne au XIIIe siècle reproduit par MM. Bisson frères* (19 plates) in 1853 in Lemercier's studio. As well as twelve images included in the *Monographie de Notre-Dame de Paris et de la nouvelle sacristie de MM. Lassus et Viollet-le-Duc* published the same year. In 1857, Lemercier also edited prints of Varroquier's and the series of stereoscopic views of Furne and Tournier's, who settled in the studio at rue de Seine two years later. The subjects were genre studies and living compositions of trade and craft, like farmers, launderess, blacksmith, hitchers, landscapes, mythology recomposed, models of nudes, scenes from operas, interiors of artist studios, taverns, and oriental interiors.

Photolithography was practice until about 1867 in Lemercier's studios, "putting his press at the service of clichés of authors at the same price conditions as ordinary lithography" write Joly-Grangedor in 1871 (BSFP 1871, 110.) The same year, Poitevin won the great duc de Luynes competition for his process of photolithography and Lemercier received a medal from the SFP for his works on his technique. But because it was not cost efficient, the process was flawed, and in December 1866, Lemercier complained to Poitevin of not making any profits off his patent. Poitevin later made an agreement with Cyprien Tessié du Mothay, associated with Charles Maréchal, who bought in March 1867 the rights of Poitevin. Lemercier, who did so much for photolithgraphy modified it into phototypy which yielded superior images. In 1873, Lemercier bought the patent of Albert of Munich's process of "Albertypy" and uses it until 1887. He also practiced photoglypty in his establishment. He presented prints in 1881 at the Ring of bookshop exhibition and in 1882 at the photographic exhibition of the Central union of decorative arts. He was awarded, at this exhibition a gold medal. Also, in 1879, Lemercier participated in the Léon Vidal lectures on industrials reproductions of works of art which took place on Wednesday at the National School of the Decorative Arts, stating, "Thanks to the obliged support of the Lemercier & Cie house, photoglyptic experiences could have been made in the presence of the pupils of the School" (*Le Moniteur de la photographie,* March 1, 1879, 33–34).

In 1887, he donated to the Société française de photographie an album of Algeria and Tunisia views. He died in Paris in January the same year.

In spite of his efforts, Lemercier stayed with the lithograph, and thus photography for him, never took a real importance in his printing house. Photolithography and the following processes born from this, remained as images printed on a plate, which represented a retreat in relation to wood engravings printed in text and,

later photoengraving. Lemercier's production however, marks an important step in the insertion of photography into books.

LEMERE, BEDFORD (1839–1911)

Bedford Lemere and his son Harry Bedford Lemere are the most outstanding English architectural photographers of the nineteenth century by virtue of the sheer scale and duration of their quality output. Studies of English urban life cannot take place without taking into account these key visual documents of late Victorian England.

From the early 1870s until well into the twentieth century both photographers operated from the same address, 147 Strand which was conveniently and symbolically situated on the border between the City of Westminster and the City of London. By the 1880s the company had became the standard for large format architectural work in Britain. Taking over the premises of Valentine Blanchard the firm did not vacate the same studio until after 1945. The core clientele of Lemere existed between the poles of the City of London and fashionable Westminster thus covering both the domestic and tourist areas of the West End as well as the intensive banking and commerce in the City. It thus encompassed the entire spectrum of business, bourgeois and aristocratic London. Though London generated much of the business there were extensive clients throughout the rest of England: Lemere was employed by the Rothschild family to document their county estates, their mansions in Westminster and their offices in the City—along with their sporting and collecting activities. The key art dealer Duveen used Lemere to provide the best images of his desirable stock of antiques and paintings. In the dark winter months studio commissions also came from legal firms, piano makers and fine silver manufacturers. Urban coverage is also extensive for areas in Liverpool, Manchester, Birmingham, Edinburgh, and Glasgow and other provincial cities. The only known foreign commission is significantly linked with a holiday by Queen Victoria in a grand hotel the South of France. During World War I Lemere was able to diversity by specialising in manufacturing and armaments often linked with the peacetime shipping business.

By deliberately cultivating architects and their clients from the outset Bedford Lemere built up such a sophisticated network of designers, owners and estate agents that by the 1890s prints from his standard 12x10 inch plates could be found in key families, businesses and institutions ranging from Queen Victoria and the Rothschild family to official government bodies and department stores like Harrods. Sets were purchased by architects in the United States wishing to learn about fashionable English design like the Queen Anne movement.

The professional work of Lemere first comes to attention with the important series of carved details designed to educate those studying and applying the tenets of the Gothic Revival through the collection of medieval ornament displayed at the Architectural Museum in 1872 [later the Royal Architectural Museum]. With support from the prominent architect John Pollard Seddon and with endorsements from John Ruskin, Lemere rapidly became associated with major Architects like G. E. Street, G. G. Scott, and, later, Richard Norman Shaw. In addition there are many associations with interior decorators, stained glass and furniture designers, and a range of art-manufacturing companies.

With the exception of churches, a huge range of building types were covered: best known for his total control

of elaborately decorated domestic interiors, especially country houses, Bedford Lemere never employed more than two or three assistants who maintained the objective, sober and all-inclusive style which from 1897 was emulated by photographers employed by *Country Life* magazine. This somewhat dry style without much human incident indoors exhibits a cumulative effect through carefully controlled composition and obsessive attention to detail. The images provide unparalleled records for contemporary commissioners and, today, for several national archives. Along with architecture a profitable maritime sideline was built up recording similar interiors of ocean liners and by the mid 1880s Lemere became the single most important photographer in this area being employed by Cunard, White Star, Canadian Pacific, and other transatlantic shipping companies. In 1887 with agents in New York and Paris some 8,500 images in 17 series were being advertised.

Possible rivals for the crown of architectural photography in England include Charles Latham, Horatio Nelson King, S. B. Bolas and the photographers connected with *Country Life* but though they all created superior images none were ever able to emulate the single-minded continuity of Lemere whose ability to sum up interiors using just one plate per room was evident for over 70 years. The company survived the death of H. Bedford Lemere in 1944 [when glass was still being utilized] but the decline in demand at the same time for large format plates meant that 1944 represents the zenith of large-format architectural photography in Britain.

The output and style of Bedford Lemere was seamlessly taken over and developed into a recognisable style by his son in the late 1880s as commissions diversified yet further whilst retaining the architectural core. Apart from a complete set of negative registers very little other documentary evidence has survived which is a pity since both father and son must have had considerable skills in cultivating such an extraordinarily diverse set of contacts across England linked with every aspect of architecture and property.

Perhaps one-third of the estimated total output of 100,000+ images now survive, most of them at the National Monuments Record, English Heritage. Nevertheless, even this partial survival represents one of the most detailed records ever created of Victorian and Edwardian life; it avoids the usual topographical and tourist views and systematically depicts the exteriors and interiors of everything from modest suburban houses to factories and palaces. The quality and extent show that Bedford Lemere ought to be considered a delineator of Victorian preoccupations with décor, class and industry. These unique records should be consulted by any historian concerned with design, architecture or taste in Britain. In a medium where absences are commonplace, the survival of even a fraction of this visual density means that this work archive is one of the most important in Britain.

IAN LEITH

Biography

Bedford Lemere was born in Maldon, Essex, and established his photographic career in the 1860s before he founding his own company at 147 Strand, Westminster c. 1867. In 1862 he married Anne Pennyfeather at St Pancras church, London. By the late 1880s control of Bedford Lemere & Co. passed to his son Henry [Harry] Bedford Lemere [1865–1944] who later became President of the Professional Photographers Association [1930]. The company was at the same address until the late 1940s and then relocated to South London before being absorbed in another concern. Apart from very detailed registers and a small fraction of the negatives much has been lost including all correspondence linked with commissions and all negatives taken 1929–1944. Surviving negatives, prints and proof print albums were purchased from the 1950s onwards by the Royal Commission on the Historical Monuments of England [later English Heritage]. Over 20,000 negatives and prints along with a complete set of registers survive with the National Monuments Record, English Heritage. Scottish negatives are held by the Royal Commission on Ancient and Historical Monuments of Scotland, Edinburgh. Most Shipping negatives are at the National Maritime Museum, Greenwich. Substantial print holdings exist in the Guildhall Library, City of London, and at Westminster Archives but many others are known to exist throughout English archives. Several archives in the United States and Canada hold images of the Architectural Museum as well as later material.

LENSES: 1. 1830s–1850s
Technical and equipment

In 1812, William Hyde Wollaston showed that a positive meniscus lens, used with the concave side facing the object being viewed, significantly flattened curvature of field. Wollaston further flattened curvature of field by placing a stop at a distance in front of the lens, rather than directly in front, which had been the practice beforehand. This introduced a slight amount of barrel distortion.

Wollaston's lens was used by Nicéphore Niépce in his 1820s–1830s experiments with light-sensitive asphaltum. Due to the low light sensitivity of the processes, Niépce was forced to use the lens without a stop. He also found that the Wollaston lens suffered from chromatic aberration.

In 1833, Niépce's successor, Louis Jacques Mandé Daguerre, switched to an achromatic, positive meniscus lens constructed by Charles Chevalier. At first Daguerre reversed the lens, so that the stop faced the sensitized surface of the plate and convex side of the lens faced the object being photographed. Using the lens in this way, he hoped to take advantage of the condensed light at the center of the image. By 1839, and the public announcement of the daguerreotype process, he had returned to using the lens with the concave side of the lens facing the object being photographed and the stop in front. This marked an achromatic return to Wollaston's original lens arrangement.

The first camera marketed for Daguerre by Alphonse Giroux contained a similar achromatic, positive meniscus element. Because the lens needed to be stopped down to f/14 to obtain a flat field, portraits were impracticable due to the long exposure times involved; however, the lens was suitable for landscapes, architectural subjects, and still-lifes. Chevalier was soon overwhelmed by the demand for lenses, and an achromatic, plano-convex lens was substituted by his optical rival, Noël-Paymal Lerebours. Here the flat side of the lens faced the object being photographed.

By 1840, the public demand for photographic portraiture led opticians to attempt lens designs that could be used at full aperture. Returning to a duplet telescope he had designed 1834, in which two achromatic lens elements were separated by an appreciable distance, Chevalier modified it to arrive at his *Photographe à verres combinés* [Lens Made from Combined Glass]. For many years, this was the only lens capable of providing a flat field with whole-plate images when used at full aperture. It also was the first convertible lens, meaning that the lens barrel could be taken apart and the lens elements changed, depending on the subject being viewed and the format size desired.

Chevalier's lens was followed in 1840–1841 by another portrait lens, designed by Josef Max Petzval and marketed by the Voigtländer firm of Vienna. This lens could also be used at full aperture and was eventually achromatized, although the first 720 examples remained uncorrected for chromatic aberration. One difference it had with the Chevalier lens was that it condensed light at the center of the image. This provided for a shorter exposure time and centralized focus, combined with a gradual darkening of the borders of the image. More analogous to the aesthetic of portrait miniatures, it became an instant success with Daguerrian portraitists, and since Petzval had failed to secure the property rights to the lens, French and English opticians were free to copy the design and offer competing versions.

Throughout the remainder of the 1840s–1850s, photographic lenses generally divided into two classes: landscape lenses and portrait lenses.

Landscape or single lenses were at first identical to the 1830s achromatic positive meniscus advanced by Chevalier, with a stop being placed in front of the lens element at a distance equal to one-fifth of the lens focal length. These took in a narrow field of view and were composed of two types of glass, flint and crown, with the softer flint glass being located in front.

In 1854, J. H. Dallmeyer introduced a landscape lens that consisted of three meniscus elements cemented together to form an achromatic, positive meniscus lens element. This took in a much wider field of view, coupled with a significant amount of barrel distortion. The placement of a harder crown glass in front protected the lens from atmospheric pitting, to which previous landscape lenses had been subject. In 1857, Grubb modified this to form a two component landscape lens, with the crown glass in front and the flint glass behind.

Portrait or double lenses were generally variants of either the Chevalier or Petzval design. With the exception of Chevalier's lens, portrait lenses during the 1840s–1850s took in a very narrow field of view, and due to problems with curvature of field and astigmatism, were not suitable for landscapes or architecture.

In 1857, Petzval introduced an improved version of his portrait lens, based upon an unrealized 1840 design. This consisted of an achromatic, negative meniscus lens element in front and an achromatic, positive lens element in the rear, thus forming an early telephoto lens. The lens was capable of a flat field and even illumination, and was intended for architectural subjects and two-dimensional copy work. Introduced as the *Photographischer Dialyt* [Dialytic Lens], with the stop located in front, it came to be known as the Orthoscopic lens, with the stop being later relocated in between the lens elements.

Attempts to widen the angle the angle of view and correct curvilinear distortion during the 1840s–1850s usually involved symmetrical duplet arrangements, with the convex faces of opposing identical elements being oriented outwards. The first arrangement of this type was in 1841, when Thomas Davidson placed two achromatic landscape lenses face to face. This was followed in 1844 by G.S. Crundell mounting two uncorrected Wollaston meniscus lenses around a central stop. Such lenses were largely unsuccessful, due to the compounding of an already significant curvature of field problem.

In 1857, Thomas Sutton advanced a theory explaining how a symmetrical triplet lens, consisting of two opposing, achromatic plano-convex elements surrounding an uncorrected bi-concave element made of quartz, would be exempt from distortion and capable of a flat field. Stopped down, this would have been a practical wide-angle lens; however, due to the absence of surviving examples, it does not appear to have been a commercial success. It was allegedly marketed by Andrew Ross for a short period in 1859.

LENSES: 2. 1860s–1880s

The period 1860–1880 saw a number of developments in optical design which significantly improved the technical characteristics and speed of the photographic lens, the most important of these was the Rapid Rectilinear lens introduced in 1866.

In Britain John Henry Dallmeyer (1830–1883) and in Germany Dr. A. H. Steinheil (1832–1893) almost simultaneously announced the Rapid Rectilinear or Aplanat lens in 1866. The symmetrical design was important and came between the early period Petzval, Doublet, and meniscus-type photographic lenses, and the introduction of the Anastigmat in 1890. The design was very successful and remained one of the most popular until the 1920s and was available in wide-angle and long-focus versions. It was fitted as a general purpose lens to many field, hand and rollfilm cameras, including most standard Kodak folding cameras made between 1890 and the 1920s.

Dallmeyer's design was the subject of British patent 2502 of 27 September 1866 which described "Improvements in compound lenses suitable for photographic uses." The design as originally patented was slightly modified to become the rapid rectilinear lens which minimised optical distortion and with an aperture of up to f/6 and a field of view of around 50 degrees. Both the Dallmeyer and Steinheil lenses were composed of identical halves each half having about twice the focal length of the double objective and importantly made use of flint glass of different densities.

Steinheil introduced an almost identical design to Dallmeyer's which he called the Aplanat. It was designed by the mathematician von Seidel and was another significant example of the application of mathematical computation to lens design. Dallmeyer and Steinheil entered into a public and acrimonious debate over who had produced the lens first. Steinheil probably had priority by a few weeks but his claims of piracy of the design were not proven.

The design was extremely successful and widely copied by lens manufacturers who issued their copies under a variety of names including the well-known Euryscope, Pantoscope, Symmetrical and Universal. The Bausch and Lomb Rapid Rectilinear was particularly widespread well into the twentieth century.

While the Rapid Rectilinear lens was the most important of the 1860–1880 period there were other lenses that were useful. Steinheil began experimenting with unsymmetrical lens systems producing the Group Aplanat of 1879. The design corrected longitudinal aberrations and was further refined in his 1881 patent.

Dallmeyer, from the establishment of his firm in 1860, produced a number of other improvements to photographic optics especially producing "fast," or wide aperture, portrait lenses. In 1862 he introduced his Triple Achromatic lens which offered a lens with minimal distortion, working at around f/10. The lens was popular until it was superseded by the Rapid Rectilinear in 1866. The Dallmeyer Patent Portrait lens, also based on his 1866 patent was a variant of the Petzval lens.

The other well-known British lens manufacturer Ross introduced in 1864 a low-aperture distortionless lens which appeared in three variations all under the name

Doublet. The design was superseded by the Rapid Rectilinear. Ross also introduced the Actinic Triplet, similar to Dallmeyer's Triple Achromatic lens. In Germany Voigtländer marketed a patented portrait lens in 1878, based on the Petzval design.

While the corrected symmetrical lens designs were the most important technically and commercially there were a number of design for symmetrical lenses that were not corrected for aberrations. The resultant lenses were generally very wide-angle. The first of these was Thomas Sutton's (1819–1875) water-filled panoramic lens which was patented in 1859 and gave a field of view of around 60 degrees. More successful was the American optician C.C. Harrison's Globe lens, patented by Harrison and J. Schnitzer in 1860. The lens was made by a number of European manufacturers and remained popular throughout the century. Emil Busch's Pantoskop of 1865 was made in seven sizes. In the same year C.A. Steinheil patented the Periskop which was partly corrected although it did not become popular.

The next significant improvements in lens design were to take place from the 1880s.

LENSES: 3. 1890s–1900s

If the period of 1860–1880 was dominated by the rapid rectilinear lens, then the period 1880–1905 can be summed up with two designs, the anastigmats and the triplets.

The rapid rectilinear design had one major failing in that it suffered from anastigmatism. From 1884 new types of optical glass with high refractive indices which were being developed by Dr. Otto Schott of Jena. By 1886 his company, Abbe and Schott, had developed new glasses containing substances such as barium, and the new barium crown glass was incorporated into a number of lenses including Voigtländer's Euryscope lens of 1886. Barium glasses were to allow significant new lens designs to appear.

The first true anastigmat lens was designed by H.L. Schröeder and J. Stuart, and patented on 7 April 1888 (BP no. 5194). Schröeder was working for the Ross company that manufactured the lens as the Ross Concentric. It used barium crown glass and a new flint glass and it showed minimal signs of astigmatism or field curvature. The lens had an aperture of f/16 and was sold for many years.

In 1890 the German optician Dr. Paul Rudolph (1858–1935) designed a new lens for Carl Zeiss of Jena which offered a wider aperture and further corrections. It was an asymmetrical design also making use of barium glass. The lens was sold as the Anastigmat and from 1890–1893 various series of the lens were offered. With the loss of their rights on the name 'Anastigmat' the lens was renamed the Protar in 1900. The lens was made under license from Zeiss by Ross in London, Krauss in Paris, Bausch and Lomb in Rochester, and by others elsewhere. Sales of over 100,000 were claimed by 1900. A wide-angle version was still being sold in the 1930s. Zeiss's Double Protar lens, a convertible design, of 1895 offered the photographer a choice of three lenses in one.

Other companies were quick to introduce their own variant designs. In 1895 H.L. Aldis who was working for Dallmeyer designed the Stigmatic. Emil von Hoëgh's (1865–1915) patent of 1892 for a symmetrical lens was made as the Goerz Double Anastigmat and had an aperture of up to f/6.8. After 1904 this lens was known as the Dagor and remained popular well into the twentieth century. Von Hoëgh was made principal lens designer at Goerz.

The first wide-aperture anastigmat design was the Zeiss Planar of 1899 which had a maximum aperture of f/3.5.

The second significant lens design of the period was the triplet. On 25 November 1893 H.D. Taylor (1862–1943) was granted a patent for a triplet lens which consisted of three single spaced glasses. This was a significant departure from current lens designs. The lens was sold from 1893 by Taylor, Taylor and Hobson as the Cooke lens, the name in deference to Taylor's employers Thomas Cooke of York. The lens was simple and of low cost and with an aperture of f/6.3. In 1935 Taylor and Lee of Taylor, Taylor and Hobson claimed that "no fundamentally new principle of photographic lens design has been originated since Dennis Taylor invented this lens." The design was adapted by Voigtländer in 1900 for its Heliar design which was sold from 1902. The Ross Homocentric and Goerz Dogmar were similar triplet designs.

Rudolph at Zeiss further developed the Cooke design and in 1902 Zeiss introduced its most famous lens, the Tessar with an f/5.5 aperture. The Tessar was widely copied and appeared under such names as Ernon, Ektar Anticomar, Xtralux, and Lustrar from a large number of different manufacturers.

The first designs for a variable power telephoto lens—the forerunner of the modern varifocal zoom lens—also date from this period. This was developed independently by Dallmeyer in London, by Miethe in Germany and by Duboscq of France. It was patented on 15 December 1891 by Thomas Rudolf Dallmeyer (1859–1906) who had been running the Dallmeyer company since his father's death in 1883. In Germany Adolph Miethe (1862–1927) applied for a similar patent—leading inevitably to a dispute over precedence of similar magnitude to that which Dallmeyer's father had had with Steinheil in the 1860s. Dallmeyer produced a book *Telephotography* (1899) describing the use of his design.

A refinement of the lens was introduced in 1905 by K Martin and sold as the Busch Bis-Telar. This design overcame the limitations of Dallmeyer's original design and again was widely copied. Dallmeyer's own versions were sold as the Adon and Dallon and other companies sold under names such as Telestigmat, Telecentric, and Magnar.

Several other specific lens designs were developed during the period. Amongst them, a very wide-angle lens, the Hypergon, was made by Goerz and sold from 1900 and soft-focus lenses from Dallmeyer and Wollensak found favour with portrait photographers.

LEON, MOYSE & LÉVY, ISSAC; FERRIER, CLAUDE-MARIE; AND CHARLES SOULIER

The French photographic firm of Ferrier, Soulier, Lévy (FSL) produced a vast library of stereographic views in glass of mostly European monuments and sites during the second half of the nineteent century. In point of fact the FSL firm operated historically under eight names: (1) "Ferrier photographe," 1851–1859; (2) "Ferrier pere, fils et Soulier," 1859–1864; (3) "M. Léon et J. Lévy," 1864–1872; (4) "J. Lévy & Cie," 1872–1895; (5) "Lévy et ses Fils," or "Lévy Fils et Cie," 1895–1920; (6) "Lévy & Neurdein réunis," 1920–1932; (7) "Compagnie des Arts Photoméchaniques," 1932–1969; and (8) "Roger Viollet," 1969–present.

The phenomenon of binocular vision produced startling 3-D effects which still fascinate us today. Although FSL did from time to time produce paper stereographs, it was their superb glass stereographs which made the firm famous, and rich. Their views were universally regarded as the finest product of stereography. They produced a sense of depth that stunned first-time viewers, including Queen Victoria, at the Great Exhibition of 1851 in London. What set the glass stereograph apart from all other kinds of stereoviews—paper, tissue, daguerreotype—was the albumen-on-glass process, which offered a brilliant, very sharp, superbly contrasty and glistenningly transparent image. Viewed in direct light, it was incomparably superior to the paper stereograph, which like the stereo daguerreotype could only be viewed by reflected light.

Claude-Marie Ferrier (1811–1889) was the founder of FSL, and during the 1850s, while employed by maker of scientific instruments Jules Duboscq (1822–1894), he established the reputation of the glass stereographs. His stereographs measured 8.5 × 17 cm, the standard size for such views, whether paper, glass, or daguerreotype. These dimensions were imposed by the early stereo viewers, notably the Brewster stereoscope, which became the industry standard thanks to its enormous success at the Great Exhibition.

Claude-Marie Ferrier was born in Lyon in 1811. When he removed to Paris is unknown. The earliest mention of his work is in connection with the Great Exhibition in London of 1851, where he and Frédéric von Martens (ca. 1809–1875) produced photographic prints for Nicholas Henneman of objects figuring in the exhibition. Ferrier's photographs were printed on salted paper from albumen-on-glass negatives. The glass stereograph was "invented" at that same time, as Frederick Langenheim (1809–1879) later testified to Marcus Root: "While in Paris, in 1853, I was introduced to the celebrated optician, Dubosque-Soleil...In conversation, Mr. Dubosque told me that when he was engaged, in 1851, to arrange the display of his articles for the 'World's Fair' in London, he saw my photo magic lantern pictures, the first that he had ever seen, and thinking that such photo-positive pictures on glass might be used to supersede the daguerreotype pictures, until then manufactured for him by Mr. Ferrier, he had at once written to Mr. Ferrier, to come over to London to

Soulier, Charles. La Tour St. Jacques la Boucherie à Paris.

examine my transparent positive pictures taken on glass, and that since then, they had tried and made such transparent positive pictures on glass for the stereoscope" (*The Magic Lantern*, 1874).

Ferrier produced superb sets of views of Paris and the Ile-de-France (1851–1853, nos.1–213), followed by views of England, the Loire Valley, Provence, the Cote-d'Azur, and Italy (1853–1854, nos. 273–599). During the period 1855–1857, additional series were produced: Switzerland (nos. 600–690), a second Italy series (nos. 700–778), Savoie (nos. 778–873), a second Swiss series (nos. 874–931). Views of Constantinople (nos. 950–1055) and Athens (nos. 1060–1095) were offered to the public as of June 13, 1857. Finally, Ferrier's early work was collected in a general catalogue published in 1859 (nos. 1–2399, with extensive numerical gaps). Various series had been offered previously in a half-dozen listings published mostly in stocklists: the Paris views in *Cosmos*, 1852; the English series in the Negretti & Zambra equipment stocklist of 1854; a long series in the London Stereoscopic Company stocklist of 1855/1856, appended to the Brewster treatise of 1856; the Gaudin catalogue of 1856; an advertisement in the journal *La Lumiere*, June 1857; and in the Langenheim/American Stereoscopic Company sales catalogue of 1858.

Late in 1859 Claude-Marie Ferrier, known as "Ferrier *pere*," formed a partnership with his son Jacques-Alexandre (1831–1912), known as "Ferrier *fils*," and Charles Soulier (before 1840–after 1876). This firm was known as "Ferrier pere, fils et Soulier." Charles Soulier had been in partnership since 1854 with Athanase Clouzard, and produced glass stereographs of very fine quality during that period. These often carry a "CS" signature. An important collection of approximately 1200 "CS" negatives came with Soulier to the new partnership with the Ferriers: a Russian series depicting monuments and sites in Moscow and St. Petersburg (nos. 5001–5191), and an extensive series of views, mostly taken by Soulier

in Paris, Germany, Austria, Spain, England and Scotland (nos. 6001–6997) . These "CS" views were incorporated into the FSL general catalogue of 1864, which was more than twice the length of that of 1859. The 1864 catalogue included most of the views first published in 1859, except for a few deletions, plus nos. 2401–6997.

The firm "Ferrier pere, fils et Soulier" was short-lived; in 1864 the Ferriers and Charles Soulier sold out to two of their employees, Moisé Léon and Isaac Georges Lévy (?–before 1895), known commercially as J. Lévy. Léon had formerly been in the silk ribbon business with Lévy at 243, rue Saint-Denis, in Paris, and was probably a silent partner in the new firm. Production of the highest quality of glass stereographs continued unabated, however. Another general catalogue was published in 1870 under the Léon and Lévy imprimatur, and included views from the first two general catalogues, plus nos. 7001-10027. The best known of the new collections of views was the series devoted to the Exhibition of 1867, issued both in glass and paper. Léon disappeared from the FSL firm in 1872, when the company assumed a new name: "J. Lévy & Cie." Lévy and later his sons ran the firm for almost a half-century, until its fusion with Neurdein in 1920.

In addition to the general catalogues of 1859, 1864 and 1870, three more general catalogues were published, in 1880, in 1886 and in 1903. The 1886 catalogue carried the numerical entries down to no. 12778; that of 1903 continued the numeration of views down to no. 27325. In between the general catalogues, thirty short stocklists of FSL glass stereoviews are known to have been published during the period 1859–1908. These latter listed the very latest additions to the stock of views available to customers. All of the FSL general catalogues after 1859 included the infilling of numerical series left empty in previous catalogues. For all practical purposes all FSL views produced after 1855 were numbered, and so their identification is simple. The effective date for each and every view is the date of the catalogue or stocklist in which the view first appears.

It would be fair to say that photographic excursions to distant sites to make negatives for full-sized glass stereographs (8 × 17 cm) had stopped by 1910, as the popularity of these larger glass views had begun to decline. Fortunately for the FSL firm their sales of magic lantern slides were substantial in Europe and the United States. The title page of the first general catalogue to mention magic lantern slides along with glass stereographs was the general catalogue of 1870. Lantern slides figure on the title pages of virtually all subsequent catalogues. The lantern slide was in effect one half of a glass stereograph. The importance of the lantern slide business explains why so many of the FSL glass stereo negatives still conserved at Roger Viollet in Paris have been cut in half; it was to simplify the printing of slides. Stereo halves were also used to produce paper prints, which are of course the mainstay of Roger-Viollet's business.

FSL enjoyed a reputation in the nineteenth century that far surpasses that of today. Their glass stereographs were universally admired as the finest produced in Europe. In Adolphe Joanne's *Le Guide Parisien* of 1863 FSL is singled out among photographic firms producing stereographs: "Let us mention especially the admirable collections of stereoscopic views in glass produced by Ferrier, pere, fils, et Soulier, at 113 boulevard de Sébastopol." The fact that the firm still exists, as Roger-Viollet, with its vast collection of FSL negatives substantially intact, makes it so much easier for us to assess the firm's substantial art-historical significance.

LEUZINGER, GEORG (1813–1892)

Swiss photographer, printer, and engraver

Born in the Swiss canton of Glaris (Glarus) in 1813, Georg Leuzinger arrived in Rio de Janeiro in 1832. He originally sent daguerreotypes from Brazil to Paris to be colored by hand and printed as lithographs. By 1861 he had opened a photographic studio, Casa Leuzinger, which was also a printing and engraving firm. Marc Ferrez apprenticed there under Leuzinger's son-in-law, photographer Franz Keller. Leuzinger originally sold other photographers' work (e.g., Stahl, Klumb, Christiano Junior). Then in 1865, he published a catalogue of 400 photographs, including his own. Leuzinger's views of Rio and the surrounding region show a keen awareness of the artistic possibilities of landscape photography. He also produced intriguingly modern scientific images of plant life for the expedition led by naturalist Louis Agassiz in 1865, published in *Journey*

in Brazil in 1868. Leuzinger won silver medals at Brazilian exhibitions (1866 and 1873) and his works were shown at the International Exhibitions in Vienna (1873) and Antwerp (1885), and the Exposition Universelle in Paris (1867 and 1887), where his panoramic view of Rio taken from Cobras Island won honorable mention in 1867. Casa Leuzinger left the photography business in 1873 and its founder died in Rio in 1892.

SABRINA GLEDHILL

LEVITSKY, SERGEY LVOVICH (1819–1898)

Professional photographer

Sergey Lvovich Levitsky was born in Moscow in 1819 to a rich family. He was the cousin of Hertsen, the writer and outstanding public figure. He was born Lvov-Lvitsky but then changed his name to Levitsky. At his parent's request, Levitsky entered the school of law at Moscow State University, and graduated in 1839 becoming an official in the Ministry of Home affairs in St. Petersburg.

In 1843, Levitsky joined a research group commissioned to investigate the phenomenon of mineral springs in the Caucasus. During that period, he met U. Fritshe, an associate of the chemistry department at the Emperor's Academy of Sciences and the first Russian researcher dealing with the process of photography according to Talbot's technology. (Fritshe made his first photographs on the 23 May 1839). Levitsky having already bought a camera with a lens manufactured by French optician Chevalier, was interested in daguerreotype photography. On returning to St. Petersburg in 1844 Levitsky sent Chevalier his daguerreotypes with views of Pyatigorsk, Kislovodsk and other places in the Caucus. It was one of the first series of photographic landscapes taken in Russia. Later that year Levitsky retired and traveled abroad.

During Levitsky's visit to the Italian cities of Rome and Vena, he became acquainted with Senior Voigtlander and developed a friendship with him, eventually buying him a new lens for his camera. While in Rome, Levitsky took photographs of Russian painters and of the Russian writer Gogol, in Perro's studio, which is now believed to be the only portrait of this great personality.

In 1845, Levitsky took a course in chemistry and physics at the Sorbonne in Paris and met the leading daguerreotypists, including Daguerre, Charles Chevalier, Claude Félix Abel Niépce de Saint-Victor, and others. In 1849, Chevalier requested several large size daguerreotypes from Levitsky, who then when the works were finished, displayed them at an exhibition in Paris to illustrate how his lens contributed to the composition of photographs. The talent of Levitsky combined with Chevalier's innovative lens won them the gold medal at the exhibition.

Levitsky, Sergey Lvovich. Alexander Hertsen, 1861.
Private Collection: Alexei Loginov" Private Collection: Alexei Loginov.

After the French revolution of 1848, having lost most of his estate, Levitsky moved to St. Petersburg and established himself as a professional photographer. In October of 1849, he opened a studio on the Nevsky Prospekt, opposite the Kazansky Cathedral. According to his contemporaries, his studio was one of the most fashionable studios of the city and generated great popularity among the aristocracy, writers, and musicians. This was partly because Levitsky never stopped improving the technology of photography, and during the 1850s, he developed his use of wet collodion. His works never failed to demonstrate the highest level of technique and artistry.

During the middle of the nineteenth century, Levitsky became among the first photographers to start creating psychological photo-portraits, a prominent genre of portrait in Russia at this time. The Russian artists working with these types of portraits concentrated primarily on the personality and the spiritual life of the sitter. The artists believed it was possible to penetrate into the soul of a person and this belief founded itself not only in Russian painting, but in literature, music, theatre

and photography as well. During this period, due to the likeness between the two, photography was constantly compared to painting and therefore often said to copy it. It was from this that Levitsky developed his style to use the compositional laws of painting by employing soft light thus creating soft images. While creating artistic portraits, Levitsky successfully experimented with the pose of the model, thereby re-establishing the rules of the conventional studio portrait. Instead of employing the use of tasteless painted backgrounds and accessories, he spent more attention on the personality of the model.

In February of 1856 Levitsky made several personal, as well as group portraits of famous Russian writers such as L. Tolstoi, I. Turgjenjev, N. Ostrovsky, and others. He compiled these photographs, which effectively established the most impressive and comprehensive photographic gallery of Russian literary men, to the extent that in 1857, the limited edition of these photographs quickly sold out. Years later, these portraits were often and still are used to accompany the biographies of the writers. Levitsky's contemporaries have said that he captured the reflection of each of the writer's individuality and created cognizable psychological images. He also made a portrait of the Emperor Nikolai I, which became the best canonical portraits of the tzar.

In 1858 the photographer returned to Paris where he helped an American daguerreotypist, W. Thomson, with his work and later opened a studio of his own. In spite of the severe competition with the Parisian photographers, Levitsky enjoyed great popularity and success. A couple of highly successful works placed Levitsky among the leading portrait photographers of France. His portrait of Hertsen of 1861 was bootlegged in Russia and became a classical work of the world photographic portrait. In 1864 Levitsky made several portraits of the Emperor of France Napoleon III and his family and was thus honored with the title of "the emperor's photographer,"and was subsequently admitted into the Paris photographic society. Through his constantly successful innovations with photography, Levitsky became a well-known photographer, not only in Russia but also abroad and in 1865, Levitsky made a photo portrait of the Russian empress, the wife of Alexander II, and her elder son in Nice. The empress liked the photographs so much that she suggested that Levitsky return to St. Petersburg, which he later did.

Levitsky opened a studio with his son Lev in St. Petersburg and from 1866, and quite a long time after, he was the only photographer to take pictures of the emperor and his family. His photographs served as an archetype for painted portraits, sculptures, monuments and busts. In 1890 a special photo-studio with the "Emperor's Entry" was built where advanced technologies were used to take pictures of large groups of people in various lightings.

In 1866, Levitsky became a member of Russian Emperor Technical Society (RETS) and in 1878 was one of the founders of its photography department, making it RETS' fifth department. Levitsky was in constant demand, both in Russian and abroad, and was often given presents from royalty and persons of distinction. Due to his skill and experience, he was the expert at the Russian exhibitions and three international exhibitions. In 1873 he was an exponent of the first department of photography at the Londoner international exhibition. In 1889 he took part in an anniversary exhibition in St. Petersburg hors concours, impressing the visitors at the entry to the exhibition with a large half-length of the Emperor Alexander III made by himself.

In 1847 and 1856 he conducted experiments with taking pictures in arc light and in 1879 he demonstrated 20 successful portraits made in electric light, the first of its kind in Russia. This was extremely important to Russian photography since St. Petersburg's weather was usually poor and not conducive to taking pictures without using some type of light. Levitsky displayed several portraits made in electric light at an 1883 electro-technical exhibition in Vena.

The last few years of his life Levitsky was severely ill and died in St. Petersburg in 1898. At a conversazione dedicated to the 74th anniversary of photography, the great connoisseur of photography, professor V. Sreznevsky, described Levitsky as "the farther of Russian photography, who began by creating daguerreotype works in St. Petersburg and who then raised portrait photography to the highest level of technical and artistic perfection." He was often known as the patriarch of the Russian photography. After his death the photo-studio was run by his son Lev until 1913.

ALEXEI LOGINOV

Biography

Sergey Lvovich Levitsky was born in Moscow in 1819. He graduated from the School of Law at Moscow State University in 1839 and became an official in the Ministry of Home Affairs in St. Petersburg. His first photographs were made in 1843 during his stay in the Caucasus. In 1844 he retired and left for Europe. He studied photography in Paris and in 1849 returned to St. Petersburg. From 1849 to 1858 he worked at his photo-studio and made a series of portraits of Russian writers. He worked on improving the technique of photography. In 1858 he moved to Paris and opened a studio. While in Europe, he made a photograph of the emperor Napoleon III and his family and became "the emperor's photographer." In 1865 Levitsky returned to St. Petersburg and worked there together with his son Lev. Through his ingenuity and experimentation with technique, Levitsky became one of the leading

portrait photographers of Russia. Levitsky died in St. Petersburg in 1898.

THE LIBRARY OF CONGRESS

Established as a legislative resource for Congressional members, the Library of Congress is America's oldest cultural and research institution. With a current budget of more than $330 million, a staff of 5,000, and collections totaling more than 100 million items, the Library has grown to become one of the leading cultural institutions in the world.

The Library of Congress was founded on April 24, 1800, when President John Adams approved legislation for the purchase of "such books as may be necessary for the use of Congress." The original collection of 740 volumes and three maps arrived from London in 1801 and were stored in the U.S. Capitol in the newly created capital city of Washington, D.C.

On January 26, 1802, Thomas Jefferson signed the first law that established regulations and a budget for a Congressional library. He believed that successful self-government depended on an informed public; his faith in democracy rose from his demand for intellectual freedom. President from 1801 to 1809, Jefferson appointed the first two Librarians of Congress and recommended books for the collection. During the Revolutionary War in 1814, the British army invaded Washington and burned the Capitol, including the Library of Congress, which had grown to 3,000 volumes. Although Jefferson called himself a man who could not live without books, he sold his personal library to Congress to replace the lost collection. At 6,487 volumes, his library contained more than twice the number of books destroyed in the fire.

Today the Library comprises three buildings in Washington, D.C., near the U.S. Capitol. The Jefferson Building opened in 1897; the Adams Building opened in 1939; and the Madison Building, the largest of the three and home to the graphics arts collections, opened in 1980. Treasures in the collections include one of only three perfect vellum copies of the Gutenberg Bible, printed around 1456; the original Declaration of Independence, drafted in 1776; and the Constitution of the United States, framed in 1787 by the Constitutional Convention.

The collections expanded rapidly after 1846, when the practice of depositing items into libraries for copyright protection was established. The copyright law of 1870 required that two copies of every creative work, including books, maps, prints, photographs, and pieces of music, to be registered for copyright must be deposited in the Library of Congress. However, the Library is not required to retain all copyright deposits, and except for the period from 1870 until 1909, it was never one of the Library's objectives. As a result, contrary to popular belief, the Library does not own a copy of every book published in the United States.

In 1866 the entire Smithsonian Institution library was transferred to the Library of Congress, firmly establishing the Library as the sole national library. Especially strong in scientific materials, the Smithsonian collection rounded out the Library's already broad scope encompassing works on the arts, literature, law, geography, history, and Americana.

Special services include a program of daily readings for the blind, initiated in 1897. In 1913 Congress directed the American Printing House for the Blind to begin depositing embossed books in the Library, and in 1931 a separate appropriation was authorized for providing books for the blind. The Library of Congress Trust Fund Board Act of 1925 allowed the Library to accept private funding, which enabled the Library to support the commissioning of new works of music and to establish chairs and consultantships for scholars. The consultantship for poetry has evolved into the position of U.S. Poet Laureate.

When Mathew Brady organized a team of photographers to compile a visual record of the Civil War in the 1860s, two copies of the photographs deposited in the Library formed the incipient photography collection. An additional 300 daguerreotype portraits of prominent Americans made by Brady were transferred to the Library from the U.S. Army War College in 1920; thousands of his negatives and plates were donated by the family of Brady's nephew in 1954. Other significant contributions to the photography archive include the 1943 acquisition of Arnold Genthe's work, which contains photographs from San Francisco's Chinatown and portraits of author Pearl S. Buck and other prominent society members; and the 1949 donation of more than 300 glass plate negatives documenting the aviation successes and failures of Orville and Wilbur Wright.

The Prints and Photographs Division has grown to be among the world's largest, with more than 100,000

engravings, lithographs, woodcuts, and other graphic arts and 13 million photographs. Unique items in the collection include a volume of daguerreotype landscapes from around the world, transferred onto copper plates and printed by letterpress. The George S. Lawrence and Thomas Houseworth Collection contains mid-nineteenth century gold-toned stereographic photographs of California and Nevada. In 1893 the Library acquired its first motion picture when W.K.L Dixon deposited *Edison Kinetoscopic Records* for copyright. In 1968 the American Film Institute formalized an agreement with the Library to develop a national motion picture collection.

Special collections within the Photographs Division include the photoprints and negatives from the Detroit Publishing Company, which was formed in 1898 (and later renamed the Detroit Photographic Company) as a partnership between printer William A. Livingstone and photographer William Henry Jackson. Livingstone owned the American rights to a lithographic process that added color to black-and-white negatives and collaborated with Jackson and other photographers to produce thousands of postcards and souvenirs, primarily of the United States.

The Farm Security Administration, headed by Roy E. Stryer, commissioned photographers Walker Evans, Dorothea Lange, Russell Lee, Arthur Rothstein, Ben Shahn, Jack Delano, Marion Post Wolcott, Gordon Parks, and others to document American life between 1935 and 1943. The project focused on Southern sharecroppers and migratory agricultural workers in the Midwest and West. Transferred to the Library in 1944, the holding includes the archives of Walker Evans and Dorothea Lange, in addition to photographs made for other government agencies, such as the Office of War Information.

Contemporary photographic holdings are diverse. In 1970 Toni Frissell donated negatives and photographs from forty years as a fashion and portrait photographer. The Library's collection includes Frissell's informal portraits of Winston Churchill, Elearnor Roosevelt, and John and Jacqueline Kennedy, as well as scenes from Washington, D.C. and Europe during World Was II. The Erwin E. Smith Collection comprises portraits of American cowboys made between 1905–1915 on ranches in Texas, New Mexico, and Arizona.

The Prints & Photographs Online Catalog provides computer access to a cross-section of the Library's visual material. Material not available online can be viewed in the Prints & Photographs Reading Room in the Library's Madison Building. Much of the material held by the Library is exhibited on site; some material is available for exhibition loan. The Library also provides reference and research services.

LICHTWARK, ALFRED (1852–1914)

German photographer

Alfred Lichtwark was born November14, 1852, in Reitbrock near Hamburg as the eldest son of a poor miller. In 1860 the family moved to Altona where Alfred visited a school for the poor and worked subsequently as a teacher and librarian. In 1886 he was installed as managing director to the Kunsthalle (art hall) at Hamburg founded in 1846. Until his death on November13, 1914, Lichtwark presided the museum and bought a vast number of items for its collections: 1137 paintings, pastels, and watercolours, 890 sculptures, reliefs, and coins, 22,476 graphic prints and drawings, 8004 books, and 14,367 photographs.

Early in 1893, Alfred Lichtwark installed the first large show of the fine art photography movement on German ground, which was seen by more than 13,000 visitors in 51 days. This show started the career of the Viennese Trifolium (Hugo Henneberg, Heinrich Kühn, Hans Watzek), and instigated a number of similar exhibitions. Alfred Lichtwark published article after atricle on the pedagogic benefits of amateur photography, held lecture after lecture on the importance of collecting photographs, and by the end of the 19th century had managed to establish the German definition of the "engaged amateur." There has been no better mediator of the Art in Photography in German language since Alfred Lichtwark.

ROLF SACHSSE

LIÉBERT, ALPHONSE JUSTIN (1827–1913)

Born in 1827, Alphonse Justin Liébert began his career as a naval officer until he resigned to become photographer. In 1851, he opened a studio in the United States, in San Francisco, where he stayed twelve years long. Back in Paris, he promptly engaged in the French

photographic background until he joined in the Société française de photographie, 1873 in the hope of improving his technique.

He brought back from the United States the use of the melainotype process and was one of the first who used the carbon printing: he published many treatises on this subject.

Liébert also patented (1873) his own enlarger and invented a kind of color tint to put on pictures (1894); he also operated a sensitized paper factory between 1895 and 1900. Finally, he proposed the first studio equipped with the electric light (1879) and realized photographs of the Expositions universelles balloon (1889).

Moreover, Alphonse Liébert is known as one of those who recorded and photographed the events of the Paris Commune in 1870.

After his death, in February 1913, his son Georges Auguste Liébert continued his work in the studio.

MARION PERCEVAL

LIGHT-SENSITIVE CHEMICALS

Light, as a form of energy, has the power to promote chemical change. Of the many photochemical reactions, the few that are suited to making permanent photographic images employ light-sensitive salts of the metals silver, iron, uranium, and chromium, and some purely organic substances.

Silver halides were essential to the first 150 years of camera photography owing to their unique ability to capture an image "instantaneously." No other substance matches their unparalleled sensitivity, which depends on the formation of an invisible latent image, and its subsequent development, whereby the action of light is amplified enormously—a few hundredfold in the earliest development processes discovered by Henry Talbot and Louis Daguerre; but about ten million times in modern emulsions. All other photosensitive substances provide little or no amplification, and have no practical use in the camera, only for making positive prints or photograms, where intense illumination and lengthy exposures are no disadvantage.

Light of shorter wavelengths has greater intrinsic energy; the portion of the prismatic spectrum most effective photochemically is therefore the blue and ultraviolet—the "actinic" radiation discovered photographically by Johann Ritter in 1801. Photography usually entails the promotion by light of a chemical reduction of metal cations (positively-charged metal atoms) which take up, and are neutralized by the negatively-charged electrons supplied by an oxidisable substance, to form the elemental metal. Description of these photochemical reduction-oxidation reactions by traditional, balanced chemical equations tends to obscure the essence of the process, so this account will use ionic "half-reactions" explicitly involving the transfer of electrons, represented as e^-. The half-reactions are then combined proportionally to balance out the electrons in the overall equation.

Silver

Silver chloride was discovered in 1565 by Georg Fabricius in the mines of Bohemia, as the mineral "horn-silver" or *luna cornua*. By the 17th century, it was known to darken in sunlight; in 1614, Angelo Sala observed the same behaviour in silver nitrate (the *lapis lunearis* of the alchemists) when in contact with organic matter. Johann Heinrich Schulze was the first to demonstrate a primitive photographic effect in silver salts in 1725, and Carl Wilhelm Scheele showed in 1777 that the violet rays of the spectrum were most effective in decomposing silver chloride, and that the dark product was finely-divided silver. Knowledge of the light-sensitivity of the other silver halides had to await the discoveries of the parent halogens, bromine (by Antoine Balard, 1826), and iodine (by Bernard Courtois, 1811). In the following equations, X represents any of these, i.e., Cl, Br, or I:

$\text{Light} + X^- \rightarrow X + e^-$
Halide anion → halogen atom + electron
$Ag^+ + e^- \rightarrow Ag$
Silver cation + electron → silver metal
$X + X \rightarrow X_2$
Halogen atoms → halogen molecule

The overall net reaction is:

$\text{Light} + AgX \rightarrow Ag + {}^1/_2X_2$
silver halide → silver metal + halogen molecule

To prevent the reversal of this reaction and destruction of the image silver, a halogen absorber should be present: sodium citrate is used in many Printing-out papers. This process is discussed further under the entries for Photogenic drawing negative and Salted paper print. The chemistry of Development is described under Calotype or Talbotype. Pure silver halides react chiefly to blue and ultraviolet light. To render a balance of tones, negative emulsions must respond to the entire visible spectrum, which was achieved by Hermann Wilhelm Vogel's introduction of sensitizing dyes in 1873, extending the response to green light (orthochromatic plates), and eventually in 1904 to red wavelengths (panchromatic plates).

Iron

Many salts of iron(III) with organic acids are photosensitive; Johann Döbereiner first observed in 1831 that a green solution of iron(III) oxalate in sunlight

precipitates yellow insoluble iron(II) oxalate, evolving carbon dioxide gas:

UV light + $Fe_2(C_2O_4)_3 \rightarrow 2FeC_2O_4 + 2CO_2$
iron(III) oxalate → iron(II) oxalate + carbon dioxide

This equation is the sum of two half-reactions, involving the transfer of electrons from the oxalate anion to reduce the iron(III) cation:

$C_2O_4^{2-} \rightarrow 2CO_2 + 2e^-$
$Fe^{3+} + e^- \rightarrow Fe^{2+}$

Iron(II) oxalate is too feebly coloured to constitute a satisfactory image, so a second reaction must be employed to make a permanent print, either by reducing a noble metal salt to the metal, such as silver, gold, palladium or platinum, or by forming a pigment such as Prussian blue, or ferrogallic ink.

In 1842, Sir John Herschel was the first to use iron(III) salts photographically, as the commercially-available ammonium iron(III) citrate or tartrate; the photochemistry is more complex than the oxalate, but the same principle of reduction of iron(III) to iron (II) applies. As iron(III) carboxylates are sensitive only to the ultraviolet and blue-green portions of the spectrum, they had to be exposed to daylight or sunlight in the nineteenth century.

Uranium

Light sensitivity in uranium salts was noted by Adolph Gehlen in 1804, and first used for photographic processes by Charles Burnett in 1855. Salts of uranium(VI), such as uranyl nitrate $UO_2(NO_3)_2$, (once called "uranic" salts) can be photochemically reduced on paper to uranium(IV) (once called "uranous"):

UV light + $UO_2^{2+} + 2e^- + 4H^+ \rightarrow U^{4+} + 2H_2O$
Uranyl cation + electrons + hydrogen ions → uranium(IV) cation + water

This lower oxidation state of uranium can then reduce a noble metal salt to form the metal image of silver:

$U^{4+} + 2Ag^+ + 2H_2O \rightarrow UO_2^{2+} + 2Ag + 4H^+$
palladium:
$U^{4+} + PdCl_4^{2-} + 2H_2O \rightarrow UO_2^{2+} + Pd + 4HCl$
or gold:
$3U^{4+} + 2AuCl_4^- + 6H_2O \rightarrow 3UO_2^{2+} + 2Au + 4H^+ + 8HCl$

Alternatively, the uranium(IV) cation can be reacted with potassium ferricyanide to form the stable red pigment, uranyl ferrocyanide $(UO_2)_2[Fe(CN)_6]$, in the Uranotype process, analogous to the Cyanotype. Owing to its toxic and radiological hazards, uranium is no longer employed in photography, but it did enjoy a passing significance in the nineteenth century.

Chromium

Dichromates were discovered by Vauquelin in 1797 and used for tanning leather, before Mungo Ponton discovered in 1839 that papers coated with them changed colour on exposure to light, so launching this method of photographic imaging. The yellow-orange dichromate can oxidise many organic substances; the chromium(VI) is itself reduced to the state of blue-green chromium(III) ultimately (passing through brown intermediates of uncertain identity, possibly chromium(IV) dioxide, CrO_2). Acidic conditions are needed for the reduction half-reaction:

$Cr_2O_7^{2-} + 14H^+ + 6e^- \rightarrow 2Cr(H_2O)_6^{3+} + H_2O$
Dichromate + hydrogen ions + electrons → hexaquachromium(III) cations + water

Light stimulates dichromate to oxidise organic matter in a number of ways, for example, oxidising a primary alcohol group (present in cellulose) to an aldehyde:

$RCH_2OH \rightarrow RCHO + 2e^- + 2H^+$
Alcohol → aldehyde + electrons + hydrogen ions
So a typical overall reaction would be:
UV light + $Cr_2O_7^{2-} + 3RCH_2OH + 8H^+ \rightarrow 3RCHO + 2Cr(H_2O)_6^{3+} + H_2O$
Dichromate + alcohol + hydrogen ions → aldehyde + hexaquachromium(III) + water

The product hexaquachromium(III) cation, $Cr(H_2O)_6^{3+}$, is capable of hardening (i.e. rendering insoluble) many macromolecular colloids that are normally soluble in water: either proteins such as gelatin, casein, and animal or fish glues, or carbohydrates such as starch or plant gums. This hardening is believed to result from the chromium(III) complex forming cross-links between the long organic chains to create a net-like molecular structure which is no longer soluble: carbohydrates bind to chromium(III) via their hydroxyl (–OH) groups, and proteins via their amino (–NH–) groups. The hardened colloid then acts as a vehicle to bind a pigment image in the Carbon and Gum bichromate processes, or as an etching resist in the Photomechanical processes.

Organic Substances

The "Heliographic" process of Nicéphore Niépce entails the light-induced hardening of bitumen, which becomes insoluble in lavender oil and petroleum. Bitumen has a complex and varied structure of polycyclic aromatic hydrocarbons (linked benzene rings), containing a small proportion of nitrogen and sulphur; its hardening is undoubtedly due to further cross-linking, as is the hardening of tree resins (colophony, or abietic acid) by light, first observed by Jean Sénébier in 1782. The photochemistry of these processes, which have been studied by Marignier in the 1990s, remains rather obscure.

Extracts of many plant dyes are fugitive colours and fade within hours or days of exposure to sunlight. They provided Sir John Herschel with his unfixable Anthotype process. A more permanent, positive-working organic photochemical process results from the decomposition of diazonium salts by light:

$$UV\ light + C_6H_5N_2^+\ Cl^- + H_2O \rightarrow C_6H_5OH + N_2 + HCl$$

phenyl diazonium chloride + water → phenol + nitrogen + hydrogen chloride

The diazonium salt that remains can couple with phenolic molecules to produce azo-dyes in a variety of colours, e.g.:

$$C_6H_5N_2^+ + C_{10}H_7OH \rightarrow C_6H_5N{=}N\ C_{10}H_6OH + H^+$$

Phenyl + ß-naphthol → benzene-azo-ß-naphthol + hydrogen ion

diazonium cation (a red dyestuff—Sudan I)

This reaction forms the basis of the Primuline and Diazotype processes.

LINDSAY, SIR COUTTS (1824–1913)

English painter and photographer

Sir Coutts Lindsay, painter and founder of the Grosvenor Gallery, was born in 1824 on the outskirts of London, the son of Colonel James Lindsay and Anne, both of whom were interested in the arts. After a stint in the army, Lindsay studied painting in the 1840s and early 1850s and exhibited paintings at the Royal Academy in the 1860s. He married Caroline Blanche Fitzroy in 1864. He took up photography at some point in the late 1840s or 1850s and made salted paper prints. His subjects mostly consisted of landscapes and architecture, particularly views of Italy. Examples of work attributed to Lindsay are in the collection of the Getty Museum and the Harry Ransom Humanities Center at the University of Texas, Austin. He was also photographed by David Wilkie Wynfield and Julia Margaret Cameron in the 1860s. Lindsay is most well-known for founding the Grosvenor Gallery in 1877, which for a number of years rivaled the Royal Academy as the most important exhibition venue for British artists. Lindsay died in 1913.

DIANE WAGGONER

LINDT, JOHN WILLIAM (1845–1926)

One of Australia's pre-eminent photographers, John Lindt produced a large volume of high quality photography, remarkable for its thematic range, aesthetic consistency and technical accomplishment. His pursuit of landscape and ethnographic subjects, coupled with a rare entrepreneurial flare, continued throughout a half century career. During his early Grafton years, from 1869–1876, Lindt produced a number of significant photographic portfolios, including *Australian Aboriginals* (c.1873–1874); *Australian Types* (c.1873–1874); and *Characteristic Australian Scenery* (1875). The latter series, commissioned by the New South Wales Government for the 1876 Philadelphia Centennial Exhibition, contains images such as *The Artist's Camp (Near Wintervale)* (1875) (Grafton Regional Gallery), and *Tower Hill Creek, N.S.W.* (1875) (National Library of Australia) which demonstrate Lindt's exceptional compositional ability and meticulous attention to exposure and printing technique, qualities apparent in much of his later work.

Strikingly, these early portfolios indicate Lindt's emblematic cast of mind to work ambitiously within defined pictorial categories. Like his contemporary and friend, Nicholas Caire (1837–1918), Lindt produced photographs with one eye firmly focused on the burgeoning national and international markets for such productions. When Lindt's *Australian Aboriginals* was marketed in late 1874, it was considered "the first

successful attempt at representing the native blacks truthfully as well as artistically" (Kerr, 1992, 475). The N.S.W. Government purchased albums for presentation to scientific institutions in England, and via an established international network of collecting agencies these photographs became the most widely distributed images of Aboriginal people in the late nineteenth century (Orchard, 1999, 163–70). The artificiality of the studio tableaux adopted by Lindt, which convey a poignancy of loss and displacement of his Gumbaynggirr and Bundjalung subjects probably not intended by the photographer, has been discussed elsewhere (Jones, 1985; Poignant, 1992; Annear, 1997; Orchard, 1999).

Lindt moved to Melbourne in 1876, established a new studio in 1877, and embarked on a series of landscape portfolios, including *Fernshaw and Watts River Scenery, Victoria* (c.1878–82), *Scenery on the Ovens and Buckland Rivers, Victoria* (c.1878–82), and *Lorne, Louttit Bay, and Cape Otway Ranges* (1883). He also made an extensive record of Melbourne public buildings and streetscapes. In June 1880 Lindt was commissioned by a Melbourne newspaper to travel to Glenrowan, Victoria to document the capture of the notorious bush-rangers, the Kelly gang. Arriving in the aftermath, Lindt produced one of his most memorable wet plate images, *Body of Joe Byrne, member of the Kelly gang, hung up for photography, Benalla*, 1880 (National Gallery of Australia). It has been acclaimed as one of Australia's first press photographs (Newton, 1988, 44). In the same year Lindt commenced his use of the recently introduced dry plate negative process—he received the first consignment to arrive in Melbourne—and from 1884 operated a second studio installed behind his newly acquired estate, "Ethelred," to service demand for his work. Sales of his Blacks' Spur scenery amounted to approximately 25,000 copies printed from the original negatives between 1882 and 1892 (Lindt, 1920, 3).

From 1869 Lindt imported quality photographic equipment and supplies direct from Germany and from about 1881 he was using recently introduced Voigtländer Euryscope lenses in the field and in the studio to produce enlargements. At this time he also became the sole agent for numerous studio supplies, including Haake & Albers' studio cameras, and Enholtz's scenic backgrounds.

In 1885 he travelled to the newly proclaimed Protectorate of British New Guinea, collecting native artifacts and producing several hundred dry plate negatives of tribal life and village scenes. A selection of fifty of these illustrated his *Picturesque New Guinea*, produced using a new autotype process. In 1888 The Argus commented on exceptional quality of Lindt's New Guinea photographs with directness: "It has often been a matter of discussion how far, or whether at all, photography may be considered a fine art. By the work of J. W. Lindt this question is decided in a way that is a triumph for his profession" (*The Argus* 27 November, 1888). In 1889 Lindt moved studio to 177 Collins Street and was commissioned by the Victorian Government to document the fledgling irrigation settlement of Mildura, in north-west Victoria. Here he produced a variety of scenes, many of which are imbued with a sense of occasion and civic optimism associated with this pioneer venture.

Under the auspices of the Royal Geographical Society (R.G.S.), Lindt made further expeditions, to the New Hebrides (1890), and to Fiji (1891), the latter trip resulting in the production of a series of outstanding autotype enlargements of a fire-walking ceremony. Some of these were first published as plates in the *Transactions of the R.G.S.* (Lindt 1894, 45–58), but plans to produce a volume along the lines of *Picturesque New Guinea* were not realized due to the severe recession of the mid 1890s. One of his last ethnographic portfolios, of named members of a touring Northern Australian Aboriginal performing troupe, was produced in an indoor studio setting in 1893.

Lindt closed his Melbourne studios and removed to "The Hermitage," at Black Spur, north-east from Melbourne in 1894. Here he continued to produce works of exceptional quality, such as *Snow at the Hermitage* (c.1905) (State Library of Victoria), and kept up with the latest international developments. He became a role model for the rising generation of pictorialist photographers. In 1924, a print of Lindt's dramatic, *The Hermitage, Blacks' Spur* (c.1912) (State Library of New South Wales), taken from one of the tree-houses in "The Hermitage" garden, was given to Harold Cazneaux (1878–1953), later recognized as one of Australia's outstanding pictorialists. In 1925 it was reported that Lindt "continues to produce remarkable and most artistic pictures of the beauties of mountain landscape. He is not a believer in the blurred effects favored by many… instead he is a master of detail" (*The Argus*, 19 March 1925). Lindt died of heart failure, on Black Friday 19 February, 1926, at the height of severe bush-fires which destroyed much of the Blacks' Spur Mountain Ash forest. "The Hermitage" and a substantial body of his work survives, most significantly in the collections of the State Library of Victoria, Melbourne. Other holdings include the State Library of New South Wales, Sydney; National Gallery of Australia, Canberra; National Library of Australia, Canberra; Clarence River Historical Society, Grafton; and Grafton Regional Gallery. Further global holdings are listed in (Orchard 1999).

KEN ORCHARD

Biography

John William Lindt was born 1 January 1845 in Frankfurt-Main, Germany, the son of Peter Joseph Lindt, a

customs officer, and Justine, née Rambach. He arrived in Melbourne, Victoria, in 1862, and settled in Grafton, New South Wales in 1863. He assisted photographer Conrad Wagner (c.1818–1910) until 1869, when Lindt took over management. Lindt married Wagner's daughter, Anna on 13 January, 1872 and opened a new studio in March 1873. He moved to Melbourne in 1876 and established studios at 7 Collins St. East, Melbourne in 1877. In 1884 he moved to "Ethelred," Hawthorn, from where he operated a second studio. Lindt made three South Pacific ethno-photographic expeditions, travelling to New Guinea (1885), the New Hebrides (1890) and Fiji (1891). Lindt was made a Fellow of the Royal Geographic Society of Australasia in 1887, and judged the 1887 General International Photographic Exhibition, Frankfurt-Main. Following the death of his wife, on 27 May, 1888, Lindt was appointed Honorary Commissioner—British New Guinea Court at the Melbourne Centennial Exhibition, 1888. He married, Catherine Cousens in July, 1889. Lindt closed his Melbourne studio in 1894, and established "The Hermitage," a mountain resort at Blacks' Spur, Victoria. He lived there until his death on 19 February, 1926.

Awards include; Brisbane, 1876; New South Wales Academy of the Arts, Sydney, 1876; Philadelphia Centennial Exhibition, 1876; Paris, 1878; Sandhurst, 1879; Christchurch, 1882; Melbourne, 1880; Amsterdam, 1883; Calcutta, 1884; Frankfurt-Main, 1885; Melbourne Centennial Exhibition, 1888; World's Columbian Exhibition, Chicago, 1893. His publications include: *A Few Results of Modern Photography* (Melbourne, 1886); *Apparatus, Chemicals and Requisites for Modern Photography* (Melbourne, 1886); *Picturesque New Guinea* (London, 1887); "Ascent of the Tanna volcano and a tour through the New Hebrides group," in *Transactions* of the Royal Geographical Society of Australasia (Victorian Branch), Vol. 8, No. 2 (Melbourne, 1891); "The Resources and Capabilites of the New Hebrides," in *Transactions,* Vol. 10, (Melbourne, 1893); "The Fire Ordeal at Beqa, Fiji Islands," in *Transactions*, Vol. 11 (Melbourne, 1894); *Companion Guide to Healesville, Blacks' Spur, Narbethong, and Marysville* (co-published with Nicholas Caire, Melbourne, 1904, reprinted 1912–13, 1916–17); and *A Tale About a Wayside Inn* (1920).

LION, JULES (c. 1816–1866)

American daguerreotypist

Jules Lion, also sometimes spelled as Lyons, is the earliest known African American daguerreian artist in the United States. He was also the first daguerreian artist in New Orleans.

Born in Paris around 1816, Lion was listed as a painter in New Orleans as early as 1837. News of the daguerreotype process reached New Orleans on Oct. 1, 1839, with the publication of an article in the New Orleans Bee. Within six months, in March 1840, Lion was exhibiting daguerreotypes he had made, including images of local buildings. He also demonstrated the daguerreotype process. He may have been assisted in his early experiments by his brother Achille, a dentist.

Although no documentation exists to confirm it, Lion may have influenced the renowned southern photographer George S. Cook, as Cook was a painter in New Orleans at the time and learned the daguerreotype process in the city.

Lion maintained daguerreotype studios at several locations on Royal and Charles Streets in New Orleans from 1840 to 1844. In 1843 he began offering hand-colored daguerreotypes, but a year later largely abandoned the photography business in favor of painting and

lithography. In 1848, Lion opened an art school in New Orleans and in 1865, a year before his death, he became professor of drawing at Louisiana College.

BOB ZELLER

LIPPMANN, GABRIEL JONAS (1845–1921)

French scientist and physicist

Lippmann who was born in 1845 is known for many fundamental contributions in several scientific fields: electricity, thermodynamics, optics, photography, and photochemistry. He became interested in the theory of light and, in particular, color theory. As early as 1886, he had developed a general theory of recording colors as standing waves in a light sensitive emulsion. However, most of his time was devoted to perfecting a suitable recording emulsion for his experiments. The first plates that Lippmann used were albumen emulsions containing potassium bromide. The plates were sensitized in a silver bath, washed, flowed with cyanine solution and dried. The sensitivity was extremely low. On February 2, 1891, Lippmann announced at the Academy of Sciences in Paris that he had succeeded in recording a true-color spectrum which was permanent. A little more than one year later, on April 25, 1892, Lippmann gave a second presentation at the Academy of Sciences. This time he displayed four color photographs of different objects. Later he was able to record a landscape with a grey building surrounded with green foliage and blue sky. The size of his early photographs was 4 cm by 4 cm and later 6.5 cm by 9 cm. Lippmann developed the first theory of recording monochromatic and polychromatic spectra in a panchromatic b/w emulsion. He applied Fourier mathematics to optics, which was a new approach at that time. His color photography technique is known as *Interferential Photography* or *Interference Color Photography*, however most often referred to as *Lippmann Photography*.

The principle of Lippmann photography is clear. Because of the demand for high resolving power in making Lippmann photographs, the material had to be a very fine-grain emulsion and, thus, of very low sensitivity. The coating of emulsion on Lippmann plates was brought in contact with a highly reflective surface, mercury, reflecting the light into the emulsion and then interfering with the light coming from the other side of the emulsion. The standing waves of the interfering light produced a very fine fringe pattern throughout the emulsion with a periodic spacing of $\lambda/(2n)$ that had to be recorded (λ is the wavelength of light in air and n is the refractive index of the emulsion). The color information was stored locally in this way. The larger the separation between the fringes, the longer was the wavelength of the recorded part of image information. When the developed photograph was viewed in white light, different parts of the recorded image produced different colors. This was due to the separation of the recorded fringes in the emulsion. The light was reflected from the fringes, creating different colors corresponding to the original ones that had produced them during the recording. It is obvious that there was a high demand on the resolving power in order to record the fringes separated in the order of half the wavelength of the light. It was also clear that the processing of these plates was critically important, as one was not allowed to change the separation between the fringes because that would create wrong colors. In order to observe the correct colors in a Lippmann photograph, the illumination and observation have to be at normal incidence. If the angle changes, the colors of the image will change. This change of color with angle is called iridescence and is of the same type as found in peacock feathers and mother of pearl.

Soon after Lippmann had introduced his technique several scientists and researchers began to explore and further develop this new color photography technique. Auguste and Louis Lumière produced a special ultra-fine-grain silver halide recording emulsion which had a much higher sensitivity than Lippmann's first emulsion. With the new emulsion Louis Lumière was able to recorded the first color portrait in 1893. In Germany Richard Neuhauss and Hans Lehmann contributed extensively to the development of Lippmann photography and both recorded excellent color photographs at the end of the 19th century.

Although Lippmann photography is extremely interesting from a scientific point of view, it was not very effective for color photography since the technique was complicated and the exposure times were too long for practical use. The difficulty in viewing the photographs was another contributing factor, in addition to the copying problem, which prevented Lippmann photography from becoming a practical photographic color-recording method. However, one-hundred-year-old Lippmann photographs are very beautiful and the fact that the colors are so well preserved indicates something about their archival properties. Still today, it is the only photographic technique that can record the entire color spectrum of a scene, rendering extremely realistic e.g., human skin and metallic reflections. When the Lumière brothers introduced the more practical *Autochrome* color process in 1907, the interest in Lippmann photography disappeared. However, in the late 1990s, a new interest in Lippmann's technology has been manifested by newly recorded Lippmann photographs (without the need for mercury) as well as several recent publications on interference color photography.

HANS I. BJELKHAGEN

Biography

Gabriel Jonas Lippmann was born on August 16, 1845, in Hollerich, Luxembourg, of French parents. The family moved to Paris and in 1858 he entered the Lycée Napoleon and ten years later École Normale. Lippmann studied also in Germany, with Helmholtz in Berlin and with Kirchoff in Heidelberg where he received the degree of Doctor of Philosophy in 1873. In Heidelberg he studied the relationship between electricity and capillary phenomena which led to the development of his capillary electrometer. In 1875 he moved to Paris and later became a professor of Mathematical Physics at the Sorbonne in 1883 and member of the Institute in 1886. At the Sorbonne he was teaching acoustics and optics. There he invented color photography and developed it during ten years. Lippmann became a member of the French Academy of Sciences in 1883 and its president in 1912. He was a member of the Bureau des Longitudes and a Foreign Member of the Royal Society in London. In 1908 Lippmann was awarded the Nobel Prize in Physics for his color photography technique. Lippmann died at sea on July 13, 1921, on his return from a trip to North America.

LITERARY GAZETTE

also *Journal of Belles Lettres, Arts, Sciences*

The *Literary Gazette* was a weekly review of literature, science and the fine arts that began publication on 25 January 1817. As well as being an important journal in its own right, its format provided the model for subsequent periodicals like the *Athenaeum*. The character of the *Literary Gazette* owed much to William Jerdan, who edited the journal from July 1817 to December 1850. Jerdan was a well-known figure on the literary scene and contributors to the *Literary Gazette* included Charles Lamb, Robert Southey, Edward Bulwer-Lytton, and Sir David Brewster. The *Literary Gazette* was at its most influential during the 1820s and 1830s before the commencement of the cheaper *Athenaeum*. In 1832 it was selling 4,000 copies a week, a large circulation for the time. However by 1860 sales had dropped to around 1,000 copies.

As well as its literary merits, the *Literary Gazette* reported on the meetings of the most significant scientific and learned societies. Its Parisian correspondent also provided frequent short accounts of papers read at the *Academie des Sciences*. *Mitchell's Press Directory* (1847) declared that its pages "combine the 'utile et duce' of periodical criticism, and are often the first to promulgate the novelties of science and literature." Jerdan himself was a member of the British Association for the Advancement of Science and claimed to have attended every meeting. His autobiography declared that, with some assistance, he himself "made up the [science] reports which filled hundred of columns of my publication" (*Autobiography*, vol. 4, 292). Although its articles do not carry the same authority or technical detail as the *Athenaeum*, several significant developments in early photography were announced in the *Literary Gazette*.

Henry Fox Talbot, Antoine Claudet, and Francis Bauer were among the notable figures who sent letters to the journal. Soon after Arago had made his announcement of Daguerre's process to the *Academie Des Sciences*, Francise Baur championed the cause of Niépce though a letter to the *Literary Gazette* that was printed on 2 March 1839. Similarly, immediately prior to making a patent for his calotype method, Henry Fox

Talbot published a letter announcing his discoveries on 8 February 1841. Talbot went on to send several letters recording the way that he had discovered his new process. He also used the *Literary Gazette* to communicate new developments to a wider audience. In the edition of 10 July 1841, for example, Talbot sent a letter that he had received from Dr Schafhaeutl, in Munich, detailing advances in photography "which, it is to be regretted, are little known in England."

The important role of the *Literary Gazette* in popularising photography is particularly evident in its export to America. After reading a copy of the periodical that had been transported to New York, Dr John William Draper, a friend of Samuel Morse, constructed one of first American Daguerreotype cameras in September 1839.

During the 1850s, the *Literary Gazette*'s coverage of photography was reduced to only intermittent reviews of the various photographic exhibitions. Its declining commercial fortunes meant that it finally ceased publication on 26 April 1862.

LITHOGRAPHY

Alois Senefelder (1771–1834), an Austrian actor and playwright, announced his planographic printing process of lithography in 1798. Lithography formed a major component of the revolution in print media that took place during the first half of the 19th century. By the 1840s lithography became widespread and in London, lithographic printing houses began to outnumber those of copper- and steel-plate printers.

Lithography had several advantages over relief and intaglio processes since the printmaker no longer needed to carve, scrape or dot a design onto the plate but could draw or paint it in a greasy substance on a porous printing surface, usually stone. It was a highly versatile process since a wide variety of drawing media could be used to produce the image, including chalk, crayon and pen and wash. Another feature of lithography was that it could in some respects mimic intaglio processes.

Lithography was to act as a primary building block to the photographic processes of Niépce, Daguerre, and Talbot and, in the form of a number of 'hybrid' processes, heralded photomechanical reproduction. However, while the inventors of photolithographic processes have received attention from historians, the history of photolithographic printers themselves remains largely unwritten.

A lithographic printing plate could be produced far more quickly than could those of traditional processes. This speed became even more advantageous when coupled with the acceleration in manufacture introduced in the early nineteenth century by the new mechanical printing presses. Furthermore, the lithographic stone could produce a very large number of impressions, which again brought considerable economic benefits as did the fact that, unlike steel and wood engraving, stones could be easily re-used. These were the prerequisites for mass production and for low unit costs, and they were to be central to the ultimate success of photography. As such they help explain why lithography and photography were such suitable and effective partners.

The introduction of photolithographic processes in the 1850s was the result of research initiated by Nicephore Niépce (1765–1833) and advanced by, amongst others, commercial lithographers and printers. Rose-Joseph Lemercier (1803–1887) had already been experimenting with combinations of photography and lithography since at least 1848. Together with Louis-Alphonse Davanne (1824–1912), Noël-Marie Paymal Lerebours (1807–1873), and Charles-Louis-Arthur Barreswil (1817–1870) Lemercier developed a planographic photolithographic process (*lithophotographie*) which was deposited with the Académie des sciences on 28 June 1852. In this photolithographic process a grained lithographic stone was coated with a solution of bitumen of Judea and ether, contact-printed with the original and then developed with ether. In 1854 six photographic views of French medieval churches by Henri Le Secq were published by this photolithographic process. However, in 1857 Lemercier abandoned this process, which could pull only a limited number of proofs, and purchased and comparatively successfully used the process invented by one of the most significant figures in the history of photomechanical reproduction, the French chemical engineer Alphonse Poitevin (1819–1882) whose process could provide up to 700 impressions from one stone. In 1855 had

Poitevin patented his photolithographic process in both France and England. He went on to win both prizes awarded through the competition to find a permanent photographic print process sponsored by Albert, duc de Luynes (1802–1867). Poitevin's process was improved by F. Joubert in London in 1860.

In 1857, John Pouncy's *Dorsetshire photographically illustrated* was published. Pouncy referred to the process used as photolithography but the images are heavily retouched and Pouncy may have meant that the original photography was manually copied by lithography that was in turn photolithographed. In the same year, in the Netherlands, Eduard Isaac Asser (1809–1894) invented a photolithographic process.

Around 1860 there were a number of significant advances in photolithography—largely as a result of state funding. Photozincography—invented by Colonel Henry James of Ordnance Survey Office in Southampton in the late 1850s—was based on a zinc plate rather than stone support. The process was extensively used in the reproduction of maps, though James also reproduced a series of historical and illuminated national manuscripts including the medieval Domesday Book. The reproduction of line illustrations and map printings was first made workable in commercially viable quantities in the late 1850s by John Walter Osborne (1828–1902) while working in the Department of Lands and Survey in Melbourne.

The facsimile reproduction of important historical manuscripts was another area in which photolithography was to have a significant impact. In 1866 the London publisher Day & Son exploited photolithography to publish an "exact facsimile" of William Shakespeare's famous First Folio of plays published in1623. From 1868 William Griggs (1832–1911) of Peckham in South London, used photolithography to reproduce manuscripts, drawings and plans for a number of publications on Indian art and architecture, several of which were reports connected with the Archæological Survey of India.

Photolithography became increasingly exploited during the 1860s and this encompassed variants on the printing support and the integration of photography, lithography and other reprographic processes in 'hybrid' forms. Jules Labarte's *Histoire des Arts Industriels au Moyen Age et à l'époque de la Renaissance*, published in Paris between 1864 and 1866, is a particularly pertinent example in which photographic, photolithographic and chromolithographic processes were combined. The apogee of such a complex combination appeared in 1890 when the Art Institute Orell Fussli of Zurich invented the Photochrom—based on photolithography and used between four and fourteen asphalt coated lithographic stones to produce a "full colour" image from a black and white negative.

In Germany in the 1860s, photolithography was used to reproduce topographical views such as those printed by the firm of von Frey of Frankfurt-am-Rhein. However, it was the reproduction of architectural line drawing that saw the process's most influential role. J. Akerman of London was particularly prominent in this field. From the 1870s many of his photolithographs appeared in professional journals such as *Building News.*

Offset lithography, the commonly used photomechanical process to reproduce photographs, was introduced in England in the mid to late 1870s though the first application to print onto paper rather than metal took place in 1903 in America through the process developed by Ira Washington Rubel (died 1908)

Photolithography continues to play a prominent role in 21st century industries through its application to integrated circuits semi-conductor device fabrication.

LIVERNOIS, JULES-ISAÏE (1830–1865) AND JULES-ERNEST (1851–1933)

Canadian photographers

Jules-Isaïe Benoit *dit* Livernois was born on October 22, 1830, in Longueuil, near Montreal, Quebec. He

established his daguerreotype studio in conjunction with a sewing machine business in Quebec City in December 1854. At the height of his brief photographic career, he operated up to three studios. Married in 1849 to Elise L'Heureux (L'Hérault), she, like other husband and wife photography teams such as Darius Reynold Kinsey and his wife Tabitha, participated fully and sometimes independently in the photography business. Between 1857–1858, Elise worked under the name Madame Livernois and took daguerreotype portraits of children. After her husband died on October 11, 1865, of tuberculosis, she assumed management of his studio and established a partnership in May 1866 with her son-in-law, the photographer Louis Bienvenu; the Livernois & Bienvenu partnership dissolved in April 1873. By December 1873, her son Jules-Ernest Livernois, born on August 19, 1851, in Saint-Zéphirin-de-Courval, Quebec, assumed ownership of the Livernois studio. J.E. Livernois perpetuated his parents' vision by traveling throughout Quebec for landscape views and exterior group portraits, much as his competitor William Notman and his sons did throughout Quebec and other parts of Canada. Unlike Notman and Alexander Henderson, however, the Livernois family spent little time photographing outside Quebec. After J.E. Livernois' death on June 8, 1933 in Quebec City, the portrait studio continued to operate until 1974, first by J.E. Livernois' son Jules Livernois (1877–1952), then by an owner-operator, who left in 1969; J.E. Livernois Limitée went into bankruptcy in 1979. The largest collections of the Livernois photographs, a remarkable, detailed record of many aspects of life in Quebec, are preserved by the Library and Archives Canada and the Archives nationales du Québec. J.E. Livernois was one of four 19th-century photographers commemorated with a Canadian postage stamp in 1989. The Livernois family is also memorialized in Quebec place names.

DAVID MATTISON

LLEWELYN, JOHN DILLWYN (1810–1882)

Welsh photographer, polymath, and landowner

John Dillwyn Llewelyn was born John Dillwyn 12 January 1810 at The Willows, Swansea, the second child and eldest son of Lewis Weston Dillwyn, Fellow of the Royal Society and the Linnean Society, and Mary, *nee* Llewelyn. Upon coming of age, he assumed additionally his maternal grandfather's surname Llewelyn inheriting his estates. He usually signed himself J.D. Llewelyn.

Grandfather Llewelyn died in 1817 and the family moved to Penllergare, his former estate. In 1833 Llewelyn married Emma Thomasina Talbot, youngest daughter of Lady Mary Lucy and Thomas Mansel Talbot of Penrice and Margam, and youngest cousin of Henry Fox Talbot of Lacock Abbey. Children included the eldest, Thereza who married Nevil Story Maskelyne. At Penllergare, Llewelyn designed a supreme example of Victorian landscaping, creating two artificial lakes, a man made waterfall and growing many exotic trees and plants, some from Henry Talbot, and Sir Joseph Hooker of Kew. In his walled garden he grew tea, coffee, pineapples, and created a heated glasshouse for the propagation of orchids with a waterfall and pond.

Educated by private tutors, Llewelyn matriculated at Oriel College, Oxford in 1827. He met many of the leading scientists of the period including Sir Charles Wheatstone, Faraday, John Wheeley Gough Gutch, another early photographer, and the Groves. In 1844 he assisted Wheatstone with the first ever experiments in sub-marine telegraphy off the Mumbles, south Wales. The same year he welcomed Isambard Kingdom Brunel to Swansea for the south Wales extension of the Great Western Railway.

Llewelyn was elected a Fellow of the Royal Society, 1836, and the Linnean Society, 1837. Henry Talbot considered Llewelyn to be the first botanical photographer. In 1842 Llewleyn used the daguerreotype process to send images of rare orchids to Kew for identification. In 1848 Llewelyn demonstrated the propulsion of a small boat by an electric motor, the first time this was done in Britain, to the British Association for the Advancement of Science meeting in Swansea.

Llewelyn's public duties included being a magistrate and a member of, many local committees. He endowed schools, churches, and a large park for the people of Swansea.

News of Talbot's photographic discovery reached Penllergare in February 1839, from Talbot. Llewelyn immediately began experimenting with the new process and also the daguerreotype process. Early photogenic drawings have disappeared but the earliest daguerreotype is dated 1840. His friend, and distant relative, Calvert Richard Jones, also joined in the local excitement. Later photographic friends included Antoine Claudet, with whom Llewelyn carried out experiments on the daguerreotype process, and Philip Delamotte. Llewelyn tried all the early processes but mainly used the calotype and collodion. When Talbot challenged Laroche in 1854 for an infringement of his calotype patent, Llewelyn wrote to Peter Fry:

> I heartily grieve to hear of all his present litigation, his first step to secure himself an exclusive monopoly was a most inadvised one. It has put him in a false position and must terminate in an abundant harvest of vexation, trouble and loss. It seems however to be with him a kind of monomania—he must be a little insane on that point.

Llewleyn also tried the photoglyphic drawing process and was invited by Talbot to visit Lacock to discuss it.

Llewelyn, John Dillwyn. Thereza, From an Album of Photographs. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 [2005.100.382 (1-85)] Image © The Metropolitan Museum of Art.*

Llewelyn was a founder Council member of the Photographic Society of London in 1853, and was later nominated first Country Vice-President in December 1854. He exhibited at their first exhibition in 1854 and continued until 1858. At one exhibition Queen Victoria took away a print of the November Fifth Guy Fawkes bonfire and another had to be sent from Swansea. There are a number of Llewelyn's photographs in her albums. He also exhibited at Dundee in 1854 and the Manchester Art Treasures exhibition in 1857. In 1855 Llewelyn was one of the British photographers at the Exposition Universelle in Paris, exhibiting four images under the title of *Motion* including probably the first ever photograph, by the collodion process, *Clouds over St Catherines, Tenby* taken in 1854, where the clouds are on the same negative as the main scene. Llewelyn was awarded a silver medal of honour. His first instantaneous image was taken in 1853 of *Waves Breaking in Caswell Bay*, an exposure estimated at one twenty-fifth of a second, and probably using a falling shutter of his invention. In 1859 he contributed two images to"*The Sunbeam* a book of photographic images produced by Delamotte. Announced, by Joseph Cundall in 1854, but never published, was *Pictures of Welsh Scenery*.

The major problem with the collodion process was sensitizing, exposing, and developing in a comparatively short time. In 1856 Llewelyn announced his oxymel process, peserving the collodion in a moist state for many days or weeks. *The Illustrated London News* hailed this as one of the greatest boons for photographers. He also experimented with glycerine and dry collodion plates but was not satisfied with the results.

In 1859 Llewelyn, Maskelyne, Hadow, and Hardwich, wrote a paper on *The Present State of our Knowledge regarding the Photographic Image* for the British Association for the Advancement of Science.

Photography was a family commitment and Llewelyn taught his brother Lewis Llewelyn Dillwyn, sister Mary and daughter Thereza. In 1856 he bought Thereza a single lens Murray & Heath stereo camera for her birthday. They both used it and Thereza often made a stereo image whilst her father made a mono one. Emma

appears never to have made a camera image, but did much of his printing, to an extent that Henry Talbot asked if she needed help from Nicholas Henneman.

In the 1860s, Llewelyn joined the Amateur Photographic Association, contributing to their exchange albums and becoming a member of council. He abandoned making images around the end of the 1850s possibly due to life-long asthma. In January 1854 he had been very ill, most likely due, so his mother-in-law Lady Mary wrote to Henry Talbot, to inhaling poisonous photographic chemicals.

In 1859 local militia were organised to repel a possible French invasion. Llewelyn captained the Penllergare 5th Corps. The same year he appears in a photograph, including Roger Fenton, titled *Volunteers at Hythe*.

In the late 1870s the Llewelyns moved to London and he died at Atherton Grange, Wimbledon, on 24 August 1882. He is buried next to Emma in the churchyard of his church at Penllergaer.

LOCKEY, FRANCIS (1796–1869)
English

Francis Lockey was born at Reading, Berkshire England, in 1796 studied at Cambridge and became a priest in 1823. He became vicar of Swainswick, a small village outside Bath in 1836, where he lived with his wife Susanna and daughter Emma.

Lockey used the daguerreotype process but is chiefly known for using calotype and waxed paper negatives well into the late 1850's. Lockey documented the Medieval, Georgian and early Victorian buildings of Bath and surrounding towns and villages. His pictures show largely deserted locations, never, or only accidentally, having figures in the composition. This was partly caused by the long exposures required with his large-format paper negatives, his negative list (private collection, UK) gives exposure times between three and fifteen minutes. Lockey also produced many large-format stereo views (most negatives were 11 × 9 inches) for use in a Wheatstone viewer.

Many of his studies were made with the help of his coachman Henry Burrough, often using the roof of his carriage as a platform to record churches and other historic buildings. Lockey was very dedicated to his craft, being well into his late fifties when making his architectural views. As well as photographing in the Bath area Lockey travelled to south and west Wales and made many studies of ruined castles, abbeys and priories in and around Swansea.

Later Lockey used the wet-collodion process to make portrait studies but unfortunately these glass negatives were destroyed. Many of his paper negatives, however, survive in museums in Bristol, Bath, and Wales.

IAN SUMNER

LOECHERER, ALOIS (1815–1862)
German photographer and studio owner

To his contemporaries, Alois Loecherer was the most well known as a distinctive portraitist of the better half of Munich's society in the 1850s. From 1845 he used Talbot's process and opened his first studio in 1848 in

the house of Franz Hanfstaengl. In 1849, he was the first to announce "photography on paper" in Munich and offered lessons in this method. In 1850, he opened the first exhibition of his genre photographs at the Munich Kunstverein. He produced large numbers of view of Munich's streets, places, backroads, and old houses. Alois Loecherer was best known for his series on the construction and erection of Ludwig Schwanthaler's statue of the Bavaria which formed one of the first series in photographic journalism.

Loecherer was the pioneer of salt printing and photography on paper in the German speaking countries. His print had comparatively large formats were overtly intended to be exhibited. Due to his early death Alois Loecherer was not able to nuture the needed impact on the development of German photography as a form of art.

Alois Loecherer was born on August 14, 1815, in Munich. From 1837 to 1839, he studied chemistry and pharmacy at Munich University under Franz von Kobell. From 1840 to 1848, he worked as a pharmacist in Munich. Married in 1849, had two daughters born in 1851 and 1852. In 1853 he settled in as a portraitist in his own house in Munich. Died on Aug. 15, 1862, of a brain attack. His studio was taken over by the photographers Albert Kristfeld and Bernhard Froehlich.

ROLF SACHSSE

LONDE, ALBERT (1858–1917)

French medical researcher, chronophotographer

Londe was born in 1858, the date and place of his birth remain unknown however. Londe was one of the pioneers of medical photography and more particularly of photography with x-rays. He was also the inventor of a form of instantaneous photography: Chronophotography, which is a Victorian application of science (the study of movement), and art (photography). The word is from the Greek chronos and photography, "pictures of time." Notable chronophotographers include Eadweard Muybridge, Etienne-Jules Marey and Ottomar Anschütz. Chronophotography and Londe are both affiliated with professor Charcot's photography which marked the beginning of medical photography's history. However, Londe's photography was characterized by chronophotography's instantaneous and motion-analyses. In 1879 Londe became a member of the Société française de photographie (S.F.P.) in Paris.

In 1878 a laboratory for medical photography had been set up at La Saltpêtrière hospital in Paris. In 1882 Londe began working there as the director of photographic service in the laboratory of the Hospice of the Salpétrière, which had a partnership with the Clinic for diseases of the nervous system run by professor Charcot. Londe broached most issues of concern regarding photography. He ordered the construction of a variable-speed, circular shutter, which was destined to replace the existing guillotine and wing shutters that proved inadequate for animated subjects or swiftly moving objects. Research conducted by Muybridge and Anschütz gave him the idea, that where speed is concerned, camera should use several lenses. Londe constructed a camera fitted with nine lenses arranged in a circle. A series of electronic magnets energized a sequence regimented by a metronome device released nine shutters in quick succession, taking nine pictures on a glass plate. He used the camera to study the movements of patients during epileptic fits. Londe's improved camera of 1891 used twelve lenses (in three rows of four) and was used for medical studies of muscle movement in subjects performing a variety of actions as diverse as those of a tightrope walker and a blacksmith. The sequence of twelve pictures could be made in anything from 1/10th of a second to several seconds. The design of Londe's laboratory at La Saltpêtrière was in many ways similar to Marey's Station Physiologique, and was similarly subsidized by the Parisian authorities. Although the apparatus was used primarily for medical research, Londe noted that it was portable, and he used it for other subjects—horses and other animals, and waves, for example. General Sobert developed, in conjunction with Londe, a chronophotographic device to help in the study of ballistics. Londe's pictures were used as illustrations in several books, notably by Paul Richer, widely read in medical and artistic circles.

During 1884, Londe lectured on photography and its scientific applications.

In 1887, he worked with Tissandier, and the Société d'Excursions des Amateurs Photographes. He was the vice-president from 1887 to 1895, president from 1895 to 1900, and president for life from 1900 on. Consequently, Londe had many photographic adventures starting with the circus, bullfights and with the theatres of the streets. The excruciating exercises of collecting images of new subjects preceded the photo-journalistic iconography. Furthermore, these subjects belonged to a universe located between reality and imaginary, and because of this limbo were curiously connected to the patients that Londe photographed in Salpetrière. These portraits reveal an attraction for the marginal beings of the industrial time.

In 1888 Londe did experiments with shots of a clown doing a perilous jump at the Hippodrome and are likely considered a study of instantaneous photography.

In 1890 he was elected a board member of the Société française de photographie, and by 1892, had been elected to the position of assistant general-secretary. During that period he compiled numerous reports on prices, inventions, and cameras.

In 1893 he constructed a camera for pictures 7 × 7 cm on plates 24 × 30 and he lectured on photography at the Arts et Métiers in Paris. In 1895 with the advent of Röntgen's X, he began creating the first radiography and radioscopy laboratory for Parisian hospitals.

The beginning of 1900 he began experimenting with several ways to photograph using artificial lighting. He experimented with neon, but the results were not successful. He showed them, however to the Club Nautique in Nice. In 1904 he resigned as active member from the Société française de photographie in Paris. Londe continued experimenting with artificial light and used magnesium, which caused a short explosion, giving off a burst of light.

Around 1908 he made a chamber based on his experiments and plan of his chrono-photographic machine, which used artificial light. He discovered also the possibilities of creating duplicate images. Because of these two contributions to photography he was made an honorary member.

Londe's interest in the Autochrome process grew in the last years of his life. The autochrome was a positive colour transparency process, patented in June 1906 by Auguste and Louis Lumiére in Lyon, France. Like other techniques at the time, it employed the additive method, recording a scene as separate black and white images representing red, green and blue, and then reconstituting color with the help of filters. To do this on a single plate, the Lumiéres dusted it with millions of microscopic (avg. size 10 to 15 microns) transparent grains of potato starch that they had dyed red (orange), green and blue (violet). This screen of grains worked as a light filter to interpret the scene when the light passed through them exposing a panchromatic black & white emulsion. The exposed plate was then reverse processed which resulted in a transparency. The first time he lectured at l'Academie des sciences his presentation was on this first industrial color method. In front of many specialists and professionals, he successfully tested with the plates, which later came onto the commercial market in 1907. He published in two years 12 texts concerning this topic. However none of its experiments was publicly shown. In 1908, his experimentation abruptly ended when his wife died, but he started again with his experiments in 1909. Finally in 1914, he showed his photographs to the Photo-Club of Nice.

He left his collection of works, equipment and documents to the Société française de photographie (S.F.P.) in Paris.

He died September 11, 1917, at the Château de Bréau at Rueil, near La Ferté-sous-Jouarre in France.

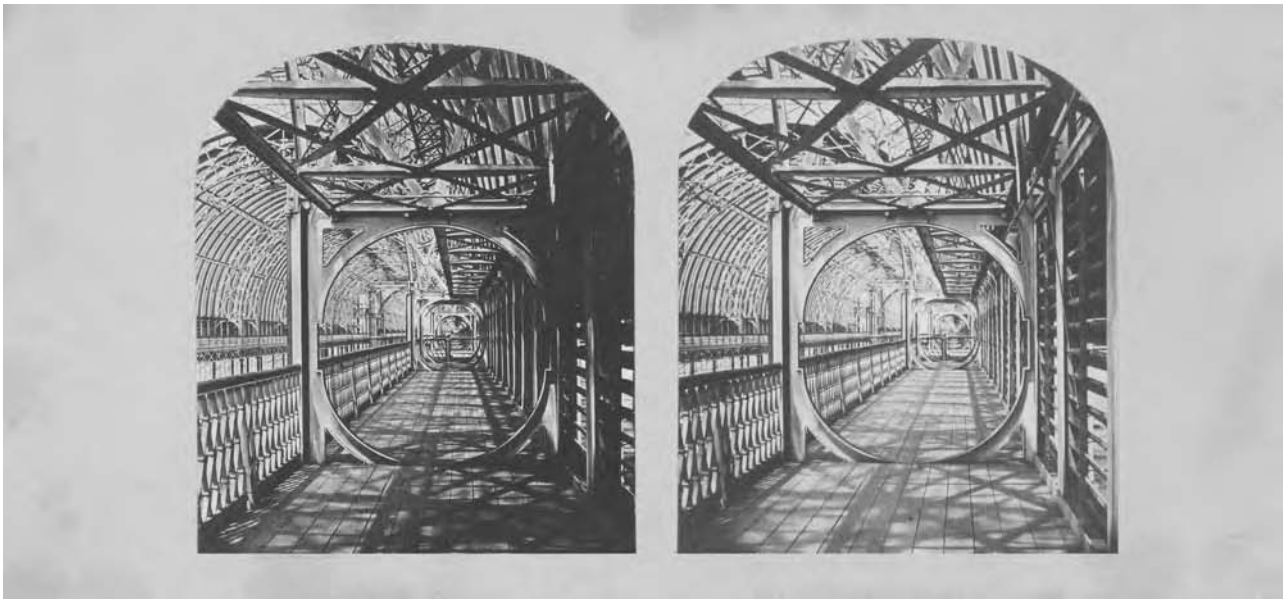
LONDON STEREOSCOPIC COMPANY (c. 1854–1922)

When stereographs were demonstrated to the public at the Great Exhibition of 1851 they started a collecting craze that was to last for the next twenty years. The principle of using binocular vision to create the illusion of space had been known for some time but the introduction of photography meant its potential could finally be realised and the stereoscope, developed by Charles Wheatstone and Sir David Brewster, allowed photographs to be viewed in "solid" three dimensions. The London Stereoscopic and Photographic Company, as its name suggests, furnished the Victorian mania for stereographs and by 1854 the company had sold over half a million viewers, proclaiming in their advertising that "no home is complete without a stereoscope."

Shopkeeper George Swan Nottage (1823–1885) founded the company with his associate Howard Kennard in the early 1850s. Nottage went on to make his fortune, and was later elected Alderman and then Lord Mayor of London (1884–1885.) London Stereoscopic was soon the largest photographer and manufacturer of



London Stereoscopic Company. The Telescopic Gallery.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

stereographs in the Victorian era. By 1858 they were advertising 100,000 views of famous buildings and places of interest in England and abroad (although the actual figure is more likely to have been a tenth of that) and manufacturing stereoscopic cameras as well as viewers for the consumer market. Their photographers travelled as far afield as the Middle East and America. William England, who was with the firm from its inception travelled in America in 1858 and 59, documenting New York, the Hudson River, and Niagara Falls, and the new railways and bridges along the route. The important "North America Series" was immensely popular, being amongst the first photographic views of the US to arrive in Britain. England was instrumental in building the firm's reputation with travels in Ireland in 1857 and Paris in 1860 and technical advances in equipment including the invention of the focal plane shutter. He also produced the popular Comic series, which though derided at the time by intellectuals as "low art" is now an important record of Victorian domesticity and street life. His last major venture for the company was as sole photographer of the 1862 International Exhibition, for which London Stereoscopic paid the enormous sum of £1,500 for exclusive photographic rights.

London Stereoscopic also bought, distributed and published material by non-commissioned photographers, including the work of William Grundy of Sutton Coldfield (1806–1859) whose collection of 200 negatives was acquired after his death. Grundy had published a series of half stereos to illustrate *Sunshine in the Country, A Book of Rural Poetry,* (Richard Griffin & Co, 1860) comprising of idyllic rustic scenes, country folk and rural occupations. London Stereoscopic's 1860 catalogue also advertised a series of views of Switzerland by Adolphe Braun and though William England left to pursue his own career in 1863 he continued to publish views through the company's catalogues under his own name. Renowned sports and war photographer Rheinhold Theile worked as a watercolourist and photographer for the company between 1880– 894. These references to individuals are unusual, however, as London Stereoscopic rarely divulged the names of their operators.

In 1862 alone the company sold one million stereoscopic views and had offices and agents as far afield as New York. During the 1860s and 1870s, however, stereoscopy began to decline in popularity. London Stereoscopic diversified their interests adding large format travel views and portraiture to their catalogues. By 1889 they advertised a comprehensive range of cameras, lenses and general photographic goods and also offered a wide range of photomechanical printing services, including Woodburytpe, collotype, photomezzotype, photolithography, and platinogravure. Their Woodburytypes were widely used in book publication and periodicals, and next to the Woodbury Company itself London Stereoscopic were the largest manufacturers of Woodburytypes in England, often donating albums of Woodburytypes to hospitals and charities. In 1896 the commercial department of the firm at 54 Cheapside, London offered letterpress printing to the trade, as well as commercial printing of photographs in silver, bromide, carbon and platinum. They had also begun to expand into newly opened area of photoengraving and made half-tone blocks for the printing trade.

An important spin-off for the company was the

carte de visite market. Originally introduced as a novel and inexpensive idea for personalising visiting cards, Disdéri's method of taking multiple images on a single plate was the perfect medium for mass producing images of the rich and famous. The Victorians wild thirst for collecting, building up albums of politicians, clerics, actresses, and sporting heroes, was termed "cartomania" and sparked an unquenchable fascination with celebrity images that persists today. In 1861 and 1864 London Stereoscopic opened portrait studios at 110 and 108 Regent Street respectively (106 was added in 1875 while 110 closed in 1888.) They were amongst the most fashionable and chic in Europe and their catalogue of clients reads as a Who's Who of the Victorian age. Names such as Charles Dickens (including a rare portrait without beard), Sarah Bernhardt, William Booth, John Everett Millais, and William Gladstone filled the catalogues. Lord Palmerston sat for four dozen portraits in one sitting alone. They also published the famous image of the *Leviathan* engineer Isambard Kingdom Brunel by Robert Howlett in various formats and became *Photographers to Her Majesty* after obtaining the Royal Warrant in 1895. In addition to their brisk trade for the private carte-de-visite collector the London Stereoscopic commercially licensed their photographs and celebrity images for use in the press and periodicals of the day such as *The London Illustrated News* and *The Graphic,* and in theatre programs and music sheets. Their photographers covered newsworthy events such as the re-opening of Crystal Palace by Queen Victoria in 1854. In 1871, during the Franco-Prussian War London Stereoscopic Company produced micro-photographic prints, each barely larger than a postage stamp, of special pages of *The Times* devoted to messages to the inhabitants of Paris, which arrived in the besieged French capital by pigeon post.

A great deal of London Stereoscopic's success can be attributed to their versatility, keeping pace with new trends and innovations in photography. Their interests were incredibly diverse and forward-looking. The company held the patent for and manufactured a popular model of the zoetrope, having earlier revived interest in persistence of vision by demonstrating the illusion of a vase by rotating a bent piece of wire and, for a time, was the sole licensee of the phonograph. Their Regent Street offices finally closed in 1922 but they should be remembered as one of the world's first and largest producers of licensed imagery on a global basis. Their catalogue is a lasting record of and tribute to the Victorian era, documenting new worlds and great engineering projects alongside the growing obsession with celebrity and home entertainment.

LOPPÉ, GABRIEL (1825–1913)
French photorapher

Born in 1825, in Montpellier, South of France, Gabriel Loppé studied in Paris and learned painting from François Diday (1820–1877), a landscape artist located in Geneva, Switzerland. A few years later, in 1848, he realized his first landscape paintings, in huge formats and panoramas appreciated by English gentlemen. Most of these patrons were members of the Alpine Club of London, as Loppé had been since 1864 who was also fascinated by exploration hikes and mountains.

Loppé's interests in photography was likely inspired by the Bisson brothers during their trip to Mont Blanc, on which he accompanied them in 1861. He never practiced as a professional photographer, and remained an amateur. As a matter of fact, he showed little interest in technique or composition, and used photography simply to create visual mementos.

Settled his studio in Geneva in 1862, Loppé opened an exhibition gallery in Chamonix in 1870. After the death of his first wife in 1874, he married Elizabeth Eccles in 1879, in London and moved to Paris in 1880, where he photographied his every day life, and of his family near the site of the Eiffel tower. Towards the end of the ninteenth century, Loppé developped a pictorialist aesthetic, particularly backlighting and smog effects under the electric light during the night.

He died in Paris in 1913.

MARION PERCEVAL

LORENT, JAKOB AUGUST (1813–1884)
Scientist and inventor

Jakob August Lorent was born on December 12, 1813, in Charleston, South Carolina. After his father died and

his mother remarried, his mother moved the family to Mannheim in 1818. In 1829, Lorent graduated from the secondary school in Mannheim and began attending the University of Heidelberg. In 1837, Lorent completed his scientific doctoral thesis, and thus graduated. Due to his family's affluence, Lorent, a private and introverted young man, was able to follow in the foot steps of his role model, Alexander von Humboldts and travelled to Egypt and Asia Minor, where he studied the natural landscape. After the death of his stepfather, Lorent received his estate which allowed him an absolute financial freedom.

During his travels to London in 1850, Lorent met W. H. Fox Talbot who introduced Lorent to photography and Talbot's own calotype process. Due to Lorent's education in science, he was able to modify Talbot's process, enabling him to become one of the most prominent photographers of his time. He understood very quickly that photographs are very easy to copy and therefore he'd only take a few photographs and focus on their quality.

His original Venice photographs measured 38 × 47 cm, but by 1856 he was using the much larger 45 × 55 cm format. These Venetian photographs increased Lorent's reputation in the European photographic community. In 1856, he exhibited these large-sized albumen prints in Brussels during a critical time of photography. Nevertheless, the editor of the photographic journal *La Lumière* based in Paris, Ernest Lacan, was absolutely enthusiastic about Lorent's work. He named Lorent the "Venetian Baldus," because Lorent's works echoed the close-up photography of Le Louvre by Edouard Denis Baldus.

Jakob August Lorent donated some of his large-format architectural photographs of Venice—worth about fourteen guilder ($160)—to help in the restoration of a church in Weimar. In the making of these large format photographs, Lorent chose to use le Gray's waxed paper process, rather than the widely popular wet collodion process on glass, greatly reducing the weight of materials he had to carry. Although the wax-paper process was favoured because it supplied sharps results, it was particularly favoured by touring photographers because of an incident that happened to Louis Auguste Bisson on his great photographic tour in 1858 through south of France when all of his glass negatives broke during a coach accident near Toulouse.

Lorent also developed the paper negative through the use of beeswax in such a way that he achieved a consistent transparency so that structure of the paper fibres, under the diffuseness of the beeswax, disappeared nearly 100 per cent. This approach influenced William Henry Fox Talbots photographs and led the French photographer Gustave Le Gray to develop a special paper negative process, which he patented 1851.

During the revolution of 1848 Lorent left Mannheim for London and married there in 1850. Lorent returned to Mannheim in 1858, from where he travelled to Granada and then to Algeria, to document old Islamic art. In 1859, Lorent took a second journey to Egypt, up the Nile, and to Nubian in pursuit of old Egyptian art that he intended to document. As was the case with his Venetian photographs, Lorent's work was also grand, the negative format being 45 × 55 cm.

Lorent reproduced the photographs of the voyages that he took between the years 1858 and 1860 in an album, that he then dedicate and personally gave to the duke of Baden, Friedrich II, entitling it, "Egypten, Alhambra, Tlemsen, Algerien" (Mannheim, 1861). Lorent noted, "As far as I know, there is no photographic work in Europe, that apprehends so completely the old manner of Egyptian art and Eastern architecture."

Lorent left for the country in November of 1860 due to political instability caused by the Bavarian King Otto I, whose reign was similar to the Osmanic Domination in Greece. Initially, he travelled to Italy and then to Corfu and Athens and in the summer 1862 he took a second trip to Greece. That same year he produced an album with "Pictures from Athens" in Mannheim.

These six years of tireless activity, both physical and artistic, are accurately represented as the apogees of his photographic career, which is evident as Lorent's large-sized photographs have no equal from 1850 to 1860. His wax paper negatives possess the outlet an hot components, that could be found, rarely through the use of wet collodium process, and mostly only through posterior tint by printing. The awards of the World Exposition in London and the Exhibition in Amsterdam in 1862 confirmed his prominent position and unrivalled talent.

In 1863 Lorent travelled to Turkey, Syria, and Egypt, then some months later in April of 1864, he went to Palestine and Egypt again. One final journey in 1865 led Lorent to Sicily. From this point on, he took photographs mainly on his "choice land," the Grand Duche of Bade, and mostly of the memorials of the Middle Ages, which he collected into three large-sized albums and produced for the Court.

Lorent donated his books and photographs to the Public Library in Mannheim. In June of 1873, Lorent moved from Mannheim to Meran, Switzerland because of health problems. Although ill, he participated in numerous international exhibitions, and occupied himself with research on platinum prints and took numerous photographs of Meran and its surroundings areas. During this time he wrote descriptive texts that accompanied his albums, giving evidence of his great intelligence and his distinct aesthetic sense. There are few documents, personal notices, and a relatively small number of photographs of this private scholar, most of

which were presumably destroyed during the shellfire of Mannheim in World War II.

On July 9, 1884, August Jakob Lorent died because of lung failure.

MILAN CHLUMSKY

Biography

In 1813, Jakob August Lorent was born in Charleston, South Carolina. He moved to Mannheim in 1818. From 1833 to 1836, he conducted his scientific studies at the University of Heidelberg. The years of 1842 and 1843 consisted of Lorent's voyages through Egypt and Asia Minor and in the autumn of 1845, Lorent revisited Egypt. During 1850 he travelled to London, and in 1851 he moved to Venice. Between 1859 and 1865, he took numerous voyages to Spain, Algiers, Egypt, Greece, Syria, Turkey, and Sicily. From 1865 to 1872 he photographed antique memorials near the Grand Duche of Baden in southern Germany. Finally, in 1873 he moved to Meran and photographed the surrounding area for the rest of his life. Jacob August Lorent died on July 9, 1884, in Meran.

Selected Works

1845 *Voyages in the Orient during the years 1842–1843*, Mannheim.

1845 *Wanderungen im Morgenlande während der Jahren 1842–1843,* Mannheim.

1861 *Egypt, Alhambra, Tlemsen, Algiers*, Mannheim (reprint: Waller F.V.,1984, *Egypten, Alhambra, Tlemsen, Algier,* Mannheim (reprint: Waller F.V.,1984).

1862 *Images from Athens*, Mannheim; *Bilder aus Athen*, Mannheim.

1865 *Jerusalem and its surroundings, Photographic album with texts from Dr. G. Roses,* Mannheim; *Jerusalem und seine Umgebung, Photographisches Album mit erläuterndem Texte von Dr. G. Rosen*, Mannheim.

1866 *Memorials of Middle Ages in the kingdoms, Württemberg: I. Department: Maulbronn; Bebenhausen, Hirschau, Alpirsbach and Herrenalb*, Mannheim

1867 *Memorials of Middle Ages in the kingdoms Württemberg: II. Department: Lorch, Murrhardt, Rieden, Oberhofen, Comburg, Faurndau and Oberstenfeld*, Mannheim. *Denkmale des Mittelalters in dem Königreiche Württemberg, II. Abteilung: Lorch, Murrhardt, Rieden, Oberhofen, Comburg, Faurndau und Oberstenfeld*, Mannheim.

1869 *Memorials of middle Ages in the kingdoms Württemberg: III. Department: Ellwangen, Blaubeuren, Denkendorf, Schwäbisch Gmünd and Brenz*, Mannheim; *Denkmale des Mittelalters in dem Königreiche Württemberg, III. Abteilung: Ellwangen, Blaubeuren, Denkendorf, Schwäbisch Gmünd und Brenz,* Mannheim.

1870 *Wimpfen on Neckar, history and topography to the historical documents and archaeologic studies*, Stuttgart**.** *Wimpfen am Neckar, geschichtlich und topographisch nach historischen Urkunden und archäologischen Studien*, Stuttgart.

LOTZE, EDUARD MORITZ (1809–1890)

German painter, artist, photographer, and studio owner

Eduard Moritz Lotze was born in 1809 in Freibergsdorf (Germany) to a family of farmers. He studied painting, drawing and lithography in Meissen and later at the Academy of Fine Arts in Dresden. In Munich began his professional career as painter and lithographer and there he learned the rudiments of photography. In 1852, he opened a photographic studio with his brother in law Hanfstaengl. Lotze moved to Verone (Italy) in 1854 where he opened a new photographic studio, which he left to his son Richard after his definitive return to Munich in 1868. He died in Munich in 1890.

While in Verone, he experienced a great professional success as a portrait photographer and photographed the Austrian military forts surrounding the city. He actively participated in the cultural life of Verone and exhibited his photographs at important expositions in the city. He was also well known in scientific circles for his *Saggio fotografico di alcuni animali e piante fossili dell'Agro Veronese* (Photographic Essay of a Few Animals and Fossils Plants of the Countryside of Verone) published together with Massalongo in 1859 and for *Monumenta graphica* as well as it is illustrated with photographic reproductions of pages from ancient codex, which was from Verone's and Padua's historical libraries.

CARLO BENINI

LUCKHARDT, FRITZ (1843–1894)

Austrian photographer, technical writer

Fritz Luckhardt was born on 17 March 1843 in Kassel (Germany, at that time seat of the government of the Kurfürstentums Hessen), the son of a soap manufacturing family. He received training as a chemist at the polytechnic institute in Kassel. During a stay in Paris he decided to become a photographer and joined the service with René Prudent Partrice Dagron. He spent a short time in England, and then in 1865 went to the establishment in Vienna where he worked first as a foreign language correspondent of the photo dealer and publisher Oskar Kramer. With the opening of his own studio in Vienna in 1867, Luckhardt's rapid ascent made him one of the most sought photographers in Viennese society at that time. In 1900 Félix Nadar called him "Le maître of the maîtres" in *Quand j'étais photographe* (Les primitifs de la photographie). For Henry Baden Pritchard in *The Photographic Studios in Europe*, 1882, Luckhardt was the epitome of a success-conscious and nonchalant gentleman. In the poses and gestures produced, in the purposeful light arrangement, Luckhardt's always more-or-less over-pointed portrait style nevertheless speaks volumes for the requirement for exclusivity of his customers and his own visual culture. In addition he also belonged to the continuous technical perfection and active lobbyism, which Luckhardt followed with the modern equipment of his studios, by various club memberships as well as by book publications and regular contributions in German-language technical periodicals.

Maren Groening

Biography

Fritz Luckhardt was born on 17 March 1843 in Kassel. As son of a family of soap-makers, he was to take over the enterprise of his grandfather and study chemistry at the Kasseler polytechnic institute, then go on to training at Hanover, and finally to work in a Paris perfumery. Instead he turned to photography. After a time with René Prudent Patrice Dragon in Paris and a stay in England, he settled in Vienna in 1865 and opened his own studio there in 1867 as an elegant society photographer. His business success stemmed from portraits of beautiful women (mostly actresses), which he exported in Stereoformat to the United States. He received the title of a K.K. photographer in 1870, and in 1883 was an honorary professor of the duke from Saxonia Meiningen. From 1871 to 1887 he was a secretary of the photographic society in Vienna. In addition he maintained memberships in the photographic Societies of Berlin and Frankfurt/Main as well as in Viennese agencies: Club of the amateur photographers (from 1888, 1893 renamed in Viennese Camera club), Association of Photographic Coworkers (from 1891), scientific association "Skioptikon" (from 1891). After Luckhardt's death in Vienna on 29 November 1894, his widow Franziska took over the studio. The best overview of the former private collection is probably given by Gerd Rosenberg in Vienna. In 1908 the Viennese city and federal state library bought 15 letters addressed to Luckhardt.

LUMIÈRE, AUGUSTE (1862–1954) AND LOUIS (1864–1948)

In French, *lumière* translates as "light." Auguste Lumière and Louis Lumière were born into a name that fittingly predicted their future as technological innovators in photography, cinema and, for Auguste, "medical biology, pharmodynamics, and experimental physiology" (Cartwright, 1992, 129). Auguste and Louis Lumière, two of the most famous brothers in the world, were born in Besançon, France. Their father Antoine Lumière (1840–1911) was a painter and a photographer. But their father was more than artistic; Antoine was a born businessman who was greatly motivated by the new inventions during the advent of France's *Belle Époque* (Beautiful Era). The spirit of their father and the spirit of their paternal name set the *mise en scène* for their invention of cinema. By the end of the nineteenth-century, there were many visionaries who were trying to animate the still photograph, including, most famously, Thomas Edison (1847–1931), Eadweard Muybridge (1830–1904) Charles-Èmile Reynaud (1844–1918) and, of course, the Lumière Brothers.

In 1870, fearing the Franco-Prussian war (1870–71), the Lumière family moved from Eastern France to Lyon. It was in the city center that Antoine opened his photographic studio. While running the studio, Antoine kept a watchful and excited eye on the education of Louis and Auguste. The two boys attended La Martinière, Lyon's largest technical high school. As a child, Louis was frequently troubled by headaches and had to spend much of his time at home, but, nevertheless managed to focus, very successfully, on inventions. As an adolescent, Louis designed the instant dry photographic plate christened the *Etiquette bleue* (blue label), which would amass the Lumière family fortune. With Louis's invention in hand, Antoine left the photo studio behind and acquired an extensive site on the outskirts of Lyon to manufacture and market *Etiquette bleue*.

In the summer of 1894, Antoine Lumière went to Paris and saw a demonstration of Edison's Kinetoscope. (In 1893, Edison had been granted a patent for "An Apparatus for Exhibiting Photographs of Moving Objects.") But the Kinetoscope was limited: only one person at a time could use the "peepshow" viewing

machine. The father of the Lumière brothers returned to Lyon and told them that they could do better than Edison. Antoine told his sons to get that image out of the box and they did.

In February of 1895, the Lumières received a patent for their invention of a lightweight (four kilos) motion picture camera: the Cinématographe. (Just as the etymology of photography is "light writing," cinématographe is "writing the movement"). On the sunny day of March 19, 1895, the Lumières managed to make the first film and marked the beginning of cinema. Their first film, *La Sortie des Usines* (*Workers Leaving the Factory*), was limited to seventeen meters of film and a time of no longer than fifty seconds, as was the case with all of the 1,408 little movies that the Lumières made with their Cinématographe. Shot by Louis (who was the principal filmmaker of the brothers), the famed brief movie features workers (mostly women) leaving the family's photographic glass-plate factory. Viewers witness the first characters, the first stars of cinema. *Workers Leaving the Factory* documented a simple piece of life, as did all of the Lumière films. Dramatic as their invention was, the Lumière Brothers did not see a big future with the Cinématographe. Like the Montgolfier Brothers and flight, the Lumière Brothers had "the genius for laying the intellectual foundation for a revolution" that would take place "elsewhere," in America (Gopnik, 151).

What was especially significant about the Lumière camera was that it could shoot, develop and, most importantly, project images onto a large screen. "This meant that the *opérateur* with this equipment was a complete working unit: he could be sent to a foreign capital, give showings, shoot new films by day, develop them in a hotel room, and show them the same night. In a sudden global eruption, Lumière operators were soon doing precisely that throughout the world" (Barnouw 1993, 6). Because they knew that most towns had no electricity, an ether lamp was used for projection. Viewers saw floods, crowds, men smoking opium, children running behind a rickshaw, trains coming and going, a gigantic ship, the drama and boredom of everyday life in Chicago, Mexico, Moscow, Jerusalem, China, Vietnam, Argentina, Algeria, Turkey, and Istanbul.

Not only did the Cinématographe give rise to the first newsreel, it also gave rise to the first family movie: as in the famous 1895 *Le Repas de bébé* (*Baby's Tea*) which features Auguste and his wife feeding their baby. Furthermore, given the Charlie Chaplinesque quality of many of their films, the Lumières can be credited with cinema's first comedies. Today audiences still laugh uproariously at the 1895 *Arroseur et arrosée* (*Watering the Gardener*): how funny the scene had to have been to an audience uninitiated in the world of cinema. In the 1896 *Démolition d'un mur* (*Demolition of a wall*), Louis made humorous use of what was originally an accidental projection in reverse: a wall is knocked down only to cinematically spring back up. Certainly, the youthfulness and lightness of the Lumière films was generated by the fifty-second format, the joyful mood of the Belle Époque, but also the spirit of two young inventors in their early thirties making art.

Not to be overlooked is the magnificence and formal precision of Lumière films. Louis was a great photographer and we see this in the "art" of the films that he made with his brother. In the hands of Lumière, a pair of opium smokers, tightly framed, shot with the camera low to the ground, is a work of staggering beauty. With its compelling use of a dramatic diagonal, Louis's 1895 *L'Arivée d'un train en gare* (*The Arrival of a Train*) is the first cinematic masterpiece. "The Lumières and their cameramen, utilized with glory the deep space and receding movement available to the camera lens, which had been ground in conformity with an idea of perspective emanating continuously from the Renaissance" (Sitney, x).

While there is general agreement that the Lumière Brothers can be credited with the invention of cinema, the process of getting to that first projection on March 22, 1895, (with the first performance to a paying audience, taking place at the Grand Café, 14 boulevard des Capucines on December 28, 1895), was a sorted and complex affair. Ingenious devices that preceded the Cinématographe (the term "cinématographe" is actually owed to Léon Bouly, 1892–93) were already developed earlier. Leading up to the invention of cinema were a range of important devices that contributed to the Lumières' Cinématographe. Most obvious is the invention of the camera obscura, the photograph itself and the magic lantern, but perhaps as important are the optical apparatuses that emphasized principles of movement. Critical here are Sir David Brewster's invention of the kaleidoscope in 1815, with its multiplication of imagery with precision, and Louis J. M. Daguerre's refinement of the diorama in the early 1820s that led to the multimedia diorama, "often sitting the audience on a circular platform that was slowly moved, permitting views of different scenes and shifting light effects." (Crary 1990, 113) In the early 1830s, Joseph Antoine Ferdinand Plateau invented the "phenakistiscope," which consisted of two spinning discs, one with a figure in a sequence of movements, the other with slits to look through. Utilizing a mirror and principles of retinal persistence, the observer sees a figure in animation (a girl jumping rope, a bird flapping its wings). By 1834, the similar devices of the stroboscope (invented by Simon Ritter von Stampfer) and the zootrope, sometimes called "the wheel of life," were invented. Charles-Émile Reynaud made the first animated films, which grew out of his 1877 "praxinoscope," projecting the first animated film in 1892. By

1888, Muybridge had learned to project sequences of his photographs on an adaptation of the magic lantern. Also in 1888, Étienne-Jule Marey used sensitized paper roll film to invent a camera that could take separate, but successive pictures on a moving strip of film. With this history in mind, it is noteworthy that Peter Kubelka notes that, in fact, cinema is "not movement…Cinema is nothing but a rapid slide projection. A slide projection which goes in a steady rhythm: twenty-four slides per second" (Kubelka 1978, 149).

Along with the Cinématographe, the Lumieres are well-known in the history of photography for contributing to the process of color photography with the invention of the Autochrome. An additive process, the Autochrome plate consisted of very fine grains of potato starch used with a gelatin silver-bromide emulsion. Autochromes were expensive and were unique images, best viewed as a transparency: their true colors were impossible to catch by the limited printing possibilities at the time. The Lumières' Autochrome plates went on sale in June of 1907. The process remained confined to Europe, especially France. The photographer Jacques Henri Lartigue made some of the most successful Autochrome images between 1912 and 1927.

In 1995, in honor of the Cinématographe's centennial anniversary, forty famous filmmakers (David Lynch, Spike Lee, Wim Wenders, Zhang Yimou, John Boorman, et al.) from around the world came together to create their own fifty-second Lumière film. Using the restored original camera forty intriguing films were made by and in tribute to the well-designed, trim, hardwood box with a hand crank.

Carol Mavor

Biography

Auguste Lumière was born on October 19, 1862, in Besançon France and Louis Lumière was born on October 5, 1864, also in Besançon. Along with their father they ran the very successful Lumière factory, which made its fortune from the innovative glass plate for dry-plate photography, the *Etiquette bleue* (blue label), which was invented by Louis when he was a teenager. The brothers are most famous for inventing "cinema" through the Cinématographe, which was patented on February 13, 1895. They shot their famous fifty-second *Workers Leaving the Lumière Factory* on March 19, 1895. The brothers also invented an early color photographic process, the Autochrome. For much of his life, Auguste worked tirelessly on medical inventions. After 1900, much of the production of the Lumière plant in Lyons was oriented towards medical research and production. Louis died on 6 June 6, 1948, in Bandol, France and Auguste died on April 10, 1954 in Lyon, France.

LUMMIS, CHARLES FLETCHER (1859–1928)

American photographer, journalist, publisher

After graduation from Harvard College, Lummis took up a career as a journalist in Ohio. When offered a position in Los Angeles he walked across country and published the account of his journey, *A Tramp Across the Continent* (1892). He covered the Apache revolt led by Geronimo in 1885 for the *Los Angeles Times*, and renewed his interest in the cultures of the American Southwest. He moved to New Mexico for his health in 1887 and assisted archaeologist Adolph Bandelier for whom he photographed in the southwest and Latin America. His photographs served as the basis for the illustrations for an ethnographic study of Pueblo Indian people. In a five year period, 1888–1893, he photographed the land, people, and dwellings, the ruins and traces of past civilizations, and persistent rituals in the Southwest, Central America, and Peru. In all he made an estimated 10,000 glass plate negatives during his lifetime. Those made after his return to Los Angeles record the cultural heritage of southern California. He became the foremost proponent for the recognition and preservation of the unique cultural heritage of southern California and the American Southwest through his writing for *Century* and the illustrated magazine which he edited, *Land of Sunshine* (*Out West* after 1902) and his books, including *The Land of Poco Tiempo* (1893), and *Some Strange Corners of Our Country: The Wonderland of the Southwest* (1892). *Mesa, Canon and Pueblo* (1925), illustrated

with one hundred photographs, brought together thirty years of writing and photography on the region. The magazine *Land of Sunshine* became an important outlet both for his photography and that of others working in the Southwest. In 1907 he joined with others in Los Angeles to form the Southwest Museum which preserves important collections of Native American objects and holds a large number of his photographs.

KATHLEEN HOWE

LUTWIDGE, ROBERT WILFRED SKEFFINGTON (1802–1873)

English

Lutwidge was born in London on January 17, 1802, the second son of Charles Lutwidge and Elizabeth Anne Dodgson. His sister, Frances Jane, married a cousin, Charles Dodgson, and in 1832 gave birth to Charles Lutwidge Dodgson—the author and photographer Lewis Carroll. Skeffington Lutwidge was a favorite uncle of Carroll's and it was his influence that encouraged him to take up photography in 1856.

Lutwidge was a London-based barrister and commissioner in lunacy, he was a friend of Dr. Hugh Diamond and they were both members of the Photographic Society and the Photographic Exchange Club. His favored subject matter was architecture and in 1855 made an unusual study, in the rain, of the entrance to Knole Castle.

Lutwidge and Carroll often spent time together and on June 15, 1872, Lutwidge was photographed by his famous nephew at his Christ Church Studio in Oxford.

In May 1873 during a visit to Fisherton Lunatic Asylum at Salisbury, Wiltshire Lutwidge was attacked by patient William McKave and died six days later. Carroll's well-known poem The Hunting of the Snark, published in 1876, was inspired by his uncle's tragic death and experiences with the Lunacy Commission.

IAN SUMNER

LUYS, JULES-BERNARD (1828–1897)

French physician

Born in Paris in 1828, Jules-Bernard Luys attended medical school with the intention of becoming an intern in Paris in 1853. He obtained his doctorate in medicine four years later and became doctor in a hospital in 1862, occupying the postitions of head of department in Salpêtrière, and then later in Charity. An Anatomopathologist of development, his research was focused on the nervous system and the brain. Anxious to represent his findings as precisely as possible, he chose not to use traditional drawings or engravings but instead photography to display and capture his research. The first examples of these images can be found in a publication which Duchenne of Boulogne influenced him to choose as this new technique of representation was considered by many to be more accurate.

In 1873, he published photographs of the nerve centers in a text edited by Jean-Baptist Baillière. The work was composed of a book of text and an atlas comprising seventy photographs of cut and drawn brains on albumen paper. The photographs were taken in collaboration with George Luys (1870–1953), his son who was also a doctor. Encouraged by the success of this first work, Luys published two other works illustrated by photography as well.

DENIS CANGUILHEM

LYTE, FARNHAM MAXWELL (1828–1906)

French photographer

Born in 1828, Farnham Maxwell Lyte was a person of wide-ranging interests and an insatiable intellectual curiosity. He trained to be an Engineer at Cambridge University. In 1853 he traveled to Pau, France and made the acquaintance of—Jean-Jacques Heilmann and John Stewart, two photographers with whom his work is often associated. Lyte photographed both the natural and the man-made wonders of the Pyrenees.

One of the founding members of the Société francaise de photographie, Lyte had several of his photographs included in exhibitions from 1857 to 1874. He was also the inventor of what became known as "the honey process" a method of prolonging the sensitivity of coated glass plate negatives.

Most of Lyte's photographs are either salted paper or albumen prints and he worked almost exclusively with the wet-plate collodion process.His albumen prints are often easily identified by the red blind stamp on the bottom left or right hand corner of the print. He often inscribed his plates with the Latin phrase Lux Fecit (made by Lyte), a pun wittily alluding to both the act of photographing, and to his family name. He died in England in 1906.

PAULI LORI

M

MACFARLANE, SIR DONALD HORNE (1830–1904)

The son of a magistrate in Caithness, where he was born in July 1830, Macfarlane went to India in the late 1850s as a partner in the firm of Begg, Dunlop and Co., agents for tea and coal interests in the subcontinent. He appears to have taken up photography as an amateur soon after his arrival and the quality of his work attracted notice when he joined the Bengal Photographic Society in 1860. He remained an active and enthusiastic member of the society until his departure from India in 1864, winning numerous medals in its competitions and contributing several papers to its journal. The most important of these, *Landscape photography in India*, appeared in September 1862 and from 1863–64 he served as the society's president. Macfarlane's landscape work, small in quantity in terms of known examples, nevertheless reflects one of the freshest and most individual responses to the Indian landscape in the early 1860s and displays a remarkably modern compositional approach. Although Macfarlane continued with photography on his return to Europe and had his work shown at the Paris Exhibition of 1867, examples of this have not so far come to light: the scarcity of surviving prints has certainly led to an unwarranted neglect of one of the most individual photographic eyes in India in the 1860s. In his later years he served as Member of Parliament for Carlow (1880) and Argyllshire (1885, 1892), dying in London on 2 June 1904.

JOHN FALCONER

MACH, ERNST (1838–1916)

Moravian physicist

From early in the second half of the nineteenth century, photographers increasingly sought not just to decrease exposure times, but to shorten them sufficiently to be able to capture moving subjects with the crispness and full tonal range that was possible in a landscape view or a studio portrait. Gustav le Gray, Count Michael Esterhazy, Albert Lugardon, Ottomar Anschütz, and others achieved international recognition through their ability to depict movements in "instantaneous" photographs that recorded the natural motion of their subjects. The most spectacular instantaneous photographs captured movements too fast to be seen by the human eye, such as bullets or cannon shells in flight, and melded advanced photographic technology with a specialised optical apparatus developed by the professor of physics in Bonn, Dr. August Toepler, at the end of the 1850s and published in 1864. Toepler was interested in observing variations in the density of gases and fluids, and devised an apparatus where an "experimental space" containing his transparent media was framed by two plano-convex lenses on opposite sides, whose focal point was then observed by a further pair of enlarging lenses. The experimental space was lit from behind, and precisely half of the rays of its lenses were blocked by a shutter just at their focal point, in front of the observing lenses. With this specialised setup, any variation in the refraction of light passing through the experimental space caused by uneven density in the material showed up at the observation point as an unfocussed streak of light, and a Schlieren ("streak") apparatus became a standard laboratory instrument, not only for work on fluids but also for checking the imperfections of optical lenses. When a camera replaced the human eye at the observation point, and an electric spark provided appropriate illumination for a darkened experimental space, any fast-moving object that passed through the space, and the effects on the air caused by its movement, could be photographed, measured, and studied, given that a proper electrical circuit timed the release of the spark

just as the object was passing through the experimental space or Schlieren Head.

Beginning in 1884 Ernst Mach began using the Schlieren Method to photograph bullets fired by a pistol, drawn into a controversy about whether or not the French had used illegal explosive bullets, outlawed in the Treaty of St. Petersburg of 1868, during the Franco-Prussian war of 1870–71. New French rifles had caused extreme, crater-like wounds, and throughout the 1870s a number of explanations for the phenomenon had been put forward, including an idea suggested by Louis Melsens of Belgium that a spherical projectile carried compressed air with it in flight, the amount depending on its velocity. In his first experiments Mach saw no significant turbulence in the air because the bullets were travelling too slowly; he asked his colleagues Peter Salcher and S. Riegler at the Marine Academy in Fiume to continue his experiments, and they modified another Schlieren apparatus to Mach's specifications, photographing bullets fired from several types of rifles. In summer 1886 the shock waves from a bullet travelling faster than the speed of sound were photographed for the first time. Mach, assisted by his son Ludwig, then continued the experiments that autumn making more photographs of the air turbulence around a variety of projectiles, and even built a remarkable apparatus at the Krupp artillery range in Meppen where a 4 cm rapid-firing cannon was fired through a specially-built shed that provided the darkness needed to make a photograph where the plate was exposed by illumination from an electric spark. Mach began publishing his results with Salcher in 1887, and caused much excitement in both the scientific and photographic worlds. Ottomar Anschütz was inspired to make the only daylight photograph of a flying cannonshell in 1888, using specially designed weighted, pneumatically driven and electrically released focal plane shutters that operated at 76 millionths of a second at the Krupp Gruson works at Buckau-Magdeburg. Sir Charles Vernon Boys, who had made photographs of falling drops of water and other liquids by moving a photographic plate by hand through a camera while a slotted rotating disk shutter ran in front of his camera lens in the late 1880s, repeated Mach's Schlieren-method work in 1891 and 1892, producing photographs of bullets piercing a sheet of glass and other materials. Unusually, Boys used no lens in his camera, relying instead on the nearness of the bullet to the plate and his own improvements in the design of the electrical release mechanism, which much improved the briefness of his spark, to produce a defined image. Helmut Gernsheim's dismissive comment on the work of Mach and Boys, based on the fact that because the subjects were back-lit from behind the Schlieren Head the photographs produced only shadows of the passing object, seems today distinctly ungenerous. Their innovative technical expansion of the usefulness of photography not only led to specific scientific discoveries, but also gave new impetus to the field of electric-spark photography pioneered by Prof. Bernhard Wilhelm Feddersen in the late 1850s, and ultimately led to the striking images of Harold Edgerton at MIT in the 1930s and the development of modern stroboscopic flash units both large and small.

DEAC ROSSELL

Biography

Born at Turas, Moravia (today Czech Republic), Ernst Mach was educated at the University of Vienna, gaining his PhD in 1860. Four years later he was named professor of mathematics at Graz, and next took the chair of physics at the University of Prague in 1867, where he remained for the next 28 years. At Prague, Mach concentrated on experiments in psychology and perception, and worked on optics, mechanics and wave dynamics. He discovered the function of the semicircular canals of the ear; a phenomenon of the eye where it sees bright or dark bands near the boundaries between areas of starkly constrasting illumination, still called Mach's Bands; and first described the shock waves in the air that precede an object travelling faster than the speed of sound, leading to the colloquial expression of "Mach I" or "Mach II" for the speed of military and experimental aircraft. This last discovery was made in a series of trials using advanced photographic methods. Parallel with his experimental work in the 1880s, Mach proposed that all knowledge is derived from physical sensations, and began to argue for a rigorous interpretation of science based only on the interpretation of verifiable empirical observation. He further developed a radical concept of inertia, which he considered was exclusively a function of the interaction between one body and all the other bodies in the universe, a view which was not only controversial but which was one of the inspirations for Einstein's theory of relativity. His rejection of the existence of atoms, and his contention that matter was constructed wholly out of pure sensation was equally influential on the logical positivist philosophers, and embroiled him in vivid public disputes with Max Planck, Oswald Külpe, and even Vladimir Lenin. Mach's scientific legacy is principally as a philosopher of science although he always considered himself nothing other than a rigorous physicist. Moving to the University of Vienna in 1895, where he became professor of the history and theory of the inductive sciences, Mach began an intense battle against Einstein's theory of relativity which dominated his later work, even though he was partially paralysed by a stroke in 1901. Widely influential on European physics practitioners during his lifetime, his fight with Einstein ultimately eclipsed his reputation until recently,

when new theories about the properties and composition of sub-atomic particles have revived interest in his concepts.

MACKEY, FATHER PETER PAUL (1851–1935)

English-born amateur photographer

Father Mackey epitomises the private photographer: a learned scholar who knew the relevance of what he was looking *for* and *at*; precise, as befits the "age of the tripod," technically expert, poetic, he had a great love of architecture. A tireless walker, he made excursions throughout Italy, and to Sardinia and Greece, c.1884–1902, and because he travelled off the souvenir routes, he photographed many places not covered by commercial photographers. His depictions of the nuraghe in Sardinia are the earliest in existence. Equally rare is his record of the natural life of the Italian countryside, a subject not recognised by the professionals. Rarer still is the way he portrays the world for it is seen through the eyes of a Dominican priest who should not have been so interested in transitory, worldly things; self-portraits depict him deep in poetic thought in his flowing habit amidst pagan, classical ruins. Born Erdington, Birmingham, Daniel Mackey studied law (1869–1871) then the priesthood at Woodchester where, after becoming a Lector in Sacred Theology at Louvain in 1874, he taught philosophy and canon law until summoned to Rome in 1881 as editor of the Leonine edition of the works of St Thomas Aquinas which he continued for the rest of his life. He also associated with artists, such as Rodin, art dealers and collectors. He presented his photographic albums to the British and American Archeological Society of Rome (one remains). He gave to the British School at Rome c.1913 his negatives (now lost) and nearly 2000 prints, together with a detailed catalogue, which remained forgotten until 1999. They are now of great interest.

ALISTAIR CRAWFORD

MACPHERSON, ROBERT (1814–1872)

Scottish photographer who specialised in photographs of Roman architecture and antiquities together with topographical views

For approximately fifteen years, from c.1851 to c.1866, Robert Turnbull MacPherson was one of the most sought after photographers working in Rome. From the mid 1850s, John Murray began to publish favourable notices of MacPherson in his popular guidebooks and by the time of the 1858 edition, he was named as one of the principal photographic artists working in that city. MacPherson had relocated to Rome from Scotland in c.1840. His specialised in large format albumen prints. His preferred subjects were architecture, works of art and in particular sculpture, together with topography. These subjects found a quick and ready market with the international tourists that Rome attracted. MacPherson photographed elsewhere in Italy including Venice, Perugia and Assisi but it for his photographs taken in Rome and the surrounding Campagna that he is best known.

Born in Scotland in 1814, Robert MacPherson studied medicine at Edinburgh University to qualify as a surgeon. However his medical practice was short-lived as he became increasingly interested in art. He relocated to Rome in c.1840 and established himself as a painter. In the early 1840s he also started a business as an art dealer, although to what extent this was carried out on a regular basis remains unclear. In 1849 he married Geraldine Bate, a niece of the art connoisseur Anna Jameson. From Nathaniel Hawthorne's recollections of visiting her palazzo in 1858, it is also known that Jameson collected art. MacPherson appears to have had a strained relationship with his wife's aunt, so the question of to what extent, if any, Jameson introduced him to any of the distinguished members of her circle, such as the Goethe family, remains unresolved. However it might be significant that Macpherson included a citation from Goethe on the title page of his handbook to the Vatican Sculptures in 1863. Aside from any connections that Jameson's may have provided, MacPherson had his own very mixed circle of friends and acquaintances including George Combe, a co-founder of the Edinburgh Phrenological Society in 1820 and who conversed with MacPherson about sculpture, and the Scottish novelist Margaret Oliphant who referred affectionately to both Robert and Geraldine in her autobiography.

MacPherson appears to have abandoned painting in

MacPherson, Robert. The Theater of Marcellus, from Piazza Montanara. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Alfred Stieglitz Society Gifts, 2005 (2005.100.59) Image © The Metropolitan Musem of Art.*

favour of photography by the early 1850s, although it is very likely that he had already begun to take photographs using the calotype process as early as the late 1840s. One or more calotypes associated with the activities of the Calotype Club of Edinburgh have a tentative attribution to MacPherson but may have been taken by James Calder MacPhail. They are consistent in format and general geographic location with a number of other calotypes which appear to have been taken by Sir James Dunlop during his Grand Tour of 1847. It is also possible but as yet unconfirmed that Dunlop introduced MacPherson to photography.

MacPherson's adopted the albumen process at the start of his commercial career and then progressed to the faster collodion-albumen process. He also experimented with modifications to photolithography and in 1853 obtained a patent for improvements employing bitumen. He went on to demonstrate photolithography at the newly formed Société française de photographie and at the Photographic Society of Scotland. MacPherson exhibited two photolithographs and five albumen prints at the British Association exhibition at in the showroom of Wylie and Lochead's Warehouse in Glasgow in 1855. He contributed an even larger representation of his photographs to exhibitions at the Photographic Institution in the same year and at the Photographic Society

of Edinburgh in 1856. His residency in Rome made it desirable to employ agents or other representatives including William Ramsey, Professor of Humanity at Glasgow University. Ramsey also described MacPherson's photolithographs to an international readership in *Frank Leslie's New York Journal* in 1856. MacPherson clearly valued his links with Scotland and kept in touch with and occasionally visited photographic colleagues there. In 1862 he also exhibited over 400 photographs in London in a gallery just off Regent Street and was present at the opening.

MacPherson favoured large format photographs which necessitated the use of long exposures. In 1862 he told *The Photographic News* that he employed an exposure time of five minutes for a distant landscape in good light but that between ten and twenty minutes were necessary for near objects. For some of the sculptures permanently housed in galleries, MacPherson stated that two hours or even two days were required to produce a good negative. Typically, MacPherson's photographs were mounted and carry his oval blind-stamp. These provide attribution but also chart the course of his various studio addresses. However it was at 12 Vicolo D'Alibert that he achieved much of his success.

Some of MacPherson's negatives bear his signature. Pencil reference numbers corresponding to his catalogues frequently appear on contemporary mounts. By 1863 he listed 305 photographs including picturesque local subjects such as "The Fish-Market in the Ghetto," as well as his usual historical themes. People rarely appear as he recognised that his customers wanted photographs of classical antiquities in Rome and nearby locations such as Terracina, Tivoli and Paestum, not life in a contemporary city. Nevertheless "The Valley of St. Anatolia with the new Railway Viaduct" indicated his preparedness to occasionally include some aspects of modernity. In a different vein, "Falls of the Terni" became on of the most famous waterfall photographs of the period.

MacPherson sold his photographs separately at a uniform price of five shillings but he also stocked ready-filled albums. Other customers evidently compiled their own albums frequently mixing MacPherson's photographs with those of his contemporaries such as Carlo Ponti. His photographs possess pronounced light and shadow effects and indicate a sensitively to both the monumental and the elemental aspects of the subject matter depicted. He did not have a standardised format, preferring to trim prints to achieve strong compositional arrangements. Helmut Gernsheim perceptively observed that his prints of surpassing beauty were not dependent exclusively on the beauty of the scenery.

Vatican Sculptures, a small volume with engravings derived from MacPherson's photographs and reduced down to miniature size by Geraldine was published in 1863 with a second revised addition appearing in 1868. A companion volume to the Lateran and Capitoline collections was planned but never materialised. However MacPherson clearly photographed at the Capitoline, as a two volume album exists in at least one copy with a bound-in pricelist dated 1871. MacPherson continued to sell works of art including fourteen examples to the National Gallery of Ireland and, famously, Michaelangelo's *The Entombment* which he purchased cheaply in 1846 and sold to the National Gallery in London in 1868 for £2000. MacPherson was disappointed that what had been known in the family as 'Geraldine's fortune' realised a smaller sum than he had anticipated, particularly when his photography business was showing signs of slowing down. His health also begun to fail at this time and he died in Rome on November 17, 1872.

JANICE HART

Biography

Robert MacPherson was born in Scotland in 1814. He studied medicine at Edinburgh University (1831–1835) but his medical career was soon abandoned in favour of a very different life as a topographical painter. He moved to Rome in c.1840 and established himself as a painter in oils and also started a business as an art dealer. The most significant aspect of his activities as a dealer was the purchase of a Michaelangelo painting in 1846 and its subsequent sale in 1868. He married Geraldine Bate, a niece of Anna Jameson, the expert in Italian art. MacPherson appears to have abandoned painting shortly afterwards and turned instead to photography. It is likely that he had already begun to take photographs using the calotype process by at least the late 1840s but in the early 1850s he had moved on to the albumen process and was to subsequently adopt the collodion-albumen process. His photographic business was founded on the production of large format prints of Roman architecture and antiquities, together with views of the surrounding Campagna. He quickly achieved commercial success. His interests extended to photo-mechanical printing. His modifications to the photolithographic process was patented in 1853. He exhibited regularly in 1850s and 1860s and achieved much critical acclaim. In 1863 he brought out a small handbook, *Vatican Sculptures*, containing illustrations derived from his photographs. By c.1866 his photographic business was still very active and in 1868 he sold an hitherto "lost" Michaelangelo painting to the National Gallery in London. In the late 1860s, both his business and his health were beginning to fail. He died in 1872.

MADDOX, RICHARD LEACH (1816–1902)

Richard Leach Maddox was born on the 4th of August 1816 in Bath, England. He traveled all over the world during the 1840s as a physician and worked for a few years in Constantinople (Turkey) before returning to England. He married twice, the first time in Turkey, to Amelia Winn Ford who died in 1871, and the second time in 1875, to Agnes Sharp. He traveled with his family, which included his three children. He returned to Southampton in England and ended his photographic activities in 1886 however he continued writing for scientific newspapers.

Richard Leach Maddox was not a professional photographer, instead he was more a scientist interested in photography and the science involved in its processes. As a scientist he is especially known for his work concerning microphotography and his research to improve the photographic process. In 1853, he began working with photography, particularly microphotography, in connection with his professional work as a scientist and exhibited his work that same year in the Photographic Society Exhibition in London.

Passionate for this kind of photography, Maddox translated Dr. Félix Dujardin's manual, *Nouveau manuel complet de l'observateur au microscope*, published in France in 1842 (*The New Complete Manual for the Microscope Observer*). The translated version never was published but he did write articles on this subject for the *British Journal of Photography* between 1855 and 1883. For his research in the beginning of the 1870s on atmospheric organisms, Maddox used an apparatus of his own design, called the "aeroconiscope" described by the *British Journal of Photography* as "a kind of multiple funnel set up as a vane. The wind traversing this instrument deposited the organisms on a thin coverglass duly prepared for the purpose" (*British Journal of Photography*, May 30, 1902, 427).

With this optical instrument connected to the camera, scientists were able to discover and study micro-organisms. During these years, they used a wet process to take photographs of their results.

Speed and picture quality were the most important topics for both scientists and photographers from the very beginning of the technique. The wet collodion process was the most sensitive technique at this time, but not practical enough because it had to be taken before it dried. At this time, the Taupenot process, also called dry collodion, was used as an alternative choice however it was a less sensitive process. A good photographic technique has to be practical and as fast as possible so researchers were always trying to improve the different processes.

One other important concern of Maddox's regarding photographic research was focused on the use of dangerous, chemical substances. His research, which required him to be at his microscope for hours up to sixteen hours a day in conjunction with him being around chemicals used for collodions vapor caused his health to deteriorate quickly. Maddox used ether to prepare his photographic plates, coating them with wet collodion and his failing health is the main reason the scientist tried to replace it in the process.

Well known from the beginning of the nineteenth century, gelatin was already being used in food and in photography (principally for photographic reproduction and impression). Maddox replaced the collodion coating with gelatin. He covered a glass with a mix of Nelson's gelatin and cadmium bromide. After drying, this plate was used as a negative, then developed with pyrogallic acid combined with silver nitrate and fixed with a sodium hyposulfite solution, which proved successful.

Maddox announced his discovery in the *British Journal of Photography*, the 8th of September of 1871, which soon was spread throughout Europe because of the various specialized newspapers and photographic associations. It's likely he realized the importance of his work, but did not follow up with improving the process. According to his notes, he did not have time to perfect it and let others scientists continue any further research.

From August 1873, the *British Journal of Photography* anticipated its future applications. Gelatin was a sensitive, fast, and dry photographic technique, which was also easy to prepare. Consequently, Richard Leach Maddox's discovery was the beginning of photographic industrialization, and one which caused a radical change concerning the picture's aesthetic due to the relatively short developing time.

Several scientists Jos. King, J. Burgess, and R. Kennett, improved the process before 1878, when Charles Bennett perfected actually perfected it by making it

more sensitive. This included warming the emulsion in a neutral medium for a few days at 32 degrees centigrade. Later, Bennett and few others like Désiré van Monkhoven, in Ghent, and George Eastman patented the process and sold readymade negatives plates.

The commercial development of the dry plate process eventually revolutionized the practice of photography, and the images produced by it. Amateur photographers did not need knowledge of chemistry or physics as this invention provided all that was needed, permitting anyone to practice photography.

Richard Leach Maddox received medals from different inventors exhibitions in Brussels, Antwerp, Belgium and the prestigious Royal Photographic Society's Progress Medal on February 12, 1901, for his research.

Maddox did not patent his various discoveries and inventions and did not make money from them as his motto was "if freely we have received, freely give" (*British Journal of Photography,* May 30, 1902, 427).

After his death on May 11, 1902, in Southampton, the *British Journal of Photography* noted that the community had lost the figure that changed photography from a long process to a more convenient one and that the part of photographic history, which had long been dominated by lengthy processes would be, for the "younger generation of photographers…ignorant of the slow and laborious manner in which gelatin photography was" (*British Journal of Photography*, May 30, 1902, 426).

MAES, JOSEPH (1838–1908)

Belgian photographer, collotype printer, and publisher

Melchior Florimond Joseph Maes was born in Ghent on June 10, 1838. His first experiments in collodion photography took place in 1852. His precocious talents came to the attention of Désire Van Monckhoven, who then employed him as an assistant. Together they set up a studio for the production of stereo views which was a commercial failure, and their stock of negatives was sold to Gaudin in Paris.

Maes decided to open a portrait studio, while still harbouring ambitions in the nascent area of photographic printing and publishing. His studio opened in Brussels, at Rue des Fripiers 26, on November 22, 1858. He soon began supplying photographs for book illustration, his first two commissions, for the Brussels publishing house of A. Schnée, appearing in 1860—a deluxe edition of *Histoire populaire de la Belgique* [*Popular History of Belgium*] by Louis Hymans, containing eleven albumen prints, and a study *Exposition générale des beaux-arts à Bruxelles. Le salon de 1860* [*General Fine Art Exhibition in Brussels*. The 1860 Salon] by the art critic Max Sulzberger, containing four prints.

Maes formed a partnership with a certain Michaux (possibly a romantic interest) from September 1862 to August 1863 and moved premises to Rue Fossé aux Loups 36 Place de la Monnaie. This partnership, the sole example in Maes' long career, was clearly meant to lay the ground for a publishing initiative in the area of art reproduction, but proved to be short-lived. Instead, Maes went on to run the portrait studio alone, domiciled at the address from 14 October 1863. In 1864 and 1865, he published his first major work, *Album des objets d'art religieux du Moyen Age et de la Renaissance exposés à Malines en 1864* [*Album of Religious Art Objects of the Middle Ages and Renaissance* exhibited in Malines in 1864], a series of 57 albumen prints to commemorate a landmark exhibition of sacred art organised by the British historian W.H. James Weale.

Maes married Emma Strybos on 27 October 1863, and they had two daughters, Augusta born in 1865 and Julia in 1867. The family moved to Antwerp in 1866, where Maes acquired a portrait studio from Auguste Blanche (1818–1866) at Rue des Aveugles 1 / Place du Musée on 15 April 1866. His interest in photomechanical processes, a natural outgrowth of his activities in photographic publishing, dates from around this period. The considerable economies of scale afforded by the printing press were clearly demonstrated when the Brussels firm of Simonau and Toovey published a second edition of Maes' Malines album in 1866. Using their patented photolithographic process, it sold at 60 francs a copy, compared to the 200 francs which Maes charged for the original print-run in albumen.

Maes recognised the especial potential of the collotype process, using minimally adapted lithographic presses in general use. Following the Paris universal exhibition in 1867, at which Maes exhibited, he visited the printing works run by Tessié du Motay and Arosa in France, but was dissatisfied that the number of good prints per plate rarely exceeded 75, insufficient for industrial-scale production. When Josef Albert advertised his process in 1869, announcing print-runs of several

hundred, Maes opened negotiations to acquire the rights, but was unable to reach agreement. Maes set about "reinventing" the process, and by November 1869 had produced prints in the full range of halftones. During the following year the collotype workshop went into operation, and in 1871 Maes imported a steam-powered collotype press from Germany, the first of four.

Always the shrewd businessman, and chastened by the failure of earlier ventures, Maes retained the portrait studio, a sure source of income which he operated in parallel to his printing works throughout the 1870s. He offered to supply illustrations in collotype, *photo-autotypie* (carbon) and Woodburytype, presumably having acquired the hydraulic press for the process previously worked by Simonau and Toovey under licence up to the mid-1870s. Maes operated from Avenue de l'Industrie 24 from 1874 to 1881, and Rempart Sainte-Catherine 23 from 1875 to 1882, then sold the portrait studio at this address to his operator Georges Raynaud. From 1884 to 1895 he ran the collotype works from Rue Gramaye 10. Maes' work graced a broad range of art-historical publications, some of which he published himself. His most extensive achievement in collotype is the folio *Documents classés de l'art dans les Pays-Bas, du Xième au XVIIIième siècles* [*Schedule of Art in the Low Countries, from the Tenth to Eighteenth Centuries*], published between 1880 and 1889 and containing 720 plates with accompanying text by the architect J.J. Van Ysendyck.

As Maes secured his social standing within Antwerp society, so his public profile grew apace. He successively founded two reviews of the arts, *Revue artistique* (1878–1884) and *Chronique des Beaux-Arts* (1884–1886), supplying the illustrations from his own printworks. Joining the *Association belge de Photographie* (ABP) in 1882, he was appointed president of the Antwerp section on 6 December 1886, a post he retained as late as 1904, and held the presidency of the Association from 1889 to 1895. Chairman of the *Union Internationale de Photographie*, he hosted sessions in Amsterdam, Liège and Brussels between 1895 and 1897. He was awarded the Order of Leopold for his services.

Maes remained commercially and publicly active into old age. Although he relinquished control of the collotype works to George and René Dero from 1892 to 1894, he appears to have regained control at least for a short time around 1895. From his final address in Antwerp, Rue Rembrandt 33(3), he was registered as a person of private means, but became an agent for the Lumière company's "Cinématographe." He edited a fortnightly broadsheet *Journal de Photographie* from October 1902 to September 1905, and frequently exhibited as an amateur at the salons of the ABP.

Joseph Maes retired to the Antwerp suburb of Berchem on 7 June 1907 accompanied by his wife and unmarried daughter Augusta. He died on 4 August 1908, and was buried in Berchem cemetery. A dynamic figure in 19th-century Belgian photography, he had participated, in his various guises as photographer, printer, publisher, and increasingly successful entrepreneur, in many of the technical developments in photography for over half a century.

There are substantial holdings of Maes' work at the Bibliothèque royale Albert Ier—Département des imprimés, Brussels, Provinciaal Museum voor Fotografie, Antwerp, Stadsbibliotheek [municipal library], Antwerp, and Stadsarchief [municipal archives], Antwerp.

STEVEN F. JOSEPH

Biography

Melchior Florimond Joseph Maes was born in Ghent on 10 June 1838. Opening his first studio in 1858, he soon began supplying photographs for book illustration. Maes married Emma Strybos on 27 October 1863, and they had two daughters, Augusta born in 1865 and Julia in 1867. The family moved to Antwerp in 1866. Always the shrewd businessman, Maes recognised the potential of photomechanical processes. He set up a collotype printing works in Antwerp in 1870, which he ran for nearly twenty-five years. A key figure in 19th-century Belgian photography, Maes participated, in his various guises as photographer, printer, publisher, and increasingly successful entrepreneur, in many of the technical developments in photography for over half a century. Maes died on 4 August 1908, and was buried in Berchem cemetery.

MALACRIDA, JULES (active 1840s–1890s)

French optician and photographer

Malacrida's date and place of birth remain unknown such as the elements about his childhood, training, death or possible heirs. Optician and daguerreotypist of the first times, he was active since 1840. Between 1848 and 1860, he cooperated with the Dr. Henri Jacquart to make daguerreotypes on anthropological pieces and animals from the *Museum d'Histoire Naturelle*. In *La Lumière,* Ernest Conduché spoke in praise of these works—for the major part collected in the *Catalogue des objets renfermés dans la Galerie d'Anthropologie du Museum du Jardin des plantes* (1857)—whose specimens were shown at the Academy of Science by Geoffroy Saint-Hilaire.

In 1850, he portrayed theatrical celebrities of his period and published a book dedicated to them with Charles Gabet. Set up at rue du Coq Saint-Honoré, 7, he was arrested in 1851 for distributing Félix-Jacques-Antoine Moulin's academic nudes. More severely convicted than the author—indeed, circulation was increasingly stigmatized by law than creation—Malacrida was condemned to one year of imprisonment and to pay 500 francs. During the trial, the President of the Seine Assize Court presented the incriminated photographs such as ''so obscene that giving their titles would be an outrage.'' Few years later, Malacrida associated with photographers and nudes diffusers addressed a petition to the Interior Minister to protest against the seizures they were subject. However, their petition to the authorities didn't receive the desired reaction, and consequentially their situation became one where with this petition, the government had at its disposal the names of the academic nudes actors market making it easier to target, control and censor their activities.

After this episode, he produced a series of portrait and scenic genre studies (36 negatives) entitled "Etudes d'après nature" published by Lemercier and registered for copyright purposes in 1853. This same year, he moved to rue de Vivienne, 12. Like his colleague Moulin, Malacrida started a more conventional career and left Paris for Toulon (south of France) in the beginning 1860's for an unspecified duration. He went on producing portraits, scenes of genre and negatives of monuments in collaboration with his wife. In 1870, he appeared once again at rue de Vivienne in the Parisian business registries and was supposedly active until 1895.

In 1980 and 1982, several Malacrida's daguerreotypes were sold respectively at Christie's (London) and Drouot's (Paris). At the moment, informations relating to his course and work are sparse and mainly combined with Félix-Jacques-Antoine Moulin's name and their justice issues.

FRÉDÉRIQUE TAUBENHAUS

Biography

Optician and daguerreotypist active from 1840 to 1895, he is essentially mentioned today for the diffusion of Félix-Jacques-Antoine Moulin's academic nudes and for the trial which resulted in 1851. Nevertheless, a major part of Malacrida's career has been dedicated to production of anthropological and zoological negatives, theatrical celebrities portraits as well as an important number of portraits, scenes of genre and photographs of monuments whose became his specialities, particularly after his justice issues.

MALONE, THOMAS AUGUSTINE (c. 1823–1867)

Malone was a competent chemist who worked with several early photographic processes but was usually remembered for his association with Talbot. Little is known of his early life. In 1844 he worked with Hippolyte Fizeau and Antoine Claudet etching daguerreotypes before being recruited by Nicolaas Henneman to work at Talbot's Calotype establishment at Reading. It was Malone that did much to refine and improve the Calotype process. When the establishment closed in 1847, Henneman and Malone opened a Calotype studio in London's Regent Street, which was funded by Talbot. Further support from Talbot allowed Malone to travel to Europe to meet distinguished photographic scientists. Around 1851 ill health caused Malone to leave the Regent Street business. After recovering, he became a lecturer and held posts at the Royal College

of Chemistry, the Royal Polytechnic Institution and the London Institution. He was a member of the Chemical Society and an active and often outspoken member of the Photographic Society of London.' When his post at the London Institution was abolished in 1864, Malone took a humble teaching job at a school in Clapham, South London. His health again became poor and in 1866, fearing for her safety and that of her five children, his wife committed him to Bethlem Hospital, a mental asylum. He died in Bethlem in 1867, a sad end that probably explains why his death does not seem to have been recorded in any major scientific or photographic publication.

JOHN WARD

MANN, MISS JESSIE (1805–1867)

Scottish assistant and photographer

Miss Jessie Mann was the assistant of the Scottish pioneering art photographers David Octavius Hill and Robert Adamson and one of the first woman photographers. She was born on 20 January 1805 in Perth, Scotland, the daughter of a house painter. She grew up there with her four sisters and one brother and her home was immediately opposite that of the family of D O Hill in a narrow street known as Watergate. When Jessie's father died in 1839 she moved with her two unmarried sisters, Elizabeth and Margaret, to live with their brother Alexander who had become a solicitor in Edinburgh. When Alexander married in 1842, the three sisters moved to a flat in Leopold Place, close to Rock House where Hill and Adamson set up their famous photographic studio.

Miss Mann in mentioned in two letters to D. O. Hill from his friend James Nasmyth dated 1845 and 1847. In the latter Nasmyth describes her as the "thrice worthy Miss Mann that most skilful and zealous of assistants." It is difficult to identify the photographs actually taken by Jessie Mann. It is recorded that on a tour of Britain the King of Saxony unexpectedly paid a visit to Rock House in 1844. The King of Saxony wanted to be photographed and as neither Hill nor Adamson were available "an assistant carried out the process." There are prints in the Scottish National Portrait Gallery. There are also photographs of the completion of the Ballochmyle railway viaduct in Ayrshire which could only have been taken in the spring of 1848 and Adamson had died earlier in January that year. These may also have been by Jessie Mann.

Like D.O. Hill Jessie and her two sisters in Edinburgh were supporters of the Free Church and Hill included them in his "Disruption" painting. It is said that two prints by Hill and Adasmon, one in the Scottish National Portrait Gallery and the other in Glasgow University Library, are of Jessie Mann. In both she wears a glove on her right hand and this could be to hide the stains of silver nitrate that would have been an occupational hazard for photographic assistants at the time.

When photographic activities ceased at Rock House following the death of Adamson, Jessie became the housekeeper of Andrew Balfour who ran a private grammar school in Musselburgh a few miles from Edinburgh. There is no record of her continuing with photography although she retained an interest and kept in contact with D.O. Hill. There is a personal letter to Hill from Jessie Mann in the archives of the Royal Scottish Academy dated 1856 which is in very person terms and refers to photography.

She later moved back to Edinburgh to live with her surviving sister. She died on 21 April 1867 a few months after suffering a stroke that paralysed her down one side. She was buried in the family plot at Rosebank Cemetery, Edinburgh. She never married.

RODDY SIMPSON

MANSELL, THOMAS LUKIS (1809–1879)

British doctor and photographer

Doctor Thomas Mansell was born on Guernsey in the Channel Islands in 1809, the eldest son of Rear-Admiral Sir Thomas Mansell and Katherine Lukis.

He was educated at Trinity College, Dublin and practised as a consulting physician as well as serving as a jurat (honorary judge) to the Royal Court of Guernsey.

Mansell, along with fellow photographers including Delamotte, Lake Price and Dr. Diamond, was one of the twenty founding members of the Photographic Exchange Club in the early 1850s. In 1854 he appealed for fellow members to supply lists of data regarding negative exposure time, development, paper manufacturer, maker,focal length of lens used, etc.

Mansell was interested in technical aspects of photography and experimented with different processes. Following his move from paper negatives to glass, he used his own 'syruped-collodion' formulae, which was convenient to use, but very slow.

A river scene, taken by Mansell in Northern France in 1856, was included in an 1857 Exchange Club album, complete with comprehensive technical information. Mansell used his syruped-collodion on a 11" × 9" glass negative (developed by pyrogallic acid) and the exposure was a full 47 minutes (in bright sunshine) with a 12.5" Ross lens. He used gold-toning to produce the finished print.

Mansell showed a selection of landscapes from glass negatives, all taken in the Channel Islands or northern France, at exhibitions between 1856–58.

IAN CHARLES SUMNER

MARCONI, GAUDENZIO (1842–1885)

Photographer

Gaudenzio Marconi (who appears in many writings under the first name, Guglielmo, is likely due to a confusion with the better-known Italian inventor) was born in 1842 in Switzerland, to a family of probable Italian origin. Few traces remain of the life of this author and his family.

Before becoming a photographer, Marconi is referred to in the documentation as an "artist-painter." Most of his photographs are images of nudes (albumen prints from wet collodium plates). During the period in which Marconi worked, nude photography was a widely popular genre, with frequently interwoven and overlapping variations in style and destination. Some of these photographs were made for private collections of a more or less openly erotic character (perhaps the majority of the daguerreotype nudes), but nude images were also frequently used in scientific journals in the fields of medicine, ethnography, and anthropology.

There was also a substantial production of these works made in photographic studios that became increasingly specialized. The work circulated in the form of actual catalogues and was destined for the use of artists, including painters and illustrators as well as for art schools. The major photographic studios, like Marconi's, that supplied this market also worked intensively on the business front. They would sometimes use external distributors for selling their works so that, once the works left the studio, they would then follow an independent course that might include many different passages. Given this scenario, it is easier to understand the reasons why certain situations occurred, such as the fact that Marconi acquired and sold some images by another well-known photographer, Auguste Belloc, under his own trademark, or the fact that some photographs taken by Marconi are either unsigned or attributed to his Austrian colleague Hermann Heid (owner of the major Viennese workshop specializing in the same kind of images), in a work such as *La Beauté de la Femme*, published by the Austrian Charles-Henri Stratz in a series edited by Paul Richer.

From the mid-1850s, the use of photographs in art schools became increasingly widespread and was a substitute for live models. At the *École des beaux-arts* in Paris specific classes were held in anatomy and morphology that relied on the use of large numbers of photographs. In general, nude drawing—the study of anatomical details and particularly representations of bodies in classical poses, the so-called *académies*—constituted a highly advanced level of teaching drawing. Starting from 1871, the Marconi studio mark bore the title "Photographe de l'École des beaux-arts," indicating his collaboration with that prestigious institution as a clear mark of distinction.

In relation to the work of other contemporary photographers engaged on the same theme, Marconi's photographs bear a number of distinguishing features. Firstly, his subjects: in a market that was heavily dominated by female nudes, Marconi often used male subjects. The compositions he created show particular attention to the plastic quality of the bodies, with a clear intent of highlighting the movements of the muscle masses. The subjects are almost always photographed against neutral backgrounds or simple landscape backdrops, making very little use of decorations or props except for a few essential drapes. The Michelangelo-style representation of the vigor and volume of the bodies comes through forcefully—contrary to the works of other artists—and excludes any evocation of unreal atmospheres or the adoption of sensual poses.

During this period, photography studios like Marconi's, increasingly open to models, artists, and decorators, were alive with all the debates and the technical and theoretical developments that characterized the artistic scene of the times, inevitably leaving a deep mark on the photographic works they produced. Evolving in close touch with this artistic climate, photography was sometimes reduced to an imitation of painting, while at other times it would develop absolutely original expressions that contributed to radically changing painting itself. In the images produced by Marconi, a strong innovation was introduced through the possibility of using photography to capture images of tensed bodies in positions that would have been very difficult for models to keep throughout lengthy painting sittings.

Like other artists of his generation, Gaudenzio Marconi left France in the 1870s due to the disastrous Franco-Prussian wars, which had a dramatic impact on the artistic community. The war left its mark on his work in a series of scenes that are quite exceptional in relation to the rest of his images (at least among those that have come down to us). This series depicts events relating to the siege of Paris, the most famous of which is *Pertes de la garde mobile après le combat de Châtillon*.

Records show that after 1870 Marconi was working in Brussels. Up to 1885, Marconi appeared in the commercial registry of Brussels, though as an artist resident abroad, working as both a painter and photographer.

This was the period of his collaboration with the sculptor Rodin, for whom he produced an image, the portrait of the soldier August Neyt (it is interesting to note that in this case he did not make use of a professional model), used for the creation of the sculpture *L'Âge d'airain* (*The Bronze Age*). Rodin also asked Marconi for a photographic reproduction of the work, which was presented in preview in Brussels in January 1877 and destined subsequently for the Salon of Paris. The Rodin Museum conserves two reproductions of *L'Âge d'airain* (front and back views) that bear the

stamp "Photographe des Beaux-Arts—Marconi—Place Gd Sablon 19—Bruxelles" on the back, as well as two standing portraits of the model, together with other photographs by Marconi with extensive cuts and pencil marks, testifying to the instrumental use of these images by Rodin and the collaborators of his *atelier*.

As far back as 1870, works by Marconi belonged to the collection of images coming from the legal deposit of the *École des beaux-arts* conserved at the *Bibliothèque Nationale de France* in Paris as well as in numerous private collections. His works often appear in catalogues of the galleries that deal in artistic photographs of the 19th century.

CLAUDIA CAVATORTA

Biography

Gaudenzio Marconi was born on March 12, 1842, in Comologne, in French-speaking Switzerland, to a family of probable Italian origin. He married Adrienne Fontaine, born in Amsterdam in 1844. As of 1862, Marconi, known as an "artist-painter" before becoming a photographer, worked in Paris, with studio at 11 rue de Buci. He specialized in photographs of nudes, which were mainly destined to art schools for teaching anatomy and morphology. As of 1869, in fact, he is registered as "photographe des beaux-arts," and from 1871 his studio trademark carried the title "Photographe de l'École des beaux-arts de Paris." In 1871, Marconi produced a number of scenes of episodes from the siege of Paris, and left France to move to Brussels. Initially he opened a studio in place du Grand-Sablon, and subsequently (as of September 22, 1876), in rue du Commerce. In 1877 he documented the sculpture *L'Âge d'airain* by Rodin. On July 23, 1879, he moved to Schaerbeck, on the outskirts of Brussels. Records show that he remained there until 1885, in rue Potter 5, working as both a painter and photographer.

MAREY, ETIENNE-JULES (1830–1904)
French scientist

Etienne-Jules Marey was a scientist—what we would nowadays call a biophysicist—who used a camera in his life-long investigation of the physiological laws governing human and animal movement. His methods and images were remarkably influential in the histories of photography, art, aviation, military reform, moving pictures, physical education, and scientific labour management.

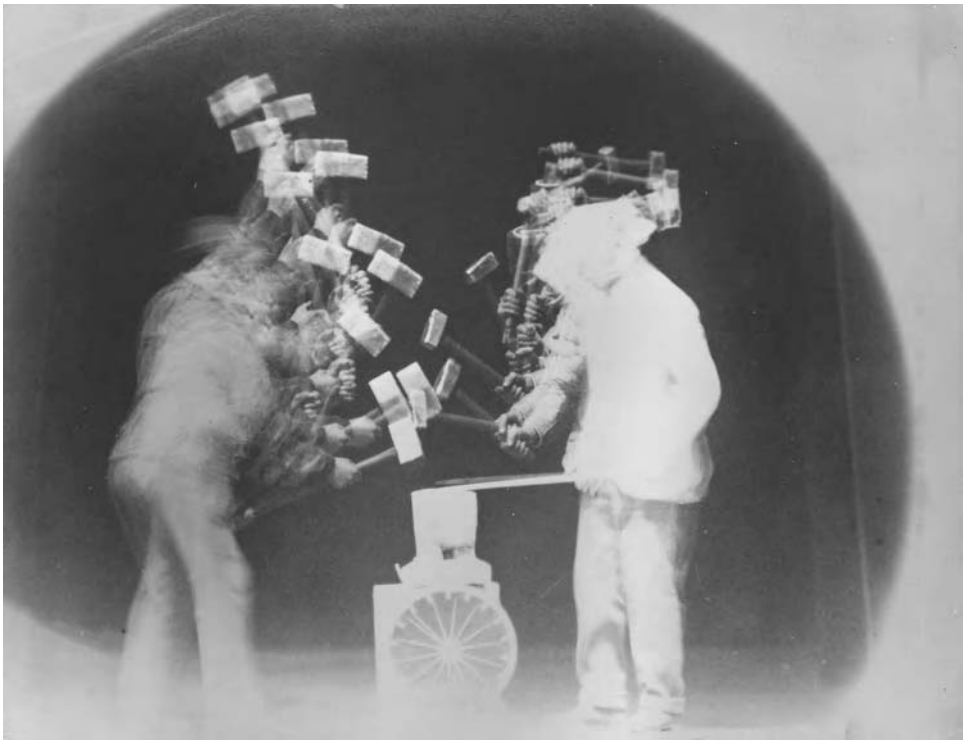
Marey was born 5 March 1830 in Beaune, capital city of wine-producing Burgundy in France. Following his father's wishes, he enrolled in Paris' Faculty of Medicine in 1849. He was drawn to the new science of physiology—the study of life processes—as a student, and after successfully passing his medical exams, he abandoned the life of a doctor for that of a physiological researcher.

Conceiving of the body as an animate machine run by a complex motor whose functions could be reduced to the newly discovered laws of thermodynamics—this was a radical concept in his day—Marey chose to study the body's most manifest form of energy: movement. He invented the graphic method, graphing instruments that traced the body's internal and external movements without interference by the practitioner. These are the mechanical ancestors of the electronic graphs and scopes universally used in medicine today.

The December 1878 publication of Eadweard Muybridge's series photographs of horses in the French journal *La Nature* showed Marey that photography could enhance the graphic method. In the winter of 1881–82 after meeting Muybridge in Paris, Marey made his first photographing instrument, a small rifle ("fusil photographique") that took twelve sequential images per second on a rotating glass disk. It was based on Jules Janssen's 1874 photographic revolver but was a notable advance, being portable, faster, and incorporating an automatic glass plate dispenser.

By summer 1882, Marey had moved his experiments to the Station Physiologique, the first large outdoor municipally-funded physiological laboratory in Europe built for him in the Bois de Boulogne. There he was aided by his talented assistant Georges Demenÿ and his mechanic Otto Lund. Marey spent each winter working on his photographic experiments at his villa in Posillipo, Naples, leaving Demenÿ in charge of the Station. This arrangement lasted until Demenÿ's 1894 departure in a disagreement over his commercialization of motion pictures.

Marey's photographic method, which he called chronophotography, was built upon his need to have what his graphing machines had provided: the visible expression of a continuous passage of time over equi-



Fremont, Charles and Etienne-Jules Marey. Trajectory of the Blacksmiths' Mallet and Hammer. *The Metropolitan Museum of Art, Purchase, The Horace W. Goldsmith Foundation Gift and Rogers Fund, 1987 (1987.1054) Image © The Metropolitan Museum of Art.*

distant and known intervals within a single tracing. He used a single glass plate in a single camera. Behind the camera's lens which was left open, Marey fixed a rotating metal disk shutter with from one to ten slots cut into it at even intervals. His subject—in these early experiments it was one of the soldier-gymnasts from the military school of neighbouring Joinville-le-Pont—was dressed all in white and moved in bright sunlight against a black background. As the shutter was rotated (by a crank) its slots exposed the plate, capturing the subject's movement as sequence of overlapping images.

To avoid the superimposition of limbs produced by too rapid shutter rotation, Marey devised a strategy astonishing for the way it operated against our usual understanding of the ontology of the photographic image, that is, that cameras inherently replicate all detail visible to the eye. He covered first half, and then the entire body of his subject in black and marked its joints in white. The resulting photographs rendered pure movement as graphic form.

With chronophotography Marey analyzed for the first time the mechanics of how we actually walk, run and jump and how the animals with whom we share this planet move. He also photographed the movement of the inorganic: the trajectories of projectiles, the geometric forms engendered by a string or wire moving around an axis, and water where there was no bearer or guide. In 1900 he moved into the area of aerodynamic forces, constructing the first wind tunnel in which he photographed smoke filets travelling around differently shaped planes.

In 1888 when paper negative stripping film appeared on the French market, Marey replaced his glass plate with a roll film and constructed a feeding mechanism for his camera. By early 1889 Marey had made a box to contain the bobbins, feeding mechanism and the film which he backed with opaque paper—one of the first examples of daylight loading film. His camera, films and the electric zoetrope he made to synthesize his films and photographs were the centre of the photography section at the 1889 Paris Exposition Universelle. And while Marey had no interest in reconstituting the illusion of movement, his work was the fundamental catalyst to all those like Edison, the Lumière brothers, and his assistant Demenÿ, who did.

Marey's graphing, photographing and cinematographing methods changed how the working body was conceived and how it was represented in both the social and aesthetic domains. He provided a scientific basis for developing the endurance of the soldier, and for the creation of a national physical education program in France. His instruments were used to analyze worker's movements and even to rationalize a physiological basis for psychology. After his death a new European science of work emerged out of his analyses. In America his separating of the phases of locomotive acts was complicit in the work of Frederick Taylor and his time-and-motion-study associates.

After Marey's death, chronophotography also influenced how the body was represented in art. The radical transformation of the experience of time and space created by the speed and pace of life at the turn of the

century, by the experience of the newly industrialized workplace, and by new technologies—the telephone, telegraph, automobile, phonograph and cinema, made Marey's chronophotography appealing to artists who sought ways of expressing modernity. For Marcel Duchamp, Franz Kupka and the Italian Futurists, in particular, Marey's chronophotography, both scientifically accurate and lyrically graceful, supplied a language with which to depict the kinetic and emotional dimensions of the subject, materialize the forces of the invisible, and give visible form to speed and dynamism.

MARTA BRAUN

Biography

Born 5 March 1830 in Beaune, Etienne-Jules Marey was the only child of Marie-Joséphine Bernard and Claude Marey. A researcher in the physiology of movement, Marey took up photography in 1882 as a way of expanding his graphic method of recording motion. Marey's contributions to medicine—he was a pioneer of cardiology—and physiology made him an important figure in the French scientific and photographic establishment . Elected to the Chair of "Organized Bodiesli" at the Collège de France in 1869 and the Academy of Sciences in 1878, he became president of that institution and the Société française de photographie in 1895. He was the author of more than three hundred scientific articles and seven books. He collaborated with Nadar, the Lumière family, Ottomar Anschütz, Gustave Eiffel and the aviation pioneer Victor Tatin. Marey died of liver cancer in Paris 15 May 1904.

MARGARITIS, PHILIPPOS (1810–1892)

Greek photographer

Philippos Margaritas is generally accepted as having been the first Greek photographer. Born in Smyrna in 1810, he spent his student years in Italy practising painting. In 1842, he was appointed teacher at the School of the Arts, where he taught Basic Drawing until 1863. He was introduced to photography in 1846–47 by the French photographer Philibert Perraud who visited Athens and within the next year he experimented with the new medium using a daguerreotype camera that had been offered to the School of Arts. In 1849, he opens the first photographic studio in Greece in the garden of his house on Klafthmonos Square. His themes were initially the ancient classical monuments and portraits of members of the royal court, fighters of the Greek War of Independence, politicians and ladies dressed in regional costume. Faithful to his training as a painter, Margaritis coloured over many of his early photographs with great precision and detail. He often travelled abroad and kept abreast of the most recent developments in photography. His frequent travels made it necessary for him to find a permanent partner for his studio. In 1870, he started his collaboration with the painter Ioannis Constantinou. Ten years later, Ioannis Lambakis became the firm's third partner.

ALIKI TSIRGIALOU

MARION AND COMPANY

Marion and Company was the largest and most important supplier of photographic equipment and material in Europe during the second half of the nineteenth century. By 1896, its retail catalogue ran to 135 pages, listing products that ranged from retouching desks to trimming knives. The frontispiece proudly declared that the firm had won nine medals for the work it had exhibited. These included awards at the Exposition Des Produits De L'Industrie (Paris, 1844), the Exposition De L'Industrie Francais A Londres (London, 1849) the Great Exhibition (London, 1851), and the L'Exposition Universelle (Paris, 1878).

Marion and Company was a French stationary and

fancy goods firm with outlets in both London and Paris. The French base of the firm was connected to Auguste Marion, who published several works on photography from the late 1850s onwards, often with particular reference to the paper used in the printing process. In 1856, an advertisement in the *London Post Office Directory* described the firm as "Stationers, importers of fancy goods and photographic papers." Based at 152 Regent St and 14 Cité Bergère, Paris, *Papeterie Marion* were, at this stage, still primarily importers of French luxury goods. They sold photographic paper alongside all varieties of decorated mourning and wedding stationery (their first advert for photographic paper in *The Times* was June 30, 1854). Their subsequent growth was a product of the commercialisation of photography during the late 1850s, and is a testimony to the high-quality albumen prints required by photography.

Marion and Company is often credited with introducing the *carte-de-visite* to Britain in 1857. They were the market leaders in the supply of celebrity photographs, a position that lasted for several decades. Throughout this period, they were located at 22–23 Soho Square, and they later had their own factory at Southgate in Middlesex. Marion and Company, a wholesale house, acted as both as a central supply point and as a distribution hub for many major photographers, including John Jabez Edwin Mayall, Camille Silvy, and the Southworth Brothers**.** Mayall was reputed to have been paid £35,000 by Marion and Co. during the 1860s for his *carte-de-visite* of the British royal family. The firm stocked thousands of celebrity photographs of every kind, in preparation for sudden changes in demand such as the death of a well-known figure. An article in *Once a Week* by Andrew Wynter described how Marion and Company made the celebrity *carte* into a modern phenomena:

> This house is by far the largest dealer in *cartes de visites* in the country; indeed, they do as much as all the other houses put together. The wholesale department of this establishment, devoted to these portraits, is itself a sight. To this centre flow all the photographs in the country that "will run." Packed in the drawers and on the shelves are the representatives of thousands of Englishwomen and Englishmen awaiting to be shuffled out to all the leading shops in the country. (Andrew Wynter, *Subtle Brains and Lissom Fingers*, 304)

Marion and Co. were instrumental in turning the *carte-de-visite* into a general consumer artefact. In 1862, their London manager, Mr. Bishop, stated that 50,000 *carte-de-visite* passed through the firm's hands every month. In later years they published their own sets of pictures such as "Marion's Series of Eminent Political Men" (24 × 18 inches and sold for between one and three guineas).

Marion and Company sold a wide range of photographic equipment and apparatus, particularly photographic albums and paper. The success of the *carte-de-visite* went hand-in-hand with the growing popularity of photographic albums for collecting celebrity and family photographs. Similarly, *carte-de-visite* themselves had to be pasted onto cards, which were often printed with the photographer's name on the reverse, often with additional decoration. Marion and Company's expertise as stationers and sellers of fancy good made them ideally suited to supply the burgeoning trade in printed photographic product. As the century progressed though, they slowly expanded their range of good, particularly in the 1880s and 1890s when the advent of dry plates helped to make photography accessible to a large number of amateurs. In 1884, they were advertising a complete beginner's set for £2 10s. By 1896, the cheapest "Nonpareil" introductory set was only 30 shillings. It came complete with camera, a dozen plates, lens, tripod, focusing cloth, and all the necessary solutions.

In 1884, *Marion's Practical Guide to Photography* was published, specially written for the use of amateurs. It was republished in 1885, 1886, 1887, and 1898, and was one of most successful photographic handbooks. A review in the *British Journal of Photography* declared that the book dealt "in a lucid and practical manner with the various operations connected with every department of the science while the *Queen* similarly noted that "A great many ladies practise photography, and they will appreciate the instructions here given."

At the same time as it tapped into the market for amateur photography, Marion and Co. continued to supply the professional studios with equipment like scenic backgrounds (£0 50s in the 1880s) and retouching apparatus. The firm supplied the latest apparatus by most other major photographic manufacturers, such as lenses by Ross**,** Voigtländers and Dallmeyer. However, it also took out several patents in its own name. In the 1880s, these included Marion's own "Parcel" detective camera, which had plates 4¼ × 3¼ inches, and was disguised as a parcel through being covered with brown linen paper and tied with string.

One technique that was re-introduced to great effect by Marion and Co. was the Cyanotype. In 1881, the firm reintroduced it under the name of the "Ferro-Prussiate or blue process." The process was used to make cheap reproductions of drawings, patterns and plans, and became popularly known as the "blueprint." The firm sold prepared papers to government departments, shipbuilders, railway companies, and architects.

Unsurprisingly, the firm remained especially pre-eminent in the supply of all forms of stationery connected to photography, particularly albums, printing paper and all types of card mounts. Its photographic mounts won a gold medal at the *L'Exposition Universelle* in 1878 and a silver medal at the London Inventions exhibition

in 1885. The albums of Marion and Company even attracted the attention of *Punch* in its edition of 24 December 1881:

> In acknowledgement of having produced the handsomest, most decorative, and most original Album for Photographs, we hereby decorate Mr Marion (of *Marion & Co.*) with his own patent clasp, and create him Duke of St Albums. The public will send him their orders.

Punch's comic praise testifies to the prominence and repute and of the firm. Marion and Co. reaped the benefits of being one of the first firms to treat photography as an industry.

MARISSIAUX, GUSTAVE (1872–1929)
Belgian photographer

Born in Marles-les Mines (Pas-de-Calais, France) in 1872, Gustave Marissiaux was the youngest of three brothers and son of Gustave Léopold Marissiaux, a mining architect. In 1883, the family left France for Liège, Belgium, the region of origin of Marie Therese Micha, Marissiaux's wife. Once of age, each child of the family became a Belgian national.

In the beginning of the 1890s, Gustave Marissiaux chose to study law, but photography soon turned him away from it. In 1894, he became interested in photography, and was elected as a member of the Association Belge de Photographie [Belgian Association of Photography] (A.B.P.), the spearhead of Pictorialism in Belgium. A lecture Marissiaux gave in 1899 to the Liège section of the A.B.P., which was published the following year in the bulletin of the association, directly showed the photographer's interests. With the title "Art and photography it clearly defined the issues of artistic photography, like how to express, through the plasticity of the image, the personality of its author, or to reveal the "temperament" of the subject. To meet this criterion, Marissiaux drew on painting more than inspiration, as a method. Frequenting museums in Belgium and France led him to elect Corot, Delacroix, and Rembrandt as models. The study of their works guided Marissiaux to a deep understanding of composition and the relations between colours and work on shadows determined his approach of photography. Contemporary painters like Le Sidaner or his friends Auguste Donnay and Armand Rassenfosse, supported his look. It was therefore not surprising to find in his early works the influence of British Pictorialism, and particularly of Peter Henry Emerson. The country views that showed an isolated figure going about its duties ("Le Bûcheron" ["The Woodcutter"], 1896) recall the motives dear to the British photographer. The naturalism of the subjects evoked the open air painters and their will to find their sources of inspiration in outdoor sceneries, in opposition to academic staged imagery. But Marissiaux did not only share with Emerson this common reference to painting. His visual processing also related to the British master, through the attention given to the graduated shading, to light variations and to atmosphere rendering. One could read this in the numerous landscapes and forest interiors, with a hint of symbolism ("Coup de vent sur les hauts plateaux" ["Blowing wind on the Highland's"], 1901). By his platinum printings, Marissiaux gave these landscapes a dimension of mystery, which expressed a part of hidden, of unutterable, characteristic of the symbolist aesthetic.

Beyond these landscapes, Marissiaux also made portraits, both as a professional and as an artist. Although it might seem contradictory for a member of Pictorialism—that assumes the status of the "amateur," in the noble meaning of the term—Marissiaux opened a portrait studio in 1899. This professional activity that he apparently dissociated from his personal work, remained unrecognised, with most of the studio negatives being lost.

Nevertheless, portrait occupied a key position in Marissiaux's work. In the room of his studio, he devoted himself to "Studies," staging young girls whose attitudes denote an activity or a state of mind ("Liseuse" ["Reader"], 1899, "Mélancolie" ["Melancholy"], 1899).

A number of them allowed a purely photographic interpretation of forms and matters, and illustrate a work of lights and contrasts, as their title, "Studies," indicates.

Broadly spread in exhibitions organized by the A.B.P., but also in photographic exhibitions abroad such as Berlin (Royal Academy, 1899), Roubaix (International Exhibition of Photography, 1900), and Glasgow (International Exhibition, 1901), and printed in national and international reviews, Marissiaux's works give him access to unanimous recognition, making him a leading photographer of Belgian Pictorialism.

To these supports is added another one: the luminous projections. Organized annually by the Liège section of the A.B.P., they achieved open success by the general public. Marissiaux almost systematically took part in these projections, between 1894 and 1924. It is in that context that he set up, in 1903, a sort of "total spectacle" entitled "Venice." It proposed, in Liège Conservatory, a projection of photographic views of the lake city, accompanied with a poem recitation and music for choir, and orchestra, composed by his friend Charles Radoux. The new version of this show, presented in 1906, gave rise to no less than 26 representations, in Belgium and abroad.

Italy was for Marissiaux a genuine source of inspiration. From 1900 onwards, he travelled there every year, and visited most Italian cities of art. The photographs taken during these travels represented an important part of his work, consisting mostly of oily inks (Rawlins process). These allowed Marissiaux to dissolve details into an evanescent and coloured rendering that particularly suited the representation of Venice. He chose to regroup those Venice views in an homonymous album, published in 1907.

Surprisingly enough, the largest public success was brought by an order that orientated Marisisaux onto unexplored paths, namely social photography. Formulated by Liège Syndiciate of Coal Board, this commission consisted of illustrating the industry of coal mining in the Liège area. The photographer was invited to work with stereoscopy, to reinforce the impression of the spectator of a true immersion into the coal mining reality. Presented in 1905 at the Universal Exhibition of Liège, the result of this order was composed of 450 pictures, a third being stereoscopic views. Entitled "The Coalmine," this series also gave birth to gum-bichromate prints that became widely exhibited. Some of them also appeared in the album entitled "Artist's Visions." This portfolio reproduced in photogravure 30 pictures that retraced Marissiaux's career between 1899 and 1908.

The attractiveness of colour on the photographer manifested itself not only in his use of autochrome, in 1911–1912, but also in the experimentation with the process of a Flemish photographer, Joseph Sury. Allowing coloured paper prints, this experimental process still remains enigmatic today. Marissiaux applied it to the nudes as well as to genre scenes and landscapes, in the 1910s and 1920s.

Interrupted by World War I, Marissiaux's creative activity was bluredr in the course of the 1920s. As Pictorialism lost steam, the death of his parents and his wife pushed the photographer to become introspective, and he exiled himself to Cagnes-sur-Mer, in the south of France. He died there in 1929.

Presently, the Museum of Photography of Charleroi preserves the work of the photographer, except the negatives of the "Coalmine" series, which are deposited at the Musée de la Vie Wallonne in Liège.

DANIELLE LEENAERTS

Biography

Gustave Marissiaux was born in 1872 in Marles-les-Mines (France). He moved to Liège (Belgium) in 1883. As a law student, he took up photography in 1894, and was elected the same year to the Belgian Association of Photography (B.A.P.). His country views denote a symbolist influence. Portrait is also an important part of his work. He not only practised it as a professional, in the studio he opened in Liège in 1899, but also as an artist, in numerous "Studies." Recognized as one of the most important Belgian Pictorialist, he not only took part in the national Salons of the B.A.P., but also in several European Salons. By combining photography projection, poetry and music, he created a new form of "total spectacle," based on his images of Venice (1903). A public order was addressed to Marissiaux by the Syndicate of Coal Board. This series of stereoscopic views entitled "The Coalmine," and the album "Artist's Visions" (1908), are Marissiaux's most well-known works. He also elaborated a colour technique with the collaboration of Joseph Sury, in the course of the 1910's and 1920's. Exiled in Cagnes-sur-mer (in the south of France) in 1925, he died there in 1929.

MARKETS, PHOTOGRAPHIC

When Louis-Jacques-Mandé Daguerre and William Henry Fox. Talbot announced their eponymous processes, neither could have envisaged the range of markets to which their inventions would be applied before the end of the century—although both men offered some early suggestions. Daguerre foresaw the primary applications of his invention being of benefit to travelers, archaeologists and naturalists—as well as the more obvious uses such as portraiture.

Also foretelling the public's enthusiasm for portraits, landscape and pictures of buildings and places, Talbot additionally predicted some novel applications of his invention. In *Pencil of Nature* (1844) he not only pioneered the photographically illustrated book as a potentially massive market for photographs, but suggested, amongst other applications, that a photographic inventory of a collection of antiques would be infinitely more useful than a written one, asking his readers, "'and would a thief afterwards purloin the treasures—if the mute testimony of the picture were to be produced against him in court—it would certainly be evidence of a novel kind?"

Others were just as enthusiastic about the potential applications of photography. The Scottish engineer Alexander Gordon, suggested to the Institution of Civil Engineers in London as early as 1840 that photography would enable "views of buildings, works, or even of machinery when not in motion, to be taken with perfect accuracy in a very short space of time and with comparatively small expense."

Such a use of photography, he suggested, would be of great value to architects and engineers, especially when managing projects at a distance. History proved him correct. The minutes of the first meeting of the newly formed Photographic Society of London on February 3, 1853, record that the engineer Charles Blacker Vignoles, who,

> … made a few remarks in illustration of the great service which the new art would be likely to render to engineers and others having to superintend important works which they could only occasionally visit, or having to make intelligible to foreign employers speaking a different language, with whom they could interchange ideas only imperfectly in conversation, the details of blocks and ropes, and complicated constructions.
>
> He instanced the pictures taken of the works now going on at Kieff for the suspension bridge he was erecting for the Emperor of Russia, over the Dneiper, on which photographic views had been taken weekly during the whole time of its construction, and especially of the method of raising the chains from the first tightening of the ropes to the final elevation of the whole to its proper position, which have been shown with the greatest accuracy and detail.

Here he was referring to the work of John Cooke Bourne, who reportedly chronicled every stage in the bridge's construction through to its opening later that year.

By the end of that decade, industrial photography had established itself as an essential market for photographers worldwide, with progress photography becoming an essential feature of every major construction project, from Ben Mulock's images of the construction of the Bahai Railway, 1859–1862 (another Vignoles project), through to Evelyn Carey's record of the construction of the Forth Bridge in Scotland as the century drew to a close.

The accuracy and reliability of the "evidence" offered by a photograph inspired and drove most early commercial applications. The first photographs brought back from ancient Egypt were avidly collected by academic institutions and scholars, who saw the value of the photographs as enabling studies to be undertaken without the time and expense incurred in actually visiting the locations. The subscription list for Francis Frith's *Egypt and Palestine Photographed and Described* (London, James S. Virtue, 1857), for example, includes many universities and colleges, and many leading academics, alongside the rich and influential.

Roger Fenton's contracts with the British Museum in the 1850s permitted the establishment of an independent sales point within the museum foyer, through which Fenton sold copies of many of the images of museum objects which the Trustees had commissioned him to produce, thus establishing the prototype for today's ubiquitous museum shop. This took the marketing of images of antiquity one stage further as, in addition to sales to academics and specialists, these photographs were sold to the more affluent members of the museum-visiting general public.

Just as with the Egyptian images of Frith and others, many of Fenton's commissions for the British Museum were published in bound editions. His 1856 photographic copies of the Museum's *Clementine Epistles* were produced in an edition of fifty sets, with printed introduction and bound in blue covers. Again, like Frith's Egyptian volumes, these were predominantly sold to museums, universities and wealthy historians, with at least three copies going in to the Museum's own library.

Photography was first exhibited at London's Hyde Park Great Exhibition of 1851, and by the time of the Exposition Universelle in Paris four years later,

commercially produced stereoscopic daguerreotypes, ambrotypes, and glass diapositives of the displays were available for sale, alongside paper prints from glass negatives, at special booths inside the exhibition halls.

By the time of the Centennial Exhibition in Philadelphia in 1876, the use of photography at exhibitions had been further extended by William Notman, with the creation of photographic identity cards for the exhibition staff and exhibitors, initiating the huge market for ID cards that now exists.

Today's market for photographs as advertising can trace its genesis back to the very earliest days of the medium. Daguerreotypes of industrial machinery, clocks and watches, and other commercial products, survive from the early to mid 1850s, the purpose for which can only have been promotional. By the height of the *carte-de-visite* era, the ubiquitous paper print format was also being widely used to allow travelling salesmen to demonstrate the full range of products from the companies they represented—and without the cumbersome bulk and weight of daguerreotypes.

The daguerreotype also played a limited but nonetheless significant part in the introduction of photography for the expanding tourist market mid-century—the most notable example being the concession operated at Niagara Falls by Platt D Babbitt, creating the ultimate memento of a visit, with the tourists posed against the magnificent backdrop.

Once the high cost of large paper prints began to decline in the 1860s, and the higher costs of travel declined as well, the advent of cheap rail travel—especially in Europe—and the parallel introduction of cheaper photography, created a vast market for tourist imagery. This market was dominated by, amongst others, such figures as Samuel Bourne in India, Francis Frith and George Washington Wilson in Britain, William Notman in Canada, Kusakabe Kimbei in Japan, the Adelphoi Zangaki, Pascal Sebah and others in Egypt, and Carleton E Watkins and others in America. Especially along the routes of the European and Middle Eastern Grand Tours—which grew in popularity from the 1860s—numerous photographic studios were established explicitly to cater for the growing tourist market.

The *carte-de-visite* was more crucially influential in the popularisation of the tourist image—and can be seen as the direct predecessor of the picture postcard market which emerged as the nineteenth century drew to a close and which dominated the twentieth century. The much lower price of the *carte-de-visite* and the common format with the family album ensured that the tourist image became just as much a part of family history as the portrait.

The first, and most obviously popular, market to be exploited commercially was, of course, portraiture, and the world's first professional portrait studio was opened by Alexander S Wolcott and John Johnson on March 4, 1840. The New York *Sun* carried an account of the opening:

> Sun Drawn Miniatures—Mr A. S. Wolcott, No. 52 First Street, has introduced an improvement on the daguerreotype, by which he is enabled to execute miniatures, with an accuracy as perfect as nature itself, in the short space of three to five minutes. We have seen one, taken on Monday, when the state of the atmosphere was far from favourable, the fidelity of which is truly astonishing. The miniatures are taken on silver plate, and enclosed in bronze cases, for the low price of three dollars for single ones.

The first photographic studio opened in France is believed to have been that of Nicholas-Marie Paymal Lerebours, which operated from late spring 1841, but Richard Beard opened what is believed to have been Europe's first professional photographic studio at London's Royal Polytechnic Institution, on March 23, 1841, just a few weeks earlier than Lerebours.

High costs limited the market for photographic portraits in the early years largely to that stratum of society which might previously have aspired, even if it could not quite afford, to have a miniature painting made. It would be the 1860s before reducing costs, simplified techniques and processes, and the advent of the populist carte-de-visite saw the portraiture market burgeon.

By the end of the nineteenth century, most cities were heavily over-populated with photographic portrait studios—many of which would never achieve a level of financial viability. In London, for example, from Beard's original studio in 1841, the number of active photographic studios in the city had swelled to almost three hundred.

Wedding photography, today one of the mainstays of the profession, first came into popularity in the mid 1850s. Bridal portrait and full-length daguerreotypes by Southworth & Hawes of Boston survive from c.1854, with other portraits of wedding couples by unknown photographers surviving from the same period. While some of these earliest examples of the genre show the bride in a wedding dress, the majority of early wedding photographs were taken after the event, with the bride and groom, hands interlinked, presenting the bride's left hand and wedding ring to the camera. In many early daguerreotypes and ambrotypes, of course, with their lateral reversal of the image, it appears to be the bride's right hand which is offered to the lens.

Four years later, in 1858, the wedding of the Princess Royal, the eldest daughter of Queen Victoria, was photographed by Caldesi, whose pictures included the eighteen year old bride with her parents, and a group picture of her eight bridesmaids. Indeed Queen Victoria, a staunch supporter of early photography in general, also did much to popularize the wedding picture in

Britain. To mark her fourteenth wedding anniversary in early 1854, she and Albert posed before Roger Fenton's camera as if they were a wedding couple, Albert in full dress uniform—black boots replacing the white leggings of his wedding tunic—and Victoria in a simplified recreation of her 1840 wedding dress.

Within a decade, with photographs of Royal weddings widely available as cartes-de-visite prints, the popularity of the wedding photograph had started to grow exponentially. From the mid 1860s, photographers regularly advertised 'wedding groups' in the range of commissions they undertook, and by the end of the century the wedding photograph was an expected part of marriage costs. The specific album of wedding photographs, while not unknown in the nineteenth century, was largely a twentieth century innovation.

After the wedding, the photograph of the baby was an obvious market to develop, and with child mortality much higher in the nineteenth century, deathbed portraits of children also proved a significant if somewhat macabre market for the high street professional. In the event of unexpected infant death, the deathbed portrait often proved the only tangible proof that the child had ever lived.

Socially, the photograph as entertainment also provided a lucrative market for photographers—especially with the introduction of the drawing-room stereoscope in the 1850s. Companies such as the London Stereoscopic & Photographic Company in Britain, and Underwood & Underwood in America, published sets of stereo cards on a wide range of subjects including humour, religion, travel, and news. Individual stereo cards were available for sale from photographers and print-sellers, and specialist journals such as *The Stereoscopic Magazine* further popularized the medium.

In the days before the advent of the half-tone illustration in newspapers, boxed sets of stereoscopic views of important events and news stories would be marketed very quickly after the event they portrayed. Often sold in boxes resembling leather-bound books, these sets sold in large numbers despite the fact that they commanded a high price.

The market for photographically illustrated books was one of Henry Fox Talbot's early predictions, and despite the high cost of his 1844 *Pencil of Nature*, it established a market for photographers which has grown ever since. While such volumes were restricted by the need to paste in real photographic prints, costs were high and production runs small, but the demand grew consistently. With the advent of the Woodburytype in the 1870s, production became somewhat easier, the permanence of the images considerably better, and the number of illustrated books published annually considerably greater.

MARTENS, FRIEDRICH (1809–1875)
French inventor and photographer

Friedrich Martens (sometimes incorrectly styled as von Martens), a resident in Paris presumed to be of German origin, designed and built the world's first daguerreotype panoramic camera in the 1840s, the first camera capable of taking, with a single exposure, a view wider than the field of vision of the human eyes.

The camera had a field of view of 150° and a geared mechanism for rotating the lens which required the controlled turning of a small handle at the side of the camera. The lens, pivoting around its centre, was connected to the camera body by a flexible leather front sleeve. At the same time, a 'v' shaped aperture traversed the curved plate making the exposure, effective exposing the sky to a smaller aperture than the foreground, and overcoming the daguerreotype's tendency to solarised in the over-exposed sky. The camera manufacturer was Paris instrument-maker, N. P. Lerebours.

By 1851 he was using collodion, and was awarded a medal for his "talbotypes on glass" [sic] at the Great Exhibition which read "for richness, effect and perfection of definition, they are the finest specimens it seems possible to produce."

He joined Léon Méhédin in the Crimea photographing scenes of the conflict, subsequently published by Bisson Frères, both men later working with Jean-Charles Langlois producing panoramic images during and after the same campaign.

JOHN HANNAVY

MARTIN, JOSIAH (1843–1916)

English-born author and publisher

Josiah Martin (1843–1916) commands high respect and a special position in the history of development of new Zealand photography. A Londoner by birth he came to New Zealand in the 1870s to establish a College of Education in Auckland. For various reasons he gave this up and turned to photography. Eventually Martin became heavily involved with an area in the middle of the North Island called the Hot Lakes District. Over a short period of time, he wrote, illustrated and published several pamphlets, papers and booklets which sang the praises of the districts tourist potential. In 1889 his work in this direction was rewarded with him being elected as the president of the Auckland Institute and Museum. Another great achievement saw him appointed to the post of editor for *Sharland¹s New Zealand Photographer,* a journal which he edited for many years. During his tenure in this position, he advocated vociferously for the injustices that were being dealt to photographers when it came to taxes and government inaction on matters that threatened their copyright over their images. He was also one of the first photographers to make extensive and tours of some of the Pacific Islands with his camera. The results of these excursions were turned into illustrated lectures with the use of a magic lantern.

William Main

MARTIN, PAUL AUGUSTUS (1864–1944)

French photographer and wood engraver, resident of Great Britain

Growing up in an era of political, technological and cultural change, Paul Augustus Martin holds a pivotal position in the evolution and growth of modern photography. Although a Frenchman by birth and by choice (he retained his natural-born citizenship throughout his life), Martin emigrated to London, England, in his youth and became a permanent resident of that city for the remainder of his life. The majority of his education, the home of his family, and the basis of his commercial and artistic life would all emanate from and resound throughout Great Britain.

Martin was born in the village of Herbeuville, France, on April 16, 1864, but at the age of five he moved with his family to Paris. The timing could not have been worse as the city endured the joint horrors of the Franco-Prussian War of 1870 and the misadventure of the Paris Commune in 1871. The family, including young Paul, faced tragedy (the loss of his younger sister) and near death on numerous occasions and immigrated to London by 1872. There the family was able to make a permanent home and Paul prospered as a student, fascinated with sports and excelling in mathematics and drawing. Following a brief period of attending preparatory school in France, he completed his private school education in London and passed his exams in 1880.

Deciding to pursue his drawing talents, Paul apprenticed himself to a wood engraver in 1880, became a professional in 1883, and excelled in the heyday of this art throughout that decade—wood engraving enjoying a popular period of growth in the illustrated press of the day. It was also during this same decade that Martin became fascinated with amateur photography, learning the technology of dry plate processing on his own and purchasing his first camera, a quarter-plate Le Meritoire, in 1884. For the next four years he continued to work in the circles of his wood-engraver friends, employing the camera on a very limited basis for holiday outings, camping trips and vacations. Despite the limitations his amateur album of this period displays a fine technological skill and a careful professional eye, probably derived from his artistic education and experience.

By 1888, however, things began to change rapidly. Martin discovered the ever-burgeoning amateur photography movement in England with its proliferation of photographic journals and its explosion of photographic salons and camera clubs with their interesting speakers, debates and competitions. It was a dynamic period in photography's history with its established pictorialists and "old-school" photographers facing the dramatic aesthetic and cultural changes being wrought by the myriad new camera and processing technologies of the era. Not of the class or the wealth to engage in the Pictorialist traditions of the masters of the age, Martin applied himself to newer aesthetics that the dry-plate (and later the roll-film) cameras were establishing. By 1889, when he won his first amateur photographic competition, he was hooked.

The decade of the 1890s would mark the time of his greatest proliferation as well as personal change. Martin still worked as a wood engraver, but he took his cameras everywhere—and the resultant imagery reflects both his excitement and mastery of the new medium and a growing understanding about the vast potential of an era of massive photographic change. During this mature amateur period he became an active figure throughout the London camera clubs and salon exhibitions—always coming up with new original imagery and trying new techniques. His purchase in 1890 of a Facile camera (a dry-plate instrument that could be concealed in a nondescript bag and could handle up to 12 exposures) led him out into the streets of London where he captured candid photographs of "London street types" which had not been seen before. The work, while fitting somewhat into the earlier documentary traditions of photography, was clearly innovative, aesthetically mature and definitely unlike any such imagery that had come before. The street types—often manipulated with hand-drawn bases and

dubbed "living statues"—were the hits of many lantern slide evening presentations and gained Martin important notices and awards at the time. He would amplify the work to more expansive environments when he also carried the hidden camera on vacations to other British locales such as the port of Whitby, the beaches of Yarmouth, and even on Swiss vacations.

The other innovative pioneering work for which he became famous derived from his continuing fascination with the aesthetic applications of newer technological innovations. Martin experimented with a variety of nature phenomena—waves at sea, dawns and sunsets, and long exposures—before he hit upon his most resounding work: night photography. Finding new ways to handle such traditional nighttime problems as halation, exposures and incidental light, the photographer began in 1895–96 to produce elegant and complex images throughout the rain-covered, foggy streets of an urban London that was itself in the days in which gas lighting was being transformed by electricity. Martin's "London by Gaslight" won him the widest fame of all, as well as the gold medal of the 1996 R.P.S. annual exhibition and the notice of the established Pictorialists of the day. No less a figure than George Davison offered Martin a position with the rapidly growing Eastman Kodak Company in 1898.

By the century's end, however, Martin made a deliberate professional choice himself. In 1899, he sensed the end of his profession of wood-engraving in an era in which press illustrations were being transformed by photomechanical reproductions of the photographic image itself. Together with Henry Gordon Dorrett he established a professional firm—variously known as Dorrett & Martin or as Athol Studios—that featured everything from freelance press photography to commercial processing and even specialized applications for portraiture such as photo-buttons and other miniature novelties. Although the enterprise was apparently highly successful from a commercial perspective, it effectively ended all of Martin's serious photography. Although he never abandoned making his own photographs—his later work includes pictures of the street and of sporting events as well as more holiday travels—he maintained his time and focus upon running the business.

At the end of 1926 Dorrett & Martin closed their doors. In old age Martin was eventually rediscovered by the camera clubs—which engaged him to give entertaining lectures based upon his Victorian era photographs—and numerous publishers which featured his work and/or reminiscences in newspapers, magazines and books of the day. In 1939 (photography's centennial year) he was encouraged and assisted by C.H. Gibbs-Smith, Research Fellow at the Science Museum, to publish a small autobiography, *Victorian Snapshots*, which would introduce his innovative "amateur" work to an entirely new generation of photographers. He lived in retirement with his two sons and, perhaps ironically re-haunted by the wars of his youth, passed away from natural causes during the London Blitz on the evening of July 7, 1944.

Martin's original prints are found in many important collections around the world. The main bulk of his amateur imagery—prints, negatives, lantern slides and an early album—form an important part of the Gernsheim Collection at The University of Texas at Austin. His manuscript diary and albums of wood engravings and other prints are in the possession of the Fine Arts Library, University of New Mexico General Library, Albuquerque. A large collection of imagery collected by the Royal Photographic Society, is now housed in the National Museum of Photography, Film and Television in Bradford.

ROY FLUKINGER

Biography

Paul Martin was born in rural France in 1864, and moved with his family to Paris in 1869, in time to survive the dangers of both the Franco-Prussian War and the Paris Commune in the following years. The family then moved to London, which would become Paul's adopted home for the remainder of his life. Combining a talent for drawing together with top grades in London and Parisian schools, he apprenticed himself to a Fleet Street engraving firm in 1880. His childhood fascination with the visual world eventually led him to become interested in amateur photography and to purchase his first dry-plate camera in 1884. Throughout the 1880s Martin joined photographic societies, read all he could about the technology and art of the medium, and honed his own skills on holidays and street scenes. The 1890s would mark his mature amateur period, during which he experimented with various light effects and documentary imagery—as well as doing revolutionary work in the areas of night photography and candid street images (made with a concealed plate camera called the Facile). During this same decade, he won both a certain fame and many awards from various amateur competitions throughout a number of London salons and camera clubs. Most critically of all, he came to recognize that his own profession of wood engraving was being replaced by photography and the increased use of such images in the popular photomechanical press of the day. In 1899 he made the jump, opening a firm in partnership with Henry G. Dorrett that featured everything from freelance press photography to commercial processing and specialized applications for portraiture such as photo-buttons. Although he never lost his aesthetic eye and always continued to experiment with the latest technological innovations, the management of his business cut deeply

into his own image-making and his commercial career soon undercut his active photographic endeavors. While never giving up entirely on photography, he closed down his business in 1926. He spent the remainder of his life reviving his early street photography of the late Victorian era, saw many of his pictures published in the popular press, and became a favorite lecturer in his beloved camera clubs showing his images and relating his experiences. He published his autobiography in 1939 and died in obscurity during World War II, but major holdings of his prolific imagery exist in many collections with the bulk of his archival materials surviving in the Gernsheim Collection at The University of Texas at Austin, the Fine Arts Library of the University of New Mexico, and the National Museum of Photography, Film and Television in Bradford.

MARVILLE, CHARLES (1816–c. 1879)
French photographer and illustrator

Marville was born in Paris and worked there all his life, but little is known about his biography. He had aspirations to a career as a painter, but seems to have had minimal access to academic training. By 1835 he was designing wood engravings, contributing a number of minor illustrations to Léon Curmer's illustrated edition of *Paul et Virginie*. He continued producing wood engraving designs and lithographs through the 1840s, providing illustrations for numerous publications, including Charles Nodier's *La Seine et ses bords* (1836), and Pierre Boitard's guide *Le Jardin des plantes* (1842). Marville also designed the panoramic view of Paris which graced the masthead of *L'Illustration* (1843). In July 1848 he received his only documented painting commission, a copy of Le Sueur's *La Mort de Saint Bruno*, for a provincial church. Around 1850 Marville started to make photographs.

Where and with whom Marville learned photography is unknown, but by the end of 1851 he had begun producing negatives for Louis-Desiré Blanquart-Evrard's manufactury in Lille. Many of these fell into the genres of landscape and monument views with which Marville was familiar, and an equal number were reproductions of works of art, work he had undertaken to a lesser degree in lithography. Marville contributed more negatives to Blanquart-Evrard's publications than any other photographer—at least one hundred, spread throughout most of the firm's albums, including all the views for the 1853 travel album *Les Bords du Rhin*. Around the same time he secured a position as photographer at the Louvre, where he photographed diverse works of art and the interiors of renovated galleries, such as the "Salle des Caryatides" published by Blanquart-Evrard. A vague pattern of working methods emerges here: Marville seems to have held some sort of contractual relationship with Blanquart-Evrard, the Louvre, and perhaps others, and he retained at least some negatives to use at his discretion. The nature of his work is further hinted at in an 1851 letter to the Ministry of Public Works, wherein Marville identifies himself as *Artiste-Peintre* and member of the Société héliographique (the only evidence of his membership in the society), and seeks access to state-owned historical monuments to make exterior and interior views, as well as photographs of objects housed in the buildings, for "an important photographic publication in preparation"—presumably one of Blanquart-Evrard's albums.

As early as his engagement with Blanquart-Evrard, Marville probably intended to earn a living by his photography. Like many photographers of the moment, he contributed inventions to facilitate photographic work: a negative chassis designed for travelling in 1851, and a method for transporting collodion negatives from glass to paper in 1857. But Marville never joined the Société française de photographie, which was slanted towards the rarified world of amateurs, and he would not share the secrets of his negative transport method with that group. On the other hand, he managed to secure an assignment to photograph collections of old master drawings in Milan and Turin for the Louvre; he also forged a relationship with the painter Ingres, who commissioned Marville to make photographic records of many of his drawings. All three of those drawing collections earned the photographer money for the rest of his career.

In 1856 *La Lumière* reported Marville's use of the wet collodion process to record the arrival of the Imperial Family at Notre Dame, for the baptism of the Prince Imperial. By 1858 Marville's shift to collodion was complete, as was his turn to contemporary Paris for photographic subjects. That year he was hired by some branch of Haussmann's administration to document the newly refurbished Bois de Boulogne, a jewel of Napoleon III's modernizing plans for Paris, and an important piece of propaganda at home and abroad. The album he produced (exhibited at the 1862 International Exposition

Marville, Charles. Rue de Constantine, Paris. *The Metropolitan Museum of Art, Purchase, The Horace W. Goldsmith Foundation Gift, 1986 (1986.1141) Image © The Metropolitan Museum of Art.*

in London) is a mélange of wooded landscapes similar to photographs made by Marville and others at places like Fontainebleau Forest, other views of a coiffed yet immature landscape, and records of the new built elements in the park. Marville's confrontation with this strange, modern space seems to have pushed his thinking about photography: wooded landscapes recede from his work, and urban topography becomes a central subject for the next twenty years. Moreover, his adeptness at organizing many details within the picture frame—evident in his calotypes (see for instance his series of the Ecole des Beaux-Arts and his Louvre interiors)—was broadened as he modified old landscape conventions which applied neither to photography nor to the new green spaces of Haussmann's Paris.

The change in Marville's subject matter certainly owed most to his continuing relationship with the city administration. The *Service des Promenades et Plantations* (which emerged from the Bois de Boulogne project) employed him to document the urban furniture of the new boulevards as well as the parks and squares which proliferated around the city. Around 1865 Marville received another commission, from the newly formed *Service des Travaux historiques*: a series of more than four hundred views of streets slated for demolition. In these repetitive views Marville's approach to photography, and to modern Paris, is remarkably expressed. Buildings frame and structure every view, producing stable—though not precisely symmetrical—compositions; vantage points are calculated to maximize length of perspective and the number of elements in the frame; views are often taken at a crossroads. Time and again the result is deep perspective, a multiplicity of options for the roaming eye, and a maximum of information. In 1877, the *Service des Travaux historiques* again approached Marville, for a series of one hundred views recording the wide boulevards which replaced the earlier streets. These, along with many of his records of street furniture, were exhibited at the 1878 Exposition Universelle in Paris. Throughout these years Marville continued to take a variety of freelance assignments, most often working with architects and builders to record their projects. He also retained the negatives from all his work for the city.

Marville seems to have remained aloof from the journals and societies which comprised the Parisian photography scene, and he received little notice in his lifetime. When he is mentioned, the high quality of his work is emphasized. Notably, Nadar refers to Marville's "remarkable" collections in the city archives. Reception of Marville was also muted in the twentieth century, in part because his long professional career and low profile did not accommodate critical preoccupations with calotype photography and *amateur* aims. However, given Marville's position as a predecessor to Eugène Atget, who presumably knew the earlier photographer's work well, and perhaps modelled his own quite different project on it, Marville's continued relative obscurity in photographic literature is surprising. For instance, the many researchers who might have embraced Marville's urban records in the

1930s—including Berenice Abbott, Giséle Freund, and Walter Benjamin—apparently overlooked him.

Many of Marville's photographs still reside in the archives for which they were made. Comprehensive holdings of his urban documentation are at the Bibliothèque historique de la Ville de Paris, the Musée Carnavalet, and the Bibliothèque administrative de la Ville de Paris. The Bibliothèque historique also possess 837 of Marville's glass negatives. The Musée des Monuments français holds a number of photographs from Marville's various projects, which were acquired from the photographer by the Commission des Monuments historiques. The Bibliothéque nationale in Paris has an extensive collection of Marville's calotype work, and the Bibliothèque municipale de Lille holds a concentration of his calotypes produced for Blanquart-Evrard.

PETER BARBERIE

Biography

Charles Marville was born in Paris in 1816. By the age of nineteen he had begun a career designing wood engravings and lithographs for books and illustrated journals. All we know of his artistic training is that at some point in the 1830s he frequented the Académie Suisse, a place where paying attendees (Courbet among them) could draw from a live model. In 1848 Marville received a commission from the state to paint of copy Le Brun's *La mort de Saint Bruno* for the Church of Saint Nicholas de Neufchâteau, in the Vosges. There is no other evidence of his career as a painter, and no known paintings by him survive. By 1851 he was practicing photography, making many images both for the Louvre and for the photographic publishing establishment begun in Lille by Louis-Desiré Blanquart-Evrard. From that point his freelance work expanded, and he seems to have enjoyed a lucrative career making art reproductions, public works records for various city agencies, and architectural photographs for architects and builders. Marville lived and worked at many Paris addresses during his photographic career: 14, rue du Dragon (1851–53); 27, rue Saint Dominique (1854–60); 6, rue de la Grande-Chaumière (1861); 86, rue Saint Jacques (1862–67); 75, rue d'Enfer (later 111 and then 75, rue d'Enfert-Rocherau) (1867–79). He exhibited at the Société française de Photographie in 1857, 1864 and 1865; his work was shown at the International expositions in London in 1862, Paris in 1867 and 1878, and Vienna in 1873. The record of Marville's death remains to be found; on September 20, 1879, one Armand Guérinet acquired his business and negatives, eventually selling the latter to the Service des Travaux historiques.

MASURY, SAMUEL (c. 1820–1874)

Samuel Masury was a prominent American daguerreian artist who learned the process from the renowned John Plumbe Jr., with whom he was associated for many years. One of Masury's most notable images is a portrait of Edgar Allen Poe taken in November 1848, less than a year before the writer's mysterious death at age forty.

Born in Salem, Massachusetts, around 1820, Masury was educated in the public schools of Boston. He became a carriage maker, but took a deep interest daguerreotypes upon their introduction in 1839. In 1842, he became affiliated with Plumbe, and in 1843 he established his daguerreotype gallery in Salem, operating as Masury and Company.

Masury also operated a gallery in Providence, Rhode Island, and operated it from 1845 to 1852. In 1851 or 1852, Masury was seriously injured while experimenting with oxyhydrogen. A fire ignited a large bag of oxygen gas, causing an explosion while Masury was standing on the bag.

Although he never fully recovered from his injuries, Masury moved to Boston and resumed resumed making daguerreotypes, and later collodion negatives. He operated galleries on Washington Street from 1852 to 1867. He also began producing images for *Ballou's Pictorial Drawing Room Companion* journal, where his photographs were reproduced as woodcut engravings.

MATTHIES-MASUREN, FRITZ (1873–1938)

German photographer, collector, and publisher

Fritz Matthies-Masuren, born in Insterburg, East Prussia on February 12, 187, was the son of the Superintendent of construction Otto Friedrich Albert Matthies and his wife Ida Johanna, and an important proponant and theorist of pictorialism in Germany. He studied painting at the Academy of Fine Arts for two years in Karlsruhe but developed a particular interest in lithography and the graphic arts. Between 1894 and 1902 he was active as a photographer (mostly of portraits and landscapes). Matthies-Masuren became an editor of and contributor to photographic journals like *Photographisches Centralblatt* [*Photographic Central Periodical*], *Photographische Rundschau* [*Photographic Review*] and *Das Atelier des Photographen* [*Photograph's Studio*], where he supported the new ideas of pictorialism. He published on the theory of pictorial photography and curated large exhibitions which travelled through Austria and Germany around 1900. Although he continued to take part in the developments of photography until the 1920s, from 1910 he became less and less active in writing. Matthies-Masuren resigned from his editorial work in 1938 and died on 10 September that year in Berlin. His collection of pictorial photographs was bequeathed to the Museum of Arts and Crafts library in Berlin, now the *Kunstbibliothek* Berlin, in 1914.

Stefanie Klamm

MAULL & CO. (MAULL & FOX, MAULL & POLYBLANK)

Henry Maull and his successive partnerships form one of the most outstanding examples of Victorian photographic portrait work, and their publication of the photographs of celebrities of the day, starting in 1856, was the first of its kind in the world. It was rapidly imitated allover Europe during the succeeding decades, as was the use of a brief biographical essay to accompany each portrait.

The senior partner, Henry Maull (1829–1914) began his career as an artist and printer in Bloomsbury, close to his birthplace in Clerkenwell In 1854 he went into partnership with George Henry Polyblank (1828–?) in a studio at 55 Gracechurch Street, in the City of London and two years later, in May 1856, began the issue of "Photographic portraits of living celebrities issued on a monthly basis, with biographical notes for the first four by Herbert Fry, thereafter by Edward Walford. The first number featured Richard Owen; the entire sequence ran as follows: 1) May 1856, Richard Owen; 2) June 1856, Thomas Macaulay; 3) July 1856, Robert Stephenson; 4) August 1856, John Roebuck; 5) September 1856, Sir Benjamin Brodie; 6) October 1856, Edward Hodges Bailey; 7) November 1856, Samuel Warren; 8) December 1856, Professor Thomas Graham; 9) January 1857, Edward Matthew Ward; 10) February 1857, Lord Campbell; 11) March 1857, George Cruikshank; 12) April 1857, Rowland Hill; 13) May 1857, Sir William Fenwick Williams; 14) June 1857, William Frith; 15) July 1857, Cardinal Wiseman; 16) August 1857 Lord Brougham; 17) September 1857, Martin Farquhar Tupper; 18) October 1857, Michael Faraday; 19) November 1857, John Gibson; 20) December 1857, Earl of Rosse; 21) January 1858, Charles Kean; 22) February 1858, William Gladstone; 23) March 1858, Sir Archibald Alison; 24) April 1858, William Stemdale Bennett; 25) May 1858, David Uvingstone; 26) June 1858, Earl of Aberdeen; 27) July 1858, Daniel Maclise; 28) August 1858, Lord Stanley; 29) September 1858, Dr. Tait, Bishop of London; 30) October 1858, Austen Layard; 31) November 1858, Clarkson Stanfield; 32) December 1858, Lord Panmure; 33) January 1859, John Buckstone; 34) February 1859, Comte de Montalembert; 35) March 1859, Samuel Lover; 36) April 1859, Lord John Manners; 37) May 1858, Bishop Samuel Wilberforce; 38) June 1859, Sir John Lawrence; 39) July 1859, Lord Colchester; 40) August 1859, Archbishop of Canterbury. In October 1859, the complete set was issued in book form, distributed by William Kent & Co.

The series was an overwhelming success. *The Literary Gazette* (October 18, 1856) commented 'We acknowledge with unmixed satisfaction the excellence of the portraits. They are as successful specimens of the art as any that have yet appeared, both as to the pose of the figures, and in sharpness and delicacy of detail. They have also the advantage of being simply printed from the negatives, and entirely free from any after touches." Their success was matched by a parallel series of portraits collectively known as "Literary and Scientific Portrait Club," it was issued 1855–c 1858, without text. Among those included were the cream of the Victorian scientific world—Darwin, Playfair, Lanchester, Lyell, Murchison, Bowerbank, De La Rue, Gosse, etc. Several incomplete sets exist—one of 54 portraits, at the National Portrait Gallery, another series of 95 at the Linnean Society. The club itself "was instituted for the purpose of attaining a uniform set of portraits of the literary and scientific men of the present age at a moderate cost." The terms of admission to the club being that each member having a photograph of himself taken by the artists of the club, Messrs Maull and Polyblank, at the cost of 10s. 6d'.

The success of these series enabled Maull and Polybank to open a second studio at 187a Piccadilly, Westminster in May 1857, and a third, at 252 Fulham Road, Chelsea, in 1864, specialising in equestrian portraits. A private album of similar portraits was issued in 1856,

with eleven portraits, under the title "On the introduction and progress of the screw propeller" notably featuring Francis Pettit Smith and Charles Manley.

The partnership was dissolved March 8, 1865, and Maull continued the firm as Maull & Co., closing the City studio and opening a new one at 62 Cheapside. Polyblank filed for bankruptcy November 2, 1867, and was eventually discharged in the following January. A persistent rumor in the Polyblank family suggests that he emigrated to the United States in the late 1860s, but no further trace of him has been recorded, and the end of his career is unknown.

In 1877, Henry Maull reconstituted the firm, and took as his partner his former manager, John Fox (1832–1907). As Maull & Fox, the firm soon closed the surviving City studio, and concentrated their photographic work at 187a Piccadilly, a second-floor studio situated above the well- nown bookshop, Hatchards. The partnership was dissolved after only eight years, on May 21 1885, but Fox's son, Herbert Fox (1870–) continued the firm, assisted by Frederick Glover after Maull's retirement to Ramsgate in 1890. He died in Brighton June 26, 1914, a year after Maull & Fox became a limited company in order to acquire the Piccadilly business. In 1924 the West End studio was moved to 200 Gray's Inn Road; it was wound up October 26, 1928, and the copyright and negatives acquired by the Graphic Photo Union, eventually absorbed into Kemsley Newspapers, publishers of the *Sunday Times*, in 1952.

Like many other Victorian photographic studios, Maull found the transition to the twentieth century a leap too far. In addition, their substantial contracts with the illustrated weeklies to supply a constant stream of portraits for reproduction as wood engravings, began to decline dramatically with the introduction of photogravure and the rise of specialist firms. The firm's very static poses, with an occasional prop, had gone irretrievably out of fashion by the end of the nineteenth century .

Henry Maull's elder brother, George Maull (1820–1885) operated two photographic studios in the Lewisham area of South London in the 1860s and 1870s, but is not known to have participated in the West End studios. A good selection of work by Maull's various partnerships is held by the National Portrait Gallery, with smaller collections at the Victoria & Albert Museum & Hulton Getty.

MAWSON & CO. (ESTABLISHED 1828)

The company originated as Mawson and Company in 1828 when John Mawson (1815–1867) began trading in Newcastle-upon-Tyne, England, specialising in pharmaceutical products. Mawson followed the photographic discoveries of the times and once the new discipline was established, he began to produce the necessary chemicals. By 1848, he had engaged Joseph Wilson Swan (1828–1914) as his assistant, but made him a junior partner in 1865, by forming Mawson & Swan. Within two years, however, Mawson was killed in a nitro-glycerine explosion whilst officiating as Mayor of Newcastle and Swan took control. Mawson's widow was Swan's sister and Elizabeth now joined the company to supervise publishing and bookselling, and when the company eventually relinquished its interest in photographic materials, it continued to trade as Mawson, Swan and Morgan, into the middle of the twentieth century.

Swan had previously worked for six years as an apprentice to a local firm of druggists and joined with knowledge of chemistry and the evolving photographic processes. It was natural for the two men to explore aspects of emulsion making, and Mawson introduced his partner to local contacts and then constructed a small workshop for him above the pharmacy, at 39 Moseley Street, Newcastle. By 1854, Swan had perfected the production of collodion, and the company entered the growing photographic market by launching Mawson's Collodion. For forty years, the product maintained its reputation, as many testimonials confirm—"the first of its kind, the best as well, and doubtless the most largely used and widely sold of all collodions in existence."

Another success came in February 1864, when Swan patented the carbon printing process, which provided distinctive photographic prints, free from deterioration. The company marketed carbon prints, as well as the materials for making them, and offered the process under licence to third parties, such as The Autotype Company, which later purchased the rights. (In 1885, Swan also negotiated a business partnership with Thomas Annan, Glasgow.) Swan's expertise in working with electricity led to the invention of a carbon filament light bulb (1879) and variants of the invention were adapted for photographic applications, such as standardising studio lighting and controlling variable for exposing carbon prints and bromide prints.

Swan's success with the carbon process had capitalised on the company's prowess in combining a suitable gelatine for making the print, and a powerful lamp for making the exposure. With a general manager

replacing Mawson, the company continued to innovate and in 1871, addressed the growing market for silver emulsions, in liquid form, and later as dry plates. During preparation, Mawson & Swan utilised a heating stage to improve sensitivity. Production, however, was hampered by the need to coat dry plates by hand, a procedure George Eastman later dismissed as "tedious and slow."

To augment its negative materials, the company achieved a singular success in 1879, when Swan devised and patented the gelatino-bromide paper process based on silver bromide. Improved machinery was installed to ensure uniformity of coating of the paper base, which was "adapted to the production of bold and vigorous prints." Because of its sensitivity, it was "specially useful for enlargements and the matt surface made it "scarcely distinguishable from the finest Platinotypes."

At the time, Europe was considered to be the centre of photographic expertise, and English companies successfully traded in America. A young American entrepreneur, George Eastman, was impressed that the high prices were not affected by the lively competition. He had invented a machine which would replace hand-coating and once he received patent-protection in London, he intended to persuade the important manufacturers to purchase it.

He sailed to Liverpool in 1879, and received introductions to some English companies, including Mawson & Swan, but only made a few unsatisfactory sales. Eastman returned to America, and two years later, relinquished his position at Rochester Savings Bank so as to concentrate on the manufacture of dry plates at his own small factory. Soon he received complaints about product quality and he was forced to shut down production. Lacking a solution, he returned to England in March 1882 and appealed to Mawson & Swan. He was permitted to "stand in the works" for two weeks, during which time Eastman realized that his supplier of gelatine had changed its specification. He immediately struck a deal with his hosts whereby Eastman agreed to exchange manufacturing secrets for Mawson & Swan's emulsion-making knowledge.

Mawson and Swan published a catalogue covering chemicals, scientific apparatus, microscopes, electrical, magnetic and physical apparatus, and part four was "a singularly comprehensive work, enumerating everything in the way of photographic apparatus and materials, and containing prices and graphic illustrations of all articles used by the amateur or professional photographer." In addition, the company issued helpful booklets, such as, *The Wet Collodion Process, How to Make Transparencies, Photography Simplified*, and *Gelatino-Bromide Paper Process, Contact Printing and How to Make Enlargements*, to promote its papers. To encourage the use of its premium plates, the company regularly awarded silver medals for areas of specialisation, such as "instantaneous marine photography."

In 1892, the company adopted Hurter and Driffield's procedures for plate testing, and with justification claimed its "Mawson" was "the quickest plate" on the market, but recommended its Castle Plate "for all ordinary purposes." In a private note to Vero Charles Driffield, however, J. Smith Green, Mawson & Swan works manager, complained that "those who use Oxalate Iron for development are quite exceptional …." Improvements continued, and in 1896 Mawson & Swan was producing "extra rapid" plates for studio work, and special plates for the emerging "instantaneous" market (i.e., the use of hand-held cameras.) A representative's report stated: "Electric plates are taking on splendidly; the professional photographers appreciate them this dull weather, and everyone who has tried them is delighted with them."

Although much altered from the pharmaceutical company established early in the nineteenth century by John Mawson in a shop in Mosley Street, Newcastle, and which had evolved as the Head Office, Mawson & Swan had also established works in Newcastle and Gateshead, a dry plate factory at Low Fell, (on the south side of Gateshead), and offices and warehouses in Soho Square, London, to handle distribution throughout Europe and America. Despite the staff pension fund terminating in 1973, Newcastle recognised the company on October 12, 1978, by hosting an exhibition of its achievements.

MAXWELL, JAMES CLERK (1831–1879)

English physicist and inventor

Three photographic plates of a tartan ribbon, taken in 1861 by Thomas Sutton through red, green, and blue filters, were used by James Clerk Maxwell to demonstrate that photography in colour could be a practical proposition. Positive lantern slides made from those plates, each projected back through the taking filter,

could be reassembled on the screen to recreate the full colour of the original ribbons.

Maxwell was born in Edinburgh on June 13, 1831, and the family moved to Kirkcudbrightshire in 1834. He was educated at home for some years, but later studied at Edinburgh Academy and Edinburgh University before periods at Peterhouse and Trinity Colleges in Cambridge.

His first academic appointment was at Marischal College in Aberdeen, but four years later he was appointed Professor of Natural Philosophy at King's College, London. Already recognised as one of the eminent physicists of his day, he quickly developed a reputation as a leading authority and thinker on electro-magnetism, and was the first to offer the proposition that light was a form of electro-magnetism. He also conducted early research into colour blindness.

By 1871 he was the first Cavendish Professor of Physics in Cambridge, and a major force behind the design and establishment of the world-famous Cavendish Laboratory.

He died on November 5, 1879, at the age of only 48.

JOHN HANNAVY

MAYALL, JOHN JABEZ EDWIN (1813–1901)

John Jabez Edwin Mayall was one of the most enduringly successful professional photographers in nineteenth-century Britain. Born in Oldham in 1813, Mayall's photographic career began when he moved to Philadelphia in late 1841 or early 1842, working there at 140 Chestnut Street as a photographer until 1846. While working in Philadelphia between 1843 and 1844, Mayall made an important series of ten daguerreotypes depicting scenes from The Lord's Prayer. This illustrative use of photography was highly innovative and prefigures later work by Oscar Rejlander and Julia Margaret Cameron. In 1848, Mayall's brochure for his London studio claimed that "These are the first efforts in developing the new branch of *photographic fine art*. . .Female figures (some of the most beautiful and talented ladies of Philadelphia) have been chosen to embody the precepts of this Divine Prayer." Subsequent narrative pictures included studies of *Macbeth*, *Hamlet* and Thomas Campbell's poem "The Soldier's Dream." Many of these tableaux were shown at the Great Exhibition in 1851, where the catalogue called them "Daguerreotype pictures to illustrate poetry and sentiment."

In June 1846, Mayall returned to London. For a short while, he served as an assistant to Antoine Claudet, before setting up his own studio at 433 Strand. Mayall initially operated under the name of Professor Highschool at the "American Daguerreotype Institution." American daguerreotypes were known for their exceptional clarity and Mayall was numbered among the first rank of photographers. In April 1847, the Athenaeum reviewed the work of Kilburn and Mayall and declared that the pair were "both so fertile in resource and imagination, that in their hands it will probably be proved that this art is as yet only in its infancy." One notable feature of Mayall's work at this stage was his repudiation of the practice of colouring daguerreotypes; he was worried that a reaction with the photographic chemicals would harm the permanency of the image.

Mayall, John Jabez Edwin. The Prince of Wales (Edward VII). *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

According to Baden Pritchard, Mayall's great coup came in 1851 when he was asked to take pictures of the Great Exhibition. He subsequently became friends with Prince Albert and, in 1855, was invited to photograph the British royal family. In 1855, the military authorities also turned to him for advice. Two soldiers, Ensign Brandon and Ensign Dawson, were trained by Mayall for a month so they could operate as photographers in the Crimea. His improving commercial fortunes are also reflected in his opening another establishment at 224 Regent Street in 1853, which was expanded to 226 Regent Street in 1856.

Mayall was responsible for several technical developments: throughout his career he was concerned with improving the potential of the medium. On 25 January 1853, he took out a patent for the production of imitation

crayon drawings. As early as October 1850, Mayall had written to the *Athenaeum* detailing his process, and had exhibited examples at the Great Exhibition. His invention interposed a slowly revolving disc between the camera and the object being pictured. The disc, arranged on a support, had a star-shaped hole in its centre. The revolving star design made the resultant photograph similar to a vignette portrait. In 14 October 1855, Mayall also took out a patent for the making of artificial ivory to receive photographic pictures. Another area of expertise was in the enlargement of photographs. He claimed credit for being the first photographer to successfully use the collodion process to enlarge and copy daguerreotypes.

After the Photographic Society of London was founded in 1853, Mayall took an active interest in its proceedings, attending meetings and giving several papers. He was also a member of the committee set up to organise a testimonial fund for the widow of Frederick Scott Archer. His perceived debt to Archer is evident in that that, of the £747 raised, he was the largest contributor.

When photography became a commercial medium, Mayall was one of the principal beneficiaries. Unlike many of the gentlemen amateurs who dominated photography in the mid 1850s, Mayall enthusiastically embraced the rage for celebrity portrait *carte-de-visites*. In 1858, he took part in a venture with D.J. Pound, the publisher of the *Illustrated News of the World*. Together they published a series of engravings of eminent personages that were based on photographs by Mayall. Along with Maul and Polyblank's *Photographs of Living Celebrities* (1856–58), the venture represents one of the earliest attempts to exploit the value of celebrity photographs.

Mayall's commercial prosperity was secured when, in May 1860, he was again invited to Buckingham Palace to photograph the royal family. Mayall's *Royal Album* was published in August 1860 and was a phenomenal success. Consisting of fourteen *carte-de-visites* of Victoria, Albert and their children, it was the ever first set of royal photographs that were widely available. The *Athenaeum* claimed that each portrait reproduced "with a homely truth, far more precious to the historian than any effort of a flattering court painting, the lineaments of the royal race." In March 1869, the British Journal of Photography reported that Mayall had been paid £35,000 by Marion & Co. for his royal pictures. He went on to publish several sets of royal photographs, including the wedding photographs of the Prince and Princess of Wales in March 1863.

Mayall's royal patronage led to numerous commissions from distinguished personages such as Gladstone, Lord Derby, and Lord Brougham:

> Imitating this high example, distinguished persons of rank and pursuit availed themselves of the photographer's services, and left him with a negative impression of themselves, from which thousands could be printed. (M.A. Root, *Camera and Pencil,* Philadelphia: J.P Linnicot, 1864: 381)

Prior to the introduction of the Copyright Bill in July 1862, one innovative feature of Mayall's celebrity *cartes-de-visite* is his attempt to counter the numerous quasi-illegal reproductions. In the early 1860s, many of his pictures are inscribed with his initials and the date of their exposure. This inscription was intended to act as the equivalent of an official trademark, which it would be illegal to copy.

Several London establishments were managed under Mayall's name from the 1860s to the 1890s, as he himself moved to the genteel environs of Brighton in 1864. His studio at 433 Strand later was complemented by others at 224 Regent Street West 1853–94; 224 and 226 Regent Street (1857–67); 15 Argyll Place, West (1859–67); 164 New Bond Street West(1881–1886); 90-91 King's Road, Brighton (1864–1904). Mayall & Co. operated at 164 New Bond Street (1887–92); 73 Piccadilly West (1893–96); 126 Piccadilly West (1897–1908). In Brighton he continued his work as a photographer through a studio in King's Road and his career is remarkable for its sheer longevity. He was a Photographic Society Council member in 1875 and, in 1880, his Bond Street studio was one of the first London establishments to use electric light. In Brighton, Mayall also became involved with local politics. He was elected as a councillor in 1871, an Alderman in 1874, and was Mayor between 1877 and 1878. Other late honours include being elected a fellow of the Royal Institution in 1864 and of the Chemical Society in May 1871.

Mayall died on 6 March 1901, bringing to an end a remarkable photographic career that spanned sixty years.

JOHN PLUNKETT

Biography

John Mayall was born in Oldham in Lancashire in 1813. His father, John Meal, was a manufacturing chemist in West Yorkshire. Mayall, who was born Jabez Meal, married Eliza Parkin in 1834, with whom he had three sons and one daughter. He left Britain for Philadelphia in late 1841 or early 1842, returning to London in 1846 and resumed his professional career. His first studio was at 433 Strand (1847–55). Many of the later studios were managed under Mayall's name as he himself moved to Brighton in 1864. Mayall was one of the foremost daguerreotypists during the late 1840s and maintained his reputation when he moved to collodion process dur-

ing the 1850s. Best known for his pictures of the Great Exhibition and the British royal family, it was the advent of the celebrity *carte-de-visite* that secured his commercial fortune. Other publications include *The Illustrated News of the World and National Portrait Gallery of Eminent Personages* (1858–63), *Royal Album* (1860), and *Mayall*'s *Celebrities of the London Stage; A series of photographic portraits in character* (1867–68). After being widowed, Mayall married for a second time in 1871, and had two daughters and one daughter by Celia Victoria Hooper. A prominent member of the Brighton community in later life, he died on 6 March 1901.

MAYER AND PIERSON COMPANY

The fashionable Parisian commercial photography firm of Mayer and Pierson, consisting of Ernest Mayer, his brother Frédéric and Pierre Louis Pierson, was first established as Mayer Frères in the early 1850s as a purveyor of photographic supplies and studio portraits. Pierson, a daguerreotypist, joined the firm by 1854 and the company operated out of lavish studios on the Boulevard des Capucines serving such powerful Second Empire figures as Napoleon III and his one-time mistress the Countess de Castiglione (Virginia Oldoini), actress Rachel and composer Rossini. The firm, together with the many others that populated Paris during this period, was nurtured by the modernizing principles of Napoleon III which promoted photography as both a symbol of modern France and a desirable luxury good. Specializing in studio portraits, celebrity c*artes-de-visite* and the use of such novel processes and techniques as the ambrotype, Mayer and Pierson reached the pinnacle of its success in the late 1850s and early 1860s through a fruitful combination of artistry, technology and sound business practice; by 1862, however, Ernest Mayer had sold his share of the company to Pierson, who had taken over the business. In 1874 Mayer and Pierson was sold to Pierson's son-in-law Gaston Braun and was incorporated in 1876 under his father, the photographer Adolphe Braun. Pierson remained manager of the company until 1909. The Mayer and Pierson archive of glass plate negatives is housed by the Musée d'Unterlinden in Colmar and photographs representing the firm can be found in the collections of the Metropolitan Museum of Art, the J. Paul Getty Museum and many private collections.

The reputation of Mayer and Pierson rose above that of many other Second Empire commercial firms because of its illustrious clientele and high profile commissions, proficient use of hand-coloring to enhance its products, state of the art studios, effective use of advertising, prominent displays of photographs at World's Fairs, satellite studios in London and Brussels, publication of *La Photographie considérée comme art et industrie* in 1862, and successful lawsuit to change copyright laws during the same year. Napoleon III is believed to have first visited the Mayer Frères studio in 1853 and continued his family's relationship with the company until at least 1860. In 1856, the Emperor selected the firm to be the official photographers of the world leaders gathered for his triumph of diplomacy, the Paris Peace Congress. The following year Napoleon III whimsically appeared with the Empress Eugénie, their son and his pony for a portraiture session at the studio. The company, however, had its detractors, including their competitor Nadar, who denigrated the photographers as portraitists, claiming that "they restricted themselves, very profitably, to one style . . . of picture. . . . Without a thought for composing the picture in a manner favorable to the sitter" (*The Second Empire*, 1978, 421).

The Emperor, though, seemed not to notice this and encouraged members of his court to patronize Mayer and Pierson, among them his Italian mistress the Countess de Castiglione, with whom he had an affair between 1856 and 1857. The Countess worked with Pierson frequently between 1856 and 1867 and then only sporadically until her death in 1899. She is perhaps the company's most infamous, inventive, and intriguing patron, one who took

full advantage of the company's prestige and prowess to further her reputation as a femme fatale and developed a collaborative artistic relationship with Louis Pierson, who photographed her as herself as well as in the guise of the Queen of Hearts, the Hermit of Passy, and the Queen of Etruria among other fictional and historical characters who appealed to the Countess's sense of drama and often served a narrative purpose in her life. For example, after an argument with her estranged husband, the Countess sent him a Pierson photograph of herself masquerading as "Vengeance," carrying a dagger in her hand.

Many of Pierson's photographs of the Countess were hand painted, a specialty that the company first began to widely advertise with an exhibition at the 1855 Exposition Universelle in Paris and continued to capitalize on with a successful showing of photographs of the Countess at the 1867 Exposition Universelle, also held in Paris. In addition, the Countess took full advantage of the studio technology employed by Mayer and Pierson, including illusionistic backdrops that slid back and forth on rails, lighting controlled by mobile screens activated by springs and a plethora of architectural and decorative props.

Mayer and Pierson's success with the mass production of celebrity cartes-de-visite in the late 1850s and early 1860s, aided by the use of a special camera that allowed eight separate portraits to be taken on one negative, led to a highly publicized lawsuit against commercial photographers Thiebault, Betbéder and Schwabbé in 1862 that in the end won protection for photographs under French copyright laws by legally defining photography as an art form. In two separate instances, Mayer and Pierson cartes-de-visite had been copied and sold under the name of a different commercial company: Thiebault and Betbéder retouched a Mayer and Pierson photograph of the Italian minister Cavour and marketed it as their own and Schwabbé countertyped a carte-de-visite of Lord Palmerston and sold it as his own work. Until Mayer and Pierson filed their lawsuit, photographs were not protected under copyright law because they were not defined as a fine art like painting was. Thus when Mayer and Pierson won their lawsuit on appeal, they also claimed a victory for the definition of photography as a fine art rather than a product of science of technology.

MAYLAND, WILLIAM (1821–1907)

English photographer

Born in Blackheath, Lewisham, November 21, 1821, Mayland started his photographic career in Cambridge in the 1860s. In 1869 he moved to London to join Thomas Richard Williams (1824–1871) at his studio 236 Regent Street, Westminster, and on the latter's death took sole control, although the studio name was not formally changed to Williams & Mayland until 1880.

Mayland was one of the leading lights of the pioneer photographic society, the Solar Club (1865–69), succeeding Henry Peach Robinson as Chancellor, and passing on the office to William England. In Cambridge, he photographed the construction of Sandringham House, by special commission from Queen Victoria. The scale of his *carte-de-visite* work in London enabled him to survive bankruptcy in 1878. The studio featured in H. Baden Pritchard's 1882 book *The Photographic Studies of Europe*.

Mayland was an accomplished reciter and occasional private actor, often in Shakespearian productions with his wife Mary (1832–79), a niece of Sarah Siddons. Ill health forced Mayland to close his studio in May 1882, and he retired to Tunbridge Wells, although he died in Islington on October 31, 1907. His collection of negatives was acquired by Samuel Walker.

DAVID WEBB

MAYNARD, RICHARD (1832–1907) AND HANNAH (1834–1918)

Canadian photographer

Richard Maynard was born on February 22, 1832, in Stratton, Cornwall, England, and his wife was born as Hannah (or Anna) Hatherly on January 17, 1834, in Bude, Cornwall. Married in 1852, they immigrated to Canada and lived in Bowmanville, Ontario, for a decade. They resettled in Victoria, British Columbia, where she opened a photographic studio and Richard worked as a cordwainer (shoemaker). Hannah, who likely learned photography in Bowmanville from R. & H. O'Hara, taught him the

craft. Richard's photographic work between 1873 and 1892 consisted almost entirely of single-lens and stereo landscape views, chiefly along the British Columbia and Alaska coastlines, as well as construction of the Canadian Pacific Railway between 1880 and 1886. Hannah confined herself almost exclusively to studio portraiture, starting with unsophisticated carte-de-visite poses and progressing to elaborate studio backdrops and props for group portraits by the 1890s. Recognized as an artistic genius for her multiple exposure or trick photography, she was likely aided in this work by Arthur S. Rappertie (1854?–1923), her studio assistant for over 30 years. The British Columbia Archives preserves their negatives and personal papers. Buried in Ross Bay Cemetery, Victoria, the Maynards' photographic work continues to be widely reproduced and analyzed.

DAVID MATTISON

MCCOSH, JOHN (1816–1894)

British photographer, doctor, writer, and poet

The life of military surgeon Dr. John McCosh was full of incident. Present during some of the many wars of Victorian India, he took to photography as a hobby, and perhaps as a relief from the stresses of surgery under military conditions.

He was widely travelled, and survived a terrible shipwreck when the SS *Lady Munro* was lost en route to Tasmania from India in 1836. McCosh, sent on the voyage to recuperate after a serious bout of fever, went on to write about the incident in great detail. He later published his account, and during his lifetime published several volumes of writings on subjects as diverse as travel, photography, poetry, and medicine.

The early calotypes by Dr. John McCosh embrace a number of applications of photography, and at first glance defy simple classification. Their diversity is perhaps the key to understanding them. McCosh, a British military surgeon, used the medium simply to preserve images of the people and places he came into contact with, much as the majority of camera-users do today. Attributing to him the accolade of being the first war photographer—as many writers have done over the years—is to place his work within a context the photographer himself would not have recognised.

In the introduction to a surviving album of his work, we noted

> These photographs have no pretensions to merit. The negatives were taken on paper before the present process of collodion was known. Their fidelity will, however, make amends for their sorry imperfections. Like fragile remains of lost ages, their value is enhanced because the originals are no longer forthcoming.

That single album, assembled in 1859, contains over three hundred prints, the majority from calotype negatives, and thirty-one from collodion negatives. It is now in the collection of the National Army Museum, London. Contained within its pages are many portraits of friends and fellow officers, portraits of Burmese men and women, a number of views of the architecture, landscape and military installations of the places in which he served as an army doctor—Burma, Bengal, and elsewhere in India, and a single calotype image by Calvert Jones. Included are a number of images unquestionably taken while on active service in war zones, but these are far removed in subject and treatment from the photography at war—or of war—created by Roger Fenton, James Robertson, Alexander Gardner, and others.

Writing in 1856 in *Advice to Officers in India*, after he had retired from the army, McCosh wrote

> I would strongly recommend every assistant-surgeon to make himself a master of photography in all its branches, on paper, on plate glass, and on metallic plates. I have practised it for many years, and know of no extra professional pursuit that will more repay him for all the expense and trouble (and both are very considerable) than this fascinating study—especially the new process by Collodion for the stereoscope. During the course of his service in India, he may make such a faithful collection of representations of man and animals, or architecture and landscape, that would be a welcome contribution to any museum.

These remarks confirm that he had used collodion, and certainly thirty-one of the prints in the album are from collodion negatives, but the architectural views are all on paper.

While two of his early calotype self-portraits are captioned "the Artist"—two others taken on collodion are untitled—his advice to other aspiring photographers makes reference only to representation and not to any aesthetic sensibilities or intentions.

McCosh was introduced to photography some time in the 1840s. The earliest image for which a date can be conjectured is 1848, and the naivety of the images from this date suggests that these may be early examples of his photography. His interest in the medium may have been triggered some time between 1844 and 1847, when he was stationed near the Nepal border at Almra. Much of his work is small format, with images measuring no more than 10cm x 8cm, and typically limited to simply posed studies of colleagues and friends. The format of his portraits varied little whether on paper or glass, suggesting the same camera might have been used for both.

Amongst his subjects were Vans Agnew, photographed in 1848. Shortly after posing for McCosh's camera, Agnew was murdered by the local Hindu Governor, Mulráj during the 2nd Sikh War. The combination of a small camera with which to make his calotype

negatives, a large lens, and the bright light of the Indian sub-continent combined to reduce exposure times considerably. The combination of these features enabled McCosh to pose and photograph his subjects with little need to contrive positions that could be sustained for extended periods of time. Even in his early works the figures seem relaxed and natural. Several of his Burmese images show growing confidence in posing his subjects and in controlling the medium. McCosh worked outdoors often posing his subjects posed against white backgrounds. Relaxed squatting or crouching poses have been used, giving a modernity and an immediacy to the faces and figures he presents. This very direct approach belies the age of these images and the insensitivity of the process he was using.

By the time of the 2nd Burma War 1852–1853, lightweight bellows cameras—such as those designed by William [Marcus] Sparling, Major Halkett and others—were available, and by the mid 1850s when McCosh wrote his *Advice to Officers in India* they had become commonplace for military personnel and other amateurs working overseas. To McCosh, they offered no attraction whatsoever and he commented

> The camera should be made of good substantial mahogany, clamped with brass, made to stand extremes of heat. The flimsy, folding portable cameras, made light for Indian use, soon become useless.

From that it can be assumed that he remained loyal to the sliding box design, despite its weight.

Several of the images produced in 1852 and 1853 are of a larger format than those from earlier in his career, pointing to a larger—and heavier—camera. The prints from these later negatives measure up to 20cm × 22cm, suggesting a camera approaching whole plate in size, compared to the probable quarter plate size of earlier images.

Although there are no specific dates attributable to his collodion images, it is clear McCosh continued to take photographs well into the 1850s. Indeed, he appears in an 1856 photograph taken at Hampton Court by Roger Fenton to commemorate the summer outing of the three year old Photographic Society, posing in front of a horse-drawn photographic carriage similar to that used by Fenton for much of his collodion photography.

JOHN HANNAVY

Biography

John McCosh was born into a medical family in the Scottish village of Kirkmichael in Ayrshire on the 5th of March 1805. Several brothers also became doctors, and John joined the Bengal Medical Service as an assistant surgeon at the age of twenty-six. He enrolled at Edinburgh University in 1840 to take a degree in military surgery, surgery, and medical jurisprudence. His medical career was spent almost entirely in and around India, and saw service in the 2nd Sikh War (1848–1849) and the 2nd Burma War (1852–1853). It is from the period spanned by these two conflicts that his surviving photography dates. He retired from the army in 1856. In addition to his interests in medicine and photography, McCosh enjoyed writing poetry, and published several works of verse after retiring from military service. He died in London on 16th March 1885. The generally accepted spelling of his name is "McCosh although "MacCosh" and the abbreviated "M'Cosh" have also been identified. The images in the surviving album are identified as "Photographs by Jethro M'Cosh, Surgeon, Bengal Army."

MCGARRIGLE, JOHN (active 1870s)

Little is known about this photographer other than the fact that he claimed to have been employed by the Mexican government prior to his arrival in Auckland, New Zealand.. During his short stay in Queen Street, he secured a wonderful series of Maori studies in the form of carte-de-visite portrait sittings. When he left New Zealand in the early 1870s, he managed to leave these in the custody of someone who later negotiated their sale to the Dunedin firm of Burton Bros. Burton's were expanding their collection of New Zealand views at the time and this collection of Maoris portraits, which they never acknowledged, served them greatly for many decades to come. With no written records to fall back upon, it is difficult to identify or assess the true wealth of McGarrigle¹s work or how these engaging portraits came into being. Tribes coming to Auckland from their ancestral lands may have been enticed into his studio for their portrait by inducements like a free set of prints if they gave permission for them to be

used as sales to colonists who wanted to send studies of Maori heads to friends overseas. The mix and match of European costuming with traditional clothing and artifacts certainly suggests a very impromptu series of studio encounters.

William Main

MCKELLEN, SAMUEL DUNSEITH (1836–1906)

S.D. McKellen was born in Ireland in 1836 and a year later the family emigrated to Manchester where Samuel was to spend most of his working life. McKellen trained as a watchmaker and jeweller and had opened his own business by 1861.

It was around this time that McKellen developed an interest in photography making his own camera from a cigar box and lens. By 1881 he had began to design the camera that would lead one obituary to describe him as 'the father of the modern camera.' The design was made up for him by the Manchester camera maker Joshua Billcliff which McKellen then field tested and extensively demonstrated. It was shown at the annual exhibition of the Photographic Society in October 1884 where it was awarded a gold medal—the first the Society had given for a camera. McKellen was elected to the Society the following month, although he let his membership lapse.

McKellen began commercial manufacture of his camera which was sold under the Treble Patent name and incorporated at least three of his four patents from the same year. By 1887 the camera incorporated eight McKellen patents. The design was based on McKellen's own experiences as a photographer and was intended to be: light in weight, rigid, easily erected and folded into a compact shape, to accept lenses of different focal lengths, simple in construction and with a swing back and front. The design allowed mass-production and McKellen's factory was was soon employing thirty-five workers and mechanised to allow this. The design was a significant development of the Kinnear camera of 1857 but incorporating the McKellens own principles. It camera was copied by volume manufacturers such as Thornton-Pickard against whom McKellen took legal action and the design, from different manufacturers, remained popular until the early 1900s.

McKellen produced a range of other photographic equipment including a Detective hand camera which he patented in 1888 and licensed to Marion and Company. This camera was significant for incorporating an internal mirror for reflecting the image on to a ground glass screen and a roller blind shutter for which he gave acknowledgment to Thomas Sutton and his design of 1861.

McKellen received twenty-eight photographic patents between 1884 and 1904 but he was not a good businessman and failed to secure his designs losing sales to competitors. He was also under capitalised. A move to establish a public company in 1899 and new products failed to provide financial security and by the time of his death he was penniless and estranged from his wife.

S.D. McKellen died on 26 December 1906 in a Manchester hospital.

MCLAUGHLIN, SAMUEL (1826–1914)

Irish photographer, inventor

Samuel McLaughlin was a watchmaker, publisher, and photographer; born Rathlin Island, County Antrim, Ireland, January 28, 1826; died Los Angeles, California, August 26, 1914. Born in Ireland of Scottish parentage, Samuel McLaughlin was living in Quebec City by the age of fifteen. He began work as a watch and chronometer maker, and then, after a brief period working with a firm of silversmiths in New York, became a book and periodical agent and publisher of city directories, 1854–57. He took up photography as an amateur, later turning professional, for a time, in partnership with Samuel McKenney and William Lockwood. McLaughlin produced Canada's first photographically illustrated serial publication *The Photographic Portfolio: A Monthly View of Canadian Scenes and Scenery* (1858–59), a series of twelve views in and around Quebec City, with accompanying letterpress text. In September 1861, he was appointed the first official "photographist" for the Canadian government and moved to Ottawa where he remained a civil servant for the next thirty years. Best known for his architectural views of the construction of the Parliament Buildings in Ottawa, McLaughlin worked as Chief Photographer for the Department of Public Works and later the Department of Railways and Canals, producing impressive documentation of many Canadian public works projects, most notably wharves, timber slides and booms, dams, and fish breeding works along the Saguenay River. He was succeeded by his son Daniel after he retired to Los Angeles, where he died.

MEADE, CHARLES RICHARD (1826–1858) AND HENRY W. M. (c. 1823–1865)

Subscribers to *Gleason's Pictorial Drawing-Room Companion*, found its cover for July 24, 1852, dominated by a spectacular, full-length, engraved portrait of newly-deceased statesman Henry Clay. His obituary credited this "excellent likeness" to an original daguerreotype by Meade Brothers, New York. Charles Richard and Henry William Mathew Meade were already familiar figures to readers. Their own, very handsome likenesses had graced "The Brothers Meade," an article in the June 12th issue. These talented daguerreotypists, dealers, manufacturers, and instructors, became celebrities in their own right. Their fame was obscured and much of their legacy lost due to the early demise of both brothers. For this reason and because inadequate labeling may result in surviving pictures being credited incorrectly or to "photographer unknown," critical analysis is very difficult. Nevertheless, from their firm's establishment in Albany, New York in 1842, through the period following its 1850 relocation to a magnificent gallery in New York City, at 233 Broadway, the achievements of Henry and Charles Meade rank them among the most important of professional daguerreotypists and early photographers. The largest collection of their work is at the National Portrait Gallery, Washington, D.C.

In *Esquisses Photographiques*, Ernst Lacan took note of the superiority of Meade Brothers' pictures and the great interest of French daguerreotypists in their technical excellence. Charles R. Meade published an account of how this was achieved in the prestigious journal edited by Lacan, *La Lumiere.* He revealed that Meade Brothers used Voigtlander and French lenses, an American camera by Fisch with a lens 6 inches in diameter, and either French star or Christofle (scale) plates. He described the Meade method of preparation and development in detail and noted that the extra work of electroplating star plates (with the aid of a battery by Farmer) could be avoided by using the Christofle brand. Charles also discussed lighting and backgrounds used by the Meades and said exposure time for a half plate on a beautiful day was about twenty seconds and a little more if the weather was gloomy.

Ballou's, the successor to *Gleason's,* boasted that its engraved likenesses of the Misses Fox, the Rochester spirit rappers, were from a daguerreotype by Meade Brothers "and are therefore reliable." Lola Montez inscribed a copy of a Meade picture as follows: "I consider this lithograph the best likeness I have yet had taken of myself." A review of three portraits displayed at Ernst Lacan's Paris home indicated that their appearance could only be compared to Antoine Claudet's work and that "By a very special arrangement of the light, by the care brought to the polishing, by the artistic choice of the pose, Messrs. Meade give to their portraits a relief which recalls the illusion of the stereoscope. When one has seen these beautiful plates, one understands the reputation that these artists have made for themselves in America and the value that is attached to their works" (Gaudin, Charles. "Réunion Photographique," in *La Lumiere*, February 24, vol. 1, 1855, 29–30, [Paris], J. Lafitte, 1995). The brothers also composed allegorical and genre works such as a group of scenes illustrating Europe, Asia, Africa, and America and the "Seven Ages of Man," after Shakespeare, a series of tableaux taken by Charles.

Henry toured England, France, and Germany on business in 1847–48. On Charles's subsequent trip, later in 1848, he visited Bry-sur-Marne, France, and charmed Daguerre's niece, Georgina Arrowsmith, into persuading the inventor to pose for some very rare and important daguerreotypes. One day, Charles arrived to find Daguerre working in his garden and announced that he had come to take his portrait. Daguerre immediately complied, changing into a white shirt and tie, dark vest, and formal coat with the Legion of Honor on one lapel. Charles took eight or possibly nine portraits on this occasion. During his visit, Daguerre showed Charles the first daguerreotype, a view of Bry, and told him how it was made. Charles left two originals in Europe, gratefully giving one each to Daguerre and his niece, and brought the rest home. One was displayed at the Meade gallery, whose collection would eventually include John Quincy Adams, Franklin Pierce, James Buchanan, Millard Fillmore, Napoleon III, Louis Kossuth, Commodore Perry, Sam Houston, Jenny Lind, Catherine Hayes, Edwin Forrest, Charlotte Cushman, Billy Bowlegs, and many others. From views of Niagara Falls, Broadway, and a moving train shown as if still, to H. K. Brown's equestrian statue of Washington in Union Square, and panoramas of regiments in City Hall Park, the Meades also took many fine outdoor pictures. "Meade Brothers, American Daguerreotype Galleries" reflected their patriotic theme as did the carpet with the eagle and stars chosen for their Williamsburgh branch. At the Washington Monument may be seen the block they donated; it is inscribed simply, "To Washington, An Humble Tribute, From Two Disciples of Daguerre."

On another European trip in 1853, Henry received sets of new medals from America with profiles of Henry Clay and Daniel Webster as they appeared on Meade daguerreotypes. He was to present them to Queen Victoria and Emperor Napoleon III. In London, he met the most important daguerreotypists and at a Lacan soirée in Paris, Henry displayed a Meade daguerreotype of Levi Hill. *La Lumière* reported that it was "one of the most beautiful plates we have seen" and that distinguished attendees such as Nièpce de St. Victor, another color experimenter, studied Hill's appearance with great interest. Meade Brothers had demanded Hill

show his "hillotypes" to fellow daguerreotypists; one of those who would see them was Charles R. Meade. Both brothers were honorary members of the Societe Libre des Beaux Arts and Henry brought funds they had collected for its proposed monument to Daguerre and Nicephore Niepce. He visited Daguerre's widow and niece at Bry, took pictures of Daguerre's chateau and grave monument, and operated in his laboratory.

When last in Europe in 1854–55, Charles visited London and studied new photographic processes in Paris. On June 8, 1855, he took his own daguerreotype of Rachel, star of the Comedie Francaise, as Phedre, when she came to have her portrait taken by the studio of Mayer and Pierson. Similar arrangements allowed him to take tragédienne Adelaide Ristori, also rumored to be coming to America, the King of Portugal, and Rossini. He took outdoor photographs of Notre Dame, the *Palais de l'Industrie,* and the *Cirque de l'Impératrice*, all published in the *Photographic and Fine Art Journal*, and stayed long enough to arrange the Meade exhibit at the Exposition Universelle. The following year, Charles invented a process for taking photographs on silk.

RITA BOTT

Biography

The Meade family arrived from England at the port of New York on November 7, 1834, on the ship *Philadelphia*. They lived in Troy, New York, and later moved to Albany. In their daguerreotype business, Henry W. M., b. London, c.1823, and Charles R. Meade, b. London, April 11, 1826, were assisted by their father, Henry Richard, and their sister, Mary Ann Meade, both daguerreotypists and photographers. Henry R. claimed to have helped start the firm in 1841 in a petition for financial support made to the National American Photographic Association in 1872. Mary Ann, who ran the business in its last years, died January 17, 1903, and was described as "the first woman to have practiced the art of Daguerre" in her *Brooklyn Eagle* obituary. Both she and her father were pictured on Meades' "Frontispiece for Albums" with Daguerre, Niepce de St. Victor, Charles R., and Henry W. M. Meade. The whole family, including their mother, Mary Ann, lived at 233 Broadway, New York, after relocating from Albany in 1850 and until each brother married. Charles married Marietta F. Roff on June 17, 1851, and they had two children, Kate F. and Henry A. Meade. Henry W. M. Meade married Sarah Meserole on September 7, 1853; their two children were Sarah and Jessie Meade.

Meade Brothers began in 1842 at a Douw's Building in Albany, New York, and moved to the Exchange in 1843. In addition to taking pictures, offering instructions, and producing cases and other items in their "manufactory" for sale and their own use, they became major importers and dealers of equipment and supplies. They operated branches in Buffalo, Saratoga Springs, and possibly Canada for a time but relocated completely to 233 Broadway in 1850. In July, 1853, they opened a branch in Williamsburgh, L. I., (later Brooklyn) at 1st and South 7th Streets. The 1855 New York State Census reported that the Meade firm's annual product of daguerreotypes was valued at $15,000, its tools and machinery at $1,500, and its stock at $10,000 [$1: 1855 = $22.46: 2006]. It experienced financial difficulties as early as January, 1857 due to Charles being ill with tuberculosis. After spending the next winter in Havana, Cuba, he died at St. Augustine, Florida, on March 2, 1858. Business remained difficult and a branch at 805 Broadway was unsuccessful. The main gallery was refitted and operated through the war years. After Henry died in New York on January 25, 1865, Mary Ann continued the business for another four years.

The firm won one gold, five silver (one for calotypes in 1848), and one bronze medal from the American Institute and a diploma from the New York State Agricultural Society. Complimentary letters were received from Daguerre; Lola Montez; Fletcher Webster; Louis-Philippe, King of the French; Emperor Nicholas I of Russia; Queen Victoria; and Napoleon III for receipt of either Meade pictures or medals based upon them. They exhibited twenty-four daguerreotypes at the Great Exhibition of the Works of Industry of All Nations, Crystal Palace, Hyde Park (1851) and won "Honorable Mention" for their exhibits at the Great Exhibition, New York (1853–54), and the Exposition Universelle, Paris (1855).

MEDICAL PHOTOGRAPHY

Medical photography is a broad term that encompasses photographs of patients, ward and operating theatre scenes, photomicrography, portraits of doctors, etc. The term 'medical' is synonymous with the word 'clinical.' Medical photography is however, the term most commonly used to refer to photographs of patients, diseased body parts, organs, and specimens. Medical photographs, i.e., those with a clinical content, are images of somatic diseases of the body and are distinct from images of clinical psychiatric diseases. Although the apparent visual signs of disease were often the main reason that led to the photograph being taken, in the final image, the pathology may only appear as an incidental element, disguised in conventions of nineteenth century portraiture. Many of the clinical conventions that we associate with medical photography such as the before and after shot, plain backgrounds, or the black box placed over the patient's eyes did not develop until the late nineteenth century. Improvements in photographic technology also helped the medical-clinical photograph to become part of a clinicians teaching collection and or clinical records.

Writing in 1931, Josef Maria Eder published an account of the history of photography in Europe, which was later translated by Edward Epstean in 1945 (Eder 1931). In the chapter on scientific photography, Eder describes what he believes to be one of the first applications of photography to medicine. This was in the field of photomicrography. He outlined the pioneering work by the French physician Alfred Donné (1801–1878) demonstrated in his cytology atlas, *Cours de Microscopie* (1845), made with Jean Bernard Léon Foucault (1819–1869).

One of the earliest clinical portraits identified by many was a calotype taken by the eminent Scottish photographers, David Octavius Hill (1802–1870) and Robert Adamson (1821–1848), sometime between 1843 and 1847 (Wilson 1973). The image is taken directly face on to the sitter, and cropped above her waist, perhaps in order to draw the attention of the viewer to the upper half of the body. Wilson suggests that:

> [T]he clothing around her neck has been drawn back to show the goitre. This photograph contrasts strongly with their other works, in which artistic arrangement of the sitter is a main consideration. This must be one of the earliest clinical photographs, if not indeed the first. (Wilson 1973, 104)

Wilson attempts to contextualise the image by suggesting tentative links between Hill and Adamson and Dr James Inglis (1813–1851), who had an interest in goitre. However, if one looks at this photograph within the broader context of Hill and Adamson's work it becomes apparent that the sitter's dress and bonnet are strikingly similar to those worn by fisherwomen in Hill and Adamson 'Newhaven' photographs, taken during the early-to-mid 1840s.

In general histories of photography, little reference is made to medical-clinical photography. Those who do, on the whole, tend to cite Dr Hugh Welch Diamond's (1809–1886) psychiatric portraits taken at the Surrey County Asylum in Twickenham. Using Frederick Scott Archer's (1813–1857) wet-collodion process, Diamond used photographs for diagnostic purposes and case notes. He also showed the patients their photographic portraits following treatment for therapeutic purposes.

Heimann Wolff Berend (1809–1873) was another doctor who used photography as part of his clinical practice from the 1850s. Berend founded an orthopaedic clinic in Berlin and employed a professional, L. Haase to photograph his patients before and after surgery. Berend's collection contains hundreds of photographs which combine both portrait and clinical conventions.

Many medical men began to publish their photographic endeavours in books and medical journals. Theodor Billroth (1829–1894) the Viennese surgeon and pioneer in abdominal surgery began to use photography while working at the Chirurgische Klinik in Zürich. During the 1860s he employed J. Ganz to take stereoscopic photographs to accompany cases notes published in 1867 (Gernsheim 1961). Similarly the French neurologist, Dr Guillaume Amand Benjamin Duchenne (1806–1875) was a pioneer in the use of photography as a medium for observation, representation and knowledge in medicine. Duchenne photographed patients undergoing electric stimulation of their facial muscles and published the results in his book *Mécanisme de la Physionomie Humaine* [The Mechanisms of Human Facial Expression] in 1862. In the same year he published a book containing images of pathological cases including ataxia. Duchenne de Boulogne was one of the first to use clinical photographs in his book on neurological disorders published in 1863.

In the field of dermatology Alexander Balmano Squire (1836–1908) published *Photographs* (*Coloured from Life*) *of the Diseases of the Skin* in 1865. Inspired by Squire's work A. Hardy (1811–1893), a doctor at the

Fox, George Henry. Photographic Illustrations of Cutaneous Syphilis (1 of 48).
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

St. Louis Hospital in Paris employed his former pupil, A. de Monteméja, to run a photographic studio within the hospital during the 1860s. They built up a large teaching collection of dermatogical photographs and stereoscopic images.

> In America during this period Surgeon-General Hammond had decreed that photographs should be taken of the casualties of the American Civil War (1861–1865). One of the world's largest collection of medical photographs, many of which are *carte-de-visite* [visiting cards] are now preserved at the Army Medical Museum in Washington, D.C.

Richard Leach Maddox's (1816–902) improved dry-plate available from the early 1870s encouraged and advanced the progress of photography in hospitals and other institutions. The neurologist Jean Martin Charcot (1825–1893) established a photographic Service Laboratory at La Saltpêtrière, Paris in 1878. Charcot installed Albert Londe (1858–1917) as the director of the Laboratory. In 1893 Londe published one of the first texts dedicated to medical photography entitled *La Photographie Médicale* [Medical Photography].

The in-house photography of the hospital also aided the move from commercial photographic portrait to clinical photographic conventions. Teachers, clinicians, researchers, and students used photographs of patients' bodies and their abstracted parts to visually enrich medical teaching. In Alison Gernsheim's 1961 account of the history of medical photography she states that 'I am unable to say when photography was first officially recognized by an English Hospital. St Bartholomew's Hospital at any rate had by 1893 a large number of photographs' (Gernsheim 1961, 2, 149). In Scotland, the eminent surgeon William MacEwan (1848–1924) had began taking photographs for use in his Private Journals and a collection of clinical photographs from the late 1880s which he added to throughout his teaching career at the Glasgow Royal Infirmary and later at the Glasgow Western Infirmary. MacEwan built up a collection of over seven hundred photographs covering a variety of subjects including rickets, carcinoma and hernia. The photographs were mounted on boards with case notes written on the verso. On his death his collection continued to be used and added to by his son Dr John A.C. MacEwan (1874–1944) and his colleagues at the Glasgow Royal Infirmary.

Not all medical men however, were willing to take photographs and in some instances portrait photographers would be brought into the hospital to photograph the patients or the patient would be sent to the local portrait studio.

Towards the end of the nineteenth century photography had found its way into medical journals, hospital wards journals, pathological reports and so on. Some began to devise technology that would allow them to take specialist photographic images of the body for example the human retina was photographed in 1885 by W.T. Jackman and J.D. Webster used a camera attached to a patient's head with an opthalmoscopic mirror in front of the lens; a long exposure of over two minutes was required. In 1887 Eadweard Muybridge (1830–1904) using a chronophotographic technique produced a series of images capturing the movement of subjects walking with a pathological gait.

As a subject the history of medical-clinical photography has been discussed in several fields including the history of medicine, the history of photography and medical photography, and theoretical debates from the history of art and visual culture.

Historians of medicine have been preoccupied with discussing the role of images as sources, focusing on problems of interpretation, and have, for instance, been keen to adopt theories derived from the history of art and visual culture. Discussions by historians of art and visual culture are often concerned with the 'status' of the photograph, and whether it can be understood as an 'objective document' or simply as an aesthetic object.

Conversely, historians of photography and medical photography debate technical issues, as well as locating and describing the 'first' clinical photographs and or presenting them as a seamless chronological narrative. Creating such a linear account involves leaping from one medical speciality to another, ignoring the possibility that each discipline such as orthopaedics, dermatology, etc., may have its own particular ancestry, influences and development.

It was not until 1961 that the first survey dedicated to the history of medical photography was written by Alison Gernsheim, and published in two parts (Gernsheim 1961). Since then the analysis of medical and clinical photography has thrown up dedicated historians of medical photography, resulting in attempts to go beyond identifying the first medical and clinical photographs, creating a wider debate on how they can be interpreted and used within historical research. One of the most prolific writers on this subject is Dr Stanley B. Burns. In 1988 Burns, together with Joel-Peter Witkin, an artist and photographer, published *A Morning's Work*, a selection of nineteenth-century medical photographs from the Burns Archive (Burns 1998).

The work of historians of art and visual culture relating to photography has arguably had the most impact on the way historians of medicine have considered clinical photographs. Many theories derived from the history of art and visual culture have debated the artistic-scientific-mechanical nature of photography. There is a vast body of literature, which aims to encourage us to 'look' in particular ways.

John Tagg argues that medical-clinical photography was a representational act rather than a creative undertaking (Tagg 1988). Tagg applies Michel Foucault's theories concerning observation, realism and objectivity in his exploration of the clinical gaze in nineteenth-century photography. He argues that technical advances, which occurred during the mid-to-late nineteenth century, facilitated the expansion of photography into medicine (Tagg 1984). It was within new institutions of knowledge, such as the hospital, that photography was to become perceived and accepted as a form of truth and evidence. Tagg's argument implies that the medical profession as a whole accepted photography as a medium of truth. However, in reality there was no consensus. Arguments for and against the use of photography were regularly reported in nineteenth-century medical periodicals such as the *British Medical Journal* (*BMJ*) and *The Lancet*.

The historian of art, Martin Kemp, encourages us to look at the details in medical photographs with a more discerning eye. Kemp's work has done much to stimulate debate concerning the history of photography (Kemp, 1988). He argues that individuals were faced with a series of photographic choices, which included staging, exposure and printing. By analysing each of these criteria one can gain insight into 'accessory and contextual information' (Kemp 1988, 123). Kemp suggests that the inclusion of details, such as the patient's clothes, are medically, but not socially, redundant. The border information in an image contributes to an understanding of the practice of medical photography. Kemp describes such details as 'accessory images.' It is the posing of the patient, clothes, and setting which reflect both 'conscious and unconscious choices' of the photographer. He is keen to point out that 'it was not so much that any doctor could simply become a photographer from the first, special skills and knowledge were involved in the production of photographs of the desired technical quality but rather that a layer of artistic mediation was eliminated' (Kemp 1988, 123).

Integrating images into historical research poses many problems for historians of medicine. As previously mentioned, Daniel Fox and Christopher Lawrence alerted us to potential pitfalls, such as presenting images in the form of 'coffee table books' or simply reaffirming what has already been said in the accompanying text (Fox & Lawrence 1988, 6).

Many previous studies have been content with presenting a visual and seamless chronological narrative of medical-clinical photography, irrespective of its local contexts of production, use and circulation. The contextual approach, emphasizes the need to analyze and relate images to their local contexts of production and circulation. This approach can be taken further by expressing visually the narratives that exist between photographs, images, text and artifacts. This not only encourages image-based research, but presents the results in a convincing, discursive and creative way.

MÉHÉDIN, LÉON-EUGENE (UNKNOWN)

French photographer

Léon Méhédin remains somewhat of an enigma. He was a French national but the place and date of neither his birth nor death are known.

His name first appears at the time of the Crimean War, linked with that of Colonel Charles Langlois, who hired him to assist with the taking of reference views which would later serve as the basis for Langlois' panorama painting of the *Taking of Sevastopol*, a successor to his already celebrated painting of the siege. The painting commission came from Napoleon. Some of their work is jointly credited, while other images are credited to Méhédin alone.

Méhédin's wide panoramic vistas of the destruction in the city are powerful reminders of what has been described as the first modern war. Amidst the desolation and the abandoned gun carriages, the exposure has just been short enough to preserve the image of the French flag.

Becoming interested in the potential of the panorama, he continued to produce fine studies including the aftermath of the Battle of Tchernaya.

While in the Crimea, Mehedin also collaborated with Friedrich Martens on several photographic excursions in the areas surrounding the ruined Malakoff Fort and the Redan. These may also have served as reference for Langlois.

JOHN HANNAVY

MEISENBACH, GEORG (1841–1912)

German etcher

Georg Meisenbach was born on May 27, 1841, in Nuremberg, as the son of a copper etcher and pub owner. A talented draftsman from early youth, he learned etching in copper and steel in Nuremberg and, working for several renowned companies, making himself a good name. In 1874, he moved to Munich where he started working on experiments with Gillot's zinkenite lithography. Cooperating with a number of printers and financial advisers, Meisenbach managed to develop his form of grid lithography after photographic images in 1881 and gained worldwide patents for it in 1883, parallel to the patent by Angerer & Goeschl from Vienna. The process consisted in preparing the printing plate by an exposure through two plates of very finely lined glass which converted any greyscale into small squares of different diameter. Meisenbach's business partner Josef Ritter von Schmaedel called grid lithography the "autotype process". The first publication of the autotype process was the catalogue to the exhibition of electricity in Munich in 1882, combining two of the most important media of modernity. Schmaedel helped Meisenbach to construct a machine for lining glass in 1883. Restlessly experimenting Meisenbach spent the rest of his life in devotion to the autotype process and its adaptation to any technical progress imaginable. Georg Meisenbach died in 1912 in Munich.

ROLF SACHSSE

MELHUISH, ARTHUR JAMES (1829–1895)

Arthur James Melhuish was born in London in 1829, he married in 1853, and had three sons and four daughters. Melhuish was a photographer, publisher, a portrait painter, picture dealer, and a designer of photographic apparatus. He joined the Photographic Society in 1856.

His photographic studio was his principal activity and he opened his first in Blackheath, Greenwich, in 1857, later moving to 12 York Place, Portman Square in 1863, and then Old Bond Street, and Pall Mall, all in London. This latter studio was renamed Melhuish and [James] Gale in February 1894 and lasted until Melhuish's death. Melhuish was secretary of the Amateur Photographic

Association from 1861 to 1889 the formal role giving him, a professional photographer, access to Royalty and to London fashionable society and scientific community. In 1873 he was created Photographer Royal to the Shah of Persia following his visit to London.

In addition to his main business as a photographer Melhuish formed partnerships with Thomas Miller McLean and Robert Peters Napper trading as McLean, Melhuish, Napper and Co at 26 Haymarket from 1859 until September 1861 when Napper left the firm; as McLean, Melhuish & Co.; as McLean, Melhuish & Haes, when Frank Haes joined in September 1861 until March 1863 when Melhuish left. These firms seem to have been both photographic studios, with coloured photographs a speciality, and extensive publishers of photographs.

Melhuish contributed photographs to various publications such as *The Stereoscopic Magazine* (1858–1865) published by Lovell Reeve, the Howett's *Ruined Abbeys and Castles of Great Britain* (1862) and he also printed the stereographs tipped-in to Piazzi Smyth's *Teneriffe* (1858) also published by Lovell Reeve. He exhibited widely in a personal capacity and through his businesses and was patronised by the Albert, Prince of Wales in the later 1850s on several occasions.

Melhuish patented three significant pieces photographic equipment. In 1854 (patent number 1139) he designed, with Joseph Spencer, a photographic roll holder using sensitised paper. This was described to the Photographic Society in 1856, demonstrated to the Prince of Wales and was used by Frank Haes when he photographed at London zoo. In 1859 two patents (numbers 2557 and 2965) related to the construction of cameras in metal. This was the first all-metal camera and one extant example resides in the collection of the National Museum of Photography, Film and Television in Bradford. The *Photographic News* reported on the camera in 1859.

Away from photography Melhuish started the *Church of England Pulpit and Ecclesiastical Review* in 1873 and published articles on a diverse range of subjects such as mental analysis, ghosts and the geology of the bible. He was an Honorary Fellow of the Meteorological Society and elected a Fellow of the Astronomical Society in 1863.

He died in Brondesbury, London, on 1 November 1895 leaving an estate valued at £794.

MERLIN, HENRY BEAUFOY (c. 1830–1873)

Australian

Henry Merlin is thought to have arrived in Sydney in December 1848 but may have been a newspaper reporter in Norfolk in 1851 who arrived in Australia in 1853. Speculation exists as to his prior and subsequent activities. In 1863 Merlin married in London and possibly learnt photography for in 1864 he was established as a travelling photographer in South Victoria and Victoria and by 1866 was trading as the American and Australasian Photographic Company (A.&A.Co). Such American references in brand names were popular in the gold rush era. Merlin employed an assistant, Charles Bayliss (1850–97) and together they set out to photograph house to house throughout Victoria and New South Wales. The pair worked their way north inland to Sydney where the studio was located from 1870.

In March 1872, the Merlin followed the gold rush to Hill End west of Sydney where he met the enriched German-born immigrant miner Bernard Otto Holtermann. The latter appointed Merlin official photographer for the Holtermann International Travelling Exposition, a massive photographic documentation of the colony, later shown at the 1876 Philadelphia Centennial exhibition. Merlin's involvement however, was cut short by his premature death in Sydney in September 1873. The main work fell to Bayliss. Merlin also excelled in journalism with many articles appearing in the *Town & Country Journal*.

A large collection of A&A Co negatives is held in the State Library of New South Wales but surviving prints are mostly cartes de visites, often faded.

GAEL NEWTON

MESTRAL, AUGUSTE (1812–1884)

French photographer

Until very recently, practically no biographical information was available on this photographer, who was active in France in the late 1840s and early 1850s. Even his first name was veiled in mystery. The initial O, which has frequently been mentioned since the 1970s, seemed not to appear in a single nineteenth-century document. Research carried out in the context of two major 2002 exhibitions—on the *Mission héliographique* and on Gustave Le Gray, with whom Mestral was befriended and collaborated—resulted in a rudimentary insight into his life. It seems that he was born in 1812 in the Jura region, that he adopted the family name of his mother's former husband and that he became a clerk after having studied law. He established himself in Paris in 1844 and from 1848 onwards he was reputed

to be a successful maker of daguerreotypes. In spite of the long-time mystery of his name and life, Mestral's contribution to the history of photography should not be underestimated. In 1851, he was one of the forty founding members of the Société héliographique and, three years later, one of the ninety-three founding members of the Société française de la photographie. His name appeared frequently in the pages of the journal of these associations, *La Lumière*, especially during the years 1851–1853. The journal reports, for instance, that Mestral announced some technical improvements at several occasions. It was also written that he was part of a commission responsible for the compilation of the *Album de la Société héliographique*, in which all members were directed to submit their pieces so that progress could be observed from day to day. In addition, it was stated that he occupied himself with reproductions on paper of vast amounts of daguerreotypes.

By that time, Mestral had gained a reputation with the quality of his portraits, first on daguerreotype, later on paper. In *La Lumière*, the critic Francis Wey spoke of a collection of about 1,200 portraits—none of which survived or could be identified—and mentioned their "intimate, familiar and true aspects, which unmistakably betray[ed] the spiritual kind-heartedness of their author." Wey also mentioned some landscapes and he favourably described a view representing the canal sluice in Thoraise, on the borders of the Doubs, Mestral's native region. A similar photograph that survived, taken around 1853, illustrated Mestral's talents as a landscape photographer: he succeeded in evoking the play of light on the foliage and the water surface while structuring the composition by means of a stable foreground.

Mestral's name, however, was first and foremost connected with what later has been labelled the *Mission héliographique*. This famous assignment, issued by the *Commission des Monuments Historiques* in 1851, consisted of photographing an impressive series of medieval churches and monuments from classical antiquity. This impressive task to record the highlights of French architectural heritage by means of the new medium of photography, was assigned to five members of the Société héliographique, who all became key figures in nineteenth century photography: Edouard Baldus, Hippolyte Bayard, Henri Le Secq, Gustave Le Gray, and Mestral. It is not clear how Mestral became involved in the project since he was known for his portraits and no references are made to pictures of historical monuments prior to the 1851 mission. Initially, there was probably some hesitation among the Commission as well. At a certain stage in the preparation, his name disappeared from all documents but, eventually, Mestral was assigned with the fifth mission, which included photographing monuments in the regions of the

Mestral, Auguste. Angel of the Passion, Sainte-Chapelle, Paris. *The Metropolitan Museum of Art, Gilman Paper Company Collection, Purchase, The Howard Gilman Foundation Gift, 2002 (2002.9) Image © The Metropolitan Museum of Art.*

Charente, Dordogne, Gironde, Garonne, Tarn, Aude, Eastern Pyrenees, Lot, Chorèze, Haute-Loire, Puy-de-Dôme, Nièvre, and Cher. Mestral, however, decided to join forces with Le Gray, who was assigned with the fourth mission, which followed a more western itinerary. Mestral had close connections with Le Gray, certainly since 1848 and maybe even since the early 1840s. In his 1854 treatise on photography, Le Gray mentions Mestral as one of his pupils and he also made a portrait of Mestral, which survived. One can only guess about the specific nature of their collaboration for the Mission but it is probably wrong to assume that Mestral, who had acquired a reputation at that time, was only an assistant to Le Gray. Precisely because they joined forces, they succeeded in taking multiple views of a single building. Making full use of the new technique of dry wax paper, which was developed by Le Gray a few months before, they took about thirty views on a

single day, which was really exceptional in those years. Sometimes, there were only minor differences among several shots, but as the journey progressed, more different views and fragments of a building were taken. Their collaboration resulted in some true masterpieces of nineteenth century architectural photography, such as their view of the Grand staircase of the castle in Blois, which was exhibited in London in 1854, their pictures of the Cloister of Moissac, or their photographs of the fortifications of Carcasonne.

After his participation to the Mission, Mestral continued photographing monuments. Without receiving an official commission, he explored Normandy and Brittany—both regions ignored by the Mission—in 1852. Henri de Lacretelle wrote lyrically about these pictures in *La Lumière* in 1853 and he praised in particular Mestral's talent to render both details and a general view. In addition, Mestral directed his gaze at the restoration of the Notre Dame of Paris, where he photographed the sculptures of Victor Geoffroy-Dechaume in 1854.

STEVEN JACOBS

Biography

After a long period of obscurity about essential biographical data, it recently turned out that he was born in Rans (Jura) on March 20, 1812, as Thérèse Jean-Baptiste Augustin, aka Auguste Mestral. He is the son of Pierre and Jeanne Françoise Poux, the latter was a widow of a certain Claude Etienne Mestral. After finishing law studies in Dijon in 1833, he becomes a clerk in Paris and Ecouen successively. It is possible that already here, around 1840, he meets Le Gray, who was an assistant of Mestral's predecessor. In 1844 he establishes himself in Paris, where he gains reputation as a portraitist. A founding member of the Société héliographique, he contributes to the Mission Héliographique in 1851, photographing monuments together with Le Gray. All that time, he has his studio in the Rue Vivienne in Paris. In 1856 he leaves the capital and, probably, photography as well. Many of his negatives are left to his friend Ernest Moutrille, a Besançon banker and amateur photographer. He turns up in Rans, where he marries in 1858 and lives from his fortune. He dies the first of March 1884.

MEXICO

The first photographs taken in Mexico were made by Jean François Prélier, a French engraver living in Mexico City, who returned from a trip to France with two cameras in December of 1839. He demonstrated the new daguerreotype process when he debarked in Veracruz, and shortly after his return to the capitol he took the first photograph of Mexico City—a view of the cathedral—on January 26, 1840. Thus, the first photographs made in Mexico were taken barely six months after the invention of the daguerreotype had been announced in the Mexican press (June 1839). The fact that they were made by a foreigner foreshadowed the development of photography in Mexico in the nineteenth century that resulted in a history as we now know it dominated by foreign names, particularly those of French, German, and American photographers. The reasons for this were twofold: first, from an economic perspective cameras were costly and bore high import taxes, and Mexican society lacked the well-educated middle class from which photography initially drew its ranks in England, Europe, and America. Second, for most of the nineteenth century Mexicans used photographs primarily as a private celebration of family and community, whereas foreigners were keenly interested in photographing Mexico's monuments, landscape, indigenous peoples, and political events. In fact, in the nineteenth century, only Egypt attracted as many photographers as did Mexico. Because these images by foreigners tended to be made for public consumption—they appeared in a wide range of publications and were often readily available for purchase—they gained a worldwide currency that photographs made by and for Mexicans did not.

Within two years after Prélier's first photographs, photography had become a business in Mexico. Although itinerate photographers, who traveled the traditional commercial routes were plentiful, professional studios were beginning to open in the larger cities. In 1842 Randall W. Hoit was the first photographer to establish a studio in Mexico City. He was followed shortly thereafter by fellow New Yorkers Francisco Doistua, Andrew J. Halsey, and Richard Carr. Joaquín María Díaz González, the first native Mexican daguerreotypist, opened a studio on the Calle de Santo Domingo in 1844. In 1856 there were seven photographic studios operating in Mexico City, in 1860 there were over twenty studios, and by 1870 seventy-four studios were in existence.

The years of the French Intervention (1864–1867) saw the burgeoning of photography in Mexico. Tied to

the protocol of the court of Maximilian and the official documentation of political events, photographs were a way of legitimizing the emperor. The court brought the European carte-de-viste craze to Mexico, and portraits of Emperor Maximilian, Empress Carlotta, General Bazaine, members of the court, and its Mexican supporters circulated widely in Mexico and abroad. François Aubert, the official court photographer, made images of the court at play, during ceremonial occasions, and during war, following Maximilian up to his last moments. His images of Maximilian's execution and post-mortem portraits were banned in Europe, but nevertheless circulated widely.

Other French photographers active during this period included Jules (Julio) Amiel, Auguste Mérille, Jean Baptiste Prévost, and Auguste Péraire. Photographers Julio de Maria y Campo, José Pedebiella, and J. B. Parés came from Spain. Mexican-born photographers, many of whom had studied at the Academia de San Carlos in Mexico City, included Francisco Montes de Oca, Lauro Límon, Andrés Martínez, Luis Campa, Antíoco Cruces, Agustín Velasco, Joaquín and Maximino Polo, Luis Veraza, Manuel Rizo, and Julio Valetta. Although many of these men were initially trained as painters, photography became part of the annual salon at the academy in 1870, and shortly thereafter photographs were included in the exhibitions of the Arts and Trades School.

A major trend in Mexican photography during the nineteenth century focused on travel and exploration. Foreign photographers were variously interested in documenting the ethnographic, archaeological, and natural sights of Mexico. Their interest came out of a "rediscovery" of the Americas, initially a romanticized return to pre-Conquest lands, wild and untamed in comparison to archaeological sites in Europe and the Middle East. The Viennese Baron Emanuel von Friedrichstahl was the first of the archaeologist-explorers, making daguerreotypes of sites in the Yucatan in 1840. He was followed by John Lloyd Stephens and Frederick Catherwood, Désiré Charnay, Lord Alfred Percival Maudslay, Augustus and Alice Dixon Le Plongeon, and Teobert Maler. Charnay, who began his archaeological explorations in 1858, was the first to break with the romanticized conception of ancient Mexico and use photography as a tool for scientific research.

Charnay and anthropologist-explorers such as Léon Diguet, Carl Lumholz, and Frederick Starr made ethnographic portraits of indigenous peoples and recorded daily life. While these photographers purported to have a scientific mission, the resulting images are closely aligned to the genre of "tipos" or Mexican popular types that depict people according to social category, regional costume, or profession, and that had been produced by earlier photographers such as Aubert, who made a series of studio portraits of street vendors. The genre was popular among both native and foreign practitioners. Americans William Henry Jackson and Charles B. Waite and Frenchman Abel Briquet made numerous tipos and images of "Mexican scenes." The Mexico City firm of Cruces y Campa made a carte-de-visite series of staged Mexican scenes for the 1876 Philadelphia Centennial Exposition. Lorenzo Beceril, a native-born studio photographer in Puebla was well-known for his portraits of Tehuanas, the distinctively costumed women from the Isthmus of Tehuantepec.

Promotion of Mexico was another activity of those traveler-photographers who were patronized by the Mexican government and private entrepreneurs. Focusing their lenses on the future rather than the past, photographers such as William Henry Jackson, Charles B. Waite, Abel Briquet, and Guillermo Kahlo (father of Frida Kahlo), photographed progress. Their images of landscapes in transition showed a Mexico being changed by engineering projects such as telephone lines, tunnels, railroads, bridges, and dams. The work of these chroniclers of the modernization of Mexico often appeared in the guise of tourist views, since tourists were seen as potential investors. Their work also memorialized the achievements of the ambitious Porfirian government (1884–1910), and highlighted the natural resources that could attract foreign investors. These photographers were frequently commissioned to produce albums recording the development of railways, mines, and factories.

Photography as a means for documenting historical moments and disseminating news had existed in Mexico since daguerreotypes were taken of American troops and wounded soldiers in Saltillo during the Mexican-American War (1846–1848). Aubert's images from the French Intervention were of a certain documentary nature, and were used in Europe to report the news from afar. However, it was the Porfiriato that made extensive use of photography to record its accomplishments. A cadre of photographers such as Agustín Victor Casasola and Guillermo Kahlo were always on hand to document ceremonial occasions such as the dedication of buildings and public works. In 1896 Rafael Reyes Spíndola, owner of several newspapers, began to print photographs in his papers. As Mexico moved determinedly into the twentieth century, photojournalism rapidly developed as a means for both recording change and keeping the public abreast of events. By the end of the first decade of the twentieth century the tool that the Porfirian government had recognized and used so successfully had been used to document both its apogee and its demise.

MEYDENBAUER, ALBRECHT (1834–1921)

German photographer

Albrecht Meydenbauer was born in Tholey, Saarland, on 30 April 1834, to the physician Albrecht Meydenbauer senior and his wife Friederike. In 1856–58 he studied architecture at the Bauakademie [School of Architecture] in Berlin and became a construction surveyor for the Prussian government. After an accident at the Wetzlar cathedral in 1858, Meydenbauer developed the idea that the direct measurement of sites could be replaced by indirect measurements using photographic images. In a memorandum, written in the fall of 1859, he laied out a project to photograph all Prussian monuments with the greatest detail and accuracy with the intention of gathering and protecting the images in an archive of cultural heritage. In the course of his work he designed a photogrammetric camera that combined a photographic camera with a measuring instrument and began testing it in 1867 with other scientists, on architecture and topographical views. 1885 Meydenbauer was called to the Prussian Ministry of Culture and founded the Königlich preußische Meßbildanstalt [Royal Prussian Photogrammetric Institute] in Berlin, the first institution worldwide for the photogrammatic documentation of architectural heritage. Between 1885 and 1920 the institute produced records of about 2,600 objects in nearly 20,000 photogrammetric images on glass plates, in and around Berlin and the Prussian territories until 1900, and then operating abroad (Athens, Baalbeck-Lebanon, Istanbul). Meydenbauer resigned in 1909 and moved to Bad Godesberg, near Bonn, where he died on 15 November 1921. The photogrammetric archive now resides in the Brandenburg Landesamt für Denkmalpflege [Landmark Preservation Office of the Federal State of Brandenburg] in Wünsdorf near Berlin.

STEFANIE KLAMM

MICHETTI, FRANCESCO PAOLO (b. 1851)

Francesco Paolo Michetti was born in Tocco di Casàuria (Italia) in 1851, and soon after his birth, his family moved to Chieti, where he later attended a technical school.

He was awarded a scholarship to attend the Accademia di Belle Arti (Academy of Art) in Naples, where he studied with the painter Morelli. After his studies he moved to Francavilla where he bought an ex-nunnery.

Francesco participated in the Biennale in Venice with the portrait *La figlia di Iorio*, in the Exposition Universelle in 1878, and in other expositions in Germany and in London where he displayed some of his paintings and statues. His style was similar to that of the current Verismo, but it wasn't until 1871 when he went to Paris that he devoted himself fully for the first time to photography.

He immediately understood the peculiarity of the two expressive means, and always emphasized the differences between the two techniques and their autonomy without submitting one to the other.

In the 1870s his subjects were static but after photographs become more like snapshots he devoted himself to reportage of life in Abruzzo from 1890 to 1895. He used photography not only as a way to make his paintings more realistic, but, together with painting, developed an instrument to describe natural life by giving his personal, subjective views.

After 1900 he stopped painting and devoted himself to photography.

CARLO BENINI

MICHIELS, JOHANN FRANZ (1823–1887)

Photographer

Michiels was born in Bruges (Belgium) on 4 October 1823 and he died on 21 January 1887 in Cologne (Germany). From around 1850 to 1859, Michiels worked in Bruges as a wood-carver and sculptor. He created the pulpit in the church of Saint-Jacques in Ypres and the pulpit in the church in Roesbrugge, both of which were destroyed during the First World War. He worked as wood-carver till 1843. During this period he had also become interested in photography after seeing daguerreotypes in Brussels.

Michiels became a photographer and publisher and

became famous for his photographs of city views, architecture and reproductions of art works. As an artist he used photography as a unique technique to make reproductions as a way to distribute this art.

Very well known are his photographs of the Flemish Primitives as is his view of the Quai Vert in Bruges (made in 1848), which is one of the oldest known photographs of Bruges, published by Blanquart—Evrard in the "Album de l'artiste et de l'amateur," 1851. During the years 1853–1854 he published the album "Variétés Photographiques." Some months later he left for Cologne (Prussia), but his main residence remained in Bruges however he later moved his domicile to Cologne in 1855 and became a Prussian citizen by naturalization the same year.

Museum art and the collection, classification and conservation of sculptures and other mediums became a new role for and subject of photography long before museums began to see photography themselves as objects of art. The photographer captured images of the building and its furnishings, but above all of the objects exhibited there. Michiels gained, in Cologne during the period 1852–1857, a fine reputation as an architectural photographer, thanks to his close collaboration with the publisher Franz Carl Eisen (1812–1861). He recorded the construction of Cologne Cathedral and published albums of the new stained-glass windows "Die neuen Glasgemälde im Dome zu Köln," five prints, 1853; "Album von Köln," fourteen prints, 1854; "Album von Berlin, Potsdam und Sans-Souci," sixty prints, 1857. These photographs were financially successful thanks to the commercial spirit and merchandising of Eisen who already had a flourishing business that sold graphic prints. An album of his reproductions of the shrine of Saint Ursula, 'Der Reliquienschrein der heiligen Ursula zu Brügge" with eight 22 × 31 cm albumen prints, appeared under the Eisen imprint in 1854 and in 1857, Michiels returned to Bruges.

Michiels' diplomatic skills won him a wide circle of upper class admirers. He was invited to teach photography to the crowned prince of Prussia, who later became de Emperor Friedrich III. He also had an exhibition as member of the Prussian delegation in Paris. During this period Michiels traveled to Russia to take photographs of works of art in the Hermitage Museum in Sint-Petersburg.

In 1858 he began with A. Laureyns an établissement photographique in Bruges, which found success for one year only.

During 1859–1860 he lived in Brussels working for several museums and had his photographs of works of art in the collections at European Museums published by Gestewitz in Düsseldorf.

The recognition of the history of art as a discipline was responsible for a renewed interest for Old Art and photography made a significant contribution to the rediscovery of Old Art. National heritage was transferred to a glass plate or a sheet of paper and subsequently disseminated to those interested. The search to find the best methods of reproduction of works of art stimulated the technical skills and even inventions in this field. Photography came in a position concurrent with gravure and lithography. But soon the photographic medium created its own place in artistic and contemporary debates; slowly but surely, photography became intertwined with the professional activities of lithographers and printers, while photographs became increasingly employed for illustrating of books and other publications.

From 1861 to around 1864 Michiels set up a studio in Brussels, Rue Neuve, 88. After the death of his son Bruno in 1863, he finally moved back to Germany and opened a shop selling art objects with two of his daughters.

His photographs of museums bear witness to the significance that was attached to these relatively modern institutions. In topographical surveys of cities and regions, pictures of museums were included alongside churches, palaces and old town halls. Museums had a symbolic function as guardians of material culture; they gave the nation its cultural identity, while serving as a major attraction for tourists in search of souvenirs.

He died in Cologne on 21 January 1887 and his funeral was held in the Dom in Köln.

MICROPHOTOGRAPHY

The term "microphotography" has been used to describe two very different processes. According to its etymology, the term microphotography should describe

extremely small photographs that are viewed through a microscope or magnifying lens. Throughout its history, however, the term has been routinely applied to photographs of microscopic subject matter large enough that they may be viewed unassisted. The later are more precisely termed photomicrographs and are dealt with in a separate entry.

History

In many ways the idea of combining the camera and the microscope was an obvious extension of the camera's innate potentials. Not only was the knowledge of lenses and light required by photography also required by the successful microscopist, but the projected image visualized through the microscope was analogous to that recorded in the camera. No less a pioneer than William Henry Fox Talbot (1800–1877) took photographs through the microscope as early as1835.

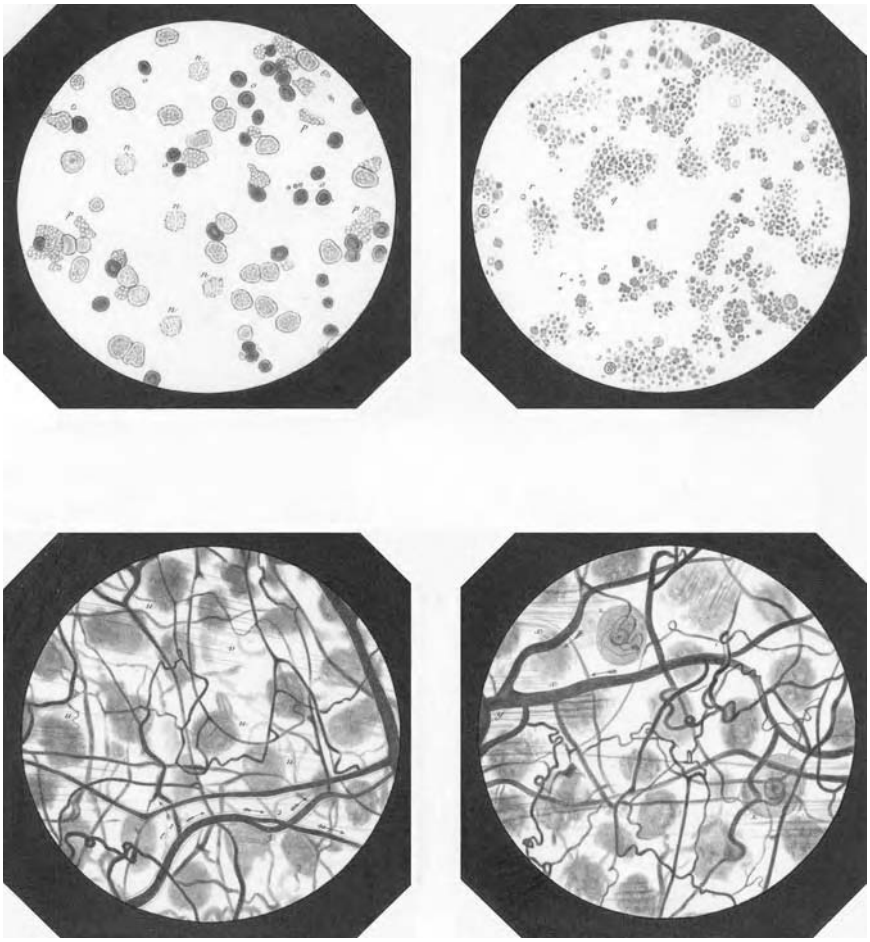
Logically, the process could just as easily be reversed, using the microscope lens to reduce rather than enlarge the image recorded by the camera. The resolution required to print an image so small, however, made the accomplishment more technically difficult. The earliest microphotographs were probably delicate, irreproducible daguerreotypes that have not survived. After these initial experiments the historical development of microphotography diverged from that of photomicrography because of the different use-value assigned to each. The value of preserving and sharing what was seen through the microscope as photomicrographs was clear. The microphotograph, on the other hand, seemed to many contemporaries to have no practical applications. George Shadbolt (1819–1901), who coined the name microphotography, was of the opinion that "microphotographs can never be more than amusing curiosities." Most microphotographs were indeed produced as novelties, and it is as a novelty product that microphotographs became a significant feature of nineteenth-century visual culture. The idea to use microphotography to reduce and store information as microfilms arose independently, and was not put into practical application until the 1930s.

Like many milestones in the history of photography, microphotography was most likely pioneered by several people working around the same time. John Benjamin Dancer (1812–1887), is generally credited with successfully producing the first microphotograph. Dancer was an optician, inventor and entrepreneur who specialized in producing optical equipment like microscopes and magic lanterns. Dancer's first successful microphotograph, a daguerreotype of a 20 inches long document reduced to 3mm in length, was printed in 1839. According to a later account, his technique involved using the eye of a freshly killed ox as a lens. The wet collodion process invented in 1851, with its excellent resolution and easy reproducibility, galvanized a new wave of experimentation. Dancer produced his first collodion microfilms early the following year. Although he lost a priority dispute with Dancer as to who could claim to be the inventor, Shadbolt was working in a microphotography around this time as well. He became the first to publish a workable microphotographic process in 1857. Others surely printed microphotographs as well, either out of curiosity or as demonstrations of technical acumen. Alfred Rosling, for example, exhibited pages of the *Illustrated London News* at the Photographic Society of London in 1853 to demonstrate the resolution of his lenses. Although they were not produced for that purpose, Rosling's microphotographs must be considered the first newspaper microfilms.

According to biographers, it was by accident that Dancer happened upon the idea to market microphotographs. When Edward William Binney asked Dancer to produce a photographic record of a memorial tablet, Dancer printed a microphotograph instead. Distributed to friends in early 1853, the image generated so much interest as to convince of microphotography's salability. Dancer's slide-mounted microphotographs quickly became a popular addition to the natural history slides and microscope equipment his company offered the bourgeois consumer. He offered microphotographs featuring local monuments, famous persons, and miniaturized texts like the Lord's Prayer. The subject choices reflect the microphotograph's status as an entertaining novelty destined for the bourgeois parlor, and simultaneously appeal to an implicit educational benefit to be derived from exercising one's faculties of visual observation.

Production of novelty microphotographs spread abroad when Sir David Brewster (1781–1868) toured Europe with examples of Dancer's work, which were displayed at the Académie des sciences in Paris and later presented to the Pope. The most prolific manufacturer was René Dagron (1819–1900) in Paris, who launched lucrative businesses selling images that were inset, along with a tiny, jewel-like magnifying lens in curios such as a signet rings, penknives, and religious charms. These trinkets, called Stanhopes, were immensely popular as souvenirs featuring a "hidden" vista that magically unveils itself to the knowing eye. Although popularity waned after the 1870's, Stanhopes remained in production through the 1970s.

The idea applying microphotography in preserving public records and library catalogs received rare mentions in periodicals as early as 1853. It was espionage, however, that provided the biggest impetus to the use of microphotography for information storage in the nineteenth century. In a 1857 article on the micrometer for the 1857 *Encyclopedia Britannica*, Brewster took up the theme in a way that echo in popular fiction for decades to come, writing that "microscopic copies of dispatches



Foucault, Jean-Bernard-Leon and O. G. Mason. Plate VI Cours de Microscope Complementaire des Etudes Medicales…Atlas execute d'apres nature au Microscope-Daguerreotype. *The J. Paul Getty Museum, Los Angeles*

and valuable papers might be transmitted by post, and secrets might be placed in spaces not larger than a full stop or a blot of ink." Microphotography was successfully employed to hide information from enemies for the first time in the Franco-Prussian War. In October 1870 Charles de Lafollye, of the Service de correspondences extraordinaires, assisted by Gabriel Blaise, produced the first microphotographic military dispatches. Messages were hand written in large script on cards and then photographed. The resulting prints were inserted in hollowed out quills and attached to a feather on a pigeon's tale. Later that year a letterpress was adopted for printing the messages, allowing copies to be kept which can be viewed in the Musée Postal, Brussles. Before escaping Paris in balloon named Niépce in 1870, Dagron was contracted to set up a similar pigeon post that would carry military and private communications back into occupied France. His prints represented a three-fold improvement over those of Blaise, recording the same amount of information on a sheet about 11×6 mm. Microphotography received more limited use in the American Civil War, where one regiment reportedly sent microphotograph dispatches across confederate lines pasted inside coat buttons. Noses, ears and fingernails became the hiding place for microscopic secrets in the Russo-Japanese war of 1904–1905. Brewster's prophecy was finally fulfilled during World War I, when messages were sent to spies hidden on top of printed periods and commas in magazines.

Microphotography in Nineteenth-Century Visual Culture

The instant demand Dancer and Dagron discovered for microphotographs may seem surprising if it were not for the immense desire to explore all modes of visuality that characterizes the latter half of the nineteenth century. This passion for new ways of seeing and being seen inspired the invention of myriad optical trinkets and devices that could exist anywhere on a continuum that ran between, but always blended, spectacular entertainment and educational intent. After the invention of the achromatic microscope in 1823, microscopy became an important element in this visual culture. Produced cheaply in the 1830s, microscopes became a common addition to the bourgeois parlor, where they offered a recreational activity that fit into a public campaign promoting the natural sciences as an appropriate

leisure occupation for those seeking self-education and improvement. The microscope slides produced for this audience, offering such sights as crystallized urine, blood cells, or an uncanny encounter with a housefly, offered access to a new visual domain and the opportunity to gain first hand experience of nature's inner truths. Studying nature in the nineteenth century was, above all, a visual process, involving extracting greater truths through visual observation and comparison.

The meaning of the microphotograph must be situated in this broader context of spectacle and optical entertainments. But where does the balance between scientific intent and specular indulgence fall with respect to microphotography's various forms? In one respect, the microphotograph was unlike its closest relatives, the microscope slide or photomicrograph in that it drew on a separate visual tradition. Whereas histology imagery would seem to invoke the scientific logic of precision and accuracy, the microphotograph offered pleasant illusions more akin to a magic lantern show. Dancer's roots as a producer of magic lanterns, and the easy fit between microphotographs and souvenirs support this idea. And yet observations taken through the microscope, recorded by whatever means, were considered to be of questionable ontological value by many contemporary scientists. Due to a lack of standardized documentation procedures, images of microscopic specimens were regarded at best as a highly suspect form of visual evidence. Photography did little to change this situation. The "objective" image recorded by the camera did not meet contemporary criteria for scientific accuracy and precision. Advocates from the domain of popular science, on the other hand, tended towards the grandiose in their estimation of the value of microscope images. They promote the edifying effects of gazing through the microscope objective both on aesthetic and scientific grounds. Moreover, in popular texts, microscope slides and illustrations were rarely organized and viewed in a way that could be called systematic or methodical. The average bourgeois viewer's experience with a microscope probably proceeded in much the same way. Microscopy and photomicrography both catered to a public whose appetite for new visual experiences outpaced its desire for education. In result, within the popular context the kind of attention directed to a microscope slide and a microphotograph seems closer than expected.

Contemporary discourse on microscopy offers reasons to further discriminate between the magical allure of optical trinkets like the Stanhopes and the practice of studying miniaturized photographs under the microscope. Microscopy between 1850–1870 was embedded in a cogent, power-laden political discourse on Nature that was used to recruit mass audiences for domesticated life science. In public discourse microscopic study was touted as an optimal means for training the public in a faculty it was sorely lacking—the ability to see independently and objectively, and thus develop vision into a tool of rational thought. Dancer's microphotograph slides often appeal to quantitative analysis, saying, for example, that 112 eminent men could be identified, or that a slide contains 1687 letters. The point was probably not to actually count but to suggestively appeal to this logic whereby microscopic study would develop the viewer's ability to synthesize discrete analysis and meta-observation.

The monuments, heroes, and landmarks featured in both souvenirs and slides likewise offer edifying content, yet seem to reveal a slightly different set of desires at play. The scopic pleasure offered must have been one of discovering what is human and familiar in the otherwise alien spaces of microscopic observation. It has even been suggested that these subjects reflect the colonial impulse of the age. Amateur literature on microscopy of the period is filled with reveries to the hidden worlds and exotic adventures the expanded vision microscopy made possible. If, therefore, amateur microscopy domesticated nature by bringing it into the space of the parlor, the projection of human artifacts and accomplishments into otherwise alien territories reads as a metaphoric attempt at domination.

Whatever the content of the image, the primary allure of the microphotograph was the possibility of experiencing a technical marvel. As tiny, perfect copies, microphotographs evince a pleasure akin to that offered by other kinds of miniatures including toys, dioramas, and staged panoramas. Souvenirs and religious effects appropriated this pleasure as a purely magical indulgence, whereas microphotography's other forms invite the viewer to play at being a scientist. Utilizing the microscope, focusing the objective, waiting for something to come into view, and scrutinizing the results, the viewer enacted the scopic logic of the natural sciences without actually submitting themselves to the intellectual rigors of scientific study.

MIETHE, ADOLF (1862–1927)

German photo-physicist and photographic writer

Adolf Miethe, born Adolf Christian Heinrich Emil Miethe in Potsdam on 25 April 1862 to city councillor and chocolate factory owner Albert Miethe and his wife Karoline, studied physics, astronomy and chemistry in Berlin and Göttingen. He had worked as an assistant at Potsdam's astro-physical observatory and in 1887, with the help of Johannes Gaedicke, invented the first widely used magnesium flash powder. After gaining his doctorate in astro-photography, Miethe was employed as a scientific collaborator by several optical firms in Potsdam, Rathenow, and Brunswick, in the latter as a director of the company Voigtländer & sons. In 1899 he was appointed successor to Hermann Wilhelm Vogel in the chair of photo-chemistry, photography and spectral analysis at the Technische Hochschule [Institute for Technology] Charlottenburg, Berlin where he expanded the photo-chemical laboratory and founded an observatory. During his lifetime Miethe undertook several expeditions, amongst others to Egypt and Norway, before he died in Berlin on 5 May 1927. He edited and contributed to several photographic journals, like Das Atelier des Photographen [Photographer's Studio] and Photographische Chronik [Photographic Chronicle] and wrote several treatises for amateur and professional photographers alike. Miethe designed several new microscope and camera lenses, including a telephoto lens, and he was much occupied with enhancements of astronomical photography, color photography and emulsion sensivity to spectral light.

STEFANIE KLAMM

MIGURSKI, KAROL JOSEF (active 1850s–1870s)

Professional photographer

Josef Migurski, a native of Poland, became interested in photography in 1850s. He owned a photographic studio in Odessa. He was also the author of the first photographic instruction manual in the Russian language, entitled *The Practical Guidance on Photography* where the descriptions of the equipment and formulas of chemical solutions were given. It also included advice on various types of photography, for example studio portraits, architectural, and landscape photography. Migurski popularized photography through this. In 1863 he lectured on the technology of the photographic processes in the Richelieu lyceum in Odessa. In the "Novorossiysk calendar of 1864" Migurski placed an announcement devoted to the photographic institute which he established. There, one could study the theory and practice of photography.

Migurski was the author of the albums *The views of the town Akkerman* (1869) and *The album of the Odessa's port works* (1869). Migurski also extensively photographed Odessa. Apart from creating city views, he also made genre scenes, for example photographs showing building works and diving works in Odessa's port.

Also notable, Migurski won the Great Silver Medal in 1872, at the Polytechnic Exhibition in Moscow. Additionally, he was a military photographer of the Russian troops' General Staff during the Russian-Turkish war of 1877–1878.

ALEXEI LOGINOV

MILITARY PHOTOGRAPHY

Apart from the portrayal of the aftermath of war and limited use on the battlefield, photography was adopted by the military in the nineteenth century to serve the causes of advancing nations of Europe and the United States. The early history of the military's use of the camera is inextricably bound to survey work in domestic and foreign exploits, including various engineering projects such as the construction of bridges and railroads, and the exploration of politically sensitive regions. This essay is not about the photography of war, but the deployment of the medium by army personnel and civilians acting on behalf of political authority or nationalist concerns who understood how photography could function outside the portrayal of conflict. In 1860, Captain Henry

Schaw, Chief Instructor of the Telegraph and Photograph School, offered a ten-point list for photography, including the recognition of borders and landmarks in remote areas, the reproduction and distribution of plans and maps, the documentation of military maneuvers and the apparatus of warfare, the depiction of "remarkable persons and costumes of foreigners, and the general picturing of building, bridges, and other structures" (Howe 2003, 231). Although these endeavors were not always directly connected with warfare, they could scarcely be called neutral in terms of ideological meaning. Even an army's contribution to public works was politically motivated by government authorities concerned with the administration and control of their domains.

Already by the mid-1850s, a close alliance existed between military trained and civilian operators in their mutual concern for applying the medium to documentary enterprises of potentially strategic significance. Roger Fenton's pictures of encampments and ships in harbor in the Crimea of 1855 and Gustave Le Gray's depictions of military exercises at Camps de Châlons of 1857 provide early indications that independent practitioners known for landscape and other genres might work in support of nationalist causes. John McCosh, surgeon in the employ of East India Company's infantry produced landscape and architectural views while engaged in at least two tours of duty, the Second Sikh War (1848–49), and the Second Burmese War (1852). His realization of the significance of the camera for multiple subjects led him to include a section on photography in his Advice to Officers in India, published in 1856. McCosh's conviction of the medium's importance coincided with the flourishing of other efforts on the subcontinent and elsewhere. In addition to McCosh's fellow doctor John Murray, British army officers Captain Thomas Biggs, Captain Linnaeus Tripe, Major Robert Tytler, and his wife Harriet Christina, were enchanted with India's splendid architectural past, and thus contributed to a growing archive that increased throughout the second half of the century. The photographic societies of the three Presidencies of Bengal, Bombay, and Madras in the late 1850s counted in their membership military personnel together with civilian amateurs and commercial practitioners who were also concerned with the preservation of antiquities and peoples of the subcontinent. Photographers like Felice Beato and Lala Deen Dayal attached themselves to military operations, Beato first in the aftermath of the Indian Rebellion of 1857, and Deen Dayal in the 1870s with the British military elite. As a native Indian, Deen Dayal was unique in his ability to straddle "princely India" and Anglo-India by working under the patronage of the wealthy sixth nizam of Hyderabad and of the British Raj, recording palaces and royalty, as well as landscape views, military maneuvers, and artillery.

The example of India underscores the considerable alignment of European military and civil authority in world affairs. Photography has frequently been characterized as an emblem of conquest and territorial appropriation; witness Eugène Durieu's report to the French Photographic Society, "that photography would conquer unknown territories as the victorious armies of France conquered land" (Marien 2002, 86). Major Charles Callwell used the term "small wars" to characterize conflicts which "dog the footsteps of the pioneer of civilization in regions far off" (Ryan 1997, 73). Callwell's observations are not exclusive to war per se, but engage an ideology of "extended empire," which can be perceived as symbolically reinforced by the production of photographs as apparently benign as a landscape or an architectural view. Early photographs of the Himalayas by Deputy Commissioner Philip Henry Edgerton function as illustrations of a remote area that could well figure into the development of a trade route into Central Asia. Though Egerton's one-time journey through Spiti was in no way clandestine, his explorations represent a gathering of intelligence fostered by competition with Russia, as evident in his published photo-illustrated account (1863). The commercial photographer John Burke extensively covered Britain's penetration into Afghanistan from the North-West Province of India during the Second Afghan War (1878–80). Like Egerton's, Burke's pictures more than suggest associations with the "Great Game," the contest of territory between Britain and Russia often covertly fought in the mountainous regions of Afghanistan, India, Tibet, China, and Russia, and made popular by the operations of Rudyard Kipling's fictional character Kim.

The Royal Engineers' school at Chatham began to teach photography in 1856. The Engineers were involved in numerous surveys of strategic military importance around the world. The mission of the Abyssinia Campaign of 1867–68 was to rescue several Europeans held captive by Theodore (Tewodros II), Emperor of Abyssinia. The expedition's leader, General Sir Robert Napier of the Royal Engineers, made sure to document the scene of the army's exploits; the powerful Sir Roderick Murchison of the Royal Geographical Society had sanctioned the entire project in the cause of empire. The Sinai Peninsula, a politically sensitive region that loomed large in the cultural imagination for its biblical associations, gained the attentions of both the British and the French in the latter half of the century. The great rivalry between these two powers, trailing back to Napoleonic France, is seen in the controversy over Egypt and the Sinai region. The Ordnance Survey of the Peninsula of Sinai was launched collaboratively in 1868 by private agency and the War Department, which administered the Royal Engineers. The expedition's objective was to map the area for both scientific and scholarly reasons. The

Engineers' Sergeant James MacDonald took at least 300 pictures of geographical and ethnographic interest. The construction of the Suez Canal was underway during the survey, and it is hard not to imagine MacDonald's record and the survey report of value in Britain's political designs to dominant the seas and global transport (Howe 2003, 237). Activity in the Middle East was not limited to Europeans: Egyptian Colonel Muhammad Sadiq (or Sadic Bey), skilled in photography, explored Arabia around 1880 with the intent to map the vast terrain. Sadiq did not use the camera an official capacity, but photographed places that would not ordinarily welcome western investigation, most notably the holy city of Medina (Madinah).

The Great Surveys of the American West following the Civil War reflect a similar correspondence—even tension—between military and civil patronage and the meaning of photographs. The case of Timothy O'Sullivan's work for three different expeditions following his employment with Mathew Brady and Alexander Gardner during the Civil War is particularly instructive. The War Department in association with the army's Chief of Engineers was a major sponsor of Clarence King's U.S. Geological Exploration of the Fortieth Parallel, for which he hired the experienced O'Sullivan. This was a matter of expediency on King's part in order to gain the support of Washington. His work was an essentially civilian enterprise, albeit with the Union's strategic interests at stake; the government would see the value of King's reports from the vantage point of economic prosperity and potential settlement in along the transcontinental railway. The U.S. Army tended to see itself traditionally in the leadership role of explorations of the western territories. Thus Brigadier General Andrew A Humphreys, the Chief of Engineers who backed George Montague Wheeler's U.S. Geographic Surveys West of the One Hundredth Meridian, looked at the civilian surveys of Powell and Hayden, as "bureaucratic rivals." How this actually plays out in the photography and reports of the Great Surveys reveals a fascination with the desert and arid mountainous regions of the Great Basin, from geological features to artifacts of the vanishing tribes. The displacement of Native Americans must be considered in any consideration of western expansion and enterprises like King's or Wheeler's. Documentation of the current hostilities between the US and the Indian nations was relatively limited in contrast to the preoccupation with their heritage and remains, as seen in O'Sullivan's picturing of the cliff dwellings in the Cañon de Chelle, New Mexico, for the Wheeler survey in 1873. O'Sullivan worked as well for the 1870 season in the Isthmus of Darién (Panama) under Lieutenant-Commander Thomas O'Selfridge of the U.S. Navy. From a military standpoint, mapping and identifying areas through photographic reconnoitering, as in the instance of Panama in preparation for the proposed canal, proved useful for the future security of U.S. interests.

Photographs related to military reconnaissance and exploration or civil operations with military associations contributed to an archive that would assist in ordering a world which, in the previous century, remained only partially comprehended. Set within the context of institutional reports, collections, exhibitions, and popular printed formats such as the stereograph and the wood engraving, photographs were instrumental in serving to engender a geographical identity for regions under industrial development or surveillance. The process of identification and recognition of subjects, repeated through the dissemination of photographic reproductions, played to imaginative conceits of the observer. Documentary photographs could not function outside of the symbolic and the utilitarian basis of their production, for which there were ideological assumptions underlying the original objectives of expeditionary and military enterprises. Such ventures yielding a photographic record circulated in the public domain had a galvanizing role in the "civilizing mission" of the west by reinforcing the power and presence of modern industrial nations throughout the world.

MIOT, PAUL-EMILE (1827–1900)

French photographer and hydrographer

The French photographer and naval officer Paul-Emile Miot produced some of the earliest known photographs of the east coast of Canada and Newfoundland. His photographs present a remarkable early picture of this coastline and its peoples, particularly because a career naval officer took them during official missions, and without compromising his successful naval career. But more importantly, his use of photography as an aid to the work of the mapmaker is an important application of the medium, and one which is still used extensively today.

Miot was born in Trinidad to a French father and a West Indian mother, and the family returned to Paris while he was still quite young. Intent on a career at sea, he entered the Naval Academy in Paris in 1843, and emerged in 1849 with the rank of sub-Lieutenant.

He first served on the *Sibylle*, being given the command of the merchant ship *Ceres* in 1849, and survived an epidemic of yellow fever which killed two thirds of his crew. From the autumn of 1855, until hostilities ceased in the spring of the following year, he served as an officer with the French naval fleet based at Kamiesch during the Crimean War

There exists in the archives of the Bibliotheque nationale a remarkable series of photographs of the French fleet taken at Kamiesch by Jean-Baptiste-Henri Durand-Brager and Pierre Lassimonne, dating for the period of Miot's service there, and some researchers have suggested, as yet without corroboration, that Miot's interest in photography may date from that time and a possible encounter with those two photographers. He started to experiment with the camera early the following year while on leave from the navy.

It is also suggested by several sources, that during that same commission, Miot, still a sub lieutenant, met Lieutenant (and later Admiral) Georges-Charles Cloué, who would play a pivotal role in the development of his naval career thereafter.

By the following year, 1857, Miot was demonstrating his photographic accomplishments, sailing with Cloué for the first time, and now promoted to full lieutenant. That voyage, to Newfoundland on board the *Ardent* resulted in his earliest known photographs, which were met with some acclaim back in Paris, and used as the basis for line illustrations in *le Monde Illustré*.

In a letter preserved in Archives nationals in Paris, dated September 27, 1857, Cloué describes the importance of Miot's photography in assisting with their hydrographic and mapping mission.

> One of the officers of the *Arden*t , Lieutenant Miot, took up photography during his last period of leave. He is remarkably successful, Commodore, as you have been able to see for yourself. I have given some thought to utilizing this new science, which, until now, might have appeared to have no more than an artistic value, for our precision work, and I believe that, thanks to the ability and the intelligence of Mr. Miot, I have achieved results that give extremely high hopes for the future.
>
> Theodolite readings taken from the main points of triangulation require a certain experience of drawing to produce the views, which, with the aid of the angles that are included in them, are invaluable in later recreating the contours of the coast and the main features of the terrain.
>
> Henceforth, a few angles taken with the theodolite will suffice, and the readings will be complemented by a photographic view on which the angles need not be calculated until the moment when the map is drawn. I have had Mr. Miot take several of these views, taking care that the focal point of the instrument's lens is in the same position for each of the views, so that the horizontal distances on the print always represent the same number of degrees in the angle.
>
> When taking measurements from the photographic views, with a graduated metal ruler, of the distances that separate the verticals drawn from various readings, I have frequently obtained accuracy to within one minute compared to the angles provided by theodolite readings.

Miot had taken his own camera and equipment on the voyage, although Cloué did arrange for a 'small, suitably-equipped photographic laboratory' to be established for him onboard the *Ardent.* It is clear that Cloué saw this work as a partnership between Miot and himself—photographer and chart maker—admitting to have no photographic knowledge himself, and to be entirely dependant upon Miot's expertise.

Further voyages to Newfoundland saw Miot's photographic productions as more and more closely integrated with the survey itself—but not exclusively so—and by 1860 he and his work had achieved official recognition, with photographic facilities established at the Dépot des cartes et plans. When the *Ardent* got trapped in ice, Miot carried his camera on to the ice-flow, and produced some magnificent studies that rival the best Arctic pictures of the nineteenth century. During stopovers in the French islands of Saint-Pierre-et-Michelon (today

the last remaining fragment of the French Empire) off the coast of Newfoundland, he also became the first person to take photographs of the islands inhabitants and their villages.

Photographs from the Newfoundland expedition were printed for Miot by Furne et Tournier of Paris, and the decision to hand the negatives over to a commercial printing house suggests that they were produced in quite large numbers. Others were used as the basis of engravings for *Le Tour du Monde* over a period of months in 1863, a part-work published intermittently until the mid 1870s.

By 1863 he had his first naval command, and almost four years later completed a tour of duty which had taken him to Mexico and Martinique. The period from 1868 to 1871, now promoted as Admiral Cloué's Chief of Staff, saw him circumnavigate South America, along the way visiting the Marquesas Islands, where he produced accomplished group portraits of the Royal Family of Vahitou.

The deands of a blossoming naval career seem to have limited Miot's time for photography, the majority of surviving images covering the period 1858-1875. By 1881 he had reached the rank of Rear-Admiral, and Vice-Admiral by 1888. By then he was deskbound in Paris, retiring from the navy at the age of sixty-five.

A substantial number of his glass plate negatives survive in the archives of the Ministére de la marine in Vincennes, France.

MISONNE, LÉONARD (1870–1943)

Known as one of the most important Belgium photographers of his time, Léonard Misonne was born in 1870 in Gilly, Belgium. After being introduced to photography in 1891 during his engineering studies in Louvain, he joined the Photo-Club of the city and decided to give time to arts—painting, music, and photography.

As he became a member of the Association belge de photographie, he took part of his first exhibition in 1896 with pictures of the country and the peasant life in a style he developed until his death in the pictorialist aesthetic. From this time he never gave up exhibitions especially in Paris, New York, London, Germany, and Austria, which gave him international acknowledgement.

He obtained the visual effects and atmosphere thanks to the different processes he used. In a first period, he printed his photographs on carbon however between 1900 and 1910 he used Fresson paper and then oil print he learned from Constant Puyo.

MARION PERCEVAL

MISSION HÉLIOGRAPHIQUE

In 1851 the *Commission des Monuments historiques*, part of the French Ministry of the Interior, sent photographers on five missions to different regions of France to make records of historic monuments which were being restored or were slated for restoration. The buildings in question were primarily examples of medieval ecclesiastical architecture, but Renaissance palaces, Gallo-Roman structures, and some pre-historic stone groupings were included. The Mission héliographique, as the project has come to be called, is one of the first instances of photography conceived and commissioned by a government agency for archival purposes. In 1851 it also constituted one of the largest photographic projects ever undertaken. The photographers involved include several great figures in the history of photography: Henri Le Secq, Edouard Baldus, Hippolyte Bayard, Gustave Le Gray and Auguste Mestral. Le Secq was sent north-east to Champagne, Lorraine and Alsace. Baldus was dispatched to Provence by way of Fontainebleau, Burgundy, and the Dauphiné. Bayard was assigned Normandy. Le Gray and Mestral were directed to the center and south-west, and undertook their missions together: they began in the Loire Valley, circled down into Languedoc, and returned through Auvergne. Each photographer was provided with a list of monuments to record; parts of buildings and even works of art were often specified on the lists.

Le Secq used Le Gray's waxed paper negative process and produced between 150 and 200 negatives, although the commission acquired a set of only 96 negatives and prints. Baldus worked with albumenized paper negatives and made 46 negatives and prints (some of his finished negatives combine multiple spliced views). Le Gray and Mestral used waxed paper negatives and contributed 120 negatives and prints. Bayard employed glass negatives with Niépce de Saint Victor's albumen process. Although Bayard's photographs were discussed in the press, it is unclear whether he ever turned them over to the Commission: only a handful of prints identified as part of his mission now exist. The other photographers' negatives (which number close to 300 with duplicates and panoramas) are housed at the Musée d'Orsay. 165 of the prints survive from the original set, and most of these are divided between the Musée des Monuments français and the Photothèque du Patrimoine in Paris.

There is some evidence that the photographers were selected out of a competition (such a contest is indicated in an 1853 letter written by a student of Baldus).

However all five photographers were members of the newly-founded Société héliographique, and several other members of that Society were government functionaries with some connection to the Commission des Monuments historiques, notably Léon de Laborde, who was a member of both bodies. Thus it appears that the Société héliographique was somehow involved in developing or at least encouraging the photographic missions. But the Society and the Commission had different objectives. The Commission devised the survey to document structures that were slated for government-sponsored restoration, so the buildings chosen were not necessarily the chief monuments of their respective cities. Moreover a number of the photographs, such as "Dolmen de Bagneux près Saumur" by Le Gray and Mestral, seem to reflect the particular enthusiasms of Prosper Mérimée, director of the Commission, more than any institutional imperative. Most of the regions of France are included in the survey, indicating some interest in a representative collection of views. But the Commission acquired only certain views made by the photographers: Le Secq, Le Gray and Mestral all made many more photographs than requested on their trips, but the extra work did not interest the Commission. Much of Le Secq's work has survived; it is comprised almost entirely of building views, and yet the Commission acquired only a portion, for instance, of the 43 photographs he made of Strasbourg Cathedral (his work not purchased by the commission is now housed at the Bibliothèque des Arts décoratifs in Paris). A photographic record for its own sake was outside the Commission's purview. The negatives and prints it acquired were filed in dossiers on the respective buildings they represented. The Commission never published or exhibited the photographs.

Such a photographic archive did not match the interests of the Société héliographique. The group's objectives were indicated as early as March 1851, when *La Lumière* reported that the photographic missions had given impetus to the Society's desire to found a photographic publishing establishment. Evidently the members envisioned printing views from the project for public dispersal. The scope of the Society's hopes for the missions is indicated by Francis Wey's 1853 reference to the projcet in his essay "Comment le soleil est devenu peintre:"

> …The public is deprived of these prints that everyone would examine and discuss; the photographers are denied the publicity they had hoped for, and our country cannot honor the most beautiful body of work that has been produced to date. We had asked for as much and we had hoped for more.

The photographs were in fact widely discussed in the photographic press, where the distinctive approaches of the photographers were noted. Baldus combined negatives with amazing skill in several views, such as "Palais des Papes et Notre-Dame-des-Doms" taken in Avignon. In this and other images he typically depicted his subject from a distance, with the entire structure placed centrally in the frame, giving it an air of monumentality. Le Secq's heroics were not on the order of combined negatives or monumental views, but in climbing all over and around a building to capture perspectives of rarely-seen details. In views such as "Cathédrale, flèche, angle nord-est" taken at Strasbourg, he combined his rooftop escapades with dynamic off-center compositions that often vivify the sculpted figures. Le Gray and Mestral frequently emphasized the graphic patterning of darks and lights in the picture frame, making imaginative use of the calotype's blank skies. Their compositions give the subjects a sense of grand scale and architectural harmony, as seen in the view "Eglise, ensemble est" taken at the church of Saint-Julien-de-Brioude. Despite these creative prerogatives, the various processes the photographers used all point to a desire for smooth negative surfaces and optimal clarity, an obvious requirement for architectural records. The fact that only Bayard employed glass is not surprising: transport of the negatives was precarious, and Niépce's process was very slow with uneven results. Along with the Mission photographs themselves, Baldus' subsequent production of finely detailed calotype views points to the desire of these photographers to make good architectural documents with the calotype process.

However hidden from view the Mission photographs remained, they were part of a wide impulse to document France's architectural heritage. Baron Taylor's *Voyages Pittoresques* is frequently cited as a lithographic model for the Mission héliographique, but the specific archival requirements fulfilled by the Mission mark its difference from Taylor's Romantic atlas. The use of photography for such a project was untested in 1851, but it was not without precedent. The *Commission des Monuments historiques* had itself ordered six "daguerreotype views" of unspecified subjects from Bayard in 1849. As early as 1843 the architect Felix Duban had hired Bayard to make between 20 and 50 daguerreotypes of the château at Blois for a restoration ordered by the Commission (a handful of these are preserved at the Société française de photographie). Closer to the sentiments of the *Voyages Pittoresques*, Le Secq had privately undertaken a photographic record of Amiens Cathedral in 1850. These endeavors and the Mission itself demonstrated that photography could serve both the public's imaginative relationship to the past and the instrumental needs of architects and committees. Throughout the 1850s photographers continued to record monuments all over France. In 1852 Charles Nègre embarked on a photographic tour of his native Provence, photographing

many of the same monuments Baldus had recorded, with publication of a de luxe album in view. That same year Le Secq began returning to the great Cathedral towns of Chartres, Amiens, Reims, and Strasbourg. His motivations seem personal, but some of his views found their way into the albums of Louis-Desiré Blanquart-Evrard, which were marketed to a broad art-world milieu. Baldus' mission launched his commercial career: he went on to photograph old and new monuments for the government, the railroad companies, and for his own trade in views. His work, and that of Charles Marville a bit later, continued to fill the archives of city and state. But both photographers retained their negatives, a lesson they had perhaps learned from the fate of this first photographic mission.

MOFFAT, JOHN (1819–1894)

One of the most widely reproduced portraits of William Henry Fox Talbot was taken in 1864 by the Edinburgh photographer John Moffat. That same year he gave the first public demonstration in Scotland of photography by the light of burning magnesium wire.

Born in Aberdeen on 26 August 1819, the son of a successful bookbinder, John Moffat moved to Edinburgh with his parents in 1827. Trained as an artist and engraver, he owned his own engraving business in Edinburgh by 1848. As an amateur photographer, examples of his work were shown at the 1851 Great Exhibition in London, and opened his first portrait studio in Edinburgh's Nicholson Square in 1853. In 1857 he opened the first of five studios on Princes Street. The studio occupied premises at 125/126 Princes Street until 1962. Throughout his professional career, Moffat combined his interests in art and photography, operating an art gallery on the first floor of his Princes Street premises, selling oils and watercolours by the leading artists of the day.

He was a leading figure in the Photographic Society of Scotland from its inception in 1856 until it ceased to function in 1873, and in the Edinburgh Photographic Society from 1863 until his death, serving as its President for many years.

Moffat's obituary was carried by the British Journal of Photography.

JOHN HANNAVY

MOIGNO, ABBÉ FRANÇOIS (1804–1884)

French religious teacher, author, nicknamed "the Apostle of Projection"

Born in 1804, Moigno entered the Society of Jesus in 1822, leaving in 1844 to become a high school chaplain. In 1850 he introduced David Brewster to Duboscq, who then constructed Brewster-pattern stereoscopes. Moigno established 'Le Cosmos,' a popular science magazine, in 1852. His visit to the Royal Polytechnic in London in 1854 fueled a lifelong enthusiasm for image projection. Moigno's initial attempts to present lectures illustrated by slide projection were forbidden by the authorities, but he persevered. In 1864 he gave presentations of photographic slides in temporary venues, and after a difficult start, his more permanent Salle de Progrès, set up in Paris in 1872, was a success. Moigno's 1872 book 'L'Art des Projections' was the first French magic lantern manual. His 1882 catalogue of photographic slides—many by professional photographer Armand Billon—comprised over 4,000 items featuring Geography, History, Biology, and other topics. Photography itself was one subject, with microscopic photographs, portraits of Niépce and Daguerre, and photographs of equipment. Moigno's later claim to have originated educational teaching by slide projection was overstated, but he was certainly a major proponent of the method for decades. He died in 1884.

STEPHEN HERBERT

MONPILLARD, FERNAND 1865–1937
French photomicrographer

Fernand Monpillard quickly acquired a reputation as an exceptional photomicrographer. His "Laboratory of Microphotography" was located at 22, Saint-Marcel boulevard in Paris, not far from the national Museum of natural history. He collaborated with many naturalists, biologists, and mineralogists whose articles were often illustrated with his work. At the end of 1870, photography acheived a scientific quality that Monpillard never failed meet. Becoming a member of Société française de photographie (SFP) in 1892, he frequently shared his research on plates with orthochromatic emulsion, which caused the indirect reproduction of colors or trichromatic synthesis. With the development of the histology and microbiology, the microscopic observations required color and Monpillard worked to obtain images that would further the succes of scientific investigations.

If he worked to integrate photomicrography into the experimental protocol, he also contributed to the history of color photography. Auguste and Louis Lumière profited from his research on coloured screens as they used them for their autochrome plates. From 1908 to 1932, during the evening he gave projection shows of his autochrome plates there that were used for scientific and geographical applications at the SFP. Monpillard published his first treatise of photomicrography in 1899 (*Microphotography*, Paris, Gauthier-Villars) according to his technical courses given t the SFP, and then another in 1926 (*Macrophotography and microphotography*, Paris, Gaston Doin and Co). He was also the director of the luxurious review *La Photographie Française* from 1901 to 1905.

Carole Troufléau

MONTFORT, BENITO DE
(active 1850s)
French aristocrat and benefactor

Writing in the journal *The Chemist* in February 1852, in an article entitled 'Photography in France', Roger Fenton described his visit to the Paris home, at 15 Rue de l'Arcade, of Colonel Benito de Montfort, son of Baron de Montfort, and the founder of the Société heliographique, the world's first photographic society. The society's rooms were in de Montfort's house in one of Paris's most desirable and elegant neighborhoods near the Bourse.

> An entire suite of apartments, consisting of four or five rooms, at the top of the house, of course, and opening on to an extensive terrace, with an excellent light, is devoted to the purposes of the society. One room is entirely occupied, walls, drawers and cupboards, with choice specimens of the art, mostly in metal; another is fitted up with a laboratory, one corner of which is an enclosure surrounded with yellow curtains, to exclude the light. In fact there is every requisite facility, both for receiving the amateurs in a suitable locale, and for their trying experimentally, any new development of the science.

Such facilities attested to Montfort's enthusiasm for the new society which had been set up in 1851 as a meeting point for a number of eminent scholars and men of science, who were interested in the new art of photography. Despite Fenton's comment that most of the images he saw were daguerreotypes, the forty founding members included many who were producing work of the highest quality with the several negative/positive processes of the time—including Baron Gros, Baldus, le Secq, Mestral, le Gray, Lerebours and Vicomte Vigier.

Fenton would later use his knowledge of the French organization as one of the triggers for the foundation of the Photographic Society of London in 1853. So, indeed, would Antoine Claudet, now accepted as the probable author of a handwritten proposal for the formation of the London Society, now in the collection of the national media Museum, Bradford. In that document, the proposal that the new society should have its own rooms (in Claudet's premises) describes a layout remarkably similar to the suite of rooms Montfort had made available to the Société heliographique.

Many of Benito de Montfort's ideas for the Société heliographique were far-sighted and inspirational. The organisation would collect exemplary works, would publish an *Album* of the finest paper photography, and would publish a journal—*la Lumière* initially edited by F A Renard, then by the Jesuit Abbé François Moigno and later by Ernest Lacan—in which all the latest advances and ideas were circulated to members, and which was available on subscription to non-members. The editorial offices of *la Lumière* were also in Montfort's house. Interestingly, Abbé Moigno went on to edit *Cosmos*, also founded by Montfort in 1852, initially as a scientific journal, but later with considerable interests in photography as well.

The first *Album* was produced in spring of 1851, the cost of binding it being met by Montfort—described by le Gray as Comte de Montfort—out of his own pocket. While *la Lumière* prospered and continued in regular publication until 1867, the Société heliographique ceased to function after only two years, to be replaced in 1854 by the Société française de photographie, which published its own journal, the *Bulletin*.

Two further albums were produced in 1852 and 1853, and despite the society's rules stating that in the event of it being wound up, the albums were to be given to the Bibliothèque nationale (then the Bibliothèque royale)

and the library being advised of the imminent gift in March 1853, there remains no trace of them.

Montfort served for a time as the Societé heliographique's first President, before being replaced by Baron Gros, and for its entire existence, the society continued to enjoy premises within Montfort's house. Remarkably, little is known of Benito de Montfort private or public life, and of his practical involvement with photography, nothing. However, in his day, as one of French photography's earliest benefactors, he was renowned for his generosity. His importance in the propagation of the understanding of photography was acknowledged by le Gray in the concluding paragraphs of his introduction to his booklet *Plain Directions for Obtaining Photographic Pictures* in 1852 (English language edition Philadelphia: A. Hart, 1853).

MOODIE, GERALDINE (1854–1945)
Canadian photographer

Geraldine Fitzgibbons Moodie was born in Toronto, Canada, on October 31, 1854, to Agnes Dunbar Moodie, an illustrator, and Charles Thomas Fitzgibbon, a lawyer and registrar. In 1870, the family relocated to Ottawa where Geraldine completed her education. She traveled to England in 1877, where she met and married her husband, John Douglas Moodie, who joined the North-West Mounted Police in 1884. The Moodies relocated frequently and lived at every major Mounted Police post in Western Canada, as well as in the Hudson's Bay district of the Eastern Arctic. Geraldine Moodie began to practice photography in the 1890s and she opened her first photographic studio in Battleford in 1895. While much of her photographic activity consisted of customary portrait work, she also photographed the activities of both the Mounted Police and the Native communities that surrounded her. Of particular interest are her photographs of the Inuit people that she encountered in the Arctic. Her interest in botany also led her to photograph plant life. John Moodie retired from the Mounted Police in 1917 and they settled in Maple Creek, later moving to British Columbia and then to Alberta, where Geraldine Moodie died on October 4, 1945.

Andrea Korda

MORAITES, PETROS (c. 1835–1905)

Petros Moraites was born on the island of Tinos in the Aegean Sea. He studied painting in Athens but very soon, fascinated by the new medium, he became involved in photography. In 1859, in collaboration with the Greek photographer Athanasios Kalfas, he opened his first studio located at Ermou Street in Athens. The very same year, the two partners presented photographs at the 1st Olympiad (held in Athens) winning a silver medal for their photographic reproductions of landscapes. In September 1860, the partnership ended and Moraites moved his studio to Aiolou Street. Many important personalities of the Greek society: politicians, intellectuals, ambassadors, actors including members of the royal family, as well as ordinary people, posed before his camera. It is assumed that around 1868, he was appointed photographer to H.M. the King, a title bestowed for the first time on a Greek photographer.

Moraites's depictions have been distinguished for their "precision in execution, purity of line, harmony and perfection, without corrections, of photographic work." He earned many distinctions in various photographic exhibitions in Greece [2nd (1870), 3rd (1875) and 4th (1888) Olympiad held in Athens] and abroad [Weltausstellung 1873 held in Vienna and Exposition Universelle (1878) held in Paris]. After his death, his studio was taken over by his son, Georgios P. Moraites, who was soon afterwards obliged to sell it to Nikolaos Pantzopoulos.

Aliki Tsirgialou

MORAN, JOHN (1831–1903)
American photographer and painter

John Moran, a Philadelphia landscape and cityscape photographer, was born in 1831 in Bolton, England to weavers, Thomas Moran Sr. and Mary Higson Moran. A brother to landscape painters Edward, Peter, and Thomas, an active member of the Photographic Society of Philadelphia, and an early proponent of photography as a fine art, Moran began his career in photography in Philadelphia in 1860. For the next decade, Moran focused on landscape photographs of the region, including notable views of the Wissahickon Valley and Delaware Water Gap in addition to stereographic views of Philadelphia landmarks and estates. In 1865, Moran

delivered his "The Relation of Photography to the Fine Arts" paper to the Photographic Society of Philadelphia for which he later served as the vice-president from 1870 to 1873. In 1870, he sold an album of views of early Philadelphia architecture to the Library Company of Philadelphia. Soon thereafter, Moran acted as official photographer for both T.O. Selfridge's expedition to the Darien Isthmus in Panama (1870–1871) and the United States' observation of the Transit of Venus in Tasmania and South Africa (1874). By the late 1870s, following his display of landscape views at the Centennial Exhibition of 1876, Moran abandoned photography for landscape painting. On February 19, 1903, Moran died of Bright's Disease at the New York City home of his son, Thomas.

ERIKA PIOLA

MORAVIA, CHARLES BARCLAY WOODHAM (c. 1821–1859)

Employed as an executive engineer with the Public Works Department in India in the 1850s, Moravia was given responsibility for the demolition of buildings in Delhi after the Mutiny. All his known photographic work appears to date from around this period, during which he produced an outstanding range of views of Indian architecture around Delhi, which survive in the form of albumen prints from his paper negatives, generally signed 'Ch. Moravia' and dated in the negative. In 1859 Moravia was appointed Principal of the Engineering School at Lahore, but his career was cut short by his death from smallpox at Sialkot, where he was buried on 30 April 1859.

JOHN FALCONER

MORSE, SAMUEL FINLEY BREESE (1791–1871)

American daguerreotypist, artist, and inventor

Morse, the eldest son of Calvinist Congregationalist minister and geographer Jedidah Morse and Elizabeth Anne Breese, was born 27 April 1791 in Charlestown, Massachusetts. Best remembered as the father of the telegraph, Morse was also known by his contemporaries as the father of American photography, an association often overshadowed by his revolutionary invention. A man blessed with a mechanical mind and cursed with financial instability, Morse pursued photography in the 1840s following a thirty-year career as an artist, inventor, author, and publisher. A recipient of a privileged education at the Phillips Academy (Andover, Massachusetts) and Yale College (Class of 1810), Morse trained for a career as an artist at the Royal Academy in London between 1811 and 1815. Through his foreign study, he developed a nativist ideology that influenced his professional decisions for the rest of his life. Morse would return to America and attempt to create a unified national culture through art and technology.

After Morse returned to the United States, he pursued his artistic career, first through a failed Boston studio and then through itinerant portrait painting. Despite a few prominent commissions in the 1820s, Morse never achieved financial stability. His two colossal paintings, *House of Representatives* (1823) and the *Gallery of the Louvre* (1833), created and exhibited as part of his nativist mission, failed as well. Consequently, Morse sought other outlets to fulfill his intellectual, financial, and professional goals. In 1826, Morse helped to establish and was elected the president of the National Academy of Design in New York. In 1827 he established the periodicals *Journal of Commerce* and *Academics of Art*. In 1832 and 1835, respectively, he was appointed professor of Painting and Sculpture and professor of Literature of the Arts and Design at the University of the City of New York, later New York University. Between 1832 and 1838, with financial and intellectual partners Alfred Vail and Leonard Gail, Morse invented and perfected the telegraph for which he received a patent in 1840. In May 1838, as a Congressional bill to appropriate funds for his invention sat in a political quagmire, Morse traveled to Europe to seek foreign investment.

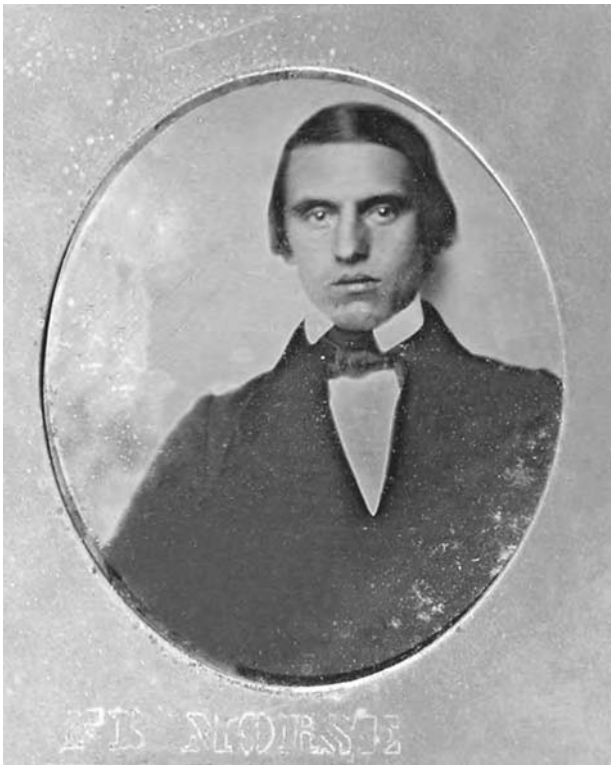
Following its inception in early 1839, the daguerreotype became the one invention that rivaled the telegraph in prestige. On 5 March 1839, during his time in Paris, Morse met with Louis Daguerre and witnessed "one of the most beautiful discoveries of the age." As a trained artist and inventor who had experimented unsuccessfully with photography in the early 1800s, Morse immediately envisioned the cultural impact of this new type of "drawing." In April 1839, Morse authored one of the first American eyewitness accounts of the daguerreotype. Soon thereafter, he became synonymous with the burgeoning field of American photography when his narrative, first published in his brothers' periodical the *New York Observer*, was republished across the country. A month later, he had Daguerre elected as an honorary member of the National Academy of Design and within days of the arrival of the description of the process to the United States in September 1839, Morse became one of the first Americans to announce success in the creation of a daguerreotype.

His daguerreotype view of the new Unitarian Church in New York City was disclosed in the 28 September 1839 edition of the *Journal of Commerce* and in the ensuing months he continued to experiment with the new process aiming to decrease the exposure time of daguerreotypes by several minutes in order to produce portraits. After engaging Daguerre agent Francois Gouraud as an instructor, Morse began keeping detailed

notebooks from January-February 1840, which are preserved in the collections of the Library of Congress, of his lessons and continued experiments with the medium in a glass enclosure on the roof of his university. Through weekly entries, sketches, and charts of carefully inventoried plates, he described his trial and error methods to properly acidize, clean, and iodize the plates, as well as, most importantly, to master the correct exposure time given available light to produce a clear image. By mid-January, Morse had discharged Gourard, whom he felt provided inadequate, outdated instruction and began to more actively collaborate with university colleague, chemist, and daguerreian, John Draper, who had calculated the proper chemical focal measurement needed for successful exposures. Within weeks, through continual trials of variant exposure times using Draper's focal calculation and with equipment designed by George Prosch, Morse overcame his "imperfect" results and produced a superb plate of City Hall in early February. By the fall, his quest to quickly expose focused portraits was finally fulfilled when he perfected a five-lens system developed by Draper. The system of corrected and concave lens allowed Morse to decrease the focal length and exposure time and still produce a distinct image using indirect sunlight. As a result, Morse reported to Draper in November 1840 that he was able to photograph an indoor portrait within five seconds.

During the same period ,Morse and Gouraud started a long public debate about each other's technical abilities and professional qualifications. Morse emerged from the feud perceived as the competent daguerreotypist while Gouraud was seen as the fraud seeking personal fame and fortune. In 1840 and 1841, his reputation unscathed, Morse made one of the earliest group portraits, a view of the Yale reunion class of 1810, and with Draper opened a commercial portrait studio, advertised as the "Palace of the Sun on Broadway," on the roof of the university. By spring 1841, Draper left the studio and Morse opened a second facility on the roof of his brothers' newspaper building.

As he had with portrait painting, Morse pursued portrait daguerreotypes as a means to support his career as an artist. Unlike many of his colleagues, Morse perceived daguerreotypes as "portions of nature herself" that were to be used in place of artists' sketches. As an ally of the medium, he concluded to the National Academy of Design on 24 April 1840 that the daguerreotype was a catalyst for a "revolution of art" that would elevate the artist and the society that viewed his work. Morse believed that daguerreotypes would lead to his long desired national American culture. Given this reputation, Morse quickly became sought after as a mentor for daguerreotypy and from 1840 to 1841 taught such prominent future photographers as Mathew Brady,



Morse, Samuel F. B. Portrait of a Young Man.

Anthony Southworth, and Samuel Broadbent. By May 1844, following the successful completion of a telegraph line between Baltimore and Washington, D.C., Morse retired as a professional daguerreotypist.

This prophetic artist, however, maintained an association with the field until the end of his life. Daguerreotype portraits of his second wife and daughter from the late 1840s in the collections of the New York Historical Society suggest that he continued to make daguerreotypes as a pastime. From 1851 to1852, he professionally endorsed photographer Levi H. Hill in his quest to be accredited as the inventor of a color photographic process and he judged photography competitions such as the Anthony Prize in 1853. The mid-1850s saw celebrated photographers Mathew Brady and Marcus A. Root requesting Morse's views about his pioneer role in photography. In 1871, he deposited his first camera with Abraham Bogardus, president of the National Photographic Association, which was later acquired by the Smithsonian Institution. According to a July 1871 *Photographic Times* article, he also donated the "first daguerreotypes produced in this country" to Vassar College, of which he was made a trustee in 1865.

After the U.S. Supreme Court upheld Morse's telegraph patent in 1854, Morse's monetary woes ended. Financially secure from the licensing fees of his cel-

ebrated communication device, Morse spent his later years on his estate, Locust Grove, on the Hudson River. On 2 April 1872, the father of American photography, passed away at his home in New York City.

ERIKA PIOLA

Biography

Samuel Finley Breese Morse was born 27 April 1791 in Charleston, Massachusetts. Educated at Phillips Academy in Andover, Yale College, and the Royal Academy, Morse was an artist, inventor, and daguerreotypist who pursued his various professions with a desire to create a national American culture. He opened a Boston art studio in 1815 and a New York art studio in 1823. In 1818, he married his first wife, Lucretia Walker, with whom he had three children, and in 1848, married his second wife and cousin, Sarah Elizabeth Griswold, with whom he had four children. From 1826 to 1832 he organized and was elected president of the National Academy of Design and became an art professor at the University of the City of New York. In 1840, he opened a daguerreotype studio and was granted a patent for the invention of the telegraph. Between 1836 and 1854, he ran unsuccessfully for the offices of New York Mayor and Congressman. In 1854 the Supreme Court upheld his telegraph patent for which he received several national and international honors. Morse spent his later years in Europe and at his estate Locust Grove. He died 2 April 1872 in New York City.

MOSCIONI, ROMUALDO (1849–1925)

Italian photographer

From Viterbo, south of Rome, Moscioni had a successful photography business during the albumen period at various addresses in Rome from 1868 onwards. He specialised in topographical views, excavations, early Christian archaeology along with art works, including Etruscan, which will continue to provide historical information for generations to come. In 1889 his business moved to the fashionable Via Condotti which demonstrated his success on becoming the "purveyor to the Imperial museums of Berlin, Petersburg and the Art Museum of Copenhagen." He was in competition with similar material from the larger companies, such as Alinari, Anderson, Brogi. His fourth catalogue, published in 1921, listed 24,900 images (26,000 by the time of his death). Between 1868 and 1895 he had amassed 8,600 negatives. At the turn of the century he was still making, 300+ negatives on average per year but between 1903 and 1921 it rose to 700. Fortunately around 26,000 glass plate negatives, much of his life's work, were divided between the archives of the Vatican Museum, the American Academy in Rome, the Ministry of Education, and the Archivo Forografico Comunale in Rome. Thus Moscioni is one of the few photographers of the period whose large output is so fortunately preserved.

ALISTAIR CRAWFORD

MOTION PHOTOGRAPHY: PRECHRONOPHOTOGRAPHY TO CINEMATOGRAPHY

With the application of photography, the free-flowing images of the artist's *camera obscura* were frozen, and it would be several decades before motion could be recorded and reproduced by the new medium. However, moving images produced from a series of pictures preceded the commercial introduction of photography. In 1832 Belgian scientist Joseph Plateau, investigating the phenomena of Faraday's Wheel, devised the phenakistiscope, a cardboard disc with a sequence of drawings that appeared to move when the images, reflected by a mirror, were viewed through slots in the disc. Viennese Professor Simon Stampfer simultaneously developed his similar Stroboscope. These "philosophical toys" were soon being sold as conversation pieces, and led to the daedelum drum-form version, suggested by English mathematician William George Horner, and marketed from the 1860s as the zoetrope.

The application of photography to moving images was inevitable, but slow exposure times before the 1860s/70s meant that photographing sequences of subjects moving in "real time" was an impossibility. Experimenters compiled sequences from series of static

poses, the subject assuming the key positions of the action being represented.

Since stereoscopic photography was the latest advance, experimenters naturally supposed that moving photographs would be stereoscopic. London-based daguerreotypist Antoine Claudet was intrigued by the idea of stereoscopic phenakistiscopes, but limited his experiments to a two-phase stereogram. Essentially a standard stereoview portrait, each image represented the extremes of a simple staged movement; for example a man putting a cigarette to his lips and removing it. In the viewer a revolving shutter obscured and revealed each picture in turn, one to each eye, resulting in a stereo portrait with a limited motion effect. Similar stereograms were later sold in France.

Other inventors actually constructed photo-phenakistiscopes. French optician Louis Jules Duboscq's was called the Bioscope; one version used twelve sets of stereo halves, left/right images placed one above the other. Subjects—the sole surviving example shows a beam engine—were posed in incremental positions representing a sequence of motion, and brought dimensionally to life in the special viewer.

Englishman William Thomas Shaw patented his Stereotrope in 1860. A series of stereocards was mounted in an octagonal case, incorporating an ingenious drum shutter. In the United States in 1861, Coleman Sellers patented several ideas for stereo-motion viewers including his Kinematoscope, a drum-form tabletop stereoviewer holding six sequential stereograms.

The inventor of the stereoscope, Charles Wheatstone, attempted various stereo motion viewing devices between 1849 and 1870. An existing machine has a strip of images showing a soldier presenting arms.

One rather advanced result was successfully achieved in 1864 by Scottish mechanic James Laing. A conventional stereoscopic plate camera was used to photograph a wooden model village, with cotton-wool smoke rising from a cottage chimney, and a revolving windmill. Frustrated by the zoetrope's limited capacity—"this fixity of number ... does not suit the motoroscopic effect"—the pictures for his successful Motoroscope viewer were arranged on a long continuous belt, one of several ideas suggested by experimenter Peter Desvignes some years earlier. Sadly, no images have survived. This stop-motion animation preceded trick filming by thirty years.

Duboscq produced a projecting phenakistiscope c.1853, while Austrian lanternist Ludwig Leopold Döbler toured with a similar device, built by inventor Franz Freiher von Uchatius. In the 1860s lanternists developed the 'wheel of life' slide—a projection phenakistiscope, with silhouette images arranged on small glass discs—for use with an ordinary optical lantern. Another lantern device, Beale's choreutoscope (1866), comprised a sequence of images on a strip of glass, moved intermittently by a pin-and-cam movement similar to the maltese cross later used in motion picture film machines. None of these projection devices made use of photographs, but static photographic images on glass had been projected by magic lantern from around 1850.

Projection of photographic images shown sufficiently fast to give an appearance of life in motion was achieved by Henry Renno Heyl in Philadelphia in 1870. The photographs, including a repeating sequence of a waltzing couple, were posed individually. Not yet a motion picture of a subject in real-time motion, neverthless successful public Phasmatrope performances were given.

As exposure times decreased and 'instantaneous' photography became possible, attempts were made to photograph sequences taken in 'real time,' with the subject actually in movement—with or without the complications of stereoscopy.

In 1876 English political activist Wordsworth Donisthorpe patented the Kinesigraph camera for multiple glass plates. With the announcement of Edison's newly-invented phonograph Donisthorpe suggested using results from the two instruments together, to screen images of a politician speaking, for instance, but the technology was not sufficiently advanced.

In contrast to those who had a vision of reproducing moving scenes by photography, whom we could call proto-cinematographers, there were also experimenters whose main aim was to obtain a series of images showing phases of motion for purposes of analysis. Initially these chronophotographers had little interest in synthesizing such sequences into a moving picture, but later most would attempt some form of motion synthesis.

Eadweard James Muybridge, an accomplished and well-known photographer, was commissioned to photograph a trotting horse to determine whether it had all four feet off the ground at one time. His single photographs were sufficiently clear to confirm that the horse was indeed 'unsupported' during it's trot and gallop. Muybridge extended his experiments in 1878 to include sequences of animals and humans taken with 12 or more cameras, some of which were stereoscopic. Despite using low-sensitivity wet plates, his results were successful and engravings of his horse sequences widely published, proving of great interest to French physiologist Etienne Jules Marey.

Marey had been analysing human, animal and bird movement using mechanical devices attached to the subjects, connected to an instrument that drew traces on a revolving drum. Muybridge's photo sequences were important in confirming results obtained by Marey's traces, and the physiologist asked the photographer to try sequences of birds. Muybridge's success was limited, so Marey devised a photographic gun for shooting twelve photographs on a glass disc. Though small and lacking detail, the images were useful for Marey's research

on flight. Marey continued with chronophotography, devising large single-lens cameras using wheels or discs with images set around the periphery. Individual images often overlapped, enabling a larger number to be recorded. Overlapping was not of consequence for analytical purposes, and Marey was not concerned with producing motion pictures.

The interest in Muybridge's work continued. To 1870s eyes the frozen positions of the horses' limbs had seemed ludicrous. Muybridge placed the sequences in a zoetrope to synthesise the movement, which appeared perfectly natural, confirming the veracity of each component photograph. The zoetrope being limited to a small audience, he devised a projecting phenakistiscope or Zoogyroscope (later Zoopraxiscope), to present sequences in motion on a large screen. The large glass discs featured painted silhouettes based closely on his sequence photographs. The Zoopraxiscope horizontally compressed the shape of each image on projection, so the painted images were elongated to compensate. Some discs featured a composite scene based on several sequences, such as a bull chasing a man, and a few included elements that were pure imagination. Muybridge now bridged both camps: those content to simply analyze a strip of sequential images, and others trying to invent a motion picture process. In the 1880s he lectured in Europe and the USA, projecting slides of his individual photographs alternately with animated silhouette sequences, generating widespread interest in moving pictures. In 1884 Muybridge was contracted to continue his work, at the University of Pennsylvania. His sequences included zoo animals, nude studies of women, and male athletes. Taken on dry plates, they included more detail than his earlier attempts.

Meanwhile in Germany in 1884, Ottomar Anschütz—who had designed shutters for instantaneous photography—started chronophotographic experiments, with 12 and then 24 cameras. His images, taken on fast dry plates, were of high quality. Like Muybridge, Anschütz became interested in animating sequences of athletes and animals. His zoetrope introduced an ingenious arrangement of three rows of slots of different numbers, for viewing strips with differing numbers of images, essential when photographing animals moving at different speeds. Anschütz's other viewing devices included a large wheel with images rear-illuminated by a synchronised electrical flash lamp.

By 1888 Marey was using sensitized paper strips for his photographic analysis. Other inventors, with a vision of cinema, recognised the need for such a flexible medium. Their cameras mosly used some form of intermittent movement, the film being stationary as each frame was exposed. In 1888 Louis Aimée Augustin Le Prince, a Frenchman working in England, was perhaps the first of these visionaries to successfully photograph sequences on paper 'film': traffic on Leeds bridge, his son playing the melodion, and the family in their garden. The images were transferred to belts of glass slides for projection. Several projector designs failed to produce an exploitable result, and Le Prince got into debt. On a visit to France he disappeared, an apparent suicide.

With the availability of rollfilm, Donisthorpe restarted his motion picture experiments, involving draughtsman William Carr Crofts. Their 1889 camera, designed for paper rolls but later using celluloid, featured a unique optical compensation mechanism. Although taken at a slow rate, a camera test of London's Trafalgar Square seemed promising, but unperforated film made projection difficult and success eluded them.

Portrait photographer William Friese-Greene became interested in motion photography through his friend James Arthur Roebuck Rudge, whose magic lantern shows had included simple devices for animated movement. Friese-Greene demonstrated one of Rudge's lanterns, and then developed with engineer Mortimer Evans a camera for taking sequences on a flexible support—initially paper, later celluloid. At around five pictures per second the results were limited, and there was no successful method of motion projection. Their 1889 patent included pins on the drive roller to improve traction. A film of King's Road Chelsea (c. 5 fps) can today be manipulated into a proto-motion picture. In 1893 Friese-Greene patented a stereoscopic sequence camera devised by Frederick Varley, but again the framerate was slow.

These film pioneers found successful projection elusive, but the earlier chronophotographers had by the early '90s developed techniques for commercial exploitation in peepshow machines, using very short photo sequences in motion. An arcade version of Anschütz's "Electrical Wonder" machine, with images set around the periphery of a disc, was produced in quantity, and appeared at the Columbian Exposition, Chicago, in 1893.

Marey's assistant, gymnastics specialist Georges Demenÿ, supervised the production of chrono sequences featuring soldiers and athletes. Demenÿ designed the 'beater' camera movement, later adopted by many other film pioneers. Exposed on strips of unperforated celluloid negative, the individual positives were mounted around a Phonoscope disc, for direct viewing or small-scale projection. One intended use was (mute) talking portraits, to help the deaf to lip-read. Demenÿ's interest in the commercialisation of motion pictures eventually caused a split with his scientist mentor. (Marey had briefly attempted film projection, but his 1892 projector was not successful.) Initially a commercial failure, with the advent of perforated film Demenÿ's beater mechanism would be successfully exploited in early cinematograph equipment by the Gaumont Company.

Edison's latest wonder was also to have appeared at the Chicago World's Fair, but wasn't ready in time. From 1888 his assistant William Kennedy-Laurie Dickson had been in charge of developing what became the kinetoscope, the first commercial motion picture film machine. Initial experiments used tiny images set in a spiral on a sheet of celluloid wrapped around a glass cylinder, and viewed through a microscope. Soon Dickson adapted the medium recently adopted by Marey; long strips of celluloid—but Dickson added perforations to register the pictures on strips measuring 1¾ inches (approximately 35mm) in width—the industry standard still used today. The unwieldy electric Kinetograph camera was fixed in a tarpaper-covered studio with opening roof, the building movable to follow the sun. Film production started at the Orange, New Jersey, Black Maria studio in 1893.

Projected moving images of some duration were shown by artist-inventor Emile Reynaud in Paris from October 1892. In 1877 Reynaud had invented the praxinoscope—a spinning-drum toy incorporating a ring of mirrors to reflect the sequential color drawings—followed by a toy-theatre version, and a domestic projection arrangement. His large-screen development of the praxinosope projector became known as the Théâtre Optique. His *Pantomimes Lumineuses* initially used drawings painted on transparent squares mounted on a perforated horizontal belt, and manipulated to-and-fro to produce presentations of 15 minutes with typically 500 pictures. These animated cartoon figures, including Pierrot and Columbine, were superimposed onto a lantern-slide background. The show continued for years.

In 1892 Muybridge, recognising the limitations of his outdated, painted silhouette discs, decided to produce a new series with photographically-reproduced outline drawings coloured-in by hand, to show at the World's Fair. The result was even further removed from his chronophotographs.

Photographic motion picture films as a commercial reality arrived in April 1894, when Edison's kinetoscope was finally launched in a New York "kinetoscope parlour" (penny arcade). Subjects included strongman Eugen Sandow, skirt dancer Annabelle, and boxing enactments. The kinetoscope peepshow was technically simple. A long loop of film, rear-illuminated by an electric bulb, travelled continuously (not intermittently), each frame viewed for a brief fraction of a second through a slot in a revolving shutter; a glimpse short enough to avoid blurring of the image. Kinetoscopes were shipped around the world, and many inventors were inspired to develop screen projection of photographic motion picture films. Soon, many would succeed where Le Prince, Friese-Greene, and Donisthorpe had failed.

By the time Muybridge had completed his final Zoopraxiscope colored discs the Edison kinetoscope had been launched, and in Germany Anschütz had devised a twin-disc Electrotachyscope machine for projecting, with an intermittent mechanism, true photographic sequences. Anschütz arranged public showings from November 1894 featuring similar subjects to the kinetoscope, including a barbershop scene and card players; but of very limited duration. Photographic moving pictures had reached the big screen, and Muybridge abandoned his Zoopraxiscope.

Other chronophotographers also attempted to project their picture sequences. German teacher Ernst Kohlrausch worked independently on the analysis of gymnastic movement. Turning to chronophotography in 1889, he arranged 24 cameras on a wheel. A more sophisticated camera arrangement followed in 1892. Kohlrausch also studied the gait of mentally ill patients. Keen to develop a machine to show the results in movement

while lecturing, his 1892 multi-slide projector featured revolving lenses, but was not successful. A later projector used a rotating light source, but the introduction of cinematography precluded further development.

During 1895 news spread that in France the Lumière brothers, active workers in their father's photographic plate factory, had succeeded in producing the Cinématographe—for taking, printing, and projecting 35mm perforated film by means of a pin-shuttle movement. From February they demonstrated the result, including the one-minute subject *Workers Leaving the Factory*, to photographic and scientific societies.

English engineer Robert Paul was making Kinetoscope copies, but needed a cinematographer to produce the films. Birt Acres, manager of a photographic materials company, had long been interested in the idea of motion pictures, producing glass-plate chronophotographs of cloud formations, and was experimenting with a 35mm motion picture film camera. He took a new mechanism design to Paul, who built it. A successful test in February 1895 led to the production of England's first films, including the *Oxford and Cambridge Boat Race*. Acres departed to Germany in June to film the opening of the Kiel Canal under the sponsorship of the Stollwerk chocolate and vending machine company, and the Pau /Acres partnership dissolved in acrimony.

With his 1894 picture play *Miss Jerry* and others, American lecturer Alexander Black gave many performances of photographic dissolving-scene slide narratives, the "slow movie," just before the public's first view of projected films.

The first film screenings to a paying audience were those of the Eidoloscope, in New York City. Kinetoscope licensees Otway and Gray Latham produced a camera for 2-inch film, and shot an extended boxing match. The projector worked on the kinetoscope principle, with continuously moving film. To prevent a blurred image the shutter aperture was extremely narrow, limiting the size of the projected image. Nevertheless, public performances were given from May, 1895.

In September-October, at the Cotton States Exposition in Atlanta, Georgia, inventors Thomas Armat and Charles Francis Jenkins used their 35mm Phantascope projector to give screenings of kinetoscope films.

By summer 1895 German lanternist Max Skladanowsky had developed a projector using two loops of 54mm film, with double optical and lighting systems, projecting frames alternately from each band. (His first films were taken on an 1892 chronophotographic roll film camera, designed with his brother Emile). With a picture always on the screen there was no blackout period, significantly reducing flicker. The machine was used to project six-second, repeating sequences—subjects included *The Boxing Kangaroo*—at the Berlin Wintergarten theatre from 1st November, and in Hamburg on 21 December. A week later the Lumières opened public shows at the Grand Café in Paris, with such films as *Baby's Breakfast*.

Back in England, Acres demonstrated screen projection in January 1896, and Paul likewise the following month. In the USA, Jenkins and Armat argued and split up, and Armat sold the projector design to the Edison camp. When high-profile shows commenced in New York in April 1896, the machine appeared as the Edison Vitascope.

Dickson had left Edison in 1895, and after briefly assisting the Lathams joined Elias Koopman, Herman Casler and Harry Marvin in an association soon to become American Mutoscope and Biograph (with associated overseas companies). Intending to produce a peepshow to rival the Edison kinetoscope, they soon realised that their hand-cranked mutoscope had a limited future, and devised a projector. The 68mm film negative was perforated in the camera to provide a reference to register the images on the positive. The projector used a gripper-roller to pull down the unperforated print. The huge electric camera was cumbersome but the image was of high resolution, and the large-format Biograph would be used in a limited number of prestigious venues for some years before the company adopted 35mm. Their flip-photo mutoscope appeared in amusement arcades from 1896, persisting as a nostalgic novelty for decades.

As the first film pioneers struggled to project photographic motion pictures onto screens, others continued to use sequence photography for chronophotographic analysis: C.V. Boys with rifle bullets and bubbles, A.M. Worthington the shape of liquid splashes. The introduction of cinematography around the world from 1896 had little effect on chronophotography for analytical purposes, which continued apace, in turn making use of the technical developments of the commercial medium, especially the use of 35mm perforated celluloid; in 1900 Marey constructed a 35mm film version of his chonophotographic gun.

In Paris, from 1896 Reynaud adapted photographic motion pictures for his Théâtre Optique, but in 1900 his show was closed.

In the twentieth century, the high-speed motion picture insect and balistics photography of Marey's successor Lucien Bull and colleagues would provide the transition from chronophotography to scientific cinematography; and from the flickering images of Edison's peepshow would grow a worldwide motion picture industry, communication-entertainment medium, and art form.

MOULIN, FÉLIX-JACQUES-ANTOINE (1802–c. 1875)

French photographer

One of the most prominent Parisian photographers of the 1850s, Félix-Jacques-Antoine Moulin worked in many genres, utilizing a great variety of techniques. Sometimes controversial, Moulin aroused a wide range of critical opinion during his years of greatest activity. Today he is best known for his production in certain categories of subject matter, notably the female nude and orientalist figure studies; other aspects of his oeuvre that were admired in his day, particularly his staged genre scenes, are now less familiar.

Born in 1802, Moulin may have come from an artisan background and lacked the art-academy training of some other important early photographers. The circumstances of his training as a photographer are unknown. By the end of the 1840s he was active as a daguerreotypist with a studio at 31 bis, faubourg Montmartre in Paris. Moulin's first documented photographs are academy or nude studies of female models, nominally for use by artists. The fine Two Standing Nudes in the Metropolitan Museum of Art, New York belongs to a series of daguerreotypes depicting carefully lighted models in natural, relaxed poses before plain backdrops. Several of the models are adolescents, their ages carefully noted in inscriptions of the back of the cases. Several closely related daguerreotypes now in Vienna (Höhere Graphische Bundes-Lehr- und Versuchanstalt) bear the inscribed dates 1849 or 1850.

Moulin apparently also essayed less innocent studies that led him into legal difficulties. On July 23, 1851 he was tried by the Cour d'assises de la Seine, together with an optician/dealer, Jules Malacrida, and Mme. veuve René, a maker of daguerreotypes. According to a contemporary acount, the police "...seized at their homes a great number of subjects so obscene that to state even the titles given to them in the judgment would be a violation of public morality; and the reading of this document had to take place behind closed doors, along with the rest of the proceedings" (Annalesde l'imprimerie, no. 6, 1851). Moulin was sentenced to a month in prison and a fine of 100 francs, penalties considerably milder than those meted out to his co-defendants. Since the offending images have disappeared, it is not possible to determine why they were found so objectionable. Serge Nazarieff has attempted to identify a large number of anonymous erotic or pornographic daguerreotypes and salt prints, mainly stereoscopic, as works by Moulin. Of these, the most plausible attribution is an image of a clothed youth embracing a nearly nude girl against the artificial backdrop of a hayfield, a setting also used in a number of female nudes attributed to Moulin; this tableau vivant has some similarities to Moulin's later stagings of more conventional genre subjects.

After this setback Moulin was able to reinvent himself as a more respectable practitioner, opening a new entrance to the same studio through 23, rue Richer. He continued to produce "academies" or female nudes, but from 1853 onward took the precaution of placing prints of these images on legal deposit at the Bibliothèque Impérial, Paris. The young women, often well-known models, in these images adopt seductive poses and are accompanied by such boudoir props as mirrors, jewelry, and draperies, as they are in contemporary photographs by Auguste Belloc, Ambroise Richebourg and others. Usually executed as salt prints, the images are somewhat larger and more atmospheric than Moulin's

Moulin, Felix Jacques. Female Nude standing with back to full-length mirror.

daguerreotypes. In addition, Moulin offered for sale portraits, genre subjects, and pictures of scenic views and monuments. Technically innovative, he worked with Louis-Amédée Mante to produce prints on artificial ivory and marketed steroscopes and English collodion. With the help of his wife and daughter he also printed negatives by other photographers, acquiring the rights to Roger Fenton's images of the Crimean War.

During the early 1850s Moulin began to show his work in photographic exhibitions, not only in Paris but internationally in London, Amsterdam and Brussels. His work was discussed in such journals as the *Revue photographique*, *Bulletin de la Société française de photographie*, *Le Propagateur*, and *La Lumière*, in which he was mentioned some thirty times between 1852 and 1866. Critics like Ernest Lacan praised Moulin's industry and in particular the artistry of his genre subjects. With titles such as The Spinner, The Fisherwoman, The Drinkers, or Painters at Work, these vignettes of everyday life were actually staged in the studio or outdoors before moveable sets. Moulin also stubbornly continued to exhibit his female nudes, including many among 56 works he showed during the Exposition Universelle in Paris in 1855. The critic Paul Perier, however, claimed to find them vulgar and repetitive, while Moulin's first biographer, the Abbé Moigno, though praising Moulin's hard work and technical competence, suspected the photographer of not being truly contrite about his earlier indiscretions.

In 1856 Moulin traveled to Algeria, armed with a letter of introduction from the Minister of War and accompanied by 1,100 kilograms of baggage. He spent eighteen months traveling and photographing local officials, genre scenes (again often staged on sets), views, and monuments. *La Lumière* published extensive excerpts from his letters from Algeria, written in a colorful, assured style. Moulin's Algerian work again shows his strength in genre subjects, though the views are less effective. Some of these works were engraved and published in 1858 in L'Illustration. Around 1859 Moulin published more than three hundred as albumen prints in albums in several formats, variously entitled *L'Algérie photographiée* or *Souvenirs de l'Algérie*.

Moulin recorded government-sponsored festivities in Cherbourg in 1858 and continued to show his photographs in major exhibitions, but he gradually ceased making original work. In 1862 Moulin advertised the availability of his studio on the occasion of his retirement, though as late as 1866 he submitted work for inclusion in the Exposition Universelle of 1867. Still living in 1875, Moulin does not seem to have remained active as a photographer. To date the diversity of his work in subject matter and technique has perhaps discouraged monographic study or exhibition; most recent research on Moulin has appeared in the catalogues of thematic exhibitions. In recent years, however, Moulin's Algerian work has been shown in one-artist exhibitions in Arles and Algiers.

MOUNTAIN PHOTOGRAPHY

Mountain photography encompasses both mountain systems as landscape forms and the mountain summit as a photographic platform for recreational and scientific purposes. Both types of photography embodied similar technical obstacles. For the purpose of this article, the definition of a mountain will be that offered by the National Geographic Society: any landform with an elevation of more than 1,000 feet (300 metres) above the surrounding land and a pointed summit; the former distinguishes a hill from a mountain while the latter separates a mountain from a plateau. Most of the significant challenges to photography as a science occurred in mountain ranges at altitudes where photographic chemistry and optics become near to impossible due to climatic conditions (freezing temperatures or zero visibility factors). Because of the Euro-American dominance in the field of world exploration, examples of mountain photography are mainly drawn from European and North American sources.

The European Romantic arts movement of the late 18th and early 19th centuries helped set the stage for mountain photography as an art form. Artists themselves, once photographic technology improved enough by the 1880s, also used photographs as an *aide-mémoire* in two ways: in place of and as a complement to field sketches, or more directly as the visual source for their art. Prior to the widespread introduction of halftone printing at the start of the 20th century, photographs were reproduced through a variety of photomechanical processes, not all of which were equally successful at accurately rendering the tonal and other visual qualities of a photograph.

Apart from purchasing original photo prints, including stereograph views and glass lantern slides, of mountain scenes, those interested in acquiring such images could buy view albums or books in which were photomechanical reproductions of mountain photographs. The three most accurate methods of reproduction prior to the adoption of halftone printing were the photogravure, the collotype and the Woodburytype. European and British publishers dominated this market in the 19th century. Among the more prominent of these firms were the Alinari brothers (Fratelli Alinari), Adolfe Braun, George Washington Wilson, and James Valentine.

The three mountain systems which resulted in the earliest notable achievements in mountain photography and large numbers of photographs are the European Alps, the Asian Himalayas and the North American Rocky Mountains. To a lesser extent other mountain ranges in North America, South America, Russia, Asia, Africa, Australia, and New Zealand also attracted photographers.

The daguerreotype process was first used to photograph both the Rocky Mountains and the Alps. The United States Army Corps of Topographical Engineers surveyor and explorer John C. Frémont was the first to bring a daguerreotype kit into the Rocky Mountains between June and October 1842 on his initial foray into the Western United States. He was completely unsuccessful at his efforts to photograph mountain scenery in Wyoming that August. A second expedition in 1843–1844 by Frémont to the Rocky Mountains also included a daguerreotype kit, but no written record survives of its use. Frémont's third expedition in 1845 included an artist, Edward M. Kern, but no daguerreotype equipment. Due to his political activities in California between 1846 and 1848, Frémont ended up resigning from the U.S. Army. He led two further, privately financed expeditions through the Western U.S. with a goal of surveying a route for a transcontinental railroad. On the last of these, in 1853–1854, he hired New York City artist and daguerreotypist Solomon N. Carvalho (1815–1897). A second photographer who used the calotype process, Mr. Bomar, was also hired, but his services were later dispensed with. Despite having no outdoors photographic experience, Carvalho appears not to have hindered the expedition with his photography. According to Palmquist and Kailbourn (2000), it took him up to two hours to produce each view, with most of that time required for removing and repacking his equipment.

In a letter to the editor of the *Photographic and Fine-Art Journal* (v. 8, 1855, 124), Carvalho provided some details of his experiences:

> I succeeded beyond my utmost expectation in producing good results and effects by the Daguerreotype process, on the summits of the highest peaks of the Rocky Mountains with the thermometer at times from 20 degrees to 30 degrees below zero, often standing to my waist in snow, buffing, coating, and mercurializing plates in the open air. In nearly every instance Barometrical, and Thermometrical observations were obtained at the same moment, with the picture. … I had considerable trouble with iodine, which under ordinary circumstances requires 80 degrees Fht. before it will part with its fumes. I had to use artificial heat in every instance; I found it necessary to make up in quantity for the loss of temperature. I generally employed Anthony's anhydrous sensitive [iodine], and my boxes during a continuous use of five months only required replenishing four times, notwithstanding they were opened every time I made a picture, to arrange it smoothly at the bottom. The coating boxes were made expressly for my use on the Expedition by E. Anthony, Esq., and I cheerfully recommend the use of similar ones for like purposes. (Quoted from Taft, 1964, 264–65)

Carvalho's autobiography also summarized the difficulties he faced in the Rocky Mountains. At one point Frémont himself accompanied Carvalho on a three-hour climb to a mountain peak and took meteorological observations while Carvalho produced a panorama of the landscape below (Carvalho 1859, 82). Other primary problems facing mountain photographers of any era were atmospheric haze or hazardous weather conditions. During the dry season forest fires caused by lightning strikes also reduced or destroyed visibility. Although some of Carvalho's daguerreotypes were sent back East and copied by Matthew B. Brady's studio and Carvalho himself ended up an invalid for a while in Salt Lake City, the original daguerreotype plates and apparently Brady's copy prints and negatives were lost.

A similar fate to Carvalho's work also befell that of John Mix Stanley (1814–1872), a well known painter of Indian portraits, an artist on a U.S. Army exploring expedition, and a commercial daguerreotypist. He accompanied a railroad survey led by Isaac I. Stevens through the northern Rocky Mountains to Olympia, Washington, from the spring to the fall of 1853. He appears to have concentrated, given his past interest in documenting the Native American population, in taking portraits rather than attempting landscape views. Stanley's daguerreotypes from this trip are believed to have been destroyed, along with his more valuable Indian Gallery collection of his art, in a 1865 fire at the Smithsonian Institution.

The first large-scale private attempt to commercially photograph an overland route from the East to California in order to lure settlers west was undertaken by the California daguerreotypist John W. Jones in 1851. He travelled from California to Independence, Missouri. Jones also solicited daguerreotypes from other photographers in the surrounding territories. He is reported to have produced 1,500 daguerreotypes on his journey, but no trace of these photographs is known to exist (Palmquist and Kailbourn 2000, 333). Some of these photographs are supposed to have depicted the Sierra Nevada Mountains. A painted panorama based on these daguerreotypes, *Great Pantoscope of California, the Rocky Mountains, Salt Lake City, Nebraska & Kansas*, was opened in 1852 in Boston and circulated for two years in the eastern United States.

Beginning in the early 1850s, wet-collodion negative photographers produced much more dramatic results of mountain scenes than could be achieved with the daguerreotype process. In the western United States, numerous exploring expeditions and adventurous photographers acting alone in the 1860s and 1870s generated substantial numbers of Rocky Mountain views. The California side of the Sierra Nevada Mountains in which Yosemite National Park is situated also saw significant photographic activity, including mammoth-plate views. The most prominent mountain photographers in the United States of this period were Carleton E. Watkins, Timothy H. O'Sullivan, Eadweard J. Muybridge, Andrew J. Russell, and William H. Jackson. Jackson's photograph "Mountain of the Holy Cross" taken in August 1873 while a member of F.V. Hayden's geological survey party, is considered the most important mountain photograph in 19th century America. The construction and completion of the transcontinental railroad in the United States offered some photographers such as Frank J. Haynes unprecedented opportunities for national exposure, not only for his railroad photography, but also as the official photographer of Yellowstone National Park in Wyoming.

Lesser known photographs of the Canadian Rocky Mountains were taken by anonymous Royal Engineers photographers accompanying the North American Boundary Commission surveys of 1858–1862 and 1872–1875. As happened in the United States during route planning for the transcontinental railroads, survey parties looking for suitable routes through the Rocky Mountains and other mountain ranges of British Columbia included photographers. The two most notable photographers who accompanied these geological and geographical surveys were Benjamin Baltzly (1871), an employee of the William Notman & Sons firm of Montreal, Quebec, and Charles G. Horetzky (1871–1879). The construction of the Canadian Pacific Railway through the Rocky Mountains was documented by several photographers, including Richard Maynard and William McFarlane Notman and land surveyors employed by the Canadian government. General of Canada, Edouard Deville (1849–1924), is recognized as being the first to use photogrammetry (photographic surveying) on a large scale with dry-plate cameras within the Rocky Mountains beginning in 1887. As a result of the success of his method, Canadian members of the International Boundary Commission of 1892 surveying the mountainous boundary between Alaska and Canada quickly produced visual data from mountaintops which their American counterparts were unable to equal. As happened with the U.S. railroads, the Canadian Pacific Railway encouraged commercial photographers with free passes and sometimes even a special railway car equipped with a darkroom. The company also established its own photographic publicity department whose first photographer was Alexander Henderson. The CPR also imported Swiss mountain guides to the Rocky Mountains. Mountaineering and amateur photographer families such as the Vaux family of Philadelphia sometimes hired these or Canadian guides on their annual expeditions to the Canadian Rockies.

Because recreational mountain climbing developed within the European Alps, the first mountaineering photographs were taken there shortly after the daguerreotype process was announced, but possibly not before the American explorer Frémont's abortive attempts in 1842. A German photographer Friederich von Martens who lived in Paris was appointed to take photographs on a French government expedition to the Alps in 1844. The British art critic John Ruskin claimed to have daguerreotyped the Matterhorn in 1849. Frederick Crawley is credited with the 1854 daguerreotype "Mont-Blanc, Chamonix" (Frizot, 1998, 55). In the early 1860s the French Bisson Brothers produced spectacular mountaineering photographs on Mount Blanc. Some other significant Alpine photographers who were also mountaineers were William F. Donkin (Great Britain), Vittorio Sella (Italy), and Joseph Tairraz (and descendants, France). The French photographer and publisher Adolphe Braun also produced beautiful Alpine photographs during the 1860s. The first detailed photographic survey of the Alps was started in 1859 by Aimé Civiale and published in France in 1882 (*Les Alpes au point de vue de la géographie physique et de la géologie*).

Photographic documentation of recreational mountaineering was encouraged by the formation of climbing clubs beginning in the mid-1850s. Photography was used as an educational aid to assist aspiring mountain climbers in understanding the hazards and physical rigours. English Lake District mountaineers and photographer brothers George and Ashley Abraham documented their rock and mountain climbing activities beginning in the 1890s and encouraged others in this emerging sport. Due to the cumbersome nature of early photographic equipment, however, amateur photography by mountaineers did not produce significant numbers of photographs until after the late 1880s and the introduction of the Kodak roll film camera system.

The Himalayas in Asia, being the highest mountains in the world, attracted many European photographers. None were as initially successful, however, as Samuel Bourne, the first photographer to attempt photography at altitudes thought to be impossible to photograph in. Based in India, he made three trips to document the

Himalayas between 1863 and 1866. Bourne published accounts of his adventures in the *British Journal of Photography*. Like Carvalho before him in the Rocky Mountains, but at much higher altitudes, Bourne described the effects of the cold and the weather on his efforts to photograph at over 15,000 feet elevation in the Taree Pass:

> … while at this elevation I was anxious, if possible, to try a picture; but to attempt it required all the courage and resolution I was possessed of. In the first place, having no water I had to make a fire on the glacier and melt some snow. In the next place, the hands of my assistants were so benumbed with cold that they could render me no service in erecting the tent, and my own were nearly as bad. These obstacles having at length been overcome, on going to fix the camera I was greatly disappointed after much trouble to find that the sky had become obscured, and that a snow storm was fast approaching. Shivering through my whole frame and almost frozen to the ice, I stood waiting to see if it would blow over. It did so in about fifteen minutes, but not in the direction I wanted to take a view; but as there was no probability that waiting longer would better my condition, I placed the camera and proceeded to coat a plate. I thought the collodion would never set. I kept the plate at least five minutes before immersing in the bath, and even that was hardly long enough. Exposed fifteen seconds (size 12 × 10), and found it was somewhat overdone; but my hands were so devoid of feeling that I could not attempt another. I managed to get through all the operations, and the finished negative—though rather weak, and not so good a picture as it would have been if the snow storm had not prevented my taking the view as intended—is still presentable, and I keep it as a memento of the circumstances under which it was taken, and as being, so far as I am aware, a photograph taken at the greatest altitude ever yet attempted. (Bourne, "Ten Weeks with the Camera in the Himalaya," *British Journal of Photography*, February 15, 1864, quoted in Ollman, 1983, 10)

According to Scharf (1976, 91), the highest altitude at which Bourne photographed was 18,600 feet at Manirung Pass. Fabian and Adam (1981, 180) report that until 1880 this was the highest point at which a photograph was taken. The 1880 high-altitude photography was accomplished with the dry-plate process by British climber Edward Whymper during one of his ascents of the inactive volcano Chimborazo (20,703 feet) in Ecuador. Similar problems as faced Bourne in the Himalayas also challenged the Scottish Astronomer Royal and scientific photographer Charles Piazzi Smyth during 1856 expedition to Tenerife, Canary Islands, where he set up a telescope on the volanic peak of Mount Guajara at the 10,700 feet elevation and photographed his activities with a wet-collodion stereo camera. He wrote in his book, *Teneriffe, an Astronomer's Experiment* (1858), which included 20 mounted stereographs, "In taking pictures of the several volcanic phenomena, our camera and photographic tent had been blow over more than once. … [but] other unlooked-for accidents would often occur, amongst the most frequent of which, was the opening of cracks in camera-box, or plate-boards, in consequence of the desert-like dryness of the air" (Smyth, *Teneriffe*, 152, in Schaaf, "Piazzi Smyth at Teneriffe: Part 1, 296–97) Other vexatious problems that hindered Smyth's photography included heat from the sun and sulphur fumes.

The last great mountain photographs of the 19th century were taken during the Klondike Gold Rush by dedicated photographers such as E.A. Hegg, Frank La Roche, and Asahel Curtis (Edward S. Curtis' younger brother). They endured the same hardships as the gold seekers with whom they travelled. Hegg's classic "Packers Ascending Summit of Chilkoot Pass" (1898) captures the chill air as an endless line of mostly men makes their way to top of the 3,739 feet high pass dividing Alaska from British Columbia. Another nearby trail through the White Pass (2,885 feet) formed the route for a railway built between 1898 and 1900 and still operating as a tourist attraction. Harry C. Barley was the official photographer for the railway. Edward S. Curtis was himself also recognized for his 1890s mountaineering photographs in Washington State, which led to his appointment as the official photographers for the 1899 Harriman Alaska Expedition.

MOUNTING, MATTING, FRAMING, PASSE-PARTOUT, PRESENTATION

Photographs in their mounted and decorative formats often reveal how the photographs fit into a given culture. For the researcher however, the type of frame and style of its decoration define with relative accuracy the date of its making, the social and historical reference of the photo itself, the wealth of the owners of the photographs and their personal, emotional relationship to the person photographed.

The framing of photographs, daguerreotypes, and talbotypes basically served a two-fold purpose in the 19th century. Frames mainly existed to protect the picture from environmental damage, and to decorate the picture it contained. Both simple and ornate decorations established additional roles and possible implications of the frame, such as ornamental details like a larger border and various colours. These details produced the illusion of an extended space beyond the photograph and thus enhanced the effect of the picture. The aesthetic purpose of the frame was successfully fulfilled when harmony was achieved between the picture and its frame. The frame, passe-partout, and installation of the photograph changed throughout time and this was characteristic of and often determined by social groups as well as the technique, materials used, and implementation of the photograph itself.

Out of the pictures that were "written by light" or created using image producing chemicals through the use of various techniques, direct-positive and positive pictures, not the negatives, were only available for mounting or framing. The purpose of photographing played a part in whether the photo was framed or not, and if so, what kind of frame was chosen. More often

than not, artistic and family pictures, and those for private use were framed, while applied photographs for illustrated reports, and scientific purposes mostly remained without a frame unless they were later used for the formerly stated reason.

The expertise of the photographer be it professional, hobbyist or private, was not as significant as the reason or the genre of photographs in determining what would be framed. Amateur, dilettante works, landscape or event photographs were usually rarely placed in ornamental and expensive frames, and on the contrary, that was typical of portraits in the 19th century.

Photographs were thought to be similar to drawings and paintings, and in general, thought to be the more artistic product of the genre of representation, of everyday life. It was especially true if the appearance of photographs were similar to that of a drawing or painting because then the same functions were fulfilled. Early products of positive procedures, like the talbotype positives, Calotype Prints, Talbotype Prints, Salted Paper Prints or the Salted Paper Prints were produced until the 1860s, and so were Plain Paper Prints, which were used to make photographs look like large-sized coloured landscapes. Portrait photographs were meant to look as if they were painted over canvasses to strongly resemble aquarelles or temperas, and to appear passe-partouted or in traditional frames in elegant homes or at exhibitions.

Daguerreotypes were put into expertly crafted, glazed picture-frames varying in thickness mainly in order to protect them and prevent them from being damaged (Karlovits 1973, 33). Another method of protection was to place them into wooden, or from 1854 on, plastic cases called the Union case, which were lined with pressed pigskin, or more seldom with cowhide, or with paper and could be locked with embellished silver snaps. Such cases were manufactured by craftsmen and bookbinders or specialists, according to the Commercial Directory of Birmingham. For instance it is said that John Smith made thermoplastic cases in England from 1859.

The carefully designed cases were decorated with embossed motives. Manufacturers produced millions of cases; therefore the possibilities of different decorations are very vast. The lids of the wooden cases bore the popular decorative motives of plant ornaments. These traditional motives were usually replicated from the cases of miniature paintings and silhouette pictures. Many times the same cases were used for containing daguerreotypes and William Shew, for instance, made such cases in Boston.

Other types of decoration could also be seen on plastic cases to the degree that about 800 patterns can be found today. Between the prefigured earlier forms used for similar functions, replications of prayer book covers or church windows, as well as adaptations of classic paintings can also be found. The themes of the motives vary from religious scenes from the life of the Saint Family to historic Columbus stepping on the land of America to even other popular figures like Cupid, musicians, children, chess players, and fire fighters. Additionally, the art or style in which these cases were made helps historians date the making of the cases; for example, patriotic motives only appeared following the American Civil War.

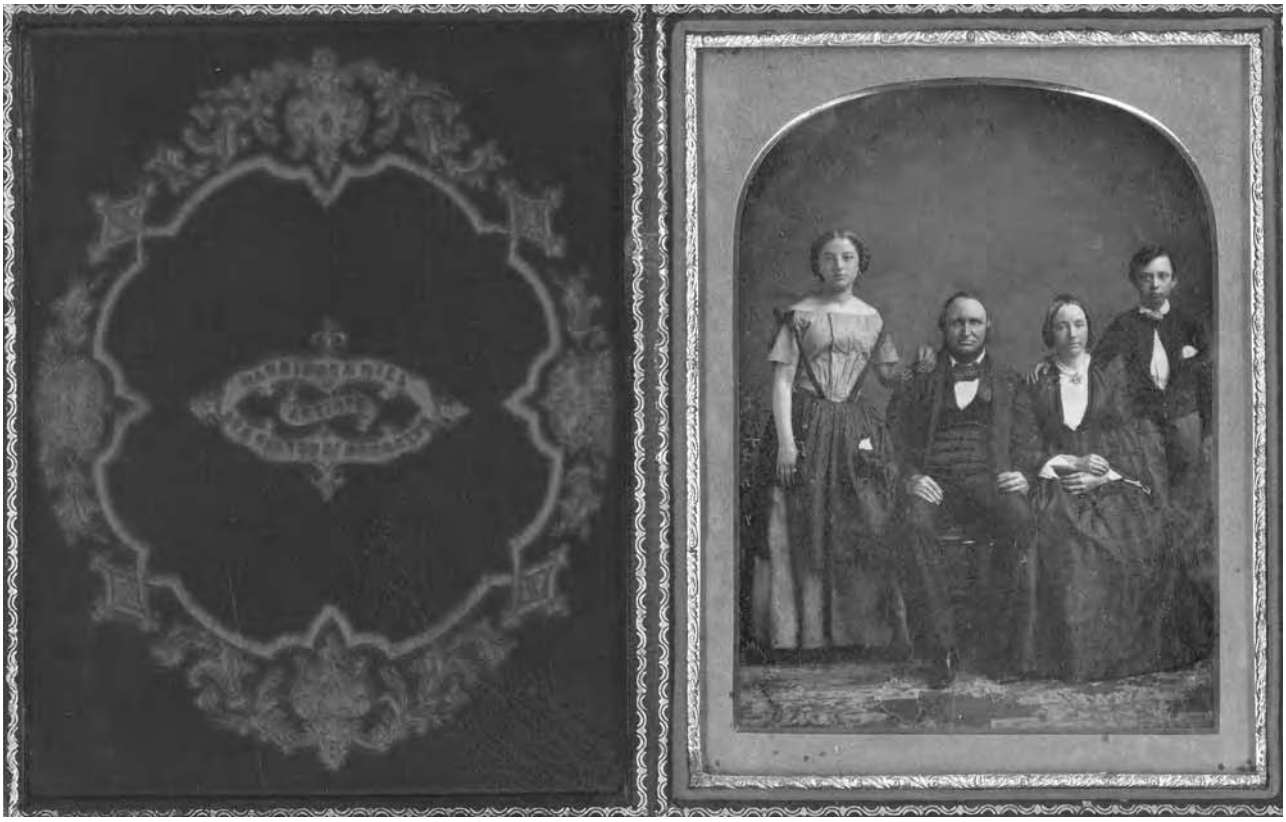
The inside of the case-lids were protected by embossed velvet, while daguerreotypes themselves were protected by decoratively tailored distance pieces like passe-partout made of copper or other material, cover glasses, airtight adhesive tape at the seal, and by carbon from behind. It was not until 1850 that the thin, flexible, gilded brass framing appeared, which held the picture, the passe-partout and the glass together.

The extension of the passe-partout placed above the daguerreotypes was extremely diverse. The shape of the passé-partout served as an indicator in identifying the time period in which they were manufactured as square forms with cut off corners and oval or arched forms were typical of the 1840s, while four-, eight-, nine- or multi-angled arched forms were used until the 1850s. In the decade that followed, the whole surface, primarily the line of the extension, was decorated. The decoration consisted of thinner or thicker lines and circles that closely fit together, thus creating the visual effect of gems or strings of pearls. The surface of the passe-partout could be plain, with no decoration in order to emphasise the picture as much as possible, or it could be richly decorated and consequently the "frame" would give the "picture" the optical illusion of spatiality.

In the 1850s daguerreotypes were relatively costly to make, therefore, they were seldom produced and mainly owned by the wealthy. Their exterior was made to suit the taste of the customers. Portraits functioned as a status symbol through the act of self-representation, and as such, these images depicted mostly people of the higher classes who were usually "framed" in most decadent ways.

Ambrotypes or Collodion Positives on Glass (1851–1885) were placed in cases similar to daguerreotypes. They were used so frequently because photograph dealers and photographers wanted to make use of their leftover stocks after daguerreotypes went out of fashion. Interestingly enough, owners of daguerreotypes often replaced the pictures with new ones in instances where they became damaged or if another person became more important to them, which indicated that installations were valuable articles and why they were inherited throughout generations.

In the decades that followed, multiple photographs became common as more inexpensive media was used. The wealthy favoured the unique, masterly elaborate,



Harrison and Hill. Group Portrait of an Unidentified Family.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

and expensive photographs. These specific forms of installation were miniature Colloido-Chloride, Printing-Out Process, Ivorytype. Photographs on Ivory, and Eburneum Print photographs were concealed and embedded into jewellery or pendants, rings, bracelets, brooches, pins, and badges. Crystoleum, Crystalotype, Chromo-Crystal portraits were fitted into brooches, lids of pocket-watches, and other ornamental pieces of jewellery as well. In such cases, the photograph was not "intended for the public" as much as it was intended for "personal" use, which is apparent not only by the size of the photograph, but also by its location and the occasions for which it was worn. The material on which the photograph lay was usually some precious metal or ivory, but the photograph held the real and symbolic value, which also expressed the personal emotional attachment between the person depicted and the person wearing the picture. One too could include Stamp Portraits (1855) in this group. Although their medium was paper and not noble metal or other valuable material, letter-paper, visit cards, brochures, keepsake albums often had value for the owners of these objects.

As more painters and dexterous craftsmen became involved in photography, unique, high-quality artworks were created with a combination of photographic and painting techniques, for example, collages by Victor Hugo like the Collage de Hauteville House, Guernesey, 1855 or Souvenir de Marine Terrace, 1855. The former picture—having the inscription "Jersey is composed of mysterious colours and details, and is reminiscent of the form of a monstrance. In the focal point of the artwork, a larger photograph taken of the cliff of the exile, can be seen surrounded by other photographs. Decorative, painted architectonic "frames" of the photographs were placed around the original image and though it were a "settings of precious stones." The colours in the picture of ultramarine, gold, and black, and the themes, which were void of the elements of everyday life, impressed upon the viewer a spiritual meaning. As a new member of the Künstler Sänger Verein, an amazing tableau created in 1858, served a similar function. The central element of this composition was an artfully planned text, decorated with graphical elements like illuminated initials. The text was surrounded by 12 ambrotypes, which appeared as ornaments of the frame as if they were "precious stones." This effect was enhanced by the frame and its gilded surface.

Family trees and tableaux of boards, which were made in the last decades of the 19th century, were made for exact purposes in predetermined forms by specialists. The genealogy of the Habsburg family, for instance, was completed in 1864. It basically used graphic elements

like heraldic symbols and traditional place-filling motives in a style typical of the era and applied illustrative elements of printed materials. However, unlike the formerly common family trees, photographs of half-length, three-quarter and full portraits of the family members appeared above the inscriptions of their names.

The second half of the 19th century photography aimed at conquering other spheres of everyday life. In 1854 photographers became interested in placing photographs on china and marble. Ceramic Photographs and Porcelain Photographs were placed on the sides and bottoms of coffee and tea sets, flowerpots, jugs, plates, fruit-dishes, bonbonnières, ashtrays, jewel-cases, vases, cups, decanters, pendants, brooches, pipe-heads, desk-sets, and. The spatial form itself and its presentation coupled with the photographs, and subsequently painted ornamental motives, created the specially shaped artistic mounting and the essence of custom work.

Additionally, mourning family members placed photographs on gravestones for quite some time. The primary function and purpose of photographs was realised here. The medium, which bore the photograph, was itself the installation and at the same time the material and place of use, being the last resting-place of the ancestor, all coalesced to capture the exact and most basic reason for photography. It was in this way that the photograph retained the image of the deceased person "to the end of times" and displayed it for all to see.

In the 1860's and 1870's visit cards, portraits of cabinet pictures, and also newspaper clips and other pictures were made with Albumen Print, Alboidin—Protalbin Paper, Matt Albumin—Albumat Paper, Solio Printing-out Paper, Ferroprussiate, Sepia Paper processes, and other different technologies and were placed in expensive and decorative photo albums of all sizes. These albums had wooden covers bound in elegant cordovan-leather, calfskin, or velvet decorated with embossment, intaglio printing with gilded metal inlays, or hand-painted or -embroidered flowers. These objects were important pieces of furnishing for drawing rooms. Their compilation and exhibition was a fashionable occupation of aristocratic women and studying them was a popular social activity.

At the end of the 1870's, photographs became parts of the interior decoration in decorative frames. They were placed on pianos or chests of drawers. The frames were still works of art, and their material, and elaborate design generally matched the culture, like that of Victorian England. These frames were made of ivory, solid glass with gilded or engraved edges, they were carved and/or engraved, painted wood, gilded or had silvered metals or nickel, and had plush velvet stamped with embroidered flower decorations, and complicated or even simple ornaments. Also "quasi" forms of frames were produced, like easels, doghouses, horseshoes, hearts pierced by an arrow, etc., but by this time, the Oxford-form already had a simple design.

Besides the prevailing modern style frames, picture mountings of former eras, generations, and periods of history remained in use not only because of their own values, but mainly because of the sentiments relating to the images, as was the case of portraits, which served as a visual historical image of a person that a particluar family wanted to respect. If a member of the family passed on, often his/her's image played an organic part in the furnishings of the home.

In the last decades of the 19th century, a procedure was developed which used a new solution, technology, and materials. The golden age of Opalotype was developed in the 1890's. Mainly landscape photographs were made for tourists in important places they wanted to remember. These photographs were applied into souvenirs, desk sets, porcelain trinkets, and into objects later worn as jewellery.

Due to the invention of quick photographs, more inexpensive materials, technological processes, more and more middle to lower class people could afford to buy photographs. Consequently, the usage of photographs in terms of materials, technologies, and decoration changed as did the formerly established norms of what photographs looked like in terms of tastes and style.

Less spectacular but more durable, were cheap pannotypes which were seldom installed, but in the case that they were, it contained a modest passe-partout, glass and a wooden frame. Penny photographs, ferrotypes were seldom placed under glass and were mainly not installed. Their more respected variations were accompanied by paper passe-partout, which were framed with gilded prints and edge ornaments, similarly to religious lithographs.

A special camera with more lenses, was developed for this purpose and very small Ferrotypes (1.5 × 2.2 cm in size), otherwise know as "gems" were made in America. They were applied into different types of jewellery like brooches, pins, pendants, or onto simple white cards, and into special, small-sized albums. One or two of these gems could be placed onto one page of an album ("Cambridge" Album, 1867), and later, even more appeared a page where one could see 3, 4, 5, or 6 at a time (Remick and Rice, Massachusetts). In the oval cut out around the picture an embossed ornament could be arranged, like a simple geometric or flower pattern with colouring. Albums with rich miniature decorations were also made for American aristocracy, while the family albums of the middle class had no decoration at all. The fashion of decorative, coloured cards and albums reached Europe and Australia from America as well. Europeans were familiar with many English, American and Australian photograph albums on which tintypes were built into visit cards. Similarly, in Europe, the edges of

the Ferrotype plates made in photograph booths of the slot automate named "Bosco automat" (Conrad Bernitt, Hamburg, 1895; Budapest, 1896) were folded up around the picture, and the inscriptions came on them such as "Millennial souvenir 1896 Budapest."

Demanding customers could enrich their collections with artworks made with more and more modern technologies, and the qualities of the pictures demanded spectacular installations. Matte Collodion Printing-Out Paper, Platinotype, Platinum print, Palladiotype, Palladium Print, Palladio Paper, Starkepapier were photographs rich in shades of tones with artful effects. The products of noble procedures—like Pigment Print, Carbon Print, Gum Print, Papyrographie, Oil, or Oil Transfer—were painting-like artistic photographs, therefore they were put in passe-partout much larger than the original picture, which was of course in accordance with the fashion of the era, and they received specially formed secessionist wooden frames.

In the last third of the 19th century the majority of photographic products were made by studios. At the same time, however, the cover or back of the photographs served as an excellent advertising surface for the photographer to list his name, site of operation, awards and prices of the studio's products. The typography on the back and at the edges followed the characteristic styles of other applied graphical products which entailed richly decorated firm logos, and medals awarded at exhibitions set into heraldic patterns and were displayed as such. Printed documents serving official and social purposes like letter headings, menu cards, invitations, ball-programmes, memorial certificates, advertisements, programmes, and boxes of photographic raw materials were all made in a manner following the similar eclectic tastes. Graphics and illustrated papers, multiplied by the ease of printing, flooded the main stream by the end of the century, and photographs were no exception.

Sometimes for personal use, pressed flowers were placed around the photograph in the corners of the passe-partout and it was thus framed. Print-clips, mostly of coloured flowers, were purchased in shops and often replaced real flowers, but some photographers copied or enlarged the photographs on designed cartons for unique designs.

The passe-partouts of enlarged photographs were mainly decorated by traditional ornaments, usually with one or more thin or thick line on the edge, while other printed materials like devotional pictures often had decorations in the corners. Embossed edges—gilded or not—were also common.

Three tendencies prevailed in the history of framing and installation of photographs. Formerly used and applied forms of high art and popular culture were inherited, which directly inspired methods of framing pictures through the use of various technologies throughout various eras, including the placement of picture so that it appeared in a mirror. Unique forms were developed particularly for the products of photography and were contigent upon the norms of the different time periods, which adapted to changing technologies. Specialists in serial production and standard forms often produced these forms. A great number of individual variations were also characteristic of framing and installing photographs however, and were conceived as the unique image creating process. These objects were not, or were only partial works of specialists. They were common in the second half of the 19th century, and were characteristic of the increasing number of photographs which were made to order, and for private use. Even if the photographs were placed in purchased prefabricated frames or ones ordered from specialists, often the one giving the present or the user added their own modifications to the frame, passe-partout, or even to the photograph itself.

The wooden frame was often modified with skin, velvet or other textile covering which was typically embroidered or covered with other various decorations. The passe-partout usually had real pressed flowers or later, flowers cut from prints or drawn flowers or leaves placed on it. The photograph itself often had a dedication or message on it. The most archaic variation is the rhyming portrait welcoming letter, which was well known by villagers of eastern towns and villages of the Carpathian Basin. The sender of photographs like these commonly wrote quasi-folklore poems on the photograph or its back, with the idea that the photograph acted on behalf of the person which served to welcome new members of the family, cite complaints, or to ask for accommodations. Photographs were created for individual use, and were most often portraits, group photographs, and sometimes photographs of a landscape or a building. These photographs adapted to the functions of decoration and to the idea of the object. In one or more places, and in different ways and forms, the photograph expressed personal contact. Different means of installation and framing of the photograph primarily fulfilled this function. The individual's tastes, skills, education, and the social status of the photographer automatically reflected this.

MUCHA, ALPHONSE MARIE (1860–1939)
Professional photographer

The arrival of the young Moravian painter, Alphonse Mucha, in Paris in 1887 heralded the beginning of a career which would elevate him to the highest echelons of the Art Nouveau movement. Mucha's paintings, posters and typographic designs epitomise the extravagance of the period.

Mucha's interest in photography dates from about the time of his arrival in Paris, initially commissioning photographs as part of the preparations for his works, but his interest soon became a passion which would endure for the remainder of his life.

By the end of the 1880s he had started to take his own photographs but, according to his son Jiri Mucha, 'he remained the world's worst photographer'—an inaccurate remark as many of his photographs show remarkable visual perception (see Ovenden, *Alphonse Mucha Photographs*, Academy Editions, 1974).

Like many painters of the period, Mucha made extensive use of photographs of models posed in his studio, and many examples of these survive, several squared and ruled up ready to be used as sources for major works.

Mucha became interested in the psychic investigations of Albert de Rochas, the librarian at the Ecole polytechnique in Paris, and in conducting photographic experiments in his studio at rue de Val de Grace, he continued work which de Rochas had started with Nadar decades earlier.

JOHN HANNAVY

MUDD, JAMES (1821–1906)
English photographer

From his photographs it is possible to show that James Mudd was working as an amateur from around 1850. In the *Manchester Trades Directory* of 1852, James Mudd and his brother, Richard are referred to as calico printers' designers at 54 George Street. By 1854 they appear as calico printers' designers and photographers at 94 Cross Street, while the George Street address remains. In 1861, James Mudd appears as a photographer at 10 St. Ann's Square while Richard is still at George Street. In 1871 the firm is recorded as J. Mudd & Son. The son, James Willis Mudd, seems to be connected with the studio from about 1865 although no particular work can be attributed to him. George Grundy worked as an assistant from about 1880 and eventually bought the business in 1895. In the *Directory* of 1900 the firm still appears under the name of J. Mudd & Son although the ownership had passed to Grundy some years previous though the address was now recorded as 10 Police Street. James Mudd and James Willis Mudd continued to work in photography from Bowdon, Cheshire until 1905, after which date all activity ceased. It was only following the death of James Mudd in 1906 that the business was known as G. Grundy & Sons.

The landscape was Mudd's initial interest in photography. Early Mudd calotypes correspond very closely in location with calotypes taken by Joseph Sidebotham in Wales in 1851 or 1852. Both Mudd and Sidebotham were involved in calico printing in the Manchester area thus providing the link for their collaboration. Two landscapes on waxed paper, "Cottages at Trefriw" and "a Watermill" were hung in the *Exhibition of Art Treasures of the United Kingdom* held in Manchester in 1857. Also that year he gave a paper, "Artistic arrangement of photographic landscapes" to the Manchester Photographic Society. It would appear from reviews of various exhibitions in London, Dublin and Edinburgh in the period from 1857 to 1865 that Mudd was considered an equal with Francis Bedford, O. G. Rejlander, Henry Peach Robinson, and Camille Silvy.

In 1857, Mudd produced a series of photographs illustrating the effects on local flora allegedly caused by emissions from a chemical works at Irlam near Manchester. These images, which catalogued the effect of pollution from the works on trees downwind of the site, were taken in support of a celebrated court case, *Regina v. Spence*, which was heard in court in 1857. The court found against the owner of the alum works in question, but while the environmental pollution was proved, the court ruled that the noxious fumes had not had any detrimental effect on the local residents! While not apparently presented in court, these photographs stand

as one of the earliest uses of photography in support of such a legal action. They are preserved in an album in the collection of Salford Library.

Interaction between individuals interested in the emergence of photography played a major factor in its early development in the Manchester area. James Mudd was a member of the Manchester Literary and Philosophical Society being elected to membership in 1852. As a member he would have come in contact with J. B. Dancer; while primarily a scientific and optical instrument maker was a key figure in the early development of photography. Other members included Joseph Sidebotham; James Nasmyth, an engineer; James Mercer, a dye-stuffs chemist; Charles Beyer, the founder of the Beyer-Peacock Locomotive Works at Gorton, near Manchester; and J. P. Joule, the chemist. In August 1855, the Manchester Photographic Society was formed and the first Council included Joule, Sidebotham, Dancer and Nasmyth. James Mudd and Alfred Brothers, who was also a professional photographer, were members of the society and on the Council by the second year of its existence.

Mudd started photographing locomotives and other machinery for Charles Beyer of the Beyer-Peacock Locomotive Works in early 1856. Beyer would have considered his choice of photographer with care. He was meticulous in his control of the designs and production of his locomotives. The photographs by Mudd show his designs to be simple and effective both in aesthetic and functional terms. Initially using the wet collodion process without much success, Mudd reverted to the waxed paper process. By 1857 he was using the dry collodio-albumen process for this work with considerable success. The majority of the photographs were taken at the Gorton Works where he used a 12 × 15 inch camera for pictures of locomotives and whole plate for many of the machines. During the period 1870–75, and in addition to his work for Beyer-Peacock, Mudd was also photographing locomotives made by Nasmyth Wilsons and the Sharpe Brothers.

By 1861, Mudd was in business as a portrait photographer in Manchester's fashionable St. Ann's Square where he used collodion for his carte-de-visites and his cabinet portraits. Later, with the popularity of the CDV reaching its peak there were many "photographic artists" within a small radius of St Ann's Square. Mudd was in direct competition with Alfred Brothers, Silas Eastham and Lachlan McLachlan who all had businesses in the Square itself. Like many of his contemporaries, Mudd would have used the portrait business to form the basis of his income to offset against his speculative activities and also to keep his darkroom assistants in work when other parts of the business were slack.

Mudd's architectural photography shows a remarkable sensitivity for the subject. His early work for Francis Frith, of which "Deakins Entire" was a reject, shows an exceptional range of tonal values as well as a remarkable lens definition over the whole area of the image that is superior to that of his contemporaries. Again he used dry collodio-albumen negatives. For his 11 × 8 inch plates, he uses 4 inch "Lerebour" lens "well stopped down," and for 7 × 5 inch plates, a Dallmeyer Triplet.

Mudd also used the photographic process as a sketchbook for his paintings. Most known paintings date from the period 1875 and 1895. They include "River Liffey, Dublin," "Alderley Church in Snow," "Dunham Park," "Seascape," and "Nant Francon Pass." His ability as a painter can be gauged from the catalogues of the period where they are listed from £50 to £100. In 1977 a painting by Mudd of the opening of the Manchester Ship Canal in 1894 was discovered in Manchester. The painting is described as having "meticulous detail of the Barton Swing Bridge and patterns of the flags which could only be done with (resource) to photographs…. The painting shows all Mudd's misty background effect."

Many of Mudd's photographs and paintings survive as do his papers and writings on aspects of photography. It is evident that he was a fine professional and versatile photographer, a craftsman and painter who achieved considerable stature in the eyes of his contemporaries.

MICHAEL HALLETT

Biography

James Mudd was born in 1821 in Halifax, the son of Robert Mudd, whose occupation was described as a cheese and bacon factor. James Mudd died in Bowdon, Cheshire in 1906. In the *Manchester Trades Directory* of 1852, James Mudd and his brother, Richard, are referred to as calico printers' designers at 54 George Street. By 1854 they appear as calico printers' designers and photographers at 94 Cross Street, while the George Street address remains. In 1861, James Mudd appears as a photographer at 10 St. Ann's Square while Richard is still at George Street. In 1871 the firm is recorded as J. Mudd & Son. The son is James Willis Mudd who seems to be connected with the studio from about 1865 although no particular work can be attributed to him. George Grundy worked as an assistant from about 1880 and eventually bought the business in 1895. By 1900 the firm still appears under the name of J. Mudd & Son although the ownership had passed to Grundy some years previous though the address was now recorded as 10 Police Street. James Mudd and James Willis Mudd continued to work in photography from Bowdon, Cheshire until 1905, after which date all activity ceased.

MULOCK, BENJAMIN ROBERT (1829–1863)

British photographer and civil engineer

Ben Mulock grew up in a Newcastle and London. When he was sixteen, his mother died and his father, the Reverend Thomas S. Mulock, deserted his three children. Because their mother's legacy was held in trust until they came of age, Ben's sister Dinah began writing for a living, and brother Tom, a promising artist, went to sea. He was killed by falling from the mast when his ship was in dry-dock in 1847. In 1848 Ben enrolled at University College London, where he studied Latin, Mathematics and Natural Philosophy with a view to becoming a civil engineer. However, when he turned 21 in 1850 he received £400 from his mother's trust and emigrated to Australia, where he became a farmer and later joined in the gold rush. Four years later, he returned to Europe due to persistent eye troubles, and underwent treatment in Germany and Switzerland in 1854 and 1855. By June 1855 he had joined the Army Works Corps. He spent the first half of 1856 in the Crimea, working on railway provision during the war. Shortly after returning to England in July 1856, he joined the Liverpool Public Offices Engineers Department. During most of 1858 he worked in the office of James Newlands, the City Engineer, and is said to have expressed a desire for "more congenial work." It was while staying at Linacre Grange, a farmhouse north of Liverpool, that he became a self-taught photographer. Some of the pictures he took there have been published in *The Mellards and their Descendants*. He also produced stereographic photographs and panoramas. By December 1858 he was in London, working as a photographer for JJ Mayall, but he was already in contact with John Watson, the contractor for the Bahia and São Francisco Railway (BSFR), who hired him to photograph the first stage of the works in northeastern Brazil. Charles Blacker Vignoles, who designed and supervised the BSFR, was a strong advocate and pioneer of recording the construction progress of engineering works using drawings or photographs.

Mulock arrived in Bahia on November 1, 1859. He described his first impression of the city with an artist's eye: "I never saw a place that pleased me more at first-sight. It stretches round the Bay in the form of a crescent—the shore is high and the houses rise one height above another, intermixed except right in the centre of the town with Banana and Cocoa-nut trees all looking so green." He immediately set about photographing the railway works, beginning with the terminus under construction in Calçada, and continued sending batches of "views" back to the head office in England, often twice monthly via the English and French mails. Mulock worked in the field with a portable darkroom of his own design (a letter he wrote about a similar invention was published in the *Photographic Journal* in 1859). This would also have held his plates and the necessary chemicals for the day's work. Glass plates were coated with chemicals (collodion) immediately prior to use. After processing they were varnished to retain the image. Printing was done on albumen-coated paper, which was sensitized the night before printing. On one particular upcountry expedition, he took 150 photographic plates and the associated chemicals with him, transported on a pack-mule. Only one glass plate broke. Towards the end of the period, he experimented with the new dry process, which enabled him to coat the negative prior to leaving base, and obviated the need to take chemicals with him. It was his practice to take additional plates of his views while in the field, and to transfer or duplicate the resulting negatives when back at base. While Ben was in Bahia, two engravings based on his photographs of the BSFR were published in the *Illustrated London News* (1860).

Mulock returned home six months before his contract expired because he felt there was nothing more for him to do. He took hundreds of photographs during his two and a half years in Brazil, including stunning portraits of the "City of Bahia." The panoramic view of the city as he first saw it, taken from a fort surrounded by water, could be considered his masterpiece. Ferrez writes that its clarity and perfection are unrivalled (1989, 33). The BSFR presented an album of Mulock's photographs to Emperor Pedro II of Brazil, himself an amateur photo-

Mulock, Benjamin. Rosario Church. *Acervo da Fundação Biblioteca Nacional, Brasil.*

grapher, in July 1861. Ironically, it would bring Mulock the recognition he longed for, but only in Brazil. The pictures in the Emperor's album are now housed in the National Library at Rio de Janeiro (an undisclosed number were stolen in 2005) and the Moreira Salles Institute, and have been published by Gilberto Ferrez (1989). The photographs reflect a combination of a civil engineer's eye and artistic sensibility. While Mulock records the facts honestly and dispassionately, he always provides plenty of detail to be gleaned by the interested observer. His style has been compared with that of the "straight photography" movement of the 20th century.

While in Bahia, Mulock had spent more time upcountry than in the city, where he had come down with a serious bout of "intermittent fever" (probably malaria). When he returned to England in the spring of 1862, he was ill, complaining of liver problems. However, by October he was in Swansea, Wales, working as an engineer and surveyor for John Watson. While there, a few months before his death, he wrote to Dinah asking her to send him the photographs of the City of Bahia, which she did. The whereabouts of these pictures are unknown. The same is true of John Watson's collection of Mulock's complete photographs of Bahia. The Vignoles family—direct descendants of C.B. Vignoles and his son Hutton Vignoles, the resident engineer of the BSFR—have donated 137 progress photos to the Institution of Civil Engineers. The Bosch Foundation in Stuttgart, Germany owns a number of Mulock's photographs. There are also four prints at the Harry Ransom Research Center, The University of Texas at Austin.

John Vignoles and Sabrina Gledhill

Biography

Benjamin Robert Mulock was born in Newcastle-under-Lyme, England, on June 18, 1829, the youngest child of Thomas Samuel Mulock, a Dublin-born nonconformist preacher descended from minor Irish gentry, and Dinah Mellard, the daughter of a prosperous Newcastle tanner. Ben had two siblings: Thomas Mellard Mulock, and Dinah Maria Mulock, who attained international fame in her time as a novelist under her married name, Mrs. Craik. In 1840, the family moved to London. That year, Ben began learning music (he played the concertina and the piano) and by 1843 he was showing an interest in civil engineering. He was educated in London. After he came of age and received his inheritance, he traveled extensively. His most important work as a photographer was done in Bahia, Brazil, between November 1859 and April 1862. In early 1863, about a year after returning from Brazil, he began showing signs of "melancholia" and was "placed in Doctor Tuke's asylum in Hammersmith" on June 7, 1863. He managed to escape but was "knocked down and run over by a heavy van" (Reade 1915, 84–85). He died of his injuries five days later.

MULTIPLE PRINTING, COMBINATION PRINTING, AND MULTIPLE EXPOSURE

The groundwork of photographic multiple printing, the combining of two or more images to form a new representation, can be found in Johann Carl Enslen's *Face of Christ Superimposed Over Leaf*, 1839. This composite photogenic drawing was made from two photogenic negatives using William Henry Fox Talbot's negative/positive paper process. Between 1841 and 1842 Talbot experimented with soft edge, out of focus masking and pin registered overlay positives to control contrast in his prints of white busts and statues against darker backgrounds to retain highlight detail. This multiple printing method is now called highlight and shadow masking and was also practiced by the Countess of Ross in the early and mid-1850s, Gustave Le Gray, Camille Silvy, and others to print in clouds and skies.

Combination printing was the practice of combining two or more negatives to make a harmoniously, seamless photograph. The practice evolved in order to overcome a major technical obstacle that was blocking photography's recognition as art. This was the collodion wet-plate's insensitivity to all parts of the spectrum except blue and ultraviolet radiation, which gave colors an inaccurate translation into black-and-white tones. Red or green subjects were not properly recorded and appeared in prints as black. Exposures, calculated to record detail in the land, overexposed the sky. The amount of overexposure was not even and produced areas of low density in the negative. When the negative was printed these sections appeared gray and mottled, an effect not suitable for picturesque landscapes. Typically the sky was masked out so that it printed as white. When clouds were needed they were created using chemicals, India ink, and other coloring methods.

The artistic solution proposed by Hippolyte Bayard in 1852 involved making two separate negatives, one for the ground and a second for the sky. This response could have been derived from the earlier daguerreotype cloud studies by Albert Southworth and Josiah Hawes and calotypes by others. After processing the two negatives were masked, with the land's features printed in from the first negative and the sky's from the second. Landscape photographers often made a stock collection of sky negatives, which were used in printing future views. George Barnard used combination printing in his *Photographic Views of Sherman's Campaign* (1866) for clouds and a group portrait of Union general William Tecumseh Sherman and his generals—one general who missed the group photograph was put in later.

William Lake Price was one of the first photographers to exhibit work utilizing this dual-negative technique in 1855. However, it was Gustave Le Gray's spectacular seascapes of 1856–1858, achieved from separately-made cloud negatives, that attracted public attention for both stopping the action of waves and their dramatic cloud formations. Le Gray was not the first to make instantaneous seascapes, but his photographs challenged the notion that photography was an automatic process by clearly demonstrating that photographers could control the medium and translate their feelings into images.

The method caught fire with Oscar G. Rejlander's allegorical tableaux, *The Two Ways of Life, 1857* that plainly verified the artistic potential of combination printing and paved its way to becoming an accepted practice. Rejlander set out to create a photograph that was morally uplifting and instructive and required "the same operations of mind, the same artistic treatment and careful manipulation" as works done in crayon or paint. Rejlander produced an elaborate allegorical piece contrasting Philosophy and Science during a six-week period in which he made sketches, hired models, and produced thirty separate negatives which he masked, printed on two pieces of paper, and connected. This work was rephotographed, and editions were reproduced. The photograph's unusually large size, 16 x 31 inches, made people stop and notice, enabling it to hold its own on a gallery wall. *The Two Ways represents* "a venerable sage introducing two young men into life—the one, calm and placid, turns towards Religion, Charity and Industry, and the other virtues, while the other rushes madly from his guide into the pleasures of the world, typified by various figures, representing Gambling, Wine, Licentiousness, and other vices; ending in Suicide, Insanity and Death. The center of the picture, in front, between two parties, is a figure symbolizing Repentance, with the emblem of Hope." Queen Victoria gave Rejlander's vision a big boost by purchasing it for Prince Albert.

Two Ways did not sell well and provoked debate on the ethics of combining negatives to manufacture an image that never existed, marking an early instance

of critical thinking about the medium. The picture's detractors claimed it was a violation of the "true nature" of photography; works of "high art" could not be accomplished by "mechanical contrivances." In the Victorian age, when piano "legs" were dressed with pantaloons, the photographic nudity of *Two Ways* was shocking. The process of combination printing led to the first photographic montages designed for a public audience, providing an intriguing set of representational possibilities that allowed for the inclusion of subjective experiences and values. As the process questioned established viewing rules, many felt threatened and rejected the new way of picturemaking. The concept that art was a matter of ideas and not limited to specific practices was given voice by the French naturalist Louis Figuier, who believed photography could improve artistic eloquence and public taste, and that "what makes an artist is not the process but the feeling."

The rise of photography as an art form would transform art's function of portraying reality. Photography encouraged artists to explore new directions that eventually included abstraction, in which the concept of art as imitation of nature was abandoned. Rejlander's efforts have been criticized as being "imitations," but were an important and necessary step to expand the boundaries of photographic practice and inspire others to enlarge photography's dialogue within society. The artistic criticism and financial hardships took their toll on Rejlander, however, who only made a few more combination prints; none of them approached the polemic nature and scale of *The Two Ways.*

Rejlander's *The Two Ways of Life* inspired Henry Peach Robinson to undertake combination printing. In 1858, Robinson exhibited *Fading Away*, made from five negatives, showing a young girl on her deathbed with her grieving mother, sister, and fiancée. By Victorian standards this sorrowful scene was scandalously morbid, as it did not conform to accepted ideas about what a photograph should picture. More distressful scenes were painted, but because *Fading Away* was a photograph the public considered it inappropriately realistic and an indecent invasion of personal privacy. After Robinson revealed that his principal model "was a fine healthy girl of about fourteen, and the picture was done to see how near death she could be made to look," the work was criticized for being manufactured.

The combination prints of Rejlander and Robinson challenged the belief that painters alone had the right to "create" scenes while photographers were workmen operating mechanical equipment. For photography to succeed in the art world it had to debunk such confining ideas. Combination printing was given the Royal seal of approval when Prince Albert bought it and gave Robinson a standing order for every pictorial image he created. Once audiences overcame the shock of the combination print, they accepted it, realizing that Robinson's fundamental ideology embraced their notions of art. This made Robinson the most popular, emulated, and well-to-do photographer of the second half of the nineteenth century. Robinson's books and articles actively articulated his position and influenced the development of future photographers. His *Pictorial Effect in Photography* (1869), which advocated the basic canons of painting, "composition and chiaroscuro," as the "guiding laws" of an art photograph, was the most widely read photography textbook of the nineteenth century.

Robinson sought methods for uniting the rational with the subjective, to allow photographers to achieve the picturesque. He believed that combination printing gave "much greater liberty to the photographer and much greater facilities for representing the nature of nature." Critics were outraged by Robinson's constructed images for violating their sense of photographic veracity. Combination printing was acceptable in landscapes as the public was conditioned by painting to expect idealized renditions, but when it came to portraying human beings viewers associated photography with unarranged truth. Robinson was able to expand photography's reach and get the public to embrace his combinations as expressing the accepted allegorical ideals and standards of the day. Robinson's work possesses a duality common to educated practitioners born before the invention of photography who thought like painters. Although Robinson broke no new representational ground, he showed that photography could achieve the same artistic goals as painting, thus allowing the next generation to explore photography's own morphology.

In the short term Robinson's work had the opposite effect. His allegorical ideas, magical theatrical techniques, and moralizing sentiment were so successful that they dominated photographic discourse and stifled other ways of thinking photographically until the 1880s. Robinson's striving for a literary image, reminiscent of nineteenth-century painting, has been in critical eclipse for most of the twentieth century. Yet today Robinson's practices look like progenitors of the postmodern photographers who stage tableaux before the camera and digitally manipulate their materials.

The camera's ability to make multiple exposures was used to create the most common form of multiple imaging in the nineteenth-century that of ghost or spirit stereographs. Ghosts were created when a veiled figure entered the scene for a portion of the exposure, producing a transparent phantom. To maintain believability, less scrupulous operators concealed their methods from the public and used ploys such as: a plate with a previously recorded ghost image, a transparency of a ghost image placed in front of the lens, a miniature ghost transparency placed behind the lens, or a ghost image

Hobson, W.S. Amateurs playing ghost scene. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum,*

reflected into the lens during exposure. These representation were the result of *spiritualism*, a dubious spin-off movement of Transcendentalism that was founded in Rochester, New York, in 1848 by the medium Margaret Fox and her sisters, who later admitted their activities were fraudulent. Spiritualists believed that the human personality survived death and could communicate with the living through a medium that was sensitive to the spirit's vibrations. This gave rise to so-called spirit photography, which purported to make visual records of ectoplasmic manifestations of persons in a state beyond death. William Mumler, who ran the best-known spirit photograph studio in New York in the early 1860s, was eventually arrested as a swindler, though the charges were eventually dismissed because trickery was not proved. Nevertheless, spirit photographs attracted a large audience of predisposed believers who paid no attention when it was demonstrated that spirit photographs were produced by double exposure or multiple printing. Other photographers used these techniques and got into this commercially viable escapade without making any supernatural claims. To help sell his stereoscope, Sir David Brewster suggested making "ghost" stereo cards for fun; they quickly became a fad. Although Americans did not get involved with allegorical combination printing, spirit pictures encouraged experimentation with multiple exposure and acceptance of this style of depiction. Even though ghost cards were known to be fabricated, the fact that they were done photographically gave the appearance of truth. Spirit photography spread to Europe during the mid 1870s and again in the 1890s. These were times of recession for portrait studios, and ghosts were good for business.

For the intellectually inclined, John Thomson was the first to incorporate the multiple print concept in order to fashion two three-part panoramas in his limited edition book *The Antiquities of Cambodia; a series of photographs taken on the spot, with letterpress description*, 1867.

MUMLER, WILLIAM (1832–1884)
The first spirit photographer

Originally an engraver in Boston, Mumler was learning the trade of portrait photography in 1861 when, by his own account, a spirit 'extra' suddenly appeared on one of his plates. His newly discovered powers as a photographic medium were eagerly reported in the local Spiritualist press and he soon had many clients coming to his studio who were grieving for lost loved ones. Grateful sitters included Moses Dow, who was photographed with the spirit of his adopted daughter seeming to offer him a white rose, and the widow of Abraham Lincoln, who was photographed with Lincoln appearing to rest his hands on her shoulders. Many cartes-de-visite such as these were produced and sold as proof of spirit survival throughout the world-wide Spirititualist movement. After moving his business to New York he was arrested for fraud in May 1869. At the sensational trial prominent Spiritualists testified to their belief in his powers, whereas witnesses from the photographic industry enumerated the various ways identical effects could be obtained through double exposure. The judge reluctantly dismissed the charges because Mumler hadn't been caught in the act. He returned to Boston where he continued his business for several more years. In 1875 he published his memoirs, which were full of the testimony of grateful clients.

MUNDY, DANIEL LOUISE (c. 1826–1881)
English photographer

Daniel Louise Mundy (1826/7–1881) was born in Wiltshire, England, and arrived with sufficient capital (from the Australian goldfields perhaps) to buy into a well-established photographic business in Dunedin in 1864. At this time, the province of Otago, was experiencing a gold rush. So any previous experience he may have had in Victoria would have served him well in these turbulent times. Following on from this, Mundy staged a well timed move north to Christchurch in the mid to late 1860s. This was during the height of great public expectations about finding a route through New Zealand's Southern Alps to the West Coast Goldfields. Mundy seized upon this sense of high commercial expectation with a splendid set of scenic photographs showing the road as it existed between the two provinces. After Canterbury, Mundy moved to Wellington and then onto Auckland. Before he'd realised it, he'd practically photographed all of New Zealand's major settlements. As well he spent a lot of time in the Hot Lakes District photographing the Pink and White Terraces which were being billed as one of the Seven Wonders of the World. He returned to England in the mid 1870s and lectured on his photographic exploits, publishing two books, *Rotomahana and the Boiling Springs of New Zealand* (1875), and *The Wonderland of the Antipodes* (1873) that were illustrated with his photographs using the autotype process.

William Main

MURRAY, JOHN (1809–1898)
British surgeon and photographer in India

John Murray came to India in 1833 as a civil surgeon in the employ of the East India Company. Having settled into his post at Agra by the mid 1850s, Murray had already taken up photography, the value of which for documentary purposes was recognized in the military and civil establishment on the subcontinent. In 1856, Murray's fellow surgeon John McCosh had written in his *Advice to Officers in India*, "I would strongly recommend to every assistant-surgeon to make himself a master of photography in all its branches" (45–46). Murray focused his attentions particularly on architectural views of Mughal India and environs, which comprise some of the most intriguing imagery of the decade in a large corpus of plain and waxed paper negatives and corresponding salted paper and albumen prints.

Murray participated in the photographic culture of his day both in British India and in London. Twenty seven of his large salt prints were displayed at the first exhibition of the Bengal Photographic Society in March 1857; these were listed by title in the show's catalogue, and included landscapes of the hill station of Nynee Tal and the Mughal architecture of Agra. Like other photographic societies of the period, Bengal had formed to provide support for serious amateurs and commercial operators who shared a common passion for the medium—the best of photographs judged by their topicality or associative interest as well as artistry and technical execution. Murray continued to show his photographs at least until 1867, though they had been deemed earlier in the decade somewhat wanting in resolution compared with the results of the wet collodion on glass process. He remained a member of the Bengal Photographic Society until his departure from India at his retirement in 1871.

In November 1857 John Hogarth exhibited Murray's paper prints in London, reinforcing the political and cultural ties between the metropolitan center of the homeland and Britain's occupation of the subcontinent.

Murray was in the city during this time, having taken leave of absence from his post in Agra from April 27, 1857 to February 5, 1858. As a seller of fine prints at Haymarket, Hogarth had understood the importance of photographs not only as aesthetic objects but as agents of pronounced sentiment associated with British colonialism. The pictures offered viewers a graphic opportunity for imaginative reflection on India's past and carried potent meaning with respect to the bloodshed that was presently occurring between native India and the British. This was the rebellion of sepoys—Indians pressed into the service of the British army—which had broken out in May 1857, and was soon to become a populist uprising. Known variously as the Indian Mutiny and Rebellion of 1857, the fighting, brutal and devastating to both factions, ultimately hardened British resolve to impose imperial authority over India under Queen Victoria. Hogarth exhibited thirty of Murray's 15 × 18 inch prints from calotype negatives. The December 1 issue of *Art Journal* posted a review of Murray's work, which the writer observed to be "a series of beautiful photographs, presenting localities that must hereafter be regarded with an interest far beyond that which ordinary historic events communicate." Murray's artistry notwithstanding, the reviewer was clearly making reference to the insurgency. In 1858 Hogarth published a volume of the doctor's views, *Photographic Views in Agra, and Its Vicinity*, with descriptions by J. Middleton, Principal of the Company's College at Agra. This was followed the next year by *Picturesque Views in the North-Western Provinces of India*, also a Hogarth production, with text by Major-General J.T. Boileau. Boileau appreciated the subtlety of craft and picturesque appeal of Murray's pictures, while drawing special attention to evidence of politically symbolic import within individual views—a Union jack, for instance, atop the famous Delhi Gate of Agra Fort, "the emblem of British supremacy in India." Among other noteworthy practitioners on the scene in the aftermath of 1857 were Felice Beato, Charles Shepherd, and the photographer couple Major Robert and Harriet Christina Tytler, who were assisted in their art by Beato and Murray himself.

As a doctor Murray found correlations between the land and diseases endemic to monsoon climates. He kept a valuable medical library (moved for protection during the peak of the rebellion), published studies on cholera, and on the topography of localities in north central India. Thus, while many of his photographs emphasize the architectural legacy of the Mughal empire, they include features that bear testimony to an intimate knowledge of the terrain beyond an eye looking for the picturesque. A series of pictures from Agra Fort overlooking the Jumna River, for instance, reveal seasonal changes, where the water level varies, sand bars shift, and foliage flourishes or diminishes. They suggest an awareness of how visual evidence might serve to demonstrate existing conditions of place that would complement any written report. These and many other prints whose

main subjects appear ostensibly as the grand edifices of Mughal palace precincts and fortifications yield to the persistent observer the contrast of vernacular habitations of indigenous peoples.

Murray's documentation of such places coincided with European scholarship toward the systematic grasp of India's place in world culture. Historians under the new Raj especially venerated the achievements of the great Mughal dynasties, sometimes at the expense of India's Hindu past. Murray himself was acknowledged in the English press of the period as contributing to efforts to preserve the Taj Mahal ("Mofussil letters, Agra Dec 31, 1863," *The Englishman*, Jan 7, 1864), and the evidence of restoration is visible in certain of his pictures of Akbar's Palace and Agra Fort. Hence, however compelling subsequent photographers found the red sandstone and marble forts, palaces, and mosques, and other edifices of Britain's powerful predecessors, Murray's pictorial interests were well informed by his commitment to service and abiding concern for securing the cultural heritage of his adopted home.

GARY D SAMPSON

Biography

John Murray was born in November 1809, to Alexander Murray, a farmer in Blackhouse, Aberdeen County, Scotland. He received his M.D. at Edinburgh in 1831, successfully passed his examination to become Assistant Surgeon with the United East India Company in 1832, arriving in India the following year. By 1848 he was full Surgeon at Agra, made Deputy Inspector General in 1858, following nearly a year's leave in London during the Indian Rebellion, rising to Inspector General in 1865. His peak period of photography began in the mid 1850s and lasted until the early 1860s, which resulted in hundreds of views of Delhi, Agra, Fatehpur Sikri, Cawnpore, Benares, and elsewhere, many associated with the 1857 hostilities and Mughal India, and at least in part made at the request of Lord Canning, Governor General of India at the time. His method of choice was an variation of LeGray's waxed process, where the negative was waxed twice for greater detail—once before sensitization and once after exposure. His pictures appeared in a number of exhibitions and publications through his associations with the Bengal Photographic Society and with John Hogarth in London (see bibliography), and some were translated to wood engraving as witnessed in the *Illustrated London News*. He retired in 1871, leaving India, and died at Sherringham, Norfolk, July, 1898.

MURRAY, RICHARD (UNKNOWN) AND HEATH, VERNON (1819–1895)

The career of Murray and Heath can be divided into two phases. In late 1855 or early 1856, Richard Murray and Vernon Heath began a firm of opticians, specialising in scientific and philosophical equipment. During the following five years, they built a reputation as one of the premier firms supplying photographic apparatus and material. As well as a their own design of stereoscope and carte-de-visite cameras, Murray and Heath's stock included a variety of accompanying lenses, camera stands and special field boxes for outside work. Other scientific equipment sold by the firm ranged from opera glasses and microscopes to galvanic batteries.

Little is known about Richard Murray aside from the fact that he worked for a period at Newman's opticians in Regent St, which supplied stereoscopic lenses to Sir Charles Wheatstone in 1832. Vernon Heath (1819–1895) was the nephew of Lord Vernon, the art philanthropist who bequeathed his extensive collection of paintings to the National Gallery. Heath's reminiscences were published in 1892. They detail his career and constitute one of the first book-length memoirs by a photographer.

Many notable photographers and institutions used Murray and Heath's optical equipment. The firm supplied apparatus to Queen Victoria and Prince Albert in 1857, a privileged position that they advertised through their catalogues, all of which carry the royal arms. Other customers included the Board of Trade, the Foreign Office, Admiralty, and the East India Company. The

reliability of their cameras under difficult climactic conditions is reflected in the fact that it was used during Lord Elgin's visit to China and on Livingstone's journey to the Zambesi in 1858.

The repute of Murray and Heath was such that their equipment was reviewed in the *Art Journal* in 1859. Their cameras were praised for both their durability and the numerous minor technical innovations they had introduced. The review concluded that Murray and Heath could have "but small necessity for our praise, yet it affords us real pleasure to add to our testimony upon their photographic apparatus to that of the most distinguished photographers."

At the beginning of 1862, Murray and Heath sold their business to Charles Heisch, Professor of Chemistry at Middlesex Hospital. Heisch was also a keen photographer and a regular contributor to the pages of the *Photographic News*. A new catalogue issued by Heisch promised to "maintain the high character already established by this house, more especially for Apparatus suited to the tropical climates." The firm continued to operate under the name of Murray and Heath at 43 Piccadilly. However, the following year, Vernon Heath started as a full time photographic studio from the same address.

Heath operated at 43 Piccadilly between 1863 and 1876, and as Vernon Heath & Co. between 1877 and 1885. He was made bankrupt in early 1886, but was working at the same studio again between 1887 and 1888. Heath's interest in photography began in January 1839 when he heard Faraday announce Daguerre and Fox Talbot's discoveries at the Royal Institution. Sometime after the death of Lord Vernon in 1849, Heath started work a professional photographer. His early pupils included Dr. Livingstone and the young Prince Alfred, the future Duke of Edinburgh. Royal commissions feature prominently in Heath's career. In 1862, he was involved in a court case with a publisher, Robert Mason of Paternoster Row, over a disputed negative of Prince Albert. The case, which Heath won, centred around the number of negatives Heath had agreed to take for Mason, who wanted to use them for *carte-de-visite*.

At the wedding of the Prince of Wales in March 1863, Heath enjoyed the honour of being invited by Queen Victoria to photograph the marriage ceremony in the Chapel Royal at Windsor. Heath subsequently became a friend of the Prince and Princess of Wales. He was invited to Sandringham on several occasions, and made £1,000 from a photograph of two of the Prince's Indian mastiffs. His work for the royal family continued as late as 1887, when he was asked by Queen Victoria to photograph her Golden Jubilee garden party at Buckingham Palace.

One important technical innovation introduced by Heath was a means of reproducing and enlarging negatives. The process came about through his attempts to ensure that he could produce enough pictures of Prince Albert from the single negative involved in the court case. Heath's process involved printing a positive transparency of the negative on glass instead of paper, and then using this transparency to make more negatives. The process, with some modifications, became the principal means of enlarging negatives. Heath gave a paper describing his technique at the Photographic Society of London in March 1862, which was also published in the *British Journal of Photography*.

Heath's pictures included both portrait photographs and landscapes, although he was more renowned for the latter. His work often stemmed from high profile social connections. These included a request from Lady Burdett Coutts in 1867 to picture a garden party; photographing the Landseer's lions at the base of Nelson's column; and being commissioned by the Admiralty in 1865 to record details of the French fleet visiting Portsmouth. Much of his best photography stemmed from picturing Scottish landscape, often through long visits to the estates of Scottish noblemen. After one typical visit to the Duke of Argyll's estate in Inverary, Heath took a photograph of Glen Shira, which he then enlarged to 43 × 53 inches. For this and other pictures he sent to the Paris Exhibition in 1878, he was awarded the only gold medal for landscape photography given to British photographers. In his latter years, Heath was a strong advocate of the autotype process and gave a paper at Royal Institution on the subject in February 1874.

One unexpected admirer of Heath's landscape work was John Ruskin. In 1882, Ruskin wrote in reply to an approach from Heath to view his work:

> If you could know how often I have paused, in my greatest hurries, at that recessed window in Piccadilly, and how often I have retired from it in a state of humiliation and wretchedness of mind, and accused first the sun, and then you, and then the nature of things, of making all one's past labours hopeless, you would understand the interest I shall have in really seeing you. (Quoted in *Vernon's Heath's Recollections*, 294)

Vernon Heath died on 25 October 1895, and an obituary in *The Times* singled out his pictures of Burnham Beeches for particular praise.

MUYBRIDGE, EADWEARD JAMES (1830–1904)

Born Edward James Muggeridge, also known as Muggridge, Maygridge, Muygridge, Eduardo Santiago Muybridge. He was a photographer, inventor, and lecturer. One of the most influential and colourful photographers of the nineteenth century, Muybridge's achievements span three distinct categories: landscape photography, motion photography, and early cinema. The motion photographs, in particular, are among the most easily recognized photographs of the nineteenth century, comprised of grids of instantaneous photographs of humans and animals performing various behaviours and taken in rapid succession.

Although he was born in, and retired to, the London suburb of Kingston, his entire photographic career was spent in the United States. Muybridge was one of four sons born to Susannah and John Muggeridge, Kingston merchants recorded as selling coal and later grain. After attending Queen Elizabeth's Free Grammar School, Eadweard moved to London, apparently to receive vocational training. He may have been apprenticed in the city, but records from this period are scant, and his tendency to exaggerate biographical details renders information about his early training suspect. Around 1851–52 he settled in New York City, where he was an agent of the London Printing and Publishing Company, arranging the importation of unbound books from London for their binding and sale in the United States. He also worked for Johnson, Fry and Company, an American publishing company with offices in Boston, New York and Philadelphia. His work seems to have involved a considerable amount of travel. In his personal scrapbook, now in the collections of the Kingston Museum and Heritage Service, visits to numerous American cities are mentioned, including New Orleans and other shipping ports in the United States. Around 1855 Muybridge set out on his own, establishing a booksellers at 113 Montgomery Street in San Francisco. He also remained an agent for London Printing and Publishing. His interest in books persisted throughout his career, and many of Muybridge's photographic projects were conceived as bound volumes.

Around 1858 Muybridge's brother George joined him in the San Francisco book business, followed by his youngest brother Thomas. George is thought to have died of tuberculosis shortly thereafter. In 1860, Eadweard decided to return to New York and London, presumably on business. His decision to take a stagecoach rather than an ocean liner proved fateful. On July 2, 1860, his Overland Stage coach crashed in Northeast Texas, and Muybridge suffered a severe head injury. He was knocked unconscious and was said to have lost his senses of taste, smell, and hearing for several months. After two months convalescing in New York, he continued to London where he was under the care of Sir William Gull, Queen Victoria's private physician. In total he spent about a year recovering from the accident. Several scholars have attributed changes in Muybridge's personality to this injury, theorizing that he suffered brain damage. The veracity of this claim may never be proved, but his unorthodox and mercurial personality in his adult working life is undisputed.

Like much of his early life, Muybridge's whereabouts from 1861 to 1867 are mysterious. His return to the United States was almost certainly interrupted by the Civil War. However, by 1867 Muybridge was back in San Francisco where he quickly established himself as a successful landscape photographer. It is unclear whether he learned to photograph in England or the United States. An amateur photographer named Arthur Brown has been nominated as a possible teacher in England. In the United States, Muybridge befriended the Daguerreotypist Silas T. Selleck (active 1850s–70s), who is thought to have worked for Mathew Brady before moving to San Francisco. If Selleck provided photographic training, there is little evidence of this. Claims that Samuel Morse taught Muybridge appear to be spurious.

In late 1867 or early 1868, Muybridge and Selleck opened a studio in San Francisco specializing in photographs of California and the Pacific Coast. Landscape dominated his practice for about six years. He began with views of San Francisco, and then photographed the Yosemite Valley. By 1868 he had moved to Vancouver and Alaska; later he would photograph Pacific coast lighthouses, the Farallon Islands, geysers and railroad lines. He developed an astonishing virtuosity with the camera, producing mammoth plate albumen prints scarcely rivalled in their beauty. Soon his works challenged his principal rival in California landscape, Carleton Watkins (1829–1916). Many of Muybridge's images were published under the name "Helios," a reference to the sunlight used to expose them. He also dubbed his operation "the Flying Studio."

By 1872 Muybridge had become affiliated with the studio of Bradley and Rulofson in San Francisco, where he was recognized as the outdoor photography

specialist. When Leland Stanford, former Governor of California, United States Senator, and President of the Central Pacific Railroad, approached the studio with a commission to photograph galloping horses, Muybridge was assigned the case. Whether Stanford already knew Muybridge, possibly as a result of his railroad photographs or other contacts, is unknown. As a horse breeder and avid reader of equine literature, Stanford wished to obtain photographs of a horse's gait in order to ascertain whether it has all four hooves from the ground at any point in its stride. This necessitated an unprecedented degree of instantaneity as it required exposures faster than the naked eye could see. Initially, Muybridge set about the project using wet-plate collodion materials, which are inherently slow and awkward to use. The motivation for Stanford's commission has been the subject of much speculation, but was almost certainly prompted by a friendly disagreement with a rival. The oft-repeated claim that Muybridge was retained to settle a substantial wager does not appear to be true.

There are conflicting accounts about the date and location of Muybridge's first horse in motion experiments. The subject of the photographs is said to have been Stanford's fast horse Occident. Some reports place the first attempts to photograph him in May of 1872 at the Union Park Race Course in Sacramento, but if such experiments occurred they do not appear to have been successful. Subsequent attempts may have occurred in Sacramento the following year, but a young assistant, Sherman Blake, recalled them being conducted at the Old Bay District Track in San Francisco, which Stanford helped construct. Most probably they were begun unsuccessfully in Sacramento during one of Muybridge's trips to Yosemite (Muybridge photographed there in 1867 and 1872), and moved to San Francisco to be nearer to his base of operations. In any case, photographs from this period have not been preserved. Both Muybridge and Stanford said they were too fuzzy and indistinct to merit publication, but were adequate to judge the position of the horse's hooves. The only visual record of these earliest experiments exists in the form of drawings, possibly copied from lantern slide projections, currently in the collections of the Iris and B. Gerald Cantor Center for Visual Arts at Stanford University, and a Currier & Ives lithograph of Occident trotting published in 1873.

In 1873 Muybridge created a series of photographs documenting the Modoc Indian War. Muybridge was sympathetic to the Native American fighters, who were resisting violent forced resettlement and took refuge in the rocky chasms outside the Lava Beds, near the Oregon border. He produced some thirty-one stereo views of the campaign, which were published by Bradley & Rulofson. Muybridge claimed to have photographed both sides of the conflict, but scholars have identified his photograph of 'A Modoc Brave' as a member of a rival tribe, and his other photographs of Modocs seem to have been made exclusively from prisoners.

In 1874 Muybridge's career was interrupted by an infamous series of events culminating in the murder of his wife's lover. In 1872, at age forty-three, Muybridge had married a twenty-one year old divorcé named Flora Stone. The next year Flora began an affair with a dandyish socialite named Major Harry Larkyns. Muybridge warned them apart, and when Flora became pregnant in 1873, he had no reason to suspect the child was not his own. The truth was revealed when Muybridge found a photograph of the child, whom he and his wife had named Floredo, with an annotation on the back reading "Little Harry." Muybridge had never seen the picture before, which had evidently been sent to Flora by Larkyns. With the parentage of the child deeply in doubt, Muybridge flew into a rage and determined to avenge himself. He travelled roughly eighty miles to the city of Calistoga in northern Napa County, where Larkyns was staying. He traced him to a house on the grounds of the Yellow Jacket Mine, and called him to the door. Witnesses record him as saying, "Good evening, Major. My name is Muybridge. Here is the answer to the message you sent my wife." He then shot Larkyns once near the heart. Larkyns died instantly. Muybridge was arrested and tried, but acquitted on grounds that the killing was a justified defense of his family.

Released from jail Muybridge travelled to Central America, where he spent the next year photographing the landscapes of Guatemala and Panama, and particularly the workings of coffee plantations. The brooding, atmospheric quality of these photographs gives some indication of his turbulent mental state at the time. After his return, in January of 1877 Muybridge produced two dramatic panoramas of San Francisco from the hill at California Street: a "small" panorama of twenty-two panels each approximately 7 × 8 inches, and a "large" panorama of thirteen panels, each approximately 21 × 16 inches. When fully extended the large panorama is 17'4" long. The panoramas represent Muybridge's last concerted effort at landscape photography before fully immersing himself in the motion photography for which he became world famous.

After a hiatus of some four years, Muybridge resumed his project photographing horses for Stanford in 1877. This time, the photographs were made at Stanford's farm in Palo Alto, which would later become the campus of Stanford University. An ambitious scheme was devised not just to photograph a single moment in a horse's stride, but also to make a succession of photographs at regular intervals, each isolating a particular moment in an animal's stride. State-of-the-art lenses were ordered from Dallmeyer in London, and cameras were commissioned from Scoville in New York. Muybridge also claimed to have developed a speedier chemistry, which

enabled more rapid exposures. To maximize available light and further shorten exposure, Muybridge built a track with an angled whitewashed wall on one side to reflect light, and scattered the ground with lime. Working with Stanford's engineers (who included telegraph designers), Muybridge and his team rigged the cameras with automatic shutters—at first these were purely mechanical but later they were electrically fired. Two basic systems were employed. For free-running horses, thin threads were drawn across the track which the horses would break as they ran, each successive thread activating a shutter. For horses pulling sulkies, the threads were buried underneath the track and pressure activated by the weight of the carriage's wheels.

The new system was fully operational in 1878. Its sophistication outstripped anything attempted previously, and is hardly foreshadowed in his earlier motion experiments. Not only did it enable Muybridge to photograph animals moving at speeds never before photographed, it also resulted in distinctive sequences of imagery delineating the transitions from one posture to another. Muybridge published them in grids, initially of twelve frames. To launch the new venture Muybridge held a press conference on June 15, 1878, in Palo Alto. Newspaper and magazine representatives in attendance, and photographs were made using the new system. Two horses were photographed, Abe Edgington (trotting) and Sallie Gardner (running). The Abe Edgington photographs were published as the first in a set of six cabinet cards titled *The Horse in Motion;* the Abe Edgington image became known as *Abe Edgington trotting at a 2:24 Gait*. Abe Edgington was the subject of three sequences in the set. The others depicted Mahomet, Sallie Gardner, and Occident.

Reproduced and disseminated throughout the world, Muybridge's *Horse in Motion* grids were the most sensational photographs of their day. Contemporaneous accounts describe crowds gathering outside shop windows in which they were displayed, and Muybridge received correspondence from admirers internationally. On his mounts, Muybridge changed his title to "Landscape and Animal Photographer." The rapturous attention given the photographs prompted Muybridge to continue his experiments through 1879. However, the publicity garnered by the photographs created tensions between Muybridge and Stanford over who should receive credit for them which led to the dissolution of their partnership.

Muybridge and Stanford published competing compendiums of Muybridge's photographs. Muybridge widened the scope of his project to include other animals, including deer, dogs, cats, oxen and even humans performing various tasks. He assembled 203 of these in a handmade album he called *The Attitudes of Animals in Motion. A Series Illustrating the Consecutive Positions Assumed by Animals in Performing Various Movements Executed at Palo Alto , California, in 1878 and 1879*; it was published in 1881. The plates in this album exist in both albumen and printing-out paper versions. Stanford asked his friend the physician J.D.B. Stillman to write about the pictures, which resulted in the book *The Horse in Motion as Shown by Instantaneous Photography with a Study on Animal Mechanics* in 1882. In Stanford's book the original photographs were copied as lithographs, and Muybridge was not listed on the title page. He was mentioned merely as a skillful photographer. The publication of the book prompted Muybridge to sue Stanford, ending any hopes of continuing the project in Palo Alto. Stanford prevailed in court, mainly on the grounds that Muybridge could not lay claim to authorship as his work depended heavily on an electrical trigger mechanism designed by Stanford's engineer, John D. Isaacs.

Starting in the 1880s Muybridge spread his reputation by lecturing about his photographs in the United States and Europe. His presentations involved lantern slides made from his motion photographs, alternated with slides of historical representations (paintings, sculptures etc.) of animal motion. Muybridge pointed out inaccuracies in historical representations and the superiority of his technique. An important innovation he employed in his presentations was the zoopraxiscope, a projection device he invented in 1879 to show short animated loops of motion photographs. Because his photographs had been made in sequence, Muybridge reasoned that when shown in rapid succession they could easily be animated. This was a well-established principle of optical toys such as the phenakistiscope, but had not been perfected using photography. The zoopraxiscope combined a projecting lantern, rotating glass discs on which reproductions of Muybridge photographs were painted, and a counter-rotating slotted metal disk which spun at the same speed, acting as a kind of shutter. Contrary to popular belief, actual photographs were not used in the zoopraxiscope. Because it relied on a spinning disk with a counter-rotating aperture, the zoopraxiscope projected images that looked unnaturally short and squat. To compensate for this, skilled copyists were employed to paint the images on the disks in an elongated, stretched form so that when they were projected they returned to normal proportions. Nevertheless the illusion of animated photographs was convincing and inspired numerous other attempts to animate photography using a projector. For this reason Muybridge is often credited as one of the inventors of the motion picture.

Having severed all ties with Stanford, Muybridge approached numerous potential patrons to sponsor his continued investigations. The University of Pennsylvania finally agreed, giving him equipment and laboratory space on campus. From 1884 to 1886

Muybridge produced 781 motion studies under the partial supervision of Thomas Eakins, which he published in 1887 under the title *Animal Locomotion.* It became Muybridge's best-known work. The plates in *Animal Locomotion* were printed using the collotype photomechanical technique, although a nearly complete set of cyanotype proofs for the project is currently held at the Smithsonian Institution, National Museum of American History. Whereas in California Muybridge used trip wires to activate his shutters, in Pennsylvania he used a timer mechanism. This permitted him to photograph behaviours in which the subject does not proceed straight ahead at a constant rate. His equipment was markedly better than it had been in California. Equipped with thirty cameras which could be directed simultaneously at different angles, he was also able to take advantage of gelatine dry-plate chemistry, which was both faster and more convenient than the wet-plate materials used earlier. Although *Animal Locomotion* contains further photographs of horses and other animals borrowed from the Philadelphia Zoo, the primary focus was on humans. Men and women, nude or partially clad, are shown engaged in activities ranging from the banal to the highly esoteric: walking, running, and jumping are interspersed with dancing, smoking, and women pouring water over each others' heads. Of special interest are images made of people with physiological disorders, including an amputee, a pathologically obese woman, and a girl with multiple sclerosis. These photographs presage the diagnostic role photography would assume in scientific investigations, particularly under the influence of Etienne-Jules Marey and his colleagues in France. The volume was also highly influential among artists: subscribers to *Animal Locomotion* included the painters Lawrence Alma-Tadema, Ernest Meissonier, John Everett Millais, William Bouguereau, August Rodin, and James Abbott McNeill Whistler.

After *Animal Locomotion* Muybridge retired from photography and focused instead on lecturing and writing about his work. In 1893 he staged a zoopraxiscope theatre show at the World's Columbian Exposition in Chicago. It closed early due to tepid interest.

MYERS, EVELEEN (1856–1937)

English photographer

Eveleen Myers, née Tennant, was born in 1856 to Charles Tennant, an M.P. of Cadoxton, Glamorganshire, Wales, and his wife Gertrude, née Collier. In London, the Tennants were part of prominent artistic and literary circles. In 1880, Myers married F.W.H. Myers (1843–1901), psychical researcher and co-founding member of the Society for Psychical Research as well as writer and inspector of schools in Cambridge. The couple lived in Cambridge and had three children. Myers first began photographing to take portraits of her children in 1888, and she practiced photography, working in platinum, in the late 1880s through the early twentieth century. Her work consists of portraiture, artistic studies, and allegorical works. She photographed notable men and women, including Robert Browning and William Ewart Gladstone. These two portraits, along with *Rebekah at the Well* and *The Summer Garden*, are probably her best-known works and were reproduced in *Sun Artists*, Number 7, April 1891. Myers's photographs are in the collections of, among others, the National Portrait Gallery, London, and the Getty Museum. She died in 1937.

N

NADAR (GASPARD-FÉLIX TOURNACHON) (1820–1910)

French photographer, writer, and caricaturist

To the question—"Who do you think is the world's greatest photographer?"—French essayist Roland Barthes provided a simple, one-word answer: "Nadar." And in the history of French photography in the nineteenth century, there are few who rival the artistry and output of this man who lived for eighty years of the nineteenth century and ten of the twentieth century.

Nadar's notoriety in photography came after successful careers first in writing and publishing and then in caricature. Based in Paris, Nadar met and communed with a large circle of late-Romantic artists and writers, as well as the radical social thinkers of the time. This circle considered itself bohemian and in opposition to anything bourgeois; it was politically and socially liberal and believed in the importance of art, personal integrity, and freedom of self-expression.

Photographic Beginnings

In 1854, although working at the time on his lithographic pantheon of contemporary "poets, novelists, historians, publicists, and journalists," Nadar offered to assist his younger brother Adrien in developing a new career. Nadar not only paid for his brother's lessons with Gustave le Gray, but he also managed to establish Adrien in his own portrait studio in Paris. It appears that it was always Nadar's intention to join Adrien in taking up photography; later that year Nadar commenced photography lessons with the firm of Adolphe Bertsch and Camille d'Arnoud. By September of 1854, however, Adrien's studio was failing to the point that Nadar felt compelled to step in and take control. Together the brothers made a small series of portraits, some of which were used to complete the portraits used in the *Panthéon Nadar*. Nadar also arranged for the studio's work to be exhibited at the Exposition Universelle of 1855.

By January of 1855 Adrien requested that the brothers separate, leaving Nadar to set up shop in his own residence at 113, rue Saint-Lazure. Adrien also adopted the name "Nadar jeune." Nadar had created his own name in 1838—a pen name (with a few variations) by which he was known his entire professional life. Beginning in 1855 (with appeals ending only in June 1859), a lawsuit was filed by Nadar to make Adrien cease and desist his use of the appellation "Nadar jeune." During those years Adrien did have some success as a photographer, while Nadar also established himself as a portrait photographer, becoming a member of the Société française de photographie in 1856 and winning a gold medal at the Exposition Photographie in Brussels in the same year.

Photographic Technique

In line with what he would have learned from Adolphe-Auguste Bertsch (who invented a faster and aesthetically finer collodion process for negative plates), Nadar's first prints were made from wet-collodion negatives on high-quality salted paper. By 1855 Nadar produced signed, mounted, salted paper prints: they measured 11 × 8¼ inches. Although disparaging of Disdéri's *carte de visite* format (Nadar considered it unaesthetic), by 1860 he had "submitted" to the raging fashion and was producing both full-size and *carte* prints (both salted paper and albumen, although the low-cost, commercially produced albumen papers would eventually prevail). From his earliest days as a photographer, it appears that Nadar manipulated his negatives in the darkroom; by the 1860s it is clear that he was retouching his negatives, making the retouching of prints rare. Nadar also experimented with artificial lighting not only for his portraits but also for his work photographing the Paris catacombs and sewers. He had always been a master at manipulating

natural light to aesthetic effect in his studio and soon abandoned electric light for his portraits.

Portrait Photographer

Nadar's turn to portrait photography appears to be a natural progression from his work in caricature. Already focused on capturing the essence of individuals' physiognomy through drawing and then mass producing the caricatures through lithography, Nadar possessed the aesthetic and interpersonal skills to use the medium of photography to its best advantage. Not only did he study with a photographer producing the finest-quality prints in Paris in 1854, but he also had a ready-made clientele, as well as name recognition. His circle of acquaintances was very broad, and many up-and-coming and established artists, writers, and social activists had already sat for Nadar. One of two extant albums that Nadar used for guests to sign when sitting for their portraits comprises over 400 names (with accompanying commentaries or samples of drawing, music, or poetry) of the most famous individuals working in music, art, poetry, fiction, politics, and the military in a twenty-year period between the mid-1850s and the early 1870s.

In 1876 Ernest Lacan—editor-in-chief of France's first photography magazine, *La Lumière*—evaluated Nadar's eminence in portrait photography: "His prints, their formats large for that period, had an entirely new look about them. Nadar generally worked in broad sunshine or at least lit his sitter in such a way that one side of the face was very bright and the other very dark. The pictures generally resembled what are today called 'portraits à la Rembrandt.' They were very artistic and enjoyed a great success" (quoted in Françoise Heilburn, "Nadar and the Art of Portrait Photography," *Nadar*, New York: Metropolitan Museum of Art, 1995, 36). Many scholars consider a mere six-year period from 1855 to 1860 to be Nadar's era of greatness in portrait photography. In 1860 Nadar undertook the construction of a new, large photographic studio at 35 boulevard des Capucines. Completed in 1861, it cost 230,000 francs, all of which Nadar borrowed. Financial considerations, therefore, and the popularity and economy of the *carte de visite* format forced Nadar to alter his original method of photographic portraiture. The results included smaller, less detailed prints as well as the miniaturization of his existing archive of prints (he re-shot original prints to create smaller negatives that would accommodate the *carte* format).

Typical of a Nadar photographic portrait is the lack of props or elaborate backgrounds. He also patented a technique in which the edges of the prints are faded. All attention centers on the subject, and most prints comprise only one individual. Nadar's subjects are never harshly cast, but they are not idealized either. In general, he de-emphasizes clothing, requesting that his subjects choose dark garments for their sitting. Nadar also de-emphasizes the subject's hands—frequently eliminating them from the shot or hiding them inside clothes or the folds of cloth. There is no one pose that Nadar adopts for his sitters. Some look left, some right—with eyes looking forward or with eyes looking down; some sit or stand and look directly at the camera, although most are posed standing or sitting at an angle from the camera. But as one scholar comments: "As Nadar is forced into rapid, high-volume production in the early 1860s [. . .] a bland, stereotyped portrait emerges [. . .] which relies on conventional dress and body language, flat lighting, and traditional studio props" (Ulrich Keller, "Sorting Out Nadar," *Nadar*, New York: Metropolitan Museum of Art, 1995, 86).

Among those photographed by Nadar are: Mikhail Bakunin, Théodore de Banville, Charles Baudelaire, Hector Berlioz, Sarah Bernhardt, Jules Champfleury, Gustave Courbet, Honoré Daumier, Eugène Delacroix, Gustave Doré, Alexandre Dumas (père and fils), Théophile Gautier, Edmond and Jules de Goncourt, Constantin Guys, Victor Hugo, Edouard Manet, Jules Michelet, Jean Français Millet, Henri Mürger, Gérard de Nerval, Jacques Offenbach, Pierre Joseph Proudhon, Gioacchino Rossini Rossini, George Sand, Giuseppe Verdi, and Alfred de Vigny.

Aerial Photography

In 1858 Nadar took his first aerial photographs from a balloon tethered near the Arc de Triomphe. He had actually attempted this endeavor the year before but was unsuccessful in making photographs, because the gases used in the balloon chemically interacted with his negatives. Nadar was a firm believer that the path to human flight lay with machines heavier than air, so he had his own balloon, called *le Géant* [Giant], built in 1863 in anticipation that the profits from its rides would generate enough income to build a helicopter. Between 1863 and 1867 he made five ascents in *le Géant* and remarkably increased his notoriety, but this adventure ultimately proved to be a financial disaster.

Subterranean Photography

In his quest for technological innovation and new pursuits, Nadar negotiated the right to photograph underground in Paris—first the catacombs in 1861–62, then the sewers in 1864–65. Victor Hugo had made the sewers famous in *Les Misérables*, and the catacombs fascinated such compatriots as Gustave Flaubert and the Goncourt brothers, all of whom toured the burial sites in 1862. Of course, the idea of going underground after having soared above ground seems only fitting. Although less

than pleased with the results of using artificial light in his portrait sittings, Nadar understood that electric light was absolutely necessary for underground photography; he represents the first photographer ever to attempt such a task. Using magnesium flares for light in the catacombs, Nadar needed to expose the negatives for upwards of 18 minutes. As a result, he decided to use mannequins rather than living humans to simulate workers (although at least one image exists in which Nadar himself appears). These staged images with their harsh lighting, nevertheless, represent a progressive experiment to push the boundaries of the medium and increase Nadar's fame as well. His work in the sewers a few years later was more problematic technically and yielded approximately two dozen images. They failed to capture the full extent of recent renovations, nor did they depict the ancient sewers described by Hugo. His power source entailed long wires attached to batteries that remained above ground.

Retirement

In 1873 Nadar purchased a home in the countryside outside of Paris where he and his wife Ernestine then spent most of their time. Political upheavals that included the fall of Napoléon III, the siege of Paris, and the subsequent Commune (itself overturned by the second siege of Paris) left Nadar physically, emotionally, and financially spent. He vacated his large studio on the boulevard des Capucines and relocated to small quarters in the rue d'Anjou. Interesting to note, however, is that Nadar allowed the Impressionist artists to mount their first exhibition in his old establishment on the boulevard for which he still held the lease. His son Paul now managed the business, although it was not until 1895 that Nadar formally turned over all rights to the name and all remaining partnership in the business. In his retirement Nadar began yet another career as a memoirist, which included the 1900 publication, *Quand j'étais un photographe* [*When I Was a Photographer*].

Nadar's final work as a photographer occurred in 1897 after his son failed to pay him his annuity: he opened a portrait studio in Marseilles but sold it in 1899. In 1900 Nadar was honored with a retrospective exposition of his work at the Exposition Universelle. The last decade of his life found him in failing health, although he survived both his younger brother Adrien and his wife Ernestine. Upon Paul Nadar's death in 1939, the Nadar studio ceased to exist.

NANCY M. SHAWCROSS

Biography

Born Gaspard-Félix Tournachon on 6 April 1820 in Paris, Nadar was the first child of printer/publisher Victor Tournachon and Thérèse Maillet. Originally educated in and around Paris, Nadar began but never completed the study of medicine in Lyons, where his father had relocated the family. In 1838 Nadar returned to Paris on his own and adopted "Nadar" (sometimes "Nadard") as his pen name. In Paris in the 1840s, Nadar allied himself with a band of vagabond artists that Henri Mürger immortalized in *Scènes de la vie Bohème* [Scenes from the Life of Bohemia]; among them was Charles Baudelaire. Nadar's first career was as a writer, but by 1846 he had embarked on a second career as a caricaturist, culminating in his 1854 tour de force, *Panthéon Nadar* (a revised version appeared in 1858), a set of two enormous lithographs comprising caricatures of noted Parisians. In 1854 Nadar also married Ernestine-Constance Lefèvre and assisted his brother Adrien by financing photography lessons for him with Gustave Le Gray and setting up a photographic studio, first for Adrien and then for himself. Though he continued to do caricatures throughout the 1850s, by the 1860s Nadar was an established portrait photographer in Paris, becoming a member of the Société française de photographie in 1856, exhibiting in its Salon in 1859, and pioneering a number of photographic techniques and locations, such as the first aerial photography and artificial lighting in 1858, equestrian photography in 1861, and photographing the catacombs and sewers of Paris in 1861–62 and 1864–65, respectively. In addition to these careers Nadar was also an aeronaut and financed a hot-air balloon called *le Géant* [*Giant*]. Nadar retired from photography in 1873, leaving his studio to his son Paul (1856–1939) to run. During his retirement Nadar continued to write and publish memoirs; he briefly re-emerged as a photographer in 1897 in Marseilles. Nadar died in Paris on 20 March 1910, fourteen months after the death of his wife.

NADAR, PAUL (1856–1939)

French photographer, entrepreneur, and son of Nadar

Paul Nadar was born February 8, 1856, in Paris, the only son of Ernestine and Félix Tournachon, better known as Nadar. Considered one of the premier portraitists of his time, Félix Nadar was celebrated for his *Panthéon Nadar,* caricatures of mid-to late 19th century Parisian cultural players, and his informal photographic portraits of these artists, writers, and performers.

Nadar's collodion-on-glass portraits were renown for their intimacy and details. As opposed to the work of contemporaries such as Disdéri, Nadar used minimal props. In lieu of elaborate backdrops and costumes, his subjects were shown in everyday clothing, either in frontal or three-quarter angle views. Mirrors, combined with natural and artificial lights, created dramatic shadows and framed his subjects in light, an effect intended to mirror their personal aura. Amongst the most intimate of Nadar's works were his photographs of Paul. In a celebrated work of 1856, the infant Paul is shown being fed by his wet nurse. Two years later, Paul is shown resting against the body of Madame Lefranc in a work that recalls late Italian Renaissance and Baroque images of the Madonna and Child.

By 1862, Nadar lost interest in studio photography, yet was forced to accept commissions from politicians and prosperous bourgeoisie. As a result, his celebrated aesthetic was often compromised as he, like most studio photographers, focused on lucrative *carte-de-visites*.

Nadar increasingly relied on studio assistants, who sometimes worked without him, to create his photographs. Despite the commissions, Nadar closed his studio on the fashionable boulevard des Capucines in 1871. That same year, he established a smaller practice at 51 rue d'Anjou. Run by his wife, Ernestine, this studio catered to a more affluent clientele and prospered. Paul, who had been trained by his father, acted as the artistic director, while Nadar pursued other interests. Paul became manager in 1874 and led the Nadar Studio in a different direction. While Nadar photographed wealthy clients in order to fund other projects, Paul actively sought such commissions, even photographing theater troupes and producing the occasional nude postcard to make the studio profitable.

Paul changed the celebrated Nadar aesthetic in order to accommodate this new clientele. Paul and Ernestine embraced conventional studio photographic props that Nadar despised, such as artificial backdrops, contrived poses, and elaborate furniture to create a more decorative style. Although the photographs show more generic expressions and less personality than in his father's portraits of his friends, this fashionable aesthetic catered to the new style and allowed the studio to financially prosper.

Between 1880 and 1885, Paul ran the Nadar studio. Because of his aesthetic and production methods, critics have portrayed Paul as less concerned with craftmanship than his father. Paul worked with gelatin instead of collodion negatives to increase the number of negatives and did not use salted paper or albumen for printing as Nadar had done. Therefore, when he reworked his father's glass negatives, his prints lacked the delicacy and degrees of tonality of the originals. In addition, he often altered Nadar's negatives, minimizing the rich backgrounds to make more pictorialist, and hence more fashionable, images. Although not actively involved in the studio, Nadar disapproved of these changes and, after years of fighting, father and son were estranged around 1885.

This estrangement proved to be brief as in 1886 the Nadars worked together on the celebrated *Entretien de M. Nadar avec M. Chevreul, le jour de son centenaire (M. Nadar Interviews M. Chevreul on his Hundredth Birthday).* Intended to illustrate scientific and technological progress, the photographs anticipated the photographic series and photojournalism. Originally made for the newspaper *L'Illustration*, eight of the twenty-seven photographs had a delayed debut on September 5, 1886, in *Le Journal Illustré*. Termed the first photo-interview, it was to be a conversation between the noted chemist and color theorist Eugène Chevreul and Félix Nadar on the former's birthday recorded by Nadar on a photophone and photographed by Paul using a camera with a roll-film attachment, which due to technical problems had to later be rewritten by Nadar.

In 1886, Paul Nadar took control of the Nadar Studio and began photographing from a hot-air balloon as his father had earlier, even photographing the infamous fire at the at l'Opéra Comique in 1887. He exhibited these works at the Société française de la photographie and was caricatured in the press as "The Fearless Paul Nadar" for his courage and his photographic experimentation. In 1890, Paul embarked on a trip across Europe and Asia to Turkestan following the ancient silk route. Paul acted as an early photojournalist, documenting his travels and photographing sites as diverse as bazaars, mosques, and desert landscapes. During his voyage, he worked with experimental new equipment from Eastman Kodak that used flexible films, which proved more portable and instantaneous than the standard glass plates. In 1893, he became the French agent for George Eastman and Eastman Dry Plate & Film Company, known as Eastman Kodak, and opened the first Parisian Office of Photography, which sold photographic equipment, including hand cameras, designed for amateur photographers.

Paul presented his work to prominent photography associations, including la Société Française de la Photographie and la Société des Hautes Etudes Commerciales. In 1891, he founded the journal *Paris-Photographe*, which, despite publishing prominent pictorials, was in financial trouble by 1894. The same year, he married Marie Degrandi, an actress at the Opéra Comique. In 1895, Félix Nadar officially transferred legal ownership of the Nadar Studio to his son, which he ran until his death on September 1, 1939. The Nadar studio, run by Paul's daughter, Marthe closed a few years after Paul's death. In 1950, Paul's second wife, Anne Nadar, sold the photographic collection, archives, and documents from the Nadar studio to the French government. The Caisse Nationale des Monuments Historiques et des Sites acquired about 60,000 negatives while the Bibliothèque Nationale acquired all prints, archives, and documents made by and concerning Félix and Paul Nadar. Discovered amongst the 400,000 glass negatives acquired by the Ministry of Education were Paul's photographs of Marcel Proust and his circle of friends and family members. In 2001, Anne-Marie Bernard edited a critically acclaimed book, *The World of Proust, as seen by Paul Nadar,* which featured a selection of these images.

Jennifer Farrell

Biography

Paul Nadar was born on February 8, 1856, in Paris. He was the only son of Ernestine and Félix Tournachon, better known as Nadar. Paul Nadar was trained in photography by his father, the celebrated portraitist. First as artistic director and later as manager, he ran his father's

third and final studio at 51 rue d'Anjou. Under Paul, the new studio catered to a more affluent clientele and prospered. As a photographer, Paul made fashionable images of the bourgeois and aristocratic clientele. In 1890, he began shooting from a hot-air balloon as his father had earlier. After these works were exhibited, he was caricatured in the press as "The Fearless Paul Nadar" for his courage and his experimentation with photography. In 1890, Paul photographed sites in Europe and Asia along the ancient silk route. He worked with new equipment from Eastman Kodak and, in 1893, he became an agent for George Eastman in France. He inherited the Nadar Studio after his father's death in 1910. The studio survived only a few years after Paul's death on September 1, 1939.

NARCISO DA SILVA, JOAQUIM POSSIDÓNIO (1806–1896)

Joaquim Possidónio Narciso da Silva was one of the main 19th century Portuguese photographers. Particularly during the 1860s, he produced beautiful salt paper prints of Portuguese monuments, however he is best known as an architect and archeologist. His photography was, as a matter of fact instrumental to his research in architecture and archeology. Very young he went with the Portuguese Royal Family escaping from the Napoleonic invasions to Brazil. Latter, between 1821 and 1834, he studied and worked in France and Italy. He was a founding member of the Real Associação dos Arquitectos Civis e Arqueólogos Portugueses in 1863 and latter of the Museu Nacional de Arquelogia. Before that, in 1862–63 he published the illustrated magazine *Revista Pitoresca e Descritiva,* which, in several issues, presented 26 photographs as salted paper prints of some of the most important Portuguese monuments. As a photographer, as well as an architect and archeologist he promoted nationalism by means of knowledge of monuments and history. In 1875 he was a member of the commission charged of the reform of fine arts where he proposed the inclusion of photography in museums.

Nuno Pinheiro

NASMYTH, JAMES HALL (1809–1890) AND CARPENTER, JAMES (1840–1899)

James Nasmyth's place in the history of photography lies in the area of scientific illustration. He was a successful inventor who was able to retire in 1856 to pursue his interests as an amateur astronomer. Nasmyth had built his first telescope in 1827 and began to study the surface of the moon in 1846. He made a series of drawings recording his observations as photography was not yet able to record images under these conditions. These drawings received a medal when they were exhibited at the Great Exhibition in London in 1851. Nasmyth then constructed three dimensional models of the surface of the moon based on these drawings. These models were then photographed under conditions of bright sunlight to emphasis the contours of the terrain.

These photographs were of the special type used in the Woodburytype process. In the process of developing these special photographs, the lighter areas were rinsed away, leaving intaglio matrices. Lead was pressed into these matrices to form a relief and this relief was used to print the illustration in the book. The result was an image that more faithfully reproduced the continuous value gradations within the emulsion of a photographic print than the hatching technique of engravings. These Woodburytypes were published in a book titled *The Moon as a Planet, a World, and a Satellite* in 1874 in collaboration with James Carpenter, Nasmyth's friend and a professional astronomer associated with the Royal Observatory at Greenwich.

The creation of Woodburytypes was a cumbersome and time-consuming procedure. At the time, however, it was a practical medium for printing a photograph with a text. Tipping actual photographs into a text strained the limits of producing large amounts of positive prints from a single negative. The economic alternative of an engraving made from an original photograph allowed the intervention of the hand to subvert the objective value of photography as a mechanical imaging process which had been one of photography's most valued attributes from its earliest development.

The Woodburytypes maintained the integrity associated with mechanical imaging technology as objectivity was a central concern for science and scientific illustration. Thus the Woodburytype would have seemed to be the perfect medium for scientific illustration despite being cumbersome and expensive. It is ironic that Nasmyth's use of drawings and the construction of models, accepted practice in scientific research and publication, may be seen as subverting the very truth value of the photograph that made photography a valued tool for science. Nasmyth's models of the moon's surface reflected his desire to present "a rational explanation of the surface details of the moon which should be in accordance with the generally received theory of planetary

formation." Some of the models were even designed to simulate volcanic activity, including eruptions. Theories of planetary formation were based on contemporary knowledge of the earth's geology and Nasmyth himself had observed volcanic activity during his travels. Yet the models involved the use of the hand in their construction, defying the advantages believed to be an inherent quality of mechanical reproduction.

The value of scientific illustration is based on an implicit faith in the processes of observation, reason, and representation. Theories of planetary formation were dependent on the reliability of the knowledge of the geology of the earth. This reasoning by analogy was based on the belief that similar effects had similar causes. Nasmyth applied this conceptual algorithm to a comparison of a dried apple and the back of a human hand. His reasoning was simple: similarities between the skin of the apple and the skin on the back of a human hand could be the product of similar subcutaneous phenomena. The evidence was supplied by the juxtaposition of photographic reproductions.

Naysmyth's faith in the objectivity of his drawings and his models was consistent with the scientific practice of the time. It was also consistent with his use of drawings and models when developing a new idea for a machine. Naysmyth was a very successful inventor. He was constructing miniature steam engines at the age of 17 and was commissioned by the Scottish Society of the Arts to create a steam powered vehicle capable of carrying up to six people in 1827. Nasmyth started his own business in 1834 at the age of 26 in which he successfully built steam engines and machine tools and, in 1839, drew sketches for the design of a steam hammer which he eventually patented in 1842.

Nasmyth's sketches and drawings represent the first stage in the concrete realization of an idea. The working models he constructed represent the second stage and demonstrate that his ideas do indeed work. The third stage is the manufacturing of the full-scale machine. In a move that was prescient for the time, he recorded these sketches in photographs as early as 1839 as record of and as proof that he had worked out the idea. There are no records of photographs having been made of the models or full-scale machines as if they themselves were the concrete documentation for the idea. In the case of the photographs of Nasmyth's models of the moon's surfaces, complete with simulated volcanic activity, one might conclude that the models themselves were the demonstration and proof of his ideas. The photographs and resulting Woodburytype illustrations were a means of making his ideas available to a wider public.

Nasmyth credited his ability to develop his ideas through drawings to the art instruction he had received from his father, Alexander Nasmyth. We can also trace his interest in mechanical reproduction, illustration and model making to the same source. Alexander Nasmyth used a *camera obscura* in his art instruction and created models when redesigning estates. The owners of the estates he painted often asked him to redesign their estates to more closely resemble the imaginative landscape paintings. Alexander Nasmyth was also considered the founder of the Scottish school of landscape painting and was also known as an artist.

NASTYUKOV, MIKCHAIL PETROVICH (active 1860s–1880s)

Professional photographer

Mikchail Petrovich Nastyukov had his own studio in Moscow since 1862, and from 1869, he worked in the Nizshni Novgorod fair. His studio photo-portraits were always performed on a high technical and artistic level. Sometimes they were *cartes-de-visite*, and sometimes when rather large they were framed and served as a decoration. His studio was quite popular among the people of various social statuses and wealth. Nastyukov photographed painters, writers, actors, and others, and is proved by the considerable number of photographic portraits in existence. Unfortunately we know nothing about his private life, his friends or his environment. It is only known that in the 1860s he was under the patronage of His Highness Crown Prince Alexander (the future czar Alexander III). In 1869 Nastyukov created a group portrait depicting Prince Alexander with his wife and his retinue

The most outstanding of his works was the series of photographs of Volga towns. The series was in 1866–67 and then comprised an album under the title "Views of Volga from Tver' to Kazan'." The photographs glued upon passe-partouts were made by contact method from negatives sized 30–40 cm. It was one of the first important photographic series showing Volga's area.

Nastyukov was one of the first photographers to work outdoors on a large scale. This outdoor work was naturally hindered by considerable technical problems due to the fact that photographers of the time had only wet-collodion method at their disposal. The cumbersome camera, low sensitivity of photo-plate—all these limited the choice of scenes for photography. But the primary objective of any photographer was to break away from the concepts of painting forced upon the artistic value of photographs. For quite a long time photography had been viewed only as an auxiliary means for painting with the main function of recording reality.

Nastyukov made photographs of the monuments of architecture paying special attention to orthodox cathedrals—and they looked grand in his photographs. He was one of the first to start taking photographic chronicles of the Russian architectural monuments. This theme later attracted the attention of the Russian photographers. Nastyukov was in constant search of new images and objects, which is how he started making photographs of peasants from the neighbouring villages.

In the second half of the 19th century, the lives of peasants (with serfdom abolished only in 1861) was a burning issue, which found its reflection in the democratic art. The photographer combined architectural images with images of common people and their life. However technical problems prevented him from rendering life the way he wanted. So that his photographs would remain descriptive he built their composition through the use of the laws of painting.

In 1867, Nastyukov worked in Simbirsk, the town that attracted another outstanding photographer working in Russia, the Scots-born William Carrick, known in Russia as Vasiliy Andreevich Carrick.

In 1869, having accumulated enough experience in outdoor photography, Nastyukov accompanied the Great Prince Alexander Alexandrovich and his wife in their trip throughout Russia. This trip included a visit to the fair in Nizshni Novgorod and Nastyukov accompanied them as their photographer. For these photographs Nastyukov was awarded a bronze medal at All-Russia Polytechnic exhibition in Moscow in 1872.

Nastyukov, Mikchail Petrovich. The Church in Yaroslavl 1867.
Private Collection: Alexei Loginov.

Nastyukov also received the title of the photographer of His Highness Crown Prince Alexander (the future czar Alexander III).

In the 1870s, Nastyukov photographed the views of Moscow and its suburbs. In the village of Borodino, where in 1812 the great battle of the Russian troops against the army of Napoleon took place, the photographer captured images of the peasant life. In 1879, Nastyukov photographed the flood which took place in Moscow in April. The album of these photographs was given to the Moscow general-governor V. Dolgorukov. At the moment the album is in the collection of the State Russian Library.

In 1883, he made a series of photographs under the following title "Groups of foremen from all over Russia taking part in the celebration of crowning of the Royal Highness in May of 1883." This album is comprised of 512 portraits. It was purchased into the collection of the Emperor's Public library. Photographic ideas introduced by Nastyukov were taken up and developed by some other prominent Russian photographers, such as Andrey Karelin and Maksim Dmitriev.

Since 1865, Karelin worked in Nastyukov's studio. By that time Karelin was already fond of photography and had retouching experience. In Nastyukov's studio he learned the technology of the photographic processes during the time when Nastyukov was busy making photographs of Volga views. Karelin's works on Volga comprised his famous "Nizshni Novgorod" album. This experience would provide Karelin the knowledge to open his own studio in future.

In 1873 Maksim Dmitriev, who was then fifteen years old, became Nastyukov's apprentice. In Russia the adolescents were often taken to various workshops to study crafts. There they usually did hard work. In Nastyukov's studio, Dmitriev became exceptional familiar with the technology of the photographic processes. Once he became a well-known photographer, he developed his teacher's ideas in the album called "Volga series."

Nastyukov was a prominent figure in Russian photography at its start, but there are unfortunately very few reference sources on his life and work, most of them nowadays are lost. In the photographic circles of his time Nastyukow was considered an important photographer. Thus his failures were always noticed. In the beginning of the 1880s there came a new generation of Russian photographers. It was probably difficult for Nastyukov to compete with them. The last mentioning of his studio work to be found in literature is dated from the year 1883.

He was one of the pioneers of the full-scale outdoor photography. It is also worth mentioning that in his work he used and developed purely photographic expressive means.

Alexei Loginov

Biography

Mikchail Petrovich Nastyukov had a studio in Moscow since 1862. He worked at the Nizshni Novgorod fair since 1869. In 1866—67s he made an album of photographs called "Views of Volga from Tver' to Kazan'." Nastyukov worked in Simbirsk and Nizshni Novgorod, and acted as an accompanying photographer to the Great Prince Alexander Alexandrovich and his wife during their trip throughout Russia. Nastyukov received the title of the photographer of His Highness Crown Prince Alexander (the future czar Alexander III). Nastyukov was one of the first in Russia to successfully complete a full-scale outdoor photo-session employing purely photographic expressive means.

NATTERER, JOSEPH (1819–1862) AND JOHANN (1821–1900)

The Natterer brothers belonged to a dynasty of Museums curators, which fostered their scientific activity, particularly in the Dienst der Naturalien-Kabinette des kaiserlichen Hofes, now the Naturhistorisches Museum in Vienna. Their grandfather had worked there, and their father Josef Natterer as well as his brother Johann Natterer (1787–1843), who traveled to Brazil.

Joseph and Johann Natterer began their career at the Institut as Assistenzkuratoren. Joseph and Johan were involved with photography for a short time, but during that time, they created a new photochemical sensitization process for the daguerreotype (iodine bromine chlorine mixture) around 1841. Their accelerated process, and a camera using the fast lens computed by Josef Petzval in 1840, resulted some of the earliest known "instantaneous" pictures (street scene with figures) with exposures of possibly less than one second. This innovation took place in the Fürstenhofrunde in Vienna, a club established by scientists, technicians, the medical profession, artists, and pioneers of photography. This club enabled the progressive orientation of photographic culture in Austria during the nineteenth century, which was extraordinarily important.

Maren Gröning

Biography

Joseph Natterer was born on 23 May 1819 in Vienna.

He did not receive special academic training. He began as Kustos Adjunkt" (Assistenz curator) at the Dienst der Naturalien-Kabinette des kaiserlichen Hofes (today the museum of Natural History in Vienna). From 1855 to 1858, he traveled Nubien (today the majority area of the Sudan) and Central Africa, where he acquired, among other things, animals for the imperial Menagerie in the park of Schoenbrunn, Vienna. He returned to Africa as an Austrian consulate representative to Khartum. He died on December 17, 1862 of malaria. Johann Natterer was born on October 13, 1821, in Vienna. He received his medical degree, but worked like his brother Joseph as an assistent curator) at the Dienst der Naturalien-Kabinette des kaiserlichen Hofes. Apart from his main profession as a physician (until 1874) and politician in the Viennese local council (1861 to 1879), he also worked as an inventor. In addition to the advancement of the Daguerreotype to instananeous photography, with the help of his brother, he created the construction of a compressor pump involving the liquefaction of carbonic acid, which set a new standard for the industry. He died on December 25, 1900, in Vienna.

NATURALISTIC PHOTOGRAPHY

Naturalistic Photography was the term introduced by Peter Henry Emerson to describe both the aspiration for and practice of photography as a distinct form of art. Initially articulated in "Photography as a Pictorial Art," first in a lecture offered at the Camera Club of London on March 11, 1886, and later printed in *The Amateur Photographer* (March 19, 1886), it received full treatment in the manual, *Naturalistic Photography for Students of Art* (1889). Emerson offered a theory of art grounded in the principle that the finest art was that which was true to nature, and, more specifically, true to nature as perceived by the human eye. "Wherever the artist has been true to nature, art has been good. Whenever the artist has neglected nature and followed his imagination, there has resulted bad art" (Emerson, 1886). Further, the element that distinguished photography from other visual systems was its inherent truthfulness. From this core principle, he advised that for photography to be an art form it must be independent, not imitative, of other artistic forms, such as painting. "Truth to Nature" was achieved under his system of "Naturalistic Photography" when the photographer turned to nature for his subjects, rather than created tableaux that mimicked the subjects and compositional strategies of painting But more than the stipulation to photograph the subjects found in nature, Emerson decreed that in order for a photograph to be "truthful" it must faithfully incorporate the way in which the human eye apprehended the scene. In a long prologue, Emerson had argued for the congruence of art and science; one did not contradict the other and art must incorporate the knowledge derived from science. This had special relevance for photography and a theory of human vision. As a medical student, Emerson had followed the developments in achieving a scientific model of human vision and he was particularly persuaded by the physiologic mechanism of vision proposed by German physicist Hermann von Helmholtz in *Handbook of Physiologic Optics* (1867). Helmholtz described a visual mechanism in which the human eye registers in sharp detail only the limited portion of the visual field that it is directly focused on and attentive to, and that elements that are not within the area of focal interest are unsharp to a greater or lesser degree depending on their position relatively to the central area of focus. For Emerson, Helmholtz's theory of selective vision explained the lack of artistry he found in photographs that were disconcertingly sharply focused across the entire image. They did not represent truthfully the world as seen by the human visual apparatus.

Emerson translated Helmholtz's model into the practice he described as "differential focus," the intervention by the photographer, through choice of lens, to limit sharpness to a single point in the image while suppressing details in surrounding areas. The resultant photograph more closely accorded with the way that nature directly perceived would register in the eye.

> Nothing in nature has a hard outline, but everything is seen against something else, and its outlines fade gently into that something else, often so subtlely that you cannot quite distinguish where one ends and the other begins. In this mingled decision and indecision, this lost and found, lies all the charm and mystery of nature. (Emerson 1889, 150)

Emerson defined the equipment and procedures for achieving naturalistic photographs: a whole plate size view camera, a tripod, and most importantly, longer focal length lenses with the correct "drawing power" to render the scene in "natural" perspective with detail correctly distributed throughout the scene in accord with

natural human vision. He declared hand cameras a tool for amateurs and condemned enlarging, retouching, and, most vehemently, combination printing. He recommended printing in platinum—the Platinotype Company had introduced commercially prepared platinum papers in 1880—or in photogravure—an ink-based printing process. Both had the potential to produce a very long scale of contrast and soft tones with a delicacy of effect that was particularly suited to natural vision and differential focus.

Emerson positioned his theory of a photographic art based in science and true to the inherent qualities of both the photographic process and nature in opposition to the practice of art photography proposed by Henry Peach Robinson in *Pictorial Effect in Photography* (1869). Robinson stated that photography in order to attain the status of an art must combine both the real and the ideal, and that in the pursuit of this standard the photographer must compose as did painters. In practice, this meant planning and organizing the picture through sketches and studies, and translating the pictorial ideas into photographs through the use of subjects posed and lighted to emulate paintings. Frequently the results were large, complex prints built up from a number of negatives. Robinson's vision of photographic art was highly constructed and artificial. Emerson articulated his theory—in lectures, articles, and his book, and in a series of combative letters to photographic journals—as diametrically opposed to a bankrupt and ill-considered practice that had no artistic merit. Although Emerson's position on photographic art is generally presented as oppositional to Robinson's, it should be recognized as a continuation of contemporary discourse on naturalism in art. Ideas of naturalism in painting had been articulated by Francis Bates, "The Naturalistic School of Painting," in 1886 and by Thomas Goodall with whom Emerson collaborated on *Life and Landscape on the Norfolk Broads*.

Illustrating his theory of naturalistic photography, Emerson produced a number of photographically illustrated books and folios in platinum and photogravure: *Life and Landscape on the Norfolk Broads* (1886); *Pictures from Life in Field and Fen* (1887); *Idyls of the Norfolk Broads* (1888); *Pictures of East Anglian Life* (1888); *Wild Life on a Tidal Water* (1890); *On English Lagoons* (1893); and *Marsh Leaves* (1895). In his work, he returned again and again to the watery fens of eastern England, recording scenes of ancient rural rhythms. Emerson's use of differential focus in photographs printed in soft Platinotype or as photogravures captured a very personal visual experience of a natural order uniting land and people. In point of fact the fens were changing under the pressures of drainage and land recovery schemes and the onslaught of modern tourism. The self-professed proponent of an equivalently scientific and artistic view of nature in photography created a romantic and nostalgic record of a vanishing way of life.

In 1891 Emerson reversed himself and acknowledged that one could not attain in photography the degree of expressive control necessary for it to be defined as an art. In 1895 he published a pamphlet the title of which, set on a black bordered page, proclaimed *The Death of Naturalistic Photography: A Renunciation*. His reading of recent scientific studies on the chemical processes in photographic development had convinced Emerson that the photographer could not control the tonal values of a print through the development process to the extent that he had assumed. He concluded that the degree of chemical determinism meant that photography could not be an art.

> The limitations of photography are so great that, though the results may and sometimes do give a certain aesthetic pleasure, the medium must always rank the lowest of all arts.…Control of the picture is possible to a *slight* degree, by varied focusing, by varying the exposure (but this is working in the dark), by development, I doubt (I agree with Hurter and Driffield, after three-and-a-half months careful study of the subject), and lastly by a certain choice in printing methods. But the all vital powers of selection and rejection are *fatally* limited, bound in and fixed by narrow barriers. (Emerson 1895, n.p)

Despite his rejection of the scientific basis of photography as an art, he continued to make and publish photographs. *On English Lagoons* and *Marsh Leaves* were both released after his repudiation of photography as an art. In 1898 he published a third and revised edition of *Naturalistic Photography* which was substantially the same as earlier editions—the same description of the technique for and justification of differential focus, the same stipulations regarding equipment, the same prohibition on enlarging and darkroom manipulation, the same guidelines for photographic printing. The most significant change was in the final chapter now titled, "Photography—Not an Art."

Despite Emerson's rejection of his position, Naturalistic Photography had a lasting effect. He had articulated a position for photography as an art form based on the inherent attributes of photography and its intimate connection with the natural world. If he had disavowed his insistence on the scientific basis of his theory of photographic practice, he had not disavowed his pugnacious criticism of previous practitioners of art photography. His stipulation to adhere to photographic principles and to use the camera in the natural world influenced succeeding generations. His luminous prints stood as exemplars of what could be achieved with the direct depiction of visual experience.

NAYA, CARLO (1816–1882)

Italian photographer and studio owner

Carlo Naya was born at Tronzano di Vercelli in 1816. He studied law at the University of Pisa. Thanks to an inheritance, he travelled extensively, visiting the most important cities in Europe, Asia and Northern Africa. In 1857 he settled in Venice where he opened a studio as a photographer. He became very well—known for his views of the city's monuments and works of art. His photographs were sold by Carlo Ponti, a photographer and seller of engravings and optical instruments. Naya collaborated with other Venetian photographers to produce an album of views of Venice in 1866, when the Venetian Republic was annexed to Italy. He then opened a studio at Procuratie Nuove which was visited by artists, scholars and tourists. He took photographs of Giotto's frescoes in the Scrovegni Chapel in Padua, in 1864—1865 and in 1867, to document the restoration works. He won many awards: the Great Medal at the Universal Exhibition of London (1862); gold medals at the Exhibitions of Groningen (1869), Trieste and Dublin (1872). He died in Venice in 1882. His wife, Ida Lessiak, was left in charge of the studio. She died in 1893 and her second husband, Antonio Dal Zotto, took over the atelier. On his death, in 1918, the studio was closed and the main part of the photographic archive was bought by the publisher Osvaldo Böhm.

SILVIA PAOLI

NÈGRE, CHARLES (1820–1880)

French photographer and painter

A successful academic painter, Charles Nègre turned to photography in the 1840s and elaborated an aesthetic of intimate, highly subjective compositions that suggested moments seized from everyday life. He produced some of the first photographic genre studies and street scenes and sought to imbue the photograph with an emotional immediacy that contradicted its reputation as a dispassionate product of science. "Photography is not a remote and barren art," he explained. "[It] does not destroy the personal feelings of the artist" (Rouillé, 133).

Nègre was born in Grasse, France on 9 May 1820, the first of four children to the owners of a confectionery business. Rather than join the family enterprise, Nègre embarked on an artistic career, taking drawing lessons

from Sébastien Pezetti of Aix-en-Provence while in high school. His father encouraged Nègre's ambitions, helping send him to Paris in 1839 to apprentice in the studio of Paul Delaroche. Delaroche was one of France's most distinguished painters and an early advocate of photography, counting among his apprentices the the budding photographers Gustave Le Gray, Roger Fenton, and Henri Le Secq.

In 1841 Nègre entered the Ecole de Beaux-Arts and in 1843 he briefly worked in the studio of Michel-Martin Drolling before moving to the studio of Jean-Auguste-Dominique Ingres, where he remained for several years. Beginning in 1843, he exhibited historical and mythological paintings at the annual Salon in Paris, and continued to exhibit there on and off until 1864**,** well after he had become better known as a photographer.

Nègre first attempted photography by making daguerreotypes in 1844 as an aid to his painting, but by 1848 he had moved to the calotype process for the greater aesthetic flexibility offered by its paper negative. Nègre would modify the negative with ink or pencil as well as adjust printing methods to meet his artistic intentions. While his first photographs were primarily model studies and studio portraits, he soon broadened his scope to produce action scenes of working people taken from the streets of Paris. From chimney sweeps to itinerant musicians or vendors at the market, Nègre sought formally challenging but unified images of harmonious effect, reminiscent of the Flemish and Dutch Masters he much admired.

These genre scenes had an immediate impact on the emerging photographic community. "The Little Rag-Picker" (1851), an image of an exhausted boy resting beside his heavy basket, was deemed "no longer a photograph" but rather "a thoughtful and intentional composition" by contemporary critic Francis Wey. Although those terms do not seem mutually exclusive, the comment underscores the early perception of the photograph as merely a mechanical exercise inconducive to producing pictorial harmony.

Nègre devised a series of lenses to allow for the very short exposure times required to capture these scenes, and while the bustling participants in his market scenes blurred slightly, each is readily distinguishable at his or her task. It was his "Chimney-Sweeps Walking" (1852), however, that attracted the most praise for delivering a sense of arrested movement. As Nègre carefully posed his three subjects in simulated stride it was not an image of motion as such, but of an effect that testified to the artist's technical and compositional capabilities. While he occasionally incorporated elements from these photographs in his Salon paintings, he also mounted and signed the prints as finished works in their own right.

By the early 1850s, Nègre was searching for ways to live as a professional at his photography without resorting to the common, stultifying choice of studio portraiture. Encouraged by the government's 1851 Mission Héliographique [Heliographic Mission], which had employed his friend Le Secq and others to photograph historic monuments, Nègre spent the summer of 1852 documenting the landmarks of his native Midi region. Although he had hoped to publish a comprehensive album of these photographs, he managed only two installments in 1854 before the project ran aground. A project to photograph all of Paris' landmarks, which occupied him for three to four years in the mid-1850s, met a similar fate. However, one image from that series, popularly known as "Le Stryge" [The Vampire] (c.1853), was a success upon exhibition and has become an icon of 19th-century photography. A striking hybrid of Romanticism and modernity, it depicts Le Secq haughtily posed in his top hat among the grotesque sculptures decorating the parapet of the cathedral of Notre Dame, from which he surveys the urban sprawl like a cosmopolitan demigod.

Nègre's two excursions to Chartres—in 1851 and around 1854—illustrate the evolution of his landscape and architectural work. During his first visit with Le Secq, Nègre produced idyllic, pastoral village scenes embodying the picturesque style he had learned while an art student. The photographs from his second visit, however, are much larger and concentrate on the city's famous cathedral, emphasizing symmetry and monumentality. Influenced by the photography of Le Secq and Edouard Baldus, Nègre approached the building like a sculptural text to be read in parts, privileging clear information over sentiment and mood. Despite his stylistic adjustments, Nègre struggled to win government commissions and, perhaps out of desperation, wildly proposed making a photographic catalog of the history of man, a suggestion that earned him only a modest contract photographing selected works in the Louvre.

It was in 1858, on one of his final projects, that Nègre reconciled his talent for capturing small genre scenes with the more grandiose demands of public photography projects. Asked to document a new imperial asylum erected in Vincennes to house disabled workers, Nègre favored large plates to depict the complex's exterior, but reverted to smaller plates (requiring shorter exposure times) to capture the interior scenes of employees at their tasks. These contemplative compositions of cooks, pharmacists and nurses present labor as simple yet ennobling and reflect Nègre's belief that a combination of "observation, sentiment and reason reproduces effects that make us dream, and simple motifs that move us." In "Vincennes Imperial Asylum: The Linen Room" (c.1858), sunlight falling gracefully on a nun folding sheets turns her endeavor into a gesture of quiet splendor worthy of Vermeer.

[Heliographic Society] and the Société française de la photographie [French Photography Society], from his first daguerreotype experiments Nègre was deeply involved in promoting photography and contributing to its technical improvement. From 1854 to 1867, in an attempt to capture the generous De Luynes prize for the advancement of photogravure, he perfected a process that used gilding via galvinoplasty to increase tonal ranges in prints. Though he lost the competition, he was invited to present his results—first patented in 1856—at industrial exhibitions throughout Europe.

His health failing, Nègre returned to his native Midi in 1863, finding work as a high school drawing instructor and opening a commercial studio in Nice. He continued to promote his photogravure process through writings, lectures and exhibitions, but was never able to parlay his efforts into commercial success beyond a small series of photogravures of Chartres cathedral assembled for the government in 1858 and a contract to produce the plates for the Duc de Luynes' book, *Voyage à la Mer Morte* [Voyage to the Dead Sea] in 1871.

Nègre's photographs from his Nice years were limited to standard carte-de-visite portraits and Riviera views intended for the tourist trade. When he died in Grasse on 16 January 1880, his career had fallen into obscurity, his photogravure process having long been forgotten and the emerging dry-plate process making motion photography a banal affair available to all with a camera. It was only with the exhibition of selections from his personal archives in the 1960s and 1970s that his reputation was reestablished.

STEPHEN MONTIERO

Biography

Charles Nègre was born on 9 May 1820 in Grasse, France. He studied at the Ecole des Beaux-Arts in Paris, apprenticing in the studios of Delaroche, Drolling and Ingres. He exhibited paintings at the annual Salon in Paris on several occasions between 1843 and 1864 and was appointed drawing instructor at the Ecole Supérieure du Commerce [Higher School of Business] in Paris in 1852. He took up photography in 1844 as an aid to his painting. Particularly known for his genre studies, he also made extensive photographic surveys of the Midi region in 1852 and of Paris landmarks during the mid-1850s. In 1858 he undertook a government commission to photograph selections from the Louvre collection, followed by a commission to photograph the Imperial Asylum in Vincennes in 1859. He exhibited his photographic work in over two dozen exhibitions throughout Europe, including the exhibition of the International Society of Industry in Amsterdam in 1855, the Universal Exhibition in Paris in 1855, 1863, 1867, 1868 and 1878, the French Photography Society exhibition in 1855, 1859, 1861 and 1864, the International Exhibition of Industrial Arts in Brussels in 1857 and 1861 and the Universal Exhibition in London in 1862. He patented an improved photogravure process in 1856. In 1863 he moved to Nice, where he opened a commercial studio and taught drawing at the Lycée Imperial [Imperial High School] until 1878. He died in Grasse, France, on 16 January 1880.

NEGRETTI AND ZAMBRA (1850–1899)

Optical instrument firm

Negretti & Zambra was established in 1850. Of the two partners, Henry Negretti and Joseph Warren Zambra, the former is by far the better documented and became known as "one of the pioneers" of British photography through his improvements to apparatuses and through his marketing of high-quality stereoscopic views.

Enrico Angelo Negretti was born on 13 November 1818 in Como, Italy. Leaving home at an early age, he had arrived in England by the time he was twelve years old and became apprenticed to Francis Augustus Pizzala at nineteen. By 1839 he set up his own establishment as a glass blower; after a brief partnership with the widow of another glass blower and barometer maker, by 1845 he was again in business for himself, soon expanding to include a range of philosophical instruments and running two branches, at 19 Leather Lane and 9 Hatton Garden. On 1 July 1845 he married Mary Peet, who subsequently worked in the firm; the couple had five children, of whom three survived their infancy.

On 24 April 1850, Negretti entered into partnership with Joseph Warren Zambra, born at Saffron Waldon in 1822 to an English father and an Italian mother. Negretti & Zambra seized the opportunity to promote their wares at the Great Exhibition of 1851, where they won a prize medal for glass instruments shown in Class 10, "Philosophical instruments and their dependent processes," the same category that featured several photographic apparatuses, such as an early stereoscope constructed by Louis Jules Duboscq. Following their success at the Crystal Palace, Negretti & Zambra were named meteorological instrument makers to the Queen, but they soon became better known for their stock of equipment relating to the daguerreotype, calotype, and collodion processes—cameras, glass plates, head rests, tripods, dark tents, frames, and chemicals. When the Crystal Palace re-opened in Sydenham in 1854, Negretti & Zambra were appointed official photographers and a year later sent a team of operators, including Philip Henry Delamotte, to produce a number of instantly popular images of Queen Victoria's reception of Napoleon III and the Empress Eugénie.

As business grew, the company moved to larger and more numerous facilities: 59 Cornhill (1860–72), 1 Hatton Gardens (1860–69), 107 Holborn Hill (1860–61), 122 Regent Street (1862–76), 153 Fleet Street (1865–73), Holborn Circus (1870–76), Charterhouse Street (1870–76), 45 Cornhill (1873–76), Crystal Palace, Sydenham (1883–99). The last-named establishment

was among London's first portrait studios to feature electric lighting.

Negretti & Zambra became best known as publishers of stereoscopic views. By the 1860s their catalogue included interiors of the Crystal Palace; genre scenes; views of Europe, America, and India; and Claude-Marie Ferrier's instantaneous transparencies on glass. The landmark series depicting the Near and Far East were eagerly anticipated and exceptionally well reviewed. The first of these, *Stereoscopic Views in the Holy Land, Egypt, Nubia, &c.*, with negatives by Francis Frith, appeared in 1858; followed by *Stereoscopic Views in China* in 1859 and *Scenes and Scenery in Java* in 1861, photographed by P. Rossier and Walter Bentley Woodbury, respectively. Contrary to contemporary reports, Negretti & Zambra did not typically commission and finance a photographer to undertake an expedition, but would purchase the negatives and assume all costs of production and distribution. These could be considerable, as in the case of the views of Japan, which featured high-quality mounting and packaging in a Japanese style, as well as special stereoscopes made to the firm's order in Japan and bearing Japanese-style decorations. Sales were very brisk, although undercut by poor-quality pirated versions.

Negretti & Zambra were responsible for innovations in several other areas of photography. In 1855 they sold packets of albumen glass plates guaranteed for one month in the attempt to popularize this process (though ultimately albumen-on-glass did not compete with collodion wet plates); in 1858 they marketed an advanced oxy-hydrogen (or limelight) magic lantern capable of magnifying a projected image to 40 feet in diameter; and in 1868 they sold an early bellows-style pocket camera designed by C.D. Smith. The firm were also pioneers in the field of photographically illustrated books and the reproduction of works of art: they produced the prints, reduced from 3-foot-square negatives, were tipped into Richard Henry Smith's *Expositions of the Cartoons of Raphael* (London: J. Nisbet, 1860) and *Expositions of Great Pictures* (London: J. Nisbet, 1863). Negretti & Zambra won a prize at the International Exhibition of 1862 for the series of 100 stereographs Frith made during a second trip to the Holy Land, published as *Egypt, Nubia, and Ethiophia* (1862), with a text by Joseph Bonomi and Samuel Sharpe, and sold with a folding stereoscope for 3 guineas. A photographic venture of Negretti's that seems not to have a commercial motivation was his flight in a balloon to take aerial photographs, accomplished on 28 May 1863, five years after Nadar's famous flight ascent in France.

A charismatic and energetic man, Negretti enjoyed a public profile, especially among the Italian community. He hosted Garibaldi when he visited London in 1854 and ten years later served as chief of the reception committee that greeted the now-famous Italian patriot. In 1864 Negretti intervened in a high-profile murder investigation, saving the innocent Serafino Pelissoni from the gallows by proving that Pelissoni's cousin Gregorio Mogni was in fact guilty of the crime. For this he received a knighthood from King Victor Emmanuel. In his last years Negretti spent time in Como, but he died at his Cricklewood home on 29 September 1879. Zambra survived him by eighteen years, dying at his home in Hampstead on 23 December 1897.

Negretti & Zambra's success was such that in 1861 the *Art Journal* credited them with completing "what we might entitle a stereographic *cordon* in and about London." But because the firm did not specialize in subsequent decades, by 1879 it as not, as the *British Journal of Photography* noted, quite as well known as it had been. The last commercial branch closed in 1899.

NEKHOROSHEV, N. (active 1870S)

N. Nekhoroshev worked in Tashkent. He was the author of *The Turkistan Album* published in 1871–72 in six copies and divided into three parts: *The Ethnographic Album*, *The Crafts Album*, and *The Historical Album*. One of these copies made its way to the Emperor Alexander II.

The Ethnographic Album consisted of two volumes and included the following types of photographs: national types of the Turkistan Territory, views of towns and villages, images of clothing, utensils, and musical instruments.

The Crafts Album included photographs of local industries.

The Historical Album included portraits of the Russian military men photographed in action during the military expedition to Middle Asia and also included landscapes and views of the Turkistan Territory from the numerous fortresses.

The Turkistan Album was a main and monumental photographic work in Russia during those times. No other Russian territory was so systematically and completely photographed as the Turkistan Territory was because of Nekhoroshev's photographs. The greatest value of the album was the fact that the life of the territory's nations was photographed from nature. The leading Russian art critic V. Stasov expressed his high praise and opinion of the album. He found the photographs therein valuable, and not just to the sphere of documentation and ethnography, but to Russian culture as well. Stasov mentioned that "each photograph is a really folk image…truly and picturesquely showing the Turkistan customs and life."

ALEXEI LOGINOV

NETHERLANDS

The invention of photography was announced in The Netherlands as soon as in other countries; newspapers and magazines reported on it in 1839, especially after the first public demonstrations of the process in Paris. The first Dutchman to take up a camera was the Amsterdam painter and dealer in artists' materials Christiaan Julius Lodewijk Portman (1799–1868), who exhibited three daguerreotypes (maybe a few more) at an art exhibition held in October 1839 in The Hague. Some of these were made in Paris—where he is supposed to have acquired equipment for making daguerreotypes—some in Amsterdam and The Hague. Portman's daguerreotypes are unknown nowadays and it is uncertain whether he took up photography as a way of earning money or as an interesting experiment. It was probably he who translated into Dutch one of Daguerre's manuals; it was published in a magazine, not separately. After the first few practitioners had come and gone and many an article had been published in newspapers and magazines in 1839, photography seemed to slip out of public notice for about two years. In 1842 a number of itinerant photographers took up the medium. Well into the 1850s most photographers travelled from one city to the other, often staying only a few days. Setting up a temporary studio in a hotel, an inn or at a private house, they sometimes showed specimens of their work in the shopwindows of local art dealers. Judging by their names, most of these itinerant photographers seem to have been French (or Belgian). However, it was recently discovered that the best known of these, Edouard François, who in his newspaper advertisements implied that he was Parisian, was actually a young Dutchman, Eduard de Prouw. He took on a French name to make a better impression onto his clientele: all things French had a good reputation in those days. Moreover, the pseudonym suggested he had been trained in one of the main centres of photography. Instead of returning each winter to Paris, as his newspaper announcements suggest, he lived in the Dutch capital all his life. Due to the fact that only in the other seasons was there sufficient light to make photographs, he was only active as a photographer part of the year, practising another (unidentified) job in winter. Those who really came from abroad sometimes visited The Netherlands as part of a larger journey from France and/or Belgium to the north west of Germany. For instance, Louis Lumière, who was the second person known to have been working as a daguerreotypist in The Netherlands—he demonstrated the process in the Hague in November 1839—was also active in Ghent and Antwerp (October–November 1839) and in Bremen (January 1840). He is believed to have been a Parisian merchant, but his name is not to be found in the literature of early French photography. The same applies to the others who visited The Netherlands: A. Derville (1842), F. la Moile (1848–1850, 1852–1853), and Louis Schweig (1846, 1853). Besides foreigners, Dutch photographers also travelled the country. Most of these earliest photographers are known to us mainly through advertisements and articles in the press, rather than through their works, which have either not survived or are unidentified today.

The earliest photographer from whom a significant body has survived is the Amsterdam amateur Eduard Isaac Asser (1809–1894), a lawyer by profession. Some fifteen daguerreotypes and four albums with about 200 prints were kept in the family until recently, when the whole collection was transferred to the Rijksmuseum in Amsterdam. Asser often directed his camera towards his family and friends and also photographed quite a few still-lifes and cityscapes. Only a few of Asser's photographs are dated, but he seems to have made most of them in the first half of the 1850s. The photographs in the four albums especially introduce us into the world of a well-to-do Amsterdam family. Unfortunately, Asser did not caption the prints, nor did he leave any written account of his working methods or aesthetic considerations. Some of his portraits have a charm and liveliness that is lacking in most portraits made by professional photographers. As far as we know, Louis Wegner (1816–1864) was the only professional photographer who did portraits in a "grand manner" in the 1850s. A series of four rather large portraits he made of the painter Nicolaas Pieneman is noteworthy.

From the late 1850s onwards, most professional photographers set up a permanent studio instead of

travelling around. This must be due to a growing number of clients, especially after the introduction of the carte-de-visite around 1860. One of the very first to realise the commercial viability of the carte-de-visite was Maurits Verveer (1817–1903), who established himself in The Hague in 1857. From 1861 he launched a rather large series of portraits of "Tijdgenooten in Kunsten en Wetenschappen" (contemporaries in the arts and sciences). Amongst them were writers, painters, university professors, and clergymen. A contemporary comment on Verveer's portraits suggests that—in general—clergymen and low-necked danseuses sold best. The habit and fashion to exchange carte-de-visite portraits is demonstrated by the diary of the Danish writer Hans Christian Andersen, who, during a stay in The Netherlands in 1866, gave away many copies of his portrait and received a similar number in return from people he met. As in other countries, it was a hobby to collect such portraits and to put them in an album specially designed for that purpose. Very often, such an album would begin with royal persons, followed first by other famous people and then by acquaintances of the one who compiled the album.

Professional photographers depended almost completely on the making and selling of portraits, both of well-known persons and of individuals who wanted a (half) dozen of their portraits to circulate among their friends and relatives. All other subjects—topographical views, art reproductions, the construction or demolition of buildings—were comparatively marginal. Pieter Oosterhuis (1816–1885) was one of the very few who closed down his portrait studio—he did so in 1869—to concentrate upon photographing the construction of railways, canals, breakwaters, bridges, sluices and other public works. In the second half of the 1850s he had already started making a great many stereoscopic views in Amsterdam and other towns. The latter survive in rather large quantities, so they must have sold well. Commissions for photographs of public works probably paid handsomely, otherwise Oosterhuis would probably not have taken the decision to close down his studio. He seems to have been the only photographer whose commissions were located throughout the country, whereas in most cases a commission was awarded to a local photographer.

Most of his colleagues, however, stuck to portraiture. In Amsterdam their number rose from six in 1851 to about sixty by 1899. The Hague and Rotterdam followed: in these cities about fifty and about fourty photographers respectively were active in 1899. Judging by the occupational censuses that were held three times in the 19th century, most studios, especially in the smaller towns, were rather small: in 1889 and 1899 the average photographer had only one assistant. The actual number of people working in a photographic studio may have been a little higher, as it is likely that in many cases the photographer's wife and/or children worked there, too, without being counted in the census. Contrary to what is regularly asserted in the literature of Dutch photography, the carte-de-visite was not within everyone's reach: many people did not earn enough to be able to afford the relative luxury of having themselves photographed or collecting pictures of famous people. A set of twelve cartes-de-visite usually cost about four or five Dutch guilders in 1865—c. 30 to 35 Euro in today's money. That was simply too much for the lower classes.

In the first two decades, photographers often took on other jobs, in order to earn a living. Like in any profession, some became quite prosperous, while others never escaped poverty. Research into assessment-lists that have survived suggests that since the 1860s most photographers managed to be independant from other jobs and earned a decent living. A popular assumption is that many photographers originally were second-rate painters who changed their profession to earn more money. In fact, only approximately one-third of the professional photographers had a background in the arts (painting and engraving, especially), while a similar number came from commerce and handicraft. Those who had started as artists did not always completely give up their original profession, but sometimes practised the two at the same time. (It is the same with printing firms, which continued to produce engraving or lithography, but took up photographic printing as an extension of their activities.) Although some photographers reached prosperity, only some of them formed part of the cultural or social elite. Societies or clubs counted few photographers among their members, with the exception of artists' societies, of which many photographers were still members even if they did give up their former artistic occupation. Photographers are seldom mentioned in letters, autobiographies and other material that might otherwise have given some information on what kind of people they were and how they were looked upon. The social standing of photography was not very high, and, assuming that in the 19th century most people still married within their own class, the professions of their fathers-in-law may serve as an indication as to which kind of occupations photography was mostly associated with. Most brides were the daughters of working men, craftsmen, and tradesmen; they nearly all had a lower or middle class background. Apparently these were the classes in which photographers belonged.

Throughout the 19th century there was no other way to learn photography than to be trained by an accomplished photographer. Until 1942 photography was a profession that could be practised without a license, i.e. the obligation of having finished some official education. Although there were occupations easier to enter

or to master (requiring less financial investments and technical-chemical skills), there may have been some charlatans in photography, many of whom were active at fairs or still wandering from one small town or village to another. Several photographers complained about these less appreciated "colleagues." (Sometimes a photographer would accuse a rival of being a quack, evidently one of the worst insults one could think of.) It is not unlikely, however, that these complaints were mainly prompted by the wish of established photographers to be accepted as full-fledged citizens or even artists. As it has already been pointed out, the photographer's social status still left much to be desired.

On the one hand, feeling superior to people who made their money on fairs or by roaming around, photographers must have felt much less secure about their relationship with the arts. They so often presented themselves as artists—especially by calling themselves "peintres-photographes" and by surrounding their names by images of putti, palettes, and other symbols of the arts on the back of their photographs—and that strongly suggests a wish to be equalled with traditional artists. The latter will not always have appreciated these efforts to claim or reach the status artists held. Photography was not considered an art. On the contrary, it was judged a technical invention that required certain skills but no artistic mastery. The camera did most of the work, not the photographer. Painters or engravers hardly ever expressed themselves upon this subject, but art critics were more outspoken. Photography might be useful as a documentary means—it was especially appreciated as a way to reproduce works of art—but it lacked artistic qualities. The ways of reasoning will have been about the same as in any other country.

To be sure, most portrait photographs *did* lack artistic merit. Carte-de-visite portraits are done in the same way to an astonishing degree. Variation was a word not in the photographer's vocabulary. The same props were used over and over again: tables, seats, carpets, columns, balustrades, in later decades also painted backgronds. The setting and postures were regardless of the persons depicted. It is striking that the wealthy, amateur photographer Alexandrine Tinne (1835–1869) used exactly the same props when she made some portraits of her relatives in the garden of her house in The Hague in 1860–1861. The same applies to a series of domestic scenes the amateur photographer Jordaan Everhard van Rheden made in the 1860s and 1870s. One would have expected an amateur to feel free to deviate from the stereotype settings professionals took to.

Regarding the invention or development of new techniques or apparatus, Dutch photographers were not in the front row. They merely followed what was being done abroad. At first France was the country that was looked upon as a source of things new, later Germany took over this role. There have been a few exhibitions—especially those in Amsterdam in 1855 and 1860—where foreign photographers like Gustave Le Gray, Edouard Baldus, and the Bisson brothers showed their works, but this seems not to have stimulated Dutch photography very much. There is no sign that it changed much after these exhibitions took place. Photographers still clung to making portraits; cityscapes, art reproductions and the like were produced on a much smaller scale. Landscapes are quite rare in Dutch photography and until the advent of Pictorialism (*picturalisme* in Dutch) in the 1890s "free photography" hardly existed. Amateurs were an exception to this, but their number was relatively modest. However, they hold an important place among the photographers who have left a considerable oeuvre that is still appreciated nowadays for its artistic qualities. Besides Asser and Tinne three men should be mentioned who were active in the last decade of the 19th century: the painter Georg Hendrik Breitner (1857–1923), his friend and colleague Willem Witsen (1860–1923), and the architect and headmaster of a technical school Jacob Olie (1834–1905). Breitner and Olie photographed extensively on the streets in Amsterdam and did portraits—Breitner also photographed many nudes—while Witsen mainly took portraits of his fellow artists and of young contemporary writers. All three made pictures that lack the stiffness and coldness of professional work. As they did not take part in exhibitions and their work was not known outside their own circles, they did not have any influence on the course of Dutch photography. Other amateurs united in societies that were founded in many a Dutch town from 1887 onwards. This was due to the introduction of smaller, easier to handle cameras and readymade negative plates. Some amateurs were quite serious about their hobby, others were just making snapshots without giving much attention to composition and other aspects of photographic aesthetics.

Snapshot photographers were fiercely attacked for lowering the average level—especially by the Pictorialists who wanted photography to be accepted as an art form rather than considered just a pleasant pastime. Pictorialism rose in the 1890s and was to dominate the scene after the turn of the century. It recruited its followers from both professionals and amateurs. They not only turned against the snapshot photographers who were criticised for being too unpretentious, but they also scorned the way most professional portrait photographers conceived their occupation. The Pictorialists took offence at the props used over an over again and at the large amount of retouching which made people look like "billiard balls" or "wax statues.." Instead, Pictorialists like P. Clausing, C.M. Dewald, and C.E. Mögle wanted to do justice to their sitters by treating them as individuals. No portrait should be the same, as

no person is identical. They also paid more attention to better printing techniques like the platinum print and the gum bichromate print. Apart from portraits, they did landscapes, genre scenes, and city views; in this, they were much inspired by the painters of The Hague School. There is, perhaps, a certain nostalgia in Pictorialist pictures; scenes of quiet life on the land constitute a substantial number of them. They usually display a quiet atmosphere, largely due to the diffused incidence of light. The concern felt for farmers, workmen, tramps, and gypsies was rather superficial, however, as they mainly served as picturesque motifs. The 1890s saw a new élan, with the founding of photographic magazines and the organisation of some international exhibitions. In 1902, the Nederlandsche Fotografen Kunstkring (NFK, Dutch Art Photographers' Circle) was founded to give some more direction to the Pictorialist school. Some belonging to the first generation of Pictorialists could also be dubbed naturalist photographers, but as their number was modest, like the amount of their pictures that have survived, it is not always easy to make a clear division between the two tendencies.

In the 19th century, Dutch photography followed a course that did not differ much from what was happening abroad. Despite international exhibitions that were held from time to time, some photographer's membership of foreign photographic societies, and the constant influx of foreign—especially German—photographers who settled in The Netherlands, 19th-century Dutch photography did not develop to the same heights as in some other countries.

NETTLETON, CHARLES (1826–1902)

English studio owner and photographer

Charles Nettleton was born in 1826 in London, the son of George Nettleton and Susannah Feathers. Charles worked as a manufacturing chemist in London and in 1854 immigrated to Melbourne, Australia where he was employed as a photographer in the studio of Duryea and McDonald. Nettleton performed the outdoor work. Nettleton set up his own studio in 1858 and plied a trade in portraiture but he remained a prolific view photographer, working for the Victorian Government and City of Melbourne Corporation, capturing all aspects of Melbourne and the Victorian countryside, including buildings, public works, transportation and sporting teams. For a brief period in 1861 Nettleton was in partnership with Charles Hewitt, during 1862 he managed the Melbourne Stereoscopic Company and then he formed another brief partnership with John Calder. Finally in 1864 he established premises in Madeline St., North Melbourne although various branch facilities were opened over the years. Nettleton produced the first commercial album in Australia, *Melbourne Illustrated by Photographs* in 1868 and he prolifically produced views in carte de visite, full plate and mammoth plate sizes for many years, being a master of the wet plate process. Nettleton exhibited widely at Australian and International Exhibitions. He finally retired from his profession in 1893 and he died on 4 January 1902.

MARCEL SAFIER

NEUHAUSS, RICHARD (1855–1915)

Richard Neuhauss was a doctor of tropical medicine who resided in Berlin but traveled widely. He published on many medical subjects but also was a superb experimentalist in photography with a special affinity for the Lippmann Process. Following German colonization he traveled to Papua New Guinea and published on his medical and photographic studies of the indigenous people there. He made a number of photographs of Otto Lilienthal's early flight experiments, and worked on early cinematography.

His Lippmann shooting records and about a half dozen plates are held by the Preus Fotomuseum in Vestfold, Norway, near Oslo. The lists describe more than 2,500 test exposures, a record for the process. Of these, only a tiny fraction, perhaps two dozen are known to survive. Most may have been failures. According to the lists, their subjects were relatively few and shot repeatedly, including self portraits, stuffed parrots, dead butterflies, still-lifes of flowers and foods, and a few outdoor images. He published a number of papers and a book on the process. He used his technical skills to publish images of microscopic thin-sections of

Lippmann images, which display their internal layered structure. Based on his surviving Lippmann images, he was a master of the process.

A primary source of interest for him in his photographic pursuits was the search for a color photographic process that would render high fidelity color images of microscopic subjects. In this goal he appears to have succeeded, as there is a superb Lippmann-type image of a microscope slide of a thin section of a human liver, showing the presence of a parasite, held at the National Technical Museum in Prague. Due to the super high resolution of Lippmann-type images, it would be capable of extreme further enlargement. As it is it is simply beautiful.

WILLIAM R. ALSCHULER

NEURDEIN FRÈRES

French company

One of the leading commercial photographic firms of the late nineteenth century, Neurdein Frères offered a diverse production including portraits, architectural and picturesque views of France and neighboring countries, and studies of provincial or North African women in traditional costume. Also heavily involved in photography of works of art shown in the Paris Salon and of the temporary architecture of several World Fairs, Neurdein Frères eventually acquired semiofficial status, managing and supplementing the French government's archives of photographs of historical monuments. These added administrative duties led to the withdrawal of Neurdein Frères from other photographic activities and to its eventual merger with a rival firm. Though its work was extensively published by Neurdein Frères itself and by other firms, it is not widely known today. Recent controversies over "Orientalist" photographs of women, however, have again brought attention to works by Neurdein Frères.

Little is known about the background of the Neurdein family. Etienne (1832–after 1915) and Louis-Antonin Neurdein (1846–after 1915) were the sons of the photographer Jean César Neurdein, who worked under the pseudonym of Charlet. In 1863, one of the Neurdeins operated a studio on the Rue des Filles-du-Calvaire in Paris. Subsequent Parisian locations of the Neurdein firm were the Rue des Filles-Saint-Thomas, Boulevard de Sébastopol, and Avenue de Breteuil. By 1868 the firm, now under the name E. Neurdein, advertised portraits of historical personalities and contemporary celebrities and already offered views of France, Belgium, and Algeria. The views were sold initially as albumin prints, later sometimes as gelatin silver prints, and were also reproduced in postcard format under the names ND Phot. or X Phot. The firm also became involved in extensive book publication based on its own photographs.

The brothers maintained a division of labor: Etienne managed the studio in Paris and made portraits, while Louis-Antonin traveled extensively, making architectural and landscape views.

The portraits, whether of prominent or little-known individuals, were usually in carte-de-visite format and differed little from comparable work produced by other photographic firms of the period. One Neurdein portrait, however, a Woodburytype of the chemist and political revolutionary François-Vincent Raspail, was included in 1878 in the prestigious *Galerie Contemporaine*, a lavish biographical publication dominated by works by the well-known portraitists Nadar and Etienne Carjat. The undated portrait of Raspail, who died in that year, depicts a still-forceful older man.

Views of castles, cathedrals, and architectural decorations, particularly in the French provinces, made up a large part of the firm's production; in this the Neurdeins emulated the role of other prominent European firms, such as Fratelli Alinari of Florence, in documenting architectural and artistic monuments. The selection of views offered was vast: a catalogue published by the firm in 1900, covering only works available in postcard format, ran more than five hundred pages. Louis-Antonin was by no means, however, the only photographer recording historic French architecture, and it is difficult to define a *style Neurdein* that might separate his work from views made by rival firms. Neurdein's photographs of medieval buildings, such as the Abbaye-aux-Hommes, Caen, are often taken from rooftop level to give views clearly separating the subject from the surrounding townscape. Other images provide valuable documentation of much vernacular architecture that has since disappeared due to war damage or modernization. This interest in bird's-eye views eventually may have led to Louis-Antonin's experiments with panoramic photography, especially of Paris, one of the most distinctive areas of his work.

Around 1900 Neurdein Frères branched into a new endeavor, depicting Algerian and Tunisian women in native costume in images disseminated both as albumin prints and postcards. This popular genre belongs more to erotica than to ethnology: the models often are overdressed and seminude at the same time. Such images have been condemned in recent years as manifestations of colonialist domination. It is true that these photographs are quite different from Neurdein's earlier, more sedate images of Alsatian or Breton women in folkloric costume, and the intervention of a local photographer working for the firm is a possibility. The North African figure studies are nevertheless more discreet than comparable images produced by rival firms such as Lehnert & Landrock, Geiser, or Lévy.

Louis-Antonin became a member of the Société française de photographie in 1884 and joined the Chambre syndicale de la photographie in 1886, followed by Etienne in 1902. The brothers were awarded prizes in several exhibitions, including the Expositions Universelle, Paris of 1889 and that of 1900, for views, often of considerable technical achievement, that were produced using a Moëssard panoramic camera. Their negatives of paintings exhibited in the annual Paris Salon were published in phototypogravure, creating lithograph-like images that were probably seen as more faithful to the original works.

In view of these accomplishments, the French government in 1898 awarded Neurdein Frères a concession to manage the photographic archives of the Service des Monuments historiques. This responsibility, which continued until World War I, involved maintaining the collection and printing and selling photographs from existing negatives by many artists. The firm also recorded additional historic monuments, particularly in Corsica, adding a thousand glass plate negatives that still exist in the archives. These activities left less time for the firm's other work, and early in the new century it merged with the Lévy firm as "Lévy et Neurdein réunis, 44, rue Letellier, Paris," operating under that designation into the 1920s.

Albumin prints, frequently large, by Neurdein Frères are found in many souvenir albums put together by British and American tourists to record their travels on the Continent. Such works preserve an architectural heritage that often has been altered or lost. The firm's popular views of Paris and of the Exposition Universelle of 1900 were issued in albums of mounted albumin prints and published in photogravure, often following a fixed order of subjects. Through these images, as well as their panoramic cityscapes and their controversial figure studies from the North African colonies, Neurdein Frères made a significant contribution to the photographic record of their time.

NEVILL, LADY CAROLINE EMILY (1829–1887); AUGUSTA, LADY HENRIETTA (1830–1912); AND FRANCES, LADY ISABEL MARY (1831–1915)

The 1852 exhibition at the Society of Arts in London included *A Portrait* by Lady Augusta Nevill, together with *Portrait of a Lady* by her sister Lady Isabel. With their sister Lady Caroline, they were the daughters of William Nevill, 4th Earl of Abergavenny.

'The Ladies Nevill' contributed two collections of work entitled *Portraits and Groups* and *Portrait Groups* to the 1854 exhibition of the Photographic Society of London, of which they were all members. All their images exhibited in 1852 and 1854 were described as by the collodion process.

These appear to be the only two occasions the ladies exhibited their work in major exhibitions, preferring instead to circulate images through the Photographic Exchange Club.

The Photographic Exchange Club album for 1855 contains two images by Lady Augusta, of the family home, Allington Castle in Kent, one by Lady Caroline, of Malling Abbey, and one titled *Allington, Kent* by L.F.C.Nevill whose identity cannot be confirmed. All are by le Gray's Waxed Paper process.

Two years later, the 1857 album included *Birling, Kent* by Lady Caroline, and two views of Eridge, East Sussex by Lady Augusta Mostyn. Lady Augusta married the Hon. Thomas Lloyd-Mostyn in 1855.

There are no records of their involvement with photography after 1857.

John Hannavy

NEW SOUTH WALES GOVERNMENT PRINTER

The New South Wales Government Printer (NSWGP), a public works department in Sydney, was established in 1859 as an extension of the postage stamp department. The first Government Printer, Mr. Thomas Richards, established the "Photolithographic and Lithographic" department in 1868 and the "Photomechanical" department in 1877. Richards' intention for the photographs was the depiction of natural features and the material progress of the colony; the distribution of the photographs was promotional. Photographs were sent to international exhibitions, including the Centennial International Exhibition, Melbourne, 1888, when the department sent 178 photographs. The main form of presentation, however, was in album format, produced internally by the Printer's binding department. The quality, style, and size of the albums were remarkable and produced as gifts for official visitors. The "Album of Views of New South Wales" presented to Lord Knutsford, the Colonial Secretary, in 1891 at the first Federal Convention includes civil works, public buildings, bridges, the Sydney Botanic Gardens and outlying districts. The photographers within the department remain unknown, but the "Narrative of the Expedition of the Australian Squadron to the South East Coast of New Guinea, October to December, 1884" (1885) has been attributed to Augustine Dyer (1873–1923). Photographs were purchased and commissioned from commercial operators including Henry King, Charles Bayliss, and Charles Kerry. Mr. Charles Potter succeeded Mr. Richards as the Government Printer in 1886.

JULIA PECK

NEW ZEALAND AND THE PACIFIC

Although the chronology of events regarding the announcement of the Daguerreotype process in late 1839 could have seen a camera and chemicals loaded on board one of the New Zealand Company's immigrant ships as it set sail from London to establish a settlement in Port Nicholson, in the lower half of the North Island, New Zealand, this was not to be. Thus the opportunity to document the founding of a British Colony from day one was passed over as other more important necessities of life found room in chests and trunks of those who braved the long voyage and the uncertainties of life in a new country. When a camera finally entered the coastal waters of New Zealand, it probably wasn't even taken out of its case before it left the northern port of the Bay of Islands in March 1841, on board a barque bound for Sydney, Australia. There its owner, a Captain Lucas of the French vessel Justine made a daguerreotype on April 13, 1841 which received publicity and is still heralded as the first photograph to be made in Australia.

The first written account of a daguerreotype being made in New Zealand appears in the journals of Lieutenant-Governor Edward John Eyre 1815–1901, who recorded that he failed in an attempt to get a likeness of Eliza Grey, wife of the Governor George Grey, who sat for him on the verandah of Government House, Wellington on September 17, 1848. Besides the amateur attempts of Eyre, trader entrepreneurs like J. Polack and J. Newman advertised their services in the art of daguerreotype portraiture in Auckland in May 1848. Promising as these announcements may seem, no New Zealand daguerreotype earlier than November 1952 can be positively attributed to any particular photographer. In this instance, it was Lawson Insley who visited several settlements in New Zealand between 1851–1853. His clients were Civil Servants, Ministers of the Church and successful trades people. When he finally left for Australia in 1853, he was one of the last itinerant photographers who came to New Zealand before crossing the Tasman Sea for more lucrative prospects in Australia.

After Insley, there was a gap of a year or so until 1855, when John Nichol Crombie 1827–1878 a Glaswegian who visited, provided portraits for whoever could pay his fees. His contribution to New Zealand photography is important for a number of reasons. First he experienced the transition from daguerreotype to collodion positives (ambrotypes) and then finally to the wet plate negatives which allowed paper prints to be made from a collodion negative. Secondly, his achievements in photography are easy to document because of numerous comments made about him in newspapers of the day. From all accounts, he was very outgoing and attracted attention wherever he went in New Zealand and overseas. During a brief visit to where he was born in 1862, he lectured the Glasgow Photographic Association on his New Zealand experiences. This event was duly reported in the British Journal of Photography which included some interesting statistics concerning how many portraits he made as a daguerreotypist in New Zealand. Thus we have a very good picture of his life and times as a pioneer photographer who spent nearly all of his professional years in New Zealand. While portraiture naturally remained his main source of livelihood, he periodically covered topical events, from a Royal Tour to Civil Engineering Projects in Auckland.

The constant flow of photographers between Australia to New Zealand continued in the 1850s and into the next decade following gold discoveries in both the North and South Islands.

Daniel Louis Mundy 1816/7–1881 was born in Wiltshire, England, and arrived in Dunedin in 1864 with sufficient capital to take over William Meluish's photographic business. Two years later he moved to

Christchurch where he made the acquaintance of geologist Julius von Haast, a person who was to play an important role in Mundy's photographic career. Leaving the portrait side of his business to a partner, Mundy commenced a series of New Zealand landscapes, starting with a journey from Canterbury to the gold fields of the West Coast through a newly discovered pass in New Zealand's Southern Alps. In doing so he depicted a route along which supplies could be transported to the diggings safely without recourse to using coastal shipping and the treacherous river ports of the West Coast. Gradually as he moved further afield from Christchurch he acquired a range of views which made him the first to go about the task of accumulating a fairly representative selection of New Zealand views.

Forever mindful of the circumstances that made New Zealand unique from the rest of the world, Mundy photographed the country's major rivers, lakes and mountains, supplementing these when he could with mining operations, flora and fauna. In 1869 with history in mind, he journeyed to the East Coast of the North Island to photograph the spot where Captain Cook had landed a hundred years ago. An exponent of the collodion process he developed many tricks of the trade to combat the stress and strain of taking photographs in a country where there were very few roads. His trials and tribulations along with other interesting anecdotes are recorded in the British Journal of Photography December 25, 1874. Altogether he made 250 photographs which he considered to be the pick of his collection. He exhibited these in London while supervising the production of his book, Rotomahana—the Boiling Springs of New Zealand, 1875. With descriptive notes by the distinguished Austrian explorer and academic Ferdinand von Hochstetter, his plates were printed using the newly discovered Autotype Process. The quality and presentation of his work at the 1873 Vienna International Exhibition and Rotomahana earned him a decoration from the Austrian Court.

In later years he moved to Australia where amongst other things he gave magic lantern lectures about his adventures in New Zealand and how he had to ford snow fed rivers in the Southern Alps and journeyed through territory in where the hostile Maori chief Hone Heke and his raiding parties were known to reside.

While Mundy and other photographers were coming to grips with landscape photography in New Zealand, Dr. Alfred Charles Barker 1819 –1873 was documenting his family and friends in Christchurch. Barker came to New Zealand from England in 1850 on one of the first four ships that founded the Canterbury settlement. When a riding accident curtailed his activities as a medical practitioner, he gave up his practice and concentrated on Civil Administration, Land Deals and Photography. His earliest adventures into photography are dated 1858 and include the way Christchurch was founded on swamplands which had to be drained before the town could be laid out to a grid pattern bounded by four avenues a mile apart. Using equipment that he improvised for his needs, his work is noted for his outdoor portraits which were made in his Œstudio—the front garden of his house. Despite a somewhat cavalier attitude towards certain technical disciplines like using odd bits of glass which he crudely shaped to fit his camera, his portraits reveal personal characteristics of many of his sitters. A distinguishing feature of his work is a series of self portraits which he made from 1858 to shortly before he died in 1873. These tell of the hardships colonial life held for him.

John Kinder 1819–1903 who was born in London came to New Zealand in 1855 and took up a position as headmaster at the Church of England Grammar School in Auckland. A brilliant draughtsman and watercolourist, he took up photography around 1860 and quickly mastered the collodion process. Because a considerable number of his photographs replicate some of his watercolour studies, an observer might be drawn to conclude that he acquired his photographic skills purely as an aide memoir for his painting. Contradicting this are his more informal photographs which disclose a sensitive eye for studies which range from a Maori youth selling fruit on an Auckland Street, to friends and neighbors posed outside their houses. Possibly the most entrancing are a series of photographs of his wife Celia who posed for him on a number of occasions. In comparison to Barker, Kinder's studies are extremely formal and correct in every detail. They reveal a meticulous person whose approach to the visual arts were based strictly on the conventions of 19th century art.

Women photographers for the most part in New Zealand during the 19th century, were confined to assisting their husbands. Elizabeth Pulman 1836–1900 who was born in Cheshire, went beyond these limitations upon the death of her husband in 1871 and took over the control of their studio in Auckland. With her son Frederick, she carried on a very successful business which was noted for its fine selection of Maori portraits.

Another notable contributor to the photographic documentation of New Zealand was James Bragge 1833 -1908 who was born in South Shields and traveled with his wife and family to Wellington in 1864. His photographs show how Wellington changed in stature from a sleepy Provincial Town to a Capital City with the transfer of Central Government from Auckland in 1865. This episode in the development of the capital was made all the more dramatic with injections of capital from overseas which had been negotiated by the then Prime Minister Julius Vogel in the 1870s. Bragge's commitment to large format photography with 16 × 14 inch glass plate negatives, leaves nothing in doubt over the

appearance of the Capital City and its hinterland—the Wairarapa. His views of this region, which were made with the aid of a horse driven van that served as a portable darkroom, encouraged investors to develop this region. His work on this project earned him medals at the Sydney and Melbourne International Exhibitions of 1879 and 1880–1881.

As admirable as the professional activities of Crombie, Mundy and Bragge might be, the colossus of New Zealand 19th century landscape photography was undoubtedly Alfred Henry Burton 1834–1914 who was born in Leicester. As one of four sons who helped their father John Burton operate a photographic business which had branches in Birmingham, Nottingham and Derby, he was no newcomer to photography when he joined his younger brother Walter in 1868, who had immigrated to Dunedin, New Zealand, two years previous to this amalgamation. This was not the first time Alfred had been in New Zealand, in 1856 he'd journeyed to there to spend three years in Auckland as a printer, following this up with a similar stay in Sydney, Australia.

The firm the brothers founded became known as Burton Brothers. It prospered with Walter responsible for the portrait trade, allowing Alfred to travel beyond Dunedin to build up a collection of scenic views in a specially constructed van which acted as a portable darkroom. The first series of negatives he made was devoted to settlements in the province which had yielded rich deposits of alluvial gold. Then by the Government steamer Luna in 1874, he accompanied an exploratory expedition to a territory on the South West corner of the South Island known as Fiordland.

After Walter's death by suicide in 1880, Alfred admitted Thomas Mintaro Muir to the partnership, an arrangement which allowed Alfred to continue documenting nearly every town and settlement in both North and South Islands. In 1884 he took his camera on a winter cruise of the South Pacific and added another valuable series of views which were known as "A Camera in the Coral Islands." The following year, he chanced upon an expedition that was being formed to explore the upper reaches of the Whanganui River. The expedition was mounted to investigate a possible route for the North Island Main Trunk Railway between Wellington and Auckland. This trek passed through an area called the King Country which was populated by Maori tribes. Over a period of 37 days in April-May 1885, Alfred managed to make 230 whole dry-plate views featuring the various villages through which he and the expedition passed. Today these photographs are considered the most important authentic visual records of the Maori in their natural habitat. Their sale under the title "Maori at Home," won him many awards including a Fellowship of the Royal Geographic Society of Great Britain.

In 1898, Alfred sold his interests in the business to George Moodie 1865–1945 who was born in Dunedin and had taken over the role of the firms scenic photography. Moodie went on to expand the business under the title of Muir and Moodie. A major part of his energies were directed towards the tourist trade with albums of scenic views and postcards. He was the first photographer, born and raised in New Zealand, to make a distinguished career for himself.

Nineteenth century photography in New Zealand was dominated by the documentation of the land. The impact that this focus had on our forefathers at the time is reflected upon by one art authority, Edward Lucie-Smith. Drawn to comment on a particular New Zealand photograph by James Bragge of bush covered hills he said. "To the eye of someone nurtured on European landscape painting, this still seems an impossible almost outrageous kind of image—a land altogether alien, hostile, and sufficient unto itself." As the land was cleared and farmed, the emphasis changed from studies of virgin bush and natural features to what had been won by clearing the land with a destructive policy called "Slash and Burn." After these pioneering years which established a sound economic footing through farming, photographers became preoccupied with providing attractive views of the natural environment for the burgeoning tourist trade. Hence when George Dobson Valentine 1852–1890 from the Scottish firm of Valentine and Sons died in Auckland after a six year residency in New Zealand, the parent firm dispatched another operator from the other side of the world to carry on his unfinished work. Valentine had come to New Zealand in an attempt to recover from tuberculosis with no thoughts of contributing anything to the firms catalogue of world views.

After a short while it appeared that he could not resist the temptation to make a number of images featuring the principal tourist attractions in the North Island. While the fascination he held for his new environment was probably no different from those who had experienced a similar commitment 30 years earlier, there was now a larger and more visually literate clientele who were as rapacious as those who looked with wonderment upon their daguerreotype likeness.

19th Century Photography in the South Pacific

Nineteenth century photography in the South Pacific falls into several phases. First, there were photographers who were based in Australia and New Zealand who visited the Islands to secure a representative selection of the natives and their environment. New Zealand firms like Burton Bros. of Dunedin and Josiah Martin of Auckland, were matched by their Australian counterparts, namely Kerry and Co. of Sydney, John William Lindt of Melbourne and John Beattie of Hobart. Gradually some of

the larger Islands boasted a resident photographer who not only supplied local needs but were well placed to cash in on the fascination which the developed world held for the people of the South Pacific. With the advent of hand held cameras, missionaries were encouraged by their Religious Orders to record their work of converting the natives to Christianity. This rather patchy coverage during the 19th century, gradually gave way to a more detailed and scientific methodology by virtue of ethnographic expeditions that were mounted by various Governments and Scientific Institutions.

The first substantial body of work to be compiled by a photographer in Samoa, was made by John Davis ?–1893 who as early as the 1870s was producing carte de visite studies while holding the job of postmaster in Apia. Following Davis's death, Alfred John Tatterstall acquired his negatives and continued to sell them for years afterwards. While the pioneering work of Davis must be acknowledged, especially the studies he made of various Samoan customs, the title of who represented the people of the South Pacific to their best advantage, must surely fall upon the shoulders of Thomas Andrew 1855–1939.

Andrew was born in Auckland, New Zealand and operated photographic businesses in both Napier and Auckland. In 1886–1887 he made a tour of the South Pacific on board the schooner *Southerly Buster* to promote trade between New Zealand and the Islands. When his Auckland photography business burnt down in 1891, he decided to move to Apia where he at first began work as an assistant to the incumbent Davis. Andrew went on to extend his range of views to take in a number of staged re-enactments relating to the way victims were dealt with in intertribal warfare in the Fiji Islands. His Samoan nude studies are keenly sought by collectors.

Alfred Henry Burton q.v. in 1884 made what some describe as the first organized expedition to consciously gather together photographs of Samoa and other Islands such as Fiji and Tonga in the Pacific. While his views of villages and plantations are notable for their fine attention to detail, a large proportion of the studio studies which Burton had listed in his catalogue under the title The "Camera in the Coral Islands," were probably the work of either Davis or Andrew.

Another New Zealand based photographer who made a solid contribution to the documentation of the people of the South Pacific was Josiah Martin 1843–1916 who wrote extensively of his experiences when he returned from a tour of The Friendly Islands—Tonga in 1896 in Sharland's *New Zealand Photographer*, a journal which he edited for a number of years.

From Australia John William Lindt 1845–1926 journeyed to the New Hebrides—Vanuatu in 1889 and backed it up with a superb series of Fijian fire walker studies the following year. While Charles Kerry 1858 –1928 was more an entrepreneur and publisher of photographs, he was also a first class cameraman. Another Australian photographer operating for Kerry & Co. called George Bell, made a splendid postcard series titled By Reef and Palm. Finally, Tasmanian John Beattie 1857–1930 spent five months on board the mission steamer Southern Cross touring the Melanesian archipelago where he amassed 1,300 plates at the turn of the century.

While the South Pacific was admittedly a very idyllic if not exotic hunting ground for photographers, their motivations for venturing forth were undoubtedly driven by European concerns. Several nations like Great Britain, France, the United States and Germany vied for control of Samoa and other dependencies when Empire Building was fashionable. No matter the motifs and its spread out nature, Oceania was surprisingly well documented in the 19th century.

NEWHALL, BEAUMONT (1908–1993) AND NANCY (1908–1974)

Beaumont was the pre-eminent photographic historian of the twentieth century. A pioneering author, curator, teacher, and photographer, Newhall is universally ac-

knowledged for his vitally important role in establishing the history of photography as a unique and serious field of study. Through his critical appreciation and rigorous scholarly inquiry Newhall championed the medium of photography as an art form in its own right. His overriding contribution to its study was to interpret photography from an historical, critical, and aesthetic perspective, rather than in a strictly technological approach.

Beaumont Newhall's mother was a semi-professional photographer. One of his earliest recollections was of "standing beside my mother in her darkroom while she developed glass plates by the red glow of the safelight. I was fascinated to watch the image appear, as if by magic in the glass tray" (*Focus*, 10). When he was fifteen Newhall taught himself photographic processing, and making photographs became a lifelong passion.

The summer prior to entering Harvard Newhall fell under the spell of the movie *Variety* (1925), directed by Ewald André Dupont, and photographed by Karl Freund. Erich Mendelsohn's *Amerika: Bilderbuch eines Architekten*, 1926, depicting skyscrapers, grain elevators and other industrial buildings was also an early influence, teaching him a new way of looking at photography. At Harvard he hoped to study film and photography, but as there were no courses offered in these subjects, he studied art history. His professors included Adolph Goldschmidt and Paul Sachs. In 1934 he presented his first paper, "Photography and Painting," on the history of photography, at the College Art Association.

In 1936 while working as the librarian at Museum of Modern Art (MOMA) in New York, Newhall, curated the museum's first exhibition of photographs at the request of Director Alfred Barr. Conceived of as an overview of the history of the art form, *Photography 1839–1937* contained a combination of historical and contemporary photographs. Its real impact however, lay in the display of the little-known nineteeth century works. Furthermore, in eschewing the then popular "pictorial" school of photography in favor of exhibiting only "pure" or "straight" [straightforward] photography, Newhall propounded a new photographic aesthetic. In the exhibition catalog Newhall also introduced formal criteria for judging photography as a fine art. The catalog was revised as *Photography: A Short Critical History* (1938), which in turn formed the basis for his *History of Photography from 1839 to the Present Day* (1949). Revised five times and translated into several languages, *History of Photography*, has been recognized as a seminal work in the history of photography and continues to be a widely read textbook.

After this first exhibition, Newhall's passion for photography became his vocation. In 1940 MOMA formed its Department of Photography with Newhall as its curator.

He remained at MOMA until 1947, although his wife Nancy Newhall (1908–1974, see summary below) served as Acting Curator from 1942–1945, while he was stationed overseas, during which time she curated fifteen exhibitions for the museum. Other seminal exhibitions curated by Newhall include the photography section of "Art of Our Time" (1939); "Photographs of the Civil War and the American Frontier" (1942); and the Edward Weston Retrospective (1946).

In 1948 Newhall became the first curator of photography at the George Eastman House and began developing his second major photography collection for an institution. Nancy Newhall arranged the Eastman House's permanent photography exhibition. In the late 1960s Beaumont and Nancy assembled a collection of photographs for the Exchange National Bank of Chicago, an early example of corporate collecting.

When Newhall arrived at Eastman House he had already spent a summer teaching at Black Mountain College. Throughout his tenure at Eastman House he continued to teach at a variety of institutions. He and James Card developed the first courses given for academic credit in the histories of motion pictures and photography at the Rochester Institute of Technology and the University of Rochester. Newhall was known for the quality of his teaching—stressing original thought and research, and the exploration of new subjects in order to expand the history of photography. Many of Newhall's students became curators or professors at major institutions.

Nancy and Beaumont Newhall counted many contemporary photographers among their close friends, most notably Edward Weston, Alfred Stieglitz, Minor White, Paul Strand, and Ansel Adams with whom Nancy collaborated on numerous projects. Nancy Newhall's concentration on working with practicing photographers was no doubt due to her own training as a painter and artist. In addition to her more than two decades of work with Ansel Adams, Nancy Newhall wrote and worked with Paul Strand and Edward Weston, whose day books she edited (1961–66). Whereas posthumous evaluations of an artist's life and work had been the norm for art history monographs, Nancy Newhall's scholarly work on living photographers set a precedent for serious publications about contemporary artists. The books that she collaborated on with Ansel Adams helped formulate another new genre of pictorial essay—scholarly nature photography books, as epitomized by *This is the American Earth* (1960).

Although Newhall revised and updated his extremely influential core study *History of Photography* five times, the book has not been without its detractors, especially in the late twentieth century when the methodology of art history and the discipline's assumptions came under close scrutiny. Newhall's methodology has sometimes been seen as old-school formalism. Yet, as Carl

Chiarenza has pointed out, "no one has yet produced a less biased, more idea-oriented, or more interesting general history of photographic picture reproduction" (*Colleagues and Friends*, 14).

John Szarkowski has aptly contextualized Newhall's long and productive career and his influence on the study of photography:

> When Beaumont Newhall was beginning his essential work, the great photographer Brassai did not know the name of the great photographer Peter Henry Emerson, and Alfred Stieglitz had not heard of Timothy O'Sullivan. No coherent sketch of photography's first century existed...A half-century later virtually every photographer of ambition has a reasonably catholic knowledge of the tradition that he or she is part of, and almost every art historian understands, at least in theory, that photography is part of their problem. Such a change was not wrought by one person, but it is clear that no one person contributed so much to that change as Beaumont Newhall. (*Colleagues and Friends*, p. 41)

Beth Ann Guynn

Biography

Beaumont Newhall was born in Lynn, Massachusetts, on June 22, 1908. His parents were Dr. Herbert William Newhall (1858–1933), and Alice Lillia Davis Newhall (1865–1940). He received A.B. and A.M. degrees in art history from Harvard University, and did further graduate work at Harvard, the Courtauld Institute of Art, the University of London, and the Institut d'Art et d'Archéologie, University of Paris.

Newhall was a lecturer at the Philadelphia Museum of Art, an assistant in the Department of Decorative Arts of the Metropolitan Museum of Art, and the founding librarian at the Museum of Modern Art, New York, before becoming that museum's first Curator of Photography in 1940. In 1948, Beaumont Newhall became the first Curator of Photography at the George Eastman House and its Director in 1958, building a significant photography collection. In 1971 Newhall became Visiting Professor of Art at the University of New Mexico, where he helped to establish the first doctoral program in the history of photography at an American university. Over the years he also taught at Black Mountain College, University of Rochester, Rochester Institute of Technology, State University of New York at Buffalo, and the Salzburg Seminar in American Studies.

His honors include two Guggenheim fellowships; Honorary Fellow, Royal Photographic Society of Great; Corresponding Member, Deutsche Gesellschaft für Photographie; Fellow of the Photographic Society of America and recipient of its 1968 Progress Medal; and the 1970 Culture Prize of the German Photographic Society.

Newhall wrote over 650 articles and essays. His books include: *History of Photograph from 1839 to the Present Day*, (1949), *Masters of Photography* (with Nancy Newhall, 1958), *The Daguerreotype in America* (1961), *Frederick Evans* (1964), *Latent Image: The Discovery of Photography* (1967); *Airborn Camera: The World from the Air and Outer Space* (1969); and *Photography: Essays and Images. Illustrated Readings in the History of Photography* (1980).

Newhall married Nancy Wynne Parker in 1936. After Nancy's death he married Christi Yates in 1975. Beaumont Newhall died in 1993.

Nancy Wynne Parker Newhall was born in Lynn, Massachusetts, on December 15, 1908. She graduated from Smith College in 1930 and studied painting at the Art Students League, New York, and married Beaumont Newhall in 1936. She served as Acting Curator of Photography at the Museum of Modern Art from 1942–1945, replacing Beaumont who was overseas with the Army Air Force reconnaissance units.

Nancy Newhall curated photography exhibitions, wrote articles about photographers, edited and introduced photography books by Ansel Adams, Paul Strand, Edward Weston, and others, collaborated with Adams on several books about the American West, including *Death Valley* (1954), *Yosemite Valley* (1959), *The Tetons and Yellowstone* (1970), and *This is the American Earth* (1960), the first title in the Sierra Club's exhibit format series; and *P. H. Emerson: the fight for photography as a fine art* (1975). *Eloquent Light* (1963), her biography of Ansel Adams, covered his career from 1902 to 1938; *The Enduring Moment*, the second volume of Adams' biography was unfinished at the time of her death. With Minor White, Nancy Newhall founded the photography magazine *Aperture*. She died in 1974, struck by a falling tree while rafting down the Snake River with Beaumont.

The papers of Beaumont and Nancy Newhall are held at the Getty Research Library; the Center for Creative Photography, University of Tucson; Houghton Library, Harvard University; and the Marion Center for Photographic Arts Library, College of Santa Fe, which also holds the bulk of their personal library.

NEWLAND, JAMES WILLIAM (?–1857)

Newland hailed from Redgrave in Suffolk, England. He was a travelling daguerreian photographer who spanned the continents. He is first noted as J. W. Neuland at 124 Royal St., New Orleans in 1845. He travelled via Panama and Jamaica until in December 1846 he was in Lima, Peru then in early 1847 in Callao. In July he was in Valparaiso then he traveled on to Fiji and Auckland, New Zealand, before arriving in Australia where he set up a studio on the corner of King and George Streets, Sydney from March 1848 for three months. Newland presented lavish lantern shows and a diorama in Sydney that he travelled with to Newcastle and Maitland, where he also operated temporary studios. From October 1848 Newland worked from a studio in Murray St., Hobart Town where he took the earliest known Australian landscape photograph and claimed to have upward of two hundred daguerreotypes in his gallery including portraits of natives from Fiji, New Zealand, Peru, Chile, and Granada and a panorama of Arequipa, Peru. The studio closed in December and it appears Newland then left for Calcutta, where he opened the first professional daguerreian studio in Loudon's Buildings, taking in F. W. Baker as his assistant. By 1857 Newland had expanded into positives on paper and glass and he offered stereoviews of Calcutta and its vicinity. He took in his half-brother Frederick Welling as an assistant, and, following Newland's tragic murder at the outset of the Indian Mutiny in May 1857, Welling continued to operate the studio until its closure in 1860.

NEWMAN, ARTHUR SAMUEL (1861–1943)

English inventor and manufacturer

Arthur Newman was born in 1861. After school he worked for H. and E. J. Dale of London, where he progressed to designing and making photographic changing boxes. He later joined Simpsons of Clerkenwell and became a partner where he was to meet Julio Guardia.

In 1886 Newman was granted his first patent for a photographic shutter (British patent number 7156) which was sold by the London Stereoscopic Company. The shutter was attached to the lens barrel and the shutter blade inserted into an aperture in the barrel.

The partnership of Newman and Guardia seems to have started in late 1891 with the Spanish-born Julio Guardia providing business experience and capital and Newman providing the engineering skill. The firm gained a reputation for producing high-quality cameras starting with a hand camera range (1892), the Nydia (1899), single lens reflexes from 1903 and, from 1908, the Sibyl range which had been originally patented by Newman and the company in 1905. Guardia died in 1906 and shortly afterwards in 1908 Newman left the company relinquishing his shares in return for retaining the rights to the film equipment he had designed. Newman and Guardia Ltd continued making cameras into the post-1946 period.

After his departure Newman established a long-lasting partnership with the photographic retailer and manufacturer James A Sinclair as Newman & Sinclair Ltd, principally producing 35mm motion picture cameras and equipment. NS cameras accompanied Herbert Ponting on Scott's 1910 Antarctic journey, Shackleton's expedition and the 1924 Everest expedition. NS cameras were used extensively for location and studio filming well into the late twentieth century.

Newman's reputation was such that he acted as a retained consultant for the Eastman Kodak Company in Rochester and he designed Pathé's very successful Baby Pathé 9.5mm amateur camera. Newman was actively involved with the Royal Photographic Society and he was instrumental in setting up the British Kinematograph Society in 1931.

He died aged eighty-three in London on 12 August 1943.

MICHAEL PRITCHARD

NEYT, ADOLPHE L. (1830–1892)

Belgian amateur photographer

Born in Gent 13 April 1830, Neyt developed a reputation as an enthusiastic amateur of scientific photography,

concentrating on astronomical and microscopical subjects. His ability to enlarge these images while retaining the clarity of the original was much admired. Most of Neyt's extant photographs were made in the 1860s, when he also joined both the Société française de photographie (1864–1885) and the Association belge de photographie. In 1869, a dozen of his photographs of the moon were presented to the Belgian Royal Academy of Sciences. Neyt perfected a method of making images through a telescope attached to a clockwork, enlarging them to a size of 25 centimeters in diameter with a camera obscura. Some, or perhaps all, of these lunar images were exhibited at the 1873 International Exhibition in Vienna. Although his photographic activity appears to have slowed after 1870, he remained involved, collaborating in 1887 with Édouard van Beneden on the book, *Nouvelles recherches sur la fécondation et la division mitosique chez l'Ascaride mégalocéphale* (Leipzig, W. Engelmann), to supply four accompanying photographs for this work on cellular biology. Neyt died in Oostende 21 September 1892.

KELLEY WILDER

NICHOLLS, HORACE WALTER (1867–1941)

Horace Walter Nicholls was born on February 17, 1867, in Cambridge, England, the eldest son of Arthur Nicholls and Charlotte Johnson, both of Norfolk. His grandfather was John Nicholls, an architect, builder and restorer of cathedrals, churches and castles. The family home was Newnham Grove, Grantchester, Cambridge.

Horace learned photography from his father and uncle, both of whom were listed as professional photographers by the late 1860s. Arthur not only taught his son the technical aspects of wet-plate photography, he maintained that a photographer, even a commercial photographer, was an artist. Horace learned from his father that the camera gives one limitless creative potential and that what some call "tricks" in photography can, with a clear aesthetic vision, purpose, or wit, produce images of originality and value. By the age of fourteen, Horace was listed in directories as a photographer working at his father's studio in Sandown, Isle of Wight.

Nicholls daughters spoke of their father's *wanderlust*. When he was about twenty years old, Nicholls saw an advertisement in a newspaper for a young man to work for a photographer in Chile. He applied and was offered the job and went on an exotic adventure. Nicholls returned to England around 1889 and began working at the Cartland Studio in Windsor. George Cartland held a Royal Warrant. It was here that Nicholls met his future wife, Florence Holderness.

After about three years in Berkshire, Nicholls again became restless and decided South Africa was the next frontier. It was, in the 1890s, an attractive location for an ambitious, talented young man; and after Chile, it may even have seemed a modest choice for someone of British origin soon to be married. Johannesburg, however, in 1889 was little more than a settlement, with acres of empty land between makeshift buildings.

Horace Nicholls arrived in Johannesburg in September 1892 and joined the photographic studio of James F. Goch. He returned to England the following year to marry, and then sailed with his new wife back to South Africa in October 1893. Nicholls now dubbed himself "the Johannesburg Photographer" having renamed his former employer's studio "Horace W. Nicholls, The Goch Studio." In 1896 he left the studio to record a year of tumultuous events: a political crisis, a railway disaster, a dynamite explosion and a huge fire (opposite his studio), a railroad accident, infestation of locusts and a drought. He became the official photographer for the London-based publication *South Africa.* And it was in South Africa, during the Boer War (1899–1902) that he first established an international reputation, making sometimes dramatic, sometimes somber photographs of the conflict. He documented the bombardment of Ladysmith, the movement of troops to frontlines, officers relaxing, the burying the dead and much more. He became one of the world's earliest photojournalists.

Nicholls helped establish the "profession," licensing his pictures for "one-time use and suing publications for infringement of copyright." He was determined, at the onset of photojournalism that photographers should be able to make a living in their new profession and be treated respectfully. It was in the early 1890s the halftone process for reproducing photographs became a commercial viability. When Nicholl's Boer War photographs appeared in the press, half the visual reportage was still drawings.

Nicholls was a quirky photojournalist. After his success documenting the Boer War, he turned aside from major events and concentrated on what today might be called "human interest" stories. He liked to stay away from the pack of early photojournalists and create his own subjects. He stated, "The chief aim of my work in photography is pictorial effect in preference to photographing anything and everything." He always tried to make strong, compelling pictures.

The one subject he could never resist, even if the field was filled with cameramen, was "the Season." Ascot, Derby, Henley, Goodwood, Cowes were annual events he photographed with wit and imagination. Even though he prided himself on being a journalist, he was always ready to montage crowd scenes, multiplying the numbers of people watching the horse race and altering juxtapositions. He liked multiplying the number of umbrellas, too, held overhead. A viewer would be mis-

guided to "believe" all Nicholls press pictures, many of which appeared in *Black and White, The Daily Sketch, The Daily Mirror, Illustrated London News, Penny Pictorial, South Africa, The Bystander, The Illustrated Sporting News, The Graphic, The Referee, The Sphere, The Sunday Companion, The Tatler, The Times and The Guardian.*

When the Great War broke out in 1914, George Nicholls, Horace's eldest son, enlisted (he died in combat in 1917). Horace envisioned himself as a war correspondent, but at 47, he was too old to be with the combat troops. He wrote frequently to the Department of Information to receive an official appointment and asked to be sent abroad. He did receive an appointment, but he would stay in England recording the home front and providing the propaganda-type images that were being requested of the agency. He was recorded events such as the review of troops by the King and also munitions factories, shipbuilding, prisoners of war, men back from the Front and everything else that was required.

The photographs taken between 1917 and 1918 constitute some of Nicholls' finest work. He will especially be remembered as capturing the moment in history when women walked out of their homes and into men's jobs. The combination of a seemingly thorough investigation, a straightforward approach, and great sensitivity make his "women at war" photographs one of his most important contributions to the history of photography. "A Woman Coke Heaver," "A Woman Grave Digger," "The Electric Trolley Driver," are among his classics.

Immediately after the end of the war, the Ministry of Information's responsibility of commissioning and collecting photographs was transferred to the Imperial War Museum where Horace Nicholls was asked to be on staff. He role was to head the darkroom and be responsible for the care, preservation and re-photographing of deteriorating negatives from all the war fronts. He, himself, had made 2,300 negatives during these years. He stayed at the Museum from 1918 until his retirement in 1932.

Even during his years of civil service, he worked freelance for newspapers and journals. In the twenties and thirties, along with scores of family photographs, he produced professional quality images on holidays at home and abroad. Horace Walter Nicholls retired to Worthing and died of diabetes on 28 July 1941. The major collections of his glass and film negatives and prints are in the Royal Photographic Society Collection at the National Media Museum in Bradford, the Imperial War Museum, London and with the Nicholls family.

NIÉPCE DE SAINT-VICTOR, CLAUDE FÉLIX ABEL (1805–1870)

French army officer and chemist

Abel Niépce de Saint-Victor was born on 26 July 1805 in Saint-Cyr, France. He was the second cousin of Nicéphore Niépce, to whom he always referred as an uncle. A career officer in the military, in 1827, he graduated from the École de cavalerie de Saumer [Cavalry School of Saumer]. In 1842, he obtained the rank of lieutenant and was stationed with the first regiment of dragoons at Montauban.

Niépce de Saint-Victor's first encounters with chemistry are legendary. One day, he accidentally stained the red pants of his military uniform with vinegar or lemon juice. Wanting to remove the stain, he tried a number of chemical solutions and finally succeeded with a few drops of ammonia. Following this, the French Minister of War decided that all the lapels, collars, and ornamental details of the uniforms of all the regiments of cavalry—which had previously been variously colored pink, saffron yellow, and crimson—should be orange. Niépce de Saint-Victor was put in charge of chemically altering the original colors of the uniforms so as to arrive at the same color. He succeeded in this, saving the army a great deal of money, and his vocation to the study of chemistry was determined.

In 1845, Niépce de Saint-Victor was stationed at the Military Police station of Paris, located in the faubourg of Saint-Martin. There he set up a laboratory in the basement and began research on photochemical operations, largely financed from his own salary.

On 25 October 1847, he published a report of his investigations to the French Academie des Sciences [Academy of Sciences]. There he described a method he called atmography, which reproduced engravings on paper, porcelain, glass, and metal surfaces, using iodine vapors and starch. In the same report, he described a method for obtaining negatives on glass, using starch.

As a consequence of the French Revolution of 1848, on 24 February 1848 his laboratory was burned down and all his equipment destroyed. He was then placed on non-active duty, whereupon he returned to the study of negatives on glass. This led to his publishing a follow-up report to the Academy des Sciences on 12 June 1848, in which he described a method for making negatives on glass using albumen. The procedure was similar to the calotype process then being used, but was capable of finer detail. One drawback was that it was difficult obtain an even coating of albumen on glass. Another

drawback was that the light-sensitivity was low, so as to make portraiture an impossibility. Nevertheless, albumen on glass may be considered significant as the prototype for the later wet-collodion process.

In July 1848, he was stationed with the 10th regiment of dragoons, outside Paris.

In April 1849, he was promoted to Captain of the Republican Guard of Paris and established a laboratory at the military barracks located on the rue Mouffetard. Also in 1849, he received a medal and 2000 francs from the Société d'Encouragement [Encouragement Society] and was awarded the Legion d'honneur [Legion of Honor].

In 1850, he indicated the use of albumen as a binding agent for paper negatives and positives. He also introduced improvements to his albumen on glass process using honey as an accelerator in the iodizing stage and the application of heat in the sensitizing stage, which made portraits possible. He also remarked on the effect of halation, noting how the rear surface of the glass plate reflected light back upon the light-sensitive surface.

Inspired by the work of Edmund Becquerel, in 1849–1852, Niépce de Saint-Victor attempted to make color photographs using a process he called *héliochromie* [heliochromy]. This involved the direct exposure in the camera of a silver plate coated with silver chloride, which had been dipped in a weak solution of sodium hypochlorite, followed by lead chloride in dextrine. Using this process in 1851–1852, he obtained colored reproductions of variously colored subjects like a bouquet of flowers, a stained glass window, and dolls with different types of clothing; however, the images were never adequately fixed and the colors soon faded.

By a miracle of preservation, three of Niépce de Saint-Victor's heliochromes dating to 1851 survive today in a close to original state, thanks to their having been stored in a light-tight box in the collection of the Parisian Musée National des Techniques [National Museum of Technology]. Using low-light level illumination, these were reproduced as color transparencies by the museum, and published in 1984 by Bernard Levebrve. Apart from having turned reddish and faded slightly, the plates show a successful rendition of original colors, the subjects being a detail of a stained glass window and two studies of dolls.

From 1853–1855, Niépce de Saint-Victor returned to Nicephore Niépce's 1820s heliographic process, using copper plates coated with light-sensitive asphaltum. Here he was assisted by the engraver François-Augustin Lemaître, who had also assisted Nicéphore Niépce. By thinning the asphaltum with benzene, he was able to obtain much thinner coatings of asphaltum and radically shorten exposure times in contact printing; however, the process rendered images which were flat and dull, and unable to render delicacy of detail. Similarly, in copying an original photograph or engraving with a camera, the resulting image was diffuse and needed to be re-engraved by hand in order to obtain details.

In 1854, he was appointed Commandant of the *Palais du Louvre* by Napoléon III. This also coincided with a decision to put him on non-active duty, effectively reducing his salary to one-third of what it had been formerly. He lived at the Louvre until his death.

From 1857–1859, Niépce de Saint-Victor experimented with reproducing images in different monochromatic colors, which he again called *héliochromie* [heliochromy]. Using paper sensitized with uranium nitrate, in combination with either potassium ferricyanide, cobalt nitrate, or gold chloride, he arrived at red, green, and violet toned prints. Blue prints were made with paper feebly sensitized with potassium ferricyanide, followed by a bath of mercuric chloride and development with oxalic acid.

In the last years of Niépce de Saint-Victor's life, he wrote a series of articles on the action of light upon light-sensitive surfaces. In 1862, he joined the Société française de photographie [French Society of Photography] and donated a number of original negatives and prints to their collection. In 1861, 1862, and 1863 he received the *Prix Trémont* [Tremont Prize]. He died on 6 April 1870 and was buried at the *cimitaire Montparnasse* [Montparnasse Cemetery].

Alan Greene

Biography

Abel Niépce de Saint-Victor was born on 26 July 1805 in Saint-Cyr, France. A career officer in the army, he devoted his life to the study of photo-chemistry. In 1848, he introduced the albumen on glass process, a precursor of the wet-collodion process. In 1851, he made color photographs on silver plates, which reproduced the different colors of the original subjects, but he never successfully fixed the images. In the mid-1850s, he furthered the earlier research of his second cousin, Nicéphore Niépce, increasing the light-sensitivity of Niépce's 1820s heliographic printing process. In the late 1850s, he discovered ways to make photographic prints with different monochromatic hues, using uranium nitrate. He wrote numerous articles concerning his research, in different scientific and photographic journals, throughout the 1840s–1860s. A recipient of the French Legion d'honneur, as well as many other medals and prizes, he was commander of the Palais du Louvre from 1854 until his death on 6 April 1870.

NIÉPCE, JOSEPH NICÉPHORE (1765–1833)

French inventor

A decade of intense experimentation with light-sensitive chemicals and the camera obscura led the Frenchman Joseph Nicéphore Niépce to produce the first permanent images made by the action of light in a camera sometime between 1826 and 1827. The ultimate inability of Niépce to capitalize upon his discovery, which he called Heliography, during his lifetime, left his work in relative obscurity for more than a century. At the time of his death in 1833, Niépce was in a business partnership with Louis-Jacques-Mandé Daguerre, and the extent of Niépce's contribution to the wildly successful Daguerreotype process, made public in 1839, has been the subject of considerable debate. Although Niépce did not himself succeed in perfecting a marketable photographic process, he did resolve perhaps the greatest problem facing early experimenters, how to fix the action of light so as to preserve images formed in light-sensitive materials. Moreover, Daguerre's eponymous process can be seen to emerge directly out of his partnership with Niépce, in the specific chemicals and materials that Daguerre used. More broadly, the details of Niépce's career as an inventor illustrate many of the social and economic forces that fueled the rise of photography in the mid nineteenth century. Niépce sought to bring together advances in optics, chemistry, and mechanics to create a fully automatic means of image production, and thereby to make his fortune.

Niépce's father Claude and his father before him had been King's Counselors, and held land in and around Chalon-sur-Saône in Burgundy, where Niépce was born the third of four children. Following school in Chalon he enrolled in 1786 at the Oratoire in Angers with the intention of entering religious service but withdrew after two years, prior to taking his vows. In the course of his studies he had developed a strong interest in chemical and physical science. After 1788, six years of Niépce's life were devoted to military service, both domestic and foreign. During the early years of the Revolution Niépce was in the National Guard in Chalon, and in 1792 he joined the Revolutionary Army, serving in Sardinia and Italy. He left the army in 1794 with an ocular disorder and settled in Nice, where his older brother Claude joined him. Niépce married Agnès Roméro in 1794, and their first child (the only of three to survive childhood), a son Isidore, was born in 1795. While in Nice, Nicéphore and Claude began investigations into the idea of an internal-combustion engine, work that eventually led to their invention of a boat motor called the Pyréolophore, patented in 1807.

Nicéphore and family, with Claude, returned to Chalon in 1801. In addition to overseeing the family lands and vineyards, the two brothers began to pursue a host of engineering and manufacturing projects. In this respect they were early examples of the new occupation offered to middle-class Frenchmen in the post-Revolutionary years: inventor. The Pyréolophore, which they tested successfully on the River Saône, was the first internal combustion boat motor. Also in 1807, in response to a public competition, the brothers conceived a new hydraulic pump system for the town of Marly to deliver water to Versailles. In 1811, Nicéphore answered a government call for a new process of extracting indigo dye from the woad plant, undertaking nearly two years of intense experimentation. When the new printing process of lithography, invented by Alois Senefelder in 1798, was introduced to France in 1813, Niépce endeavored to practice the technique in Chalon, largely self-taught and at a distance from the material and technical resources found in Paris (in a similar spirit, when the first bicycle, the Draisienne, invented in Germany by Baron Karl von Drais, appeared in 1817, Niépce responded by building his own working model). According to Isidore Niépce, his father's approach to lithography was far from conventional, as he would experiment with different varnishes and acids, on a variety of supports. He also began to attempt to impress designs onto lithographic plates through the action of light, perhaps out of a lack of drawing facility (Gernsheim, 29).

In 1816, with the ten-year patent on the Pyréolophore due to expire the following year, work on the boat engine was taken up again in earnest. The brothers experimented with liquid instead of powdered fuel, including an asphalt known as Bitumen of Judea, and developed what stands as the first fuel-injection system (Hardenberg, 78). At the same time, Claude moved to Paris, in search of supporting partners for the enterprise. When patent renewal in France was rejected, despite several improvements to the device, Claude moved to London, submitting a letter of patent in 1817. With Claude permanently away from Chalon in 1816, Nicéphore began his first experiments with the camera obscura and light-sensitive materials. From this point forward, Claude would largely take responsibility for the boat engine, while Nicéphore turned increasingly to experiments in what he would come to call Heliography, or sun-writing, which he undertook in a workroom at the Niépce family estate, Le Gras, in the village of Saint-Loup-de-Varennes, near Chalon.

Niépce's first experiments with light-sensitive materials placed in a homemade camera obscura were conducted in 1816. He succeeded in taking impressions of views out of his workroom window using paper coated with muriate (or chloride) of silver, but the images were not permanent. Moreover, they were negative images, and attempts to print them in the positive were not successful. At the same time, he experimented with the use of light-sensitive resins on stones or plates, with the intention of etching the images thereby made, and then using the etched plates for ink printing. He foresaw his greatest success lying in this direction: etching would render the fleeting image permanent, and printing would allow its endless reproduction.

It was at this point that he began to experiment with bitumen of Judea (previously used as a fuel for the brothers' engine) as a light-sensitive coating. The bitumen, he had discovered, hardened when exposed to the sun's rays, whereas parts that had not been exposed could be dissolved and washed away by oil of lavender. The result was a fine image formed where light had fallen. His first success with this technique, in 1822, was made by placing an oiled engraving of Pope Pius VII directly on a glass plate coated with a thin layer of bitumen. The image, which was later accidentally destroyed, would have been a negative impression of the engraving. Niépce then turned to applying this process to pewter plates, which he etched in acid, the plate being receptive to the acid in precisely those parts where the lines occurred in the original engraving, and resistant where the exposed bitumen formed a barrier. The etched plate could then be printed in the traditional manner. In 1826, Niépce used this technique to copy an engraving of Cardinal d'Ambroise by Isaac Briot onto pewter plates. He enlisted a Paris engraver, Augustin François Lemaître, to etch the plates and pull prints for him, with considerable success. This technique would come to be called heliogravure.

Niépce envisioned adapting this process to the camera, so that images made from nature could be etched and printed. While never realizing this goal, he was able to capture a faint reverse image of a camera view onto polished stone as early as 1824, though attempts to etch the stone and bring out the nearly invisible image may well have destroyed it altogether. In 1826 he turned increasingly to pewter plates, the reflective surface of which rendered the image more clearly visible, and he acquired more sophisticated equipment from renowned opticians Charles and Vincent Chevalier in Paris, purchasing a camera and several lenses. He began to refer to his efforts to take directly the image of nature as "heliographic," i.e., drawn by the sun. The *View from the Window at Le Gra*s, in the Gernsheim Collection of the Harry Ransom Humanities Research Center of the University of Texas at Austin, is an especially durable example of this technique and seems to have been viewed as a significant accomplishment by Niépce himself. The view out his workroom window, onto the chicken house and fields, was one that Niépce's letters describe repeatedly as a subject for his attempts with a camera, starting in 1816 with his silver-chloride images on paper. The large heliographic plate (measuring 20.3 × 16.5 centimeters) carries a faint coating of bitumen where light struck the plate within the camera; by viewing the plate at an appropriate angle one sees the shadow areas, reflected in the bare pewter, appearing dark in contrast to the relatively light film of bitumen, the result being a legible, if elusive, positive picture of the estate's buildings and the landscape beyond. The exposure time for this image is not known; estimates range from eight hours, proposed by Helmut Gernsheim, who recovered the specimen in 1952, to three or more days, the latter assertion being consistent with attempts to recreate the technique as well as in line with evidence from Niépce's letters (Marignier, "Heliography," 58).

Whether produced in 1826 or, as seems more likely given his increasingly excited letters, 1827, the *View from the Window at Le Gras* was in any case executed prior to September, 1827, when Niépce brought it to London, via Paris, with an assortment of examples of his technique, now christened *Héliographie*. On the way to London with Agnès, to visit Claude who had fallen ill, Niépce met with Daguerre, who had written to him in early 1826 after hearing of his experiments. Daguerre was eager to learn the technique devised by Niépce, who for his part was reluctant to share his findings. Niépce had eventually relented and sent Daguerre an example of an etched heliographic plate. Daguerre had responded with criticisms and suggestions but with overall enthusiasm. Visiting Daguerre in Paris, Niépce

was thoroughly awe-struck by Daguerre's renowned Diorama, yet he remained skeptical about sharing his secrets, given Daguerre's lack of proven experience in fixing the action of light (Daguerre's efforts in this regard had consisted of transitory images made in phosphorescent materials). At the same time he was clearly impressed by the ambition and energy of the worldly Daguerre, whose forward thinking and business acumen might bring about the long sought-after success.

Niépce's efforts to find interest in his Heliography in London were largely disappointed, owing both to his own reticence about the details of his process, and to the lack of visibly dramatic results to his process. At Kew, where Claude was living, Niépce met the King's Head Gardener, William Townsend Aiton, who arranged for the examples of Niépce's heliography and engravings pulled from heliographic plates to be sent to Windsor Castle and displayed alongside other items of contemporary scientific interest. The King's reaction, if any, is unknown, and the items were returned without comment. Aiton then introduced Niépce to Francis Bauer, painter in residence at the Royal Botanical Gardens and member of the Royal Society. Attempts to find support from the Royal Society were met with tentative interest but no great result, nor did Niépce succeed in efforts to arouse interest among members of the Society of Arts. Bauer, however, remained supportive, and on departing for France, Niépce presented him with several examples of his work, including the *View from the Window at Le Gras*, framed like a presentation piece. This was inscribed on the back, by Bauer, "Monsieur Niépce's first successful experiment in fixing permanently the image from nature."

On his return to France in early 1828 (Claude had died shortly after the Niépces departed), Niépce immediately sought to remedy the faintness of the heliographic image, acquiring new lenses from Chevalier, including William Wollaston's periscopic lens. To strengthen the image he proposed using a silver-coated copper plate rather than pewter as the base for the bitumen layer. Following exposure the plate would be held in contact with iodine fumes, which reacted with the bare metal, turning it dark. The bitumen could then be dissolved, leaving the plate reflective in the light areas, and blackened in the dark areas. This allowed for greater contrast and tonal range, as well as for a clearly positive image. He further sought to find a way to lighten those areas exposed to light.

On 14 December 1829, Niépce and Daguerre formally entered into business together. Their provisional agreement was for a ten-year partnership, the goal of which was for Daguerre to assist in perfecting Niépce's invention, both men sharing information freely with the other. As a result of the agreement Niépce drew up a "Note on Heliography," laying out the process for his partner. Daguerre procured new achromatic lenses for Niépce. While Daguerre traveled to Saint-Loup-de-Varennes on three recorded occasions, the bulk of the exchange between the two partners took the form of written correspondence, in which Niépce and Daguerre employed a numerical code to disguise the specific formulas and procedures under consideration, lest they be stolen before officially unveiled.

In 1832 the partners devised an essentially new process that they called the Physautotype (a neologism meaning, roughly, nature's self-image). Instead of bitumen this process used a whitish resin extracted from oil of lavender, which left a light coating affixed to the plate where it had been exposed to light, once it was developed in the vapors of white petroleum (Marignier, "Physautotype," 357–358). As with the improved Heliograph, no examples of the Physautotype appear to have survived, although both processes have been successfully recreated based on Niépce's notes (see Marignier, *Niépce)*. Another possible improvement, a heliographic picture on glass depicting a table prepared for a meal, no longer survives but was reproduced in 1891, in a form that suggests that it possessed considerable tonal gradation.

Niépce died suddenly in 1833, without having realized public success with his techniques. In1835, the partnership was renegotiated between Daguerre and Isidore, to the benefit of Daguerre, who assumed a dominant role in the enterprise, and again renegotiated in 1837 to give the name Daguerreotype to the now much advanced process (Batchen, 25). When the Daguerreotype was announced in 1839, although still within the original ten-year partnership term, emphasis was placed on the single-handed advancements made by Daguerre to salvage the ultimately impractical technique of Niépce. Defenders of Niépce, beginning with Isidore in 1840, have sought to solidify his position as the inventor of photography. In a historical irony, Daguerre's implicit claim to have invented the process that bore his name led to Niépce's first posthumous fame. Hearing of the Daguerreotype in 1839, Francis Bauer wrote a lengthy letter to the *Literary Gazette of London* declaring that Niépce had invented substantially the same technique some ten years previously. In response, a display was arranged at the Royal Society by Sir Charles Wheatstone (Smith, 49). Both William Henry Fox Talbot and Sir John Herschel saw Niépce's work in 1839, the latter declaring Niépce to be the obvious originator of Daguerre's technique, while crediting Daguerre with shortening the exposure time from several hours to as many minutes.

The dreams of both Nicéphore and his brother Claude to realize their fortunes through invention were never realized, and in the wake of Nicéphore's death in 1833 the family estate was sold to cover the many debts accrued

by the brothers. Isidore subsequently reaped the benefit of the partnership with Daguerre in the form of a share of the pension awarded by the French government. As for the reputation of Niépce, the efforts of Victor Fouque in the 1860s, Helmut Gernsheim in the 1950s, and Jean-Louis Marignier in the 1990s, have sought to account for Niépce's role in the history of photography and credit him for his innovations. Apart from debates concerning chronology, priority, and influence, the larger continuity of Niépce's heliographic work with cultural issues surrounding the early history of photography began to be explored by scholars in the 1990s.

STEPHEN PETERSEN

Biography

Joseph Nicéphore Niépce was born 7 March 1765, in Chalon-sur-Saône, in Burgundy, to a landowning family with ties to the Royal Court. The third of four children, he was educated for religious service but, at the time of the Revolution, conceived a career as a scientific inventor. He served in the National Guard from 1788–1792, and as a second lieutenant in the Revolutionary Army from 1792 to 1794. Recovering from health problems in Nice, he met and married Agnès Roméro in 1794. A son, Isidore, was born in 1795. The family returned to Chalon in 1801, where Nicéphore and his older brother Claude shared management of the family estate and worked together on a series of mechanical inventions, until Claude left in 1816. In relation to his work with lithography after 1813, Niépce began to investigate the use of light-sensitive materials for the production of images, including images formed in the camera obscura. Over the next decade he developed his process, called Heliography, but was unable to achieve public recognition. He joined in a business partnership with Louis-Jacques-Mandé Daguerre in 1829. Niépce died on 3 July 1833 in Saint-Loup de Varennes. In addition to the holdings at the University of Texas at Austin, important collections of heliographic studies are at the National Media Museum, Bath, and, with Niépce's pioneering camera equipment, at the Musée Nicéphore Niépce, Chalon-sur-Saône.

NIGHT PHOTOGRAPHY

The night, according to the French Academy's dictionary of 1858, is 'the length of time during which the sun is below our horizon.' Night is perceived as the opposite to day and daylight. It occupies a mythical space in many cultures and has been imaged through the centuries both negatively and positively. It can be unfathomable, threatening, sorrowful, sexual, modern, dreamlike or poetic. Rembrandt van Rijn's night prints and Francisco de Goya's twilight scene 'Los Caprichos' were precursors to the increasing interest in this subject to a nineteenth-century audience. Night scenes became very fashionable from the 1850s, documenting the social impact of the first gas and electric lights and immortalising the developing modernity of the city. Night and night-life captured the public imagination, spurred on by contemporary painters such as Edgar Degas, Toulouse Lautrec, Claude Monet and James McNeill Whistler.

Technically, photographing night was extremely difficult. It required a very long exposure time and therefore stillness, as well as light from the moon or an artificial source. An added complication was the urgency associated with making daguerreotypes (used from the 1840s to mid-1950s) and wet collodion negatives (used from the 1850s until the 1880s). These need to be developed straight after the image is made, and the complications for the nineteenth-century photographer being in the dark or depending on dangerous and volatile artificial light sources hindered the process.

As photography evolved, so did strategies and techniques for photographing at night. Wet collodion plate negatives must be kept moist from the time they were coated with collodion until they are developed. Exposure time was typically twenty seconds to five minutes and the plate usually dried out in ten minutes. To keep the collodion wet for longer and thus permit a longer

exposure, people experimented with adding substances such as water-absorbing zinc salts or honey. From the 1870s the invention of the highly sensitive dry plate or gelatino-bromide process reduced exposure times to 1/25 second, and soon after cameras became more portable. These advances made photographing at night much easier.

Since it was hard to take photographs in the dark, particularly with the early techniques, night effects could be achieved with photographs taken in daylight: daguerreotypes and calotype negatives produce a reversed background that could be interpreted as a night sky, black against the detailed foreground. Scenes apparently depicting the night were often taken in daylight, *The Illustrated Times* (10, 252, 1860) critiquing, for example, that 'Messrs Bissou's no.35 contains a most successful moonlight effect, though no doubt taken in sunlight.' Gustave le Gray photographed directly into the sun hidden behind clouds to obtain an artistic image that could be mistaken as night ('Brick au clair de lune,' 1856, Musée d'Orsay, Paris).

Night subjects suited many of the viewing devices that were developed. The Italian optician and photographer Carlo Ponti produced night scenes with his invention, the 'Megalethoscope,' a photographic viewer that allowed photographs, slid into the back of the device, to be viewed firstly by reflective light, and then by light from behind. 'Place St Marc avec l'eglise' (1875, George Eastman House) shows crowds in St Mark's square surrounded by illuminations. Areas on the back of the print have been embellished, and this colouring could only be seen when light shone through from the back of the print, echoing the effect of time as the image revolved from (black and white) day to—when backlit—colorful night.

Extra kudos could be earned by taking pictures at night rather than mocking darkness. One of the earliest known images of night (strictly twilight), possibly by Louis Daguerre, is captioned 'Le ponts en la galerie du Louvre, à 5.15. Soleil coucheant' (1839, National Media Museum, UK). It shows bridges along the Seine in Paris and is faint but detailed, suggesting that documentary images of night were possible, and sought after, from the beginnings of photography.

Providing documentary evidence with photographs was a significant advance in journalism, and relied on the problematic assumption that photographs always represent reality. One of the earliest reportage images was a daguerreotype of mills burning at night, taken by George N. Barnard in Oswego, New York, on 5 July 1853 (George Eastman House). The night sky is lit by huge flames, recording a dramatic moment with startling effect.

The night sky was also documented in a scientific way. Daguerre recorded an image of the moon around 1838, with others following suit. Lunar daguerreotypes of George Philips Bond and John Adams Whipple were shown at the 1851 Great Exhibition at Crystal Palace, London and were so popular that they went on tour in Europe. The subsequent wet-plate collodion prints by Warren De La Rue, along with Lewis Morris Rutherford's albumen print *The Moon, New York* (1865) continued to spark the interest in lunar photography. In 1889, Director of the Meudon Observatory, Jules Janssen, recommended that a photographic atlas of the moon be undertaken, insisting that photographs would give the most authentic results. Photographs were also used to document the movements of comets and stars in the sky, contributing to scientific evidence at the time.

Yet the subject of the moon was also used to evoke emotion or atmosphere. Ferrier and Soulier's stereoscopic photograph 'Pont Louis Philippe. Paris. Effet de lune' (1860) shows the night sky being investigated in the same way as John Constable's painterly explorations of the moody daytime sky. The aim could have been to capture a specific time and place, as well as to illuminate and fix the mysterious moon. Moonlight was a romantic symbol, favoured by schools of artists and movements such as Luminism, an American movement in the 1840s and 1850s. As industrialisation advanced in many cities and nature was revered, night landscapes either heightened the atmosphere of the modern city at night, or accentuated its dreamlike qualities.

Whilst artists were exploiting the night imagery in nature, darkness and photography was used to advance the spiritualism movement, popular from mid-century. Various techniques such as double exposures or composite printing were used to produce images of spirits in darkness. Spirit photography fuelled the fascination with the supernatural during this period.

In contrast to the darkness used to effect in spirit photography, many photographers took advantage of modern artificial light sources, such as electricity or magnesium-based inflammable powders. In the 1857 Birmingham photographic Society exhibition, an unknown photographer exhibited a photograph with the caption 'Portrait taken by Gaslight at Midnight. This is a great curiosity, being one of the few attempts made to obtain Portraits by artificial light. The observer will notice the singular effects of light and shade.' Dutch photographer Henry van der Weyde used artificial light and different lenses to take photographs at night. Much later, in Paris in the 1890s, Belliéni took artificial light out onto the night street. In the last two decades of the nineteenth century, artificial light became a key subject in photographs as well as an aid to photographers at night.

Artificial light played an important role in socio-documentary photographs. Jacob Riis used primitive flash photography techniques to document the New York

streets at night, publishing his photographs as books such as *How the Other Half Lives* (1890). At the turn of the century, Lewis W. Hine's photographs accentuated bad working conditions by concentrating on dark or artificially lit spaces. For him, natural light equalled good health and vice versa.

Lit up at night, the modern city became a fin-de-siècle fascination. The French photographer Louis-Gabriel Loppé was one of the first photographers to document cities at night, taking advantage of the dry plate process. He photographed London, Liverpool and Paris producing works such as 'Illuminations de la tour Eiffel la nuit' (c.1889, Musée d'Orsay). His work was influential: Brassai later reproached Andre Kertez for stealing Loppé's idea of photographing at night.

Paul Martin was also influential. Imaging the city in an artistic manner, his 'Piccadilly Circus at Night, London' (1896), for example, was part of the lantern-slide series 'London by Gaslight,' which won a Royal Photographic Society gold medal in 1896. The exposure time was around fifteen minutes and the camera lens was partly shielded from the lights of passing cars. Martin accentuated the gas lamps by tinting the prints in this series blue and yellow. Due in part to the interest in his work, a society of Night Photographers was founded in Britain. Photographers including Alfred Steiglitz, inspired by Martin, made works such as 'Night, New York' (1897), and continued working on night photography into the twentieth century.

A complex but popular subject, night photography in the nineteenth century broaches the gap between pictorialism and realism, scientific and imaginary scenes and, due to the technical difficulty in producing images of night, stood at the forefront of photographic advances of the nineteenth century.

NOACK, ALFRED (1833–1895)

German photographer

Augustus Alfred Noack was born in Dresden on 25th May 1833. The son of a doctor, he studied xylography, illustration and engraving at the Dresden Academy of Fine Arts with Hugo Burkner. In November 1856 he went to Rome where he was a member of the Deutschen Künstverein until April 1860. In the same year he moved to Genoa where he founded one of the most important Italian photographic factories in Vico del Filo. He devoted his activity to views of various tourist resorts in northern Italy but mainly views of Genoa and the Ligurian landscape. He also took photographs of works of art in the museums and churches of Genoa, but he became a very well-known photographer mainly through his landscapes, which were widely circulated by reviews and tourist guides and contributed to creating a typical image of the Ligurian region in accordance with the 19th century vision of pictorial tradition. In the 1880s,

Noack, Alfredo. Statue of a Little Girl.

using the instantaneous photographic process, Noack took important pictures of street life in Genoa, giving an idea of ancient crafts and social habits. He died in 1895 and his archive was taken over by Carlo Paganini. In 1926 his heir, Maria, sold the entire archive, with more than 4,000 negatives, to the City of Genoa, where it is now kept.

SILVIA PAOLI

NORMAND, ALFRED-NICOLAS (1822–1909)

French architect and photographer

Alfred-Nicolas Normand, architect, Prix de Rome scholar at the French Academy, arrived Rome 1846 and took up the calotype, usually signed 'A Normand' and dating from 1850–52. This small collection depicts views of Rome and Pompei, along with Palermo, Athens and Constantinople. His expert images, evocative and sensitive, redolent with the pathos of classical antiquity, surpassed the topographical and architectural study which became common in the commercial albumen period which mostly extinguished such private calotype photographers. The French artists on their Grand Tour to Rome were to form one of the first significant groups of calotypists in Italy, subsequently described as *La Scuola Romana di Fotografia* although there is no evidence of a group as such. Along with the other artists from Northern Europe and America they frequented the social life in Rome centred around the Caffè Greco. The French 'group' included Jean-François-Charles André (1813–83), known as Count Frédéric Flachéron, sculptor, lived Rome 1839–67; Eugène Constant, painter, lived Rome 1848–55, probably the first in Rome to use the new albumen on glass; and Prince Giron des Anglonnes, a contemporary of Normand, also working 1850–52. Normand also became known for his architectural drawings and studies which continue to be sold today in the poster market. He remained a member of the Academy des Beaux-Arts in Paris until 1890, although little would appear to be known of his life.

ALISTAIR CRAWFORD

NORWAY

Through the year of 1839 the publisher Hans Thøger Winther (1786–1851) kept the Norwegian public informed about what was happening in France. In October of 1840 the first daguerreotype was exhibited in Bergen and at the beginning of 1841 another was shown at an exhibition arranged by the Art Society in the capital Christiania (now Oslo). Winther was himself experimenting with fixing images and in 1842 he published his first photographs as lithograph reproductions "from life." Three years later he published an extensive handbook explaining the direct positive process, the negative/positive process and a method for conversion of positives into negatives and vice versa. People could also buy cameras made of wood or cardboard, built after his instructions; his work inspired a growing group of photographers in Norway.

Norway was a rural society with a small population mainly living from agriculture and fishing. There were no really big cities and only a few industrial settlements in the beginning of the 19th century. At the same time, a growing national awareness based on new political circumstances, was making room for new activity, such as building universities, industrialization, railroads, a growing media and political parties. The artistic community formed an important part of this project. So did the growing population of photographers: from 80 active photographers in 1855–60 to about 700 in the national census of 1900 (Erlandsen 2000, 175). It is an interesting fact that the new technique developed side by side with the growing society. We can very much read what was considered important by what was photographed and how the images were used. First and foremost, the community of photographers catered to the demands of the growing middle class for portraits. But they also both documented society as it developed, contributed to new fields and helped give Norwegians images to understand and develop a culture and an identity.

One of the most important early participants in the field of photography in Norway was the Danish pharmacist Marcus Selmer (1818–1900). He came to Bergen in 1852 and established a portrait-studio were he made daguerreotypes and photographs in other techniques. He soon started on a big project: photographing people in local costumes and landscapes from different parts of the country. The images were offered to the popular illustrated press and tourists—both growing industries. The probably first news photography can also be attributed to Selmer: a photograph of the remains of a house burnt down in January 1863 and advertised for sale two weeks later.

Knud Knudsen (1832–1915) probably learnt to photograph from Selmer whom he worked for for many years before he started his own studio in Bergen in 1864. He was the first to systematically photograph the whole of Norway: from Kristiansand to the North Cape. He also documented a rapidly vanishing rural culture. Knudsen made all together 9,000 images before 1898, when he retired and left his business to a relative. No doubt earlier painters and their choice of places to go influenced him, but he expanded the repertoire and that way also peoples knowledge of the country.

The Swedish photographer Axel Lindahl (1832–1906) was engaged by the publisher Richard Andvord in 1882 to photograph Norway. He travelled all through

the country and completed an archive of about 3,000 images, very much the same way Knudsen did. His perhaps most important and innovative images are those of glaciers and winter landscapes from Svalbard. Two series of pictures were published in 1892 and 1897, apart from an extensive use of the archive for illustrations and sale of mass-produced images for tourist-albums. Many more produced landscapes and cityscapes towards the end of the century: Per Adolf Thorén (1830–1909), Ole Tobias Olsen (1830–1924) and the brothers Thorvald Aron (1871–1896) and August Brunskow (1862–1906) worked as a team.

It is an interesting fact that quite a lot of women worked as photographers in Norway from the end of the 1880s and onward. There are several explanations for this. First, the improved technique at this time was easier and fast to learn, it was not very expensive to establish a photographic business, and a law was passed in 1866 that allowed women to have a trade. The large surplus of unmarried women made it necessary to find acceptable occupations. Not all could be teachers or servants, look after their old parents or be looked after by relatives. There was also the belief that women were more suited because of a special artistic understanding. They produced mostly portraiture, but also landscape postcards. It seems, though, that they did not usually travel as extensively as their male counterparts mentioned above, and if their landscapes are different, it is because children often are found playing in the streets or on the beaches. The images have no romantic meaning as defined earlier in the century. They are merely a realistic documentation of small villages and peaceful scenery in places that were popular to visit in the summer. Marie Høeg (1865–1949) and Bolette Berg (1871–1944) in Horten; Louise Abel (1841–1907) in Christiania; Augusta Charlotte Solberg (1856–1922) in Lillehammer; Louise Wold (1869–) in Holmestrand; Hulda Marie Bentzen (1858–1930) and Agnes Nyblin (1869–1945) both in Bergen, are only a few worthy of notice. Nyblin developed the firm, when her husband died in 1893, into one of the most influential in Bergen. From 1897 she also worked as a police photographer.

Towards the end of the century the photographic community started organizing to protect their trade. In 1877 the first copyright-law was passed, and in 1882 the first attempt to organize Norwegian photographers was made: Det fotografiske Selskab i Christiania (The Photographic Society in Christiania). The inspiration came from Denmark and it was started for the purpose of promoting interest and knowledge about photography through meetings, discussions and research. Both professional and amateur photographers were welcome. There was also a plan to buy photographs from well-known foreign photographers and arrange exhibitions that could inspire local photographers. One of the leading portrait-photographers, Ludwig Szacinski (1844–94) was chosen chairman, but the association did not last for long.

In 1894 there was a new attempt made and the initiator, portrait photographer Christian Gihbson (1857–1902) was chosen chairman this time. It is clear that at this time Amateurs were seen as a threat. Everyone who "… used photography as a main source of income" could join (Erlandsen 2000, 189). The most important issue at the end of the century was weather photography was art or handicraft. This was important in terms of group identification and education. In 1899 a committee was appointed to elucidate the problem and two years later they concluded that photography should be part of the Union for industry and handicraft.

NOTES AND QUERIES

Notes and Queries commenced as a weekly publication in November 1849, selling at 4d and 5d stamped. It was edited by William John Thoms, a Fellow of the Society of Antiquaries and former contributor to the *Athenaeum*. The purpose of the journal was to provide a cheap and frequent means for the interchange of information in the form of notes between "the artist, the man of science, the historian, the herald, and the genealogist." Aimed at a learned general audience, the principal concern of *Notes and Queries* was the solution of questions concerning genealogy, literary quotations, proverbs, folklore and archaeology. The scope of the periodical was also perfectly suited to appeal to the educated and eclectic gentlemen amateurs who dominated early British photography.

Thoms was a keen amateur photographer with a particular interest in architectural photography. A member of the Photographic Exchange Club, his photographs included pictures of Herne's Oak and of Pevesney Castle. Consequently, for the first five years of its existence, *Notes and Queries* was an important forum for discussions upon the refinement of the various photographic processes. Before the Photographic Society of London and the numerous local photographic societies established themselves, it provided a means for enthusiasts to exchange and disseminate new technical advances. Almost two hundred entries on photography are listed in the index to the first twelve volumes. In its edition of November 4, 1854, the *Athenaeum* noted that "Our contemporary, *Notes and Queries*, seems to be making itself the special organ of photographic discussion and intelligence." Similarly, Thoms himself described the success of the journal in furthering the cause of photography:

> The shadow of a doubt that we once felt as to the propriety of introducing the subject of Photography into our columns, has been entirely removed by the many expressions of satisfaction at our having done so which have reached us. . . (9 October 1852, 347)

The photographic coverage of *Notes and Queries* began in September 1852. Thoms asked his friend and fellow antiquary Hugh Welch Diamond to contribute a series of letters on the archaeological benefits of using photography to record old monuments and buildings. Diamond would later be a founder member of the Photographic Society of London and a future editor of the *Photographic Journal*. Many other notable amateur practitioners contributed to the journal during the early 1850s. These included Philip Henry Delamotte, Frederick Scott Archer, Edmund Kater, Sir William Newton, and George Shadbolt, founding member of the Photographic Society of London and future editor of the *Liverpool and Manchester Photographic Journal*.

The issues raised in *Notes and Queries* were primarily of a scientific nature. Diamond and Delamotte both published details of the different experiments they used for taking collodion photographs. The pages of *Notes and Queries* are thus a valuable guide to the difficulties experienced by early photographers, and their ingenious attempts to solve the problems they faced. However, the advent of specialist photographic journals, along with the establishment of the collodion process, meant that the number of entries on photography declined substantially after 1855.

NOTMAN, WILLIAM & SONS (1856–1935)

Canadian photographers

In December 1856, William Notman, fleeing arrest in Scotland, opened a photography studio in Montreal. Daguerreotypist Thomas Coffin Doane, in business from 1848, had offered to sell his operation but Notman established a new firm producing ambrotypes, tintypes, and albumen prints. By his death in 1891, Notman had built the most successful nineteenth-century photography enterprise in North America. At its peak in 1874, the Montreal studio alone, with a staff of thirty-seven men and eighteen women, produced fourteen thousand photographs. Notman's specialty was portraiture. Montreal citizens and distinguished visitors, from Sitting Bull to the Prince of Wales, were portrayed in Notman's elegant house style. Notman's was also popular for complex composite photographs, studio tableaux of hunting and sporting scenes, especially in winter, and Canadian landscape views.

An accomplished photographer and skilled businessman, Notman sought out opportunities to position his work prominently in Canada and the United States. His first major commission in 1858 was to document an engineering feat: the construction of the Victoria Bridge at Montreal, a two-mile long tubular steel railway span, the longest in the world. In honour of a visit by the Prince of Wales to inaugurate the Victoria Bridge in 1860, Notman produced the Maple Box Portfolio, a presentation album featuring five hundred photographs and stereographs of Canadian views and bridge construction. Two editions were made: one for Windsor Castle, one for the studio. After the royal family accepted the gift, Notman claimed the title Photographer to the Queen, although there is no documentation that the honour was officially bestowed.

In 1868, Notman opened his first branch studios, in Ottawa and Toronto followed by branches in Halifax and St. John, New Brunswick. While Montreal remained

the base of operations, Notman also pursued opportunities in the United States starting in 1869 with college photographs for Vassar, Harvard, Yale, Princeton, and others. These were printed and compiled into albums in Montreal. In 1875, new postal regulations governing exports to the United States jeopardized the college trade and so in 1877, Notman began opening American branches under the name of the Notman Photographic Company. Permanent studios in Boston, Albany, Newport, and Cambridge were complemented by seasonal studios operated in small college and resort towns for a total of twenty-four branches in North America. In 1876, Notman established the Centennial Photographic Company in Philadelphia to secure exclusive photography rights for the United States Centennial World Fair. Notman's Montreal studio also entered the photographic competition at the fair. One of the judges, German photographer Hermann Vogel, commending the quality of North American photography practices, wrote that "ahead of all stands Notman."

Notman shared his expertise in letters, articles, and photographs with the *Philadelphia Photographer* edited by Edward Wilson. In 1867, for example, he introduced the cabinet portrait format to North America with an article and a sample tipped into the January edition. Another Notman innovation was the first photo-identity card, called a photographic ticket, produced at the Centennial Photographic Company to regulate entry for exhibitors, press, and employees of the 1876 World Fair. Notman studio photographs were also distinguished in the United States as the first to be used in advertising. Travelers Insurance, pioneering the illustrated hanging calendar, commissioned Notman to make composites of the Union and Confederate Commanders for their 1883 calendar, followed by composites of Famous American Authors, Eminent Women, and Famous Editors.

Notman relied on his brothers, John Sloan (1830–1879) and James (1849–1932), other young men he had trained as photographers, and his sons William McFarlane (1857–1913), George (1861–1921), and Charles (1870–1955) to manage studios as he expanded operations. Although women held a variety of positions at Notman's and numbered up to thirty percent of employees, none were photographers. William McFarlane began in 1873 as an apprentice and by 1882 became a partner in the firm. He specialized in view photography and is best known for work done for the Canadian Pacific Railway between 1884 and 1909, photographing landscape along the transcontinental line between Montreal and Calgary and into the Rocky Mountains, and First Nations people in the western provinces and territories. He also photographed extensively in Nova Scotia, Newfoundland, and Quebec.

George apprenticed in Montreal in 1884 and represented Notman's in London at the 1887 Golden Jubilee. In 1890, he moved to Boston and in 1893 left the family firm to establish his own studio in New York followed by one in Boston. In 1900, he returned to Montreal but left the photography industry.

Charles apprenticed in Boston in 1888. He returned to the Montreal studio following his father's death in 1891 and established a reputation for portraiture. In 1894, Charles joined William McFarlane as a partner in William Notman and Sons. On William McFarlane's death in 1913, Charles became sole proprietor. Upon his retirement in 1935, the studio's artifacts were sold to Associated Screen News. These included four hundred thousand prints compiled in two hundred day books from 1860 to 1935, two hundred thousand negatives, employee wages books documenting names, salaries, and employment dates of four hindred employees from 1864 to 1917, and an alphabetical index to the day books. In 1955, benefactors donated these materials to the McCord Museum of Canadian History at McGill University in Montreal where the Notman Photographic Archives, housing the most extensive collection of a single nineteenth-century photography studio in the world, now resides.

COLLEEN SKIDMORE

Biography

William Notman was born in Paisley, Scotland on 8 March 1826. He was the eldest of seven children of Janet Sloan and William Notman Sr. a manufacturer of women's shawls who in 1840 established a dry goods business in Glasgow. Notman received a classical education that included drawing and painting. As a young adult he entered the family business and learned photography although the details of his training are unknown. In 1853, Notman married Alice Woodwark of Gloucestershire, England. Three sons and five daughters were born between 1856 and 1870. In May 1856, Notman fled to Montreal to avoid arrest for illegal business practices undertaken to avert bankruptcy of the Notman firm. His wife and infant daughter joined him three months later. His parents, three brothers, and one of his three sisters followed in 1859. William Notman died of pneumonia in Montreal on 25 November 1891.

NUDES

In E. M. Forster's novel, *A Room with a View* (1908), Lucy Honeychurch expressed her rebelliousness by buying a photograph of Botticelli's *Birth of Venus*—this in defiance of her chaperone's warning that "Venus, being a pity, spoiled the picture, otherwise so charming." Almost contemporaneously, in 1910, seven-year-old Kenneth Clark was "expounding" his favourite pictures to his Victorian grandmother. "Unfortunately," he recalled in his autobiography, "I began with Giorgione's *Concert Champêtre*. We were sitting on a sofa near the window and I turned to the page in triumph. 'Oh dear, it's very nude' said my grandmother, and rose from the sofa in confusion."

These episodes show that the nude was an uncomfortable subject in the Victorian and Edwardian periods. In addition, they draw attention to the tension that existed between the aesthetic and erotic aspects of such subjects. In the case of photography, this tension was exacerbated by the realism of the medium, a realism that made it difficult for the viewer to be "diverted ('sublimated') in the direction of art"—as Freud put it in his *Three Essays on the Theory of Sexuality* (1901). Susan Waller (2003) highlighted the problematic nature of photography when she observed that during the Third Republic of France photographic reproductions of paintings of nudes that had been publicly displayed in the Louvre or in the Salon could not be displayed in shop windows, even when the government censorship authority had approved their sale.

Freud's assertion that sexual curiosity might be "sublimated" to become, at least in part, an aesthetic appreciation of the body has proved contentious. "If the nude is so treated that it raises in the spectator ideas or desires appropriate to the material subject, it is false art, and bad morals," wrote philosopher Samuel Alexander in *Beauty and Other Forms of Value* (1933). Kenneth Clark, on the other hand, maintained in *The Nude* (1956): "No nude, however abstract, should fail to arouse in the spectator some vestige of erotic feeling … and if it does not do so, it is bad art and false morals. The desire to grasp and be united with another human body is so fundamental a part of our nature, that our judgment of what is known as 'pure form' is inevitably influenced by it; and one of the difficulties of the nude as a subject for art is that these instincts cannot lie hidden." More recently, Camille Paglia in her highly influential book *Sexual Personae* (1990) insisted on the fundamentally sexual nature of the nude in art; at the other end of the spectrum is Maxim Du Camp's 1863 observation that "art should have no more sex than mathematics." In fact, photographs of the nude may be situated at all points in a spectrum ranging from the chaste to the obscene. Moreover, the character of the photograph may change, depending on the nature of the consumer and whether he was an artist, medical student, scopophiliac or voyeur.

Drawing from the nude model was central to the training and practice of artists in the early modern period and remained so in academic art curricula in Europe and North America throughout the nineteenth century. This being the case, it is not surprising that photographers worked from the nude and produced studies from the

nude to be used by artists. In France Eugène Durieu produced nude studies in the 1850s working in collaboration with Eugène Delacroix. During the Second Empire, photographers made large numbers of academic studies of nude models (*académies*) for the instruction of artists. By contrast, Edgar Degas, and Pierre Bonnard**,** at the end of the century, took intimate nude studies of their own companions and models.

In Edinburgh in the 1840s, David Octavius Hill and Robert Adamson produced a remarkable half-length nude study of Dr George Bell holding a studio pose. In England Oscar Gustav Rejlander**'s** combination print *The Two Ways of Life* (1857) contained several nude women, some of whom are shown in flagrantly erotic poses. Although Queen Victoria and Prince Albert purchased a copy of this photographic allegory, it generated considerable controversy at the time. When it was exhibited in Edinburgh, for instance, the nude figures were hidden behind a curtain. In the Victorian period artists' models were presumed to be loose women, and in this instance the suspicion was heightened by the fact that Rejlander had used vaudeville artists as his models. Viewers were also offended by the mistaken assumption that male and female models had been posed together in Rejlander's studio. Rejlaender also made numerous photographs of individual nudes for the use of artists. Almost thirty of these glass negatives are preserved in the National Museum of Photography, Film and Television in Bradford; a portfolio containing nine of these studies was published when the plates were still in collection of the Royal Photographic Society.

Among nineteenth-century American painters, Thomas Eakins made extensive use of photographic nude studies, often posing his students to echo ancient sculpture. Photographs of his male students bathing, used for the painting *Swimming* (1885), are in the tradition of Michelangelo's figure studies for his unrealised mural *The Battle of Cascina*. The homoerotic nature of Michelangelo's male figures was also continued by Eakins's photographs, as was the case with photographs of nude young men taken contemporaneously by Fred Holland Day in Boston and by Wilhelm Von Gloeden at Taormina in Sicily. Von Gloeden combined Mediterranean subjects and subject matter with suggestions of Hellenic love, whereas Day invested his Christian subjects with melancholic eroticism.

Apart the production of artists' studies, there was a huge industry in France devoted to the production of commercial images of erotic, sexually explicit, and obscene photographs of nude models (McCauley 1994). The line between the artistic and the explicit or indecent was often blurred, and could depend to some extent upon the nature of the viewer. Freud provided useful retrospective guidance in this respect when he characterised the "normal" viewer as someone whose interest [could] be shifted away from the genitals on to the shape of the body as a whole." Photographs that focused exclusively upon the primary or secondary sexual characteristics of the nude were often produced as microphotographs and as stereo images; the latter had the particular attraction for the voyeur of enhancing the realistic and tactile qualities of the models. File BB3, preserved in archives of the Préfecture de Police in Paris, contains numerous obscene photographs of nudes and of individuals engaged in sexual acts; this file was compiled during the Second Empire to assist in the identification, classification and punishment of individuals involved in the illegal production of erotic images (Pellerin 2000).

Photographs of naked men and women were also taken for scientific or pseudo-scientific purposes to assist in the recording and classification of information. The accuracy and taxonomic value of photography was exploited in fields ranging from medicine to anthropology and ethnology and even to criminology. In the United States Joseph T. Zealy produced in 1850 a series of fifteen daguerreotypes of first- and second-generation African slaves on a plantation near Columbia, South Carolina. These plates, preserved in the Peabody Museum, were made for the Harvard professor Louis Agassiz to support his research into comparative anatomy and body typing (Phillips 1997). It is significant that the subjects were stripped of their clothing in order to have their bodies recorded for study and classification. This troubling aspect of the plates distinguishes them from photographs of ethnographic subjects, for whom nudity was their natural state. The non-consensual nature of the Peabody plates is a common feature of scientific studies of the nude body. It is noteworthy that Freud linked the concealment of the body to civilization, observing that "The progressive concealment of the body which goes along with civilization keeps sexual curiosity awake." In short, photographing a subject nude was itself a code indicating that the individual belonged to a "lower" or "other" form, one that was separate from normal society by illness, race or behaviour; nudity objectified the "other," whether the figure was an indigenous African, a hysteric, or a criminal convicted of indecent acts.

An especially troubling category of nude photography in the nineteenth century is that concerning child subjects. Middle-class Victorians idealised children, especially female children, as creatures untainted by society, but this romantic view coexisted with the realities of incest and child prostitution, evils that affected the middle classes as well as the poor. Charles Lutwidge Dodgson commented specifically on the naturalness and beauty of the nude female child. Moreover, he famously photographed some of his little girl friends nude. Very few of these photographs survive, and those that do have been coloured (clothed in watercolour, so to speak). Julia

Margaret Cameron also photographed nude children, often "clothing" them as allegories or presenting them as Christian subjects. Had Cameron not been female, her photographs would have caused as much concern among historians as Carroll's. Oscar Rejlander also photographed nude children, employing them to personify Painting and Photography, for instance, and having them echo *putti* in Renaissance paintings such as Raphael's renowned *Sistine Madonna*. It is exceedingly difficult for us in the twenty-first century to view such images without being affected by contemporary concerns regarding paedophilia and child pornography, and it must also have been difficult to do so in the Victorian period. Regardless of whether children are asexual or have sexuality instincts latent in them from an early age (as Freud believed), in a post-Freudian society photographs of nude children exude a disturbing eroticism.

Finally, it is useful to distinguish between the completely and the partially nude figure and to consider what effect the presence of some clothing has on the erotic nature of the image. Freud's emphasis upon the erotic nature of the partly veiled body was echoed not long ago by the French theoretician Roland Barthes. "Is not the most erotic portion of a body *where the garment gapes*?" he asked in *The Pleasure of the Text* (1975). "It is intermittence … which is erotic," he continued, "the intermittence of skin flashing between two articles of clothing." Conversely, the philosopher and legal scholar Thomas Nagel (2002) has argued that concealment and decorum are inseparable and that the exercise of restraint, especially with regard to clothing, is essential to civilized interaction among men and women.

NUTTING, WALLACE (1861–1941)

Nutting was born in Rockbottom, Maine, and raised on his uncle's farm by his widowed mother. After quitting school his mother encouraged him to become a minister. Nutting married a widow called Mariet Griswold Caswell during his theological training and was a Congregational Minister until the age of forty-three, when he retired due to Neurasthenia. Not content to just write and travel, he produced antique reproductions of American furniture and took up photography. In his lifetime he produced over a million hand-tinted platinum prints of an idealised country life and its buildings' interiors. Nutting was so successful at one point, that he was employing over a hundred people to assist him in his work. His three volume *Furniture Treasury* was a guide to American antiques, which firmly established the business of antiques within America. The guide was illustrated with more than five thousand photographs of early American furniture, mostly taken by Nutting himself. He produced a series of guide books dedicated to his extensive travels. These books depicted scenes of beauty from both Great Britain and America; for example, *England Beautiful*. He also published, in1924, a book called *Photographic Secrets*. Aside from his books, Nutting established five profit making museums in which to house his photographs and examples of American furniture. Nutting's photographic influence upon America was displayed in magazines such as Country Life, whereby in 1902 a collection of Nutting and Stieglitz's photographs were published together.

JO HALLINGTON

O

O'SULLIVAN, TIMOTHY HENRY (1840–1882)

American photographer, probably born Ireland

While little evidence survives regarding the personal life of photographer Timothy H. O'Sullivan, his photographic legacy is extensive. O'Sullivan was a major figure in two areas of early American photography: the documentation of the Civil War and the survey photography of the American West.

From the outset, O'Sullivan's personal life presents more questions than answers. He was born in 1840, probably in Ireland, to parents Jeremiah and Ann O'Sullivan. His family moved to the United States in 1842, as part of the massive wave of immigrants who fled the severe potato famine in Ireland. His birthplace has been mistakenly reported as New York City, because O'Sullivan himself made this claim on a questionnaire when applying for work at the U.S. Treasury Department, but O'Sullivan biographers have determined this to be incorrect.

By the age of 18, O'Sullivan had begun working in Mathew Brady's photographic studio in Washington D.C., which was being managed by Alexander Gardner. The studio, like most in photography's early years, was dedicated to making portraits, but with the onset of the Civil War, Brady turned his attention to the pursuit of field photography. By 1861, Gardner and O'Sullivan both belonged to Brady's "Photographic Corps" which became known for its war views. Late in 1862 Gardner had had a falling out with Brady and left to begin a photographic business of his own. O'Sullivan continued with Brady for a short time longer, but it is thought that when Gardner opened his own studio in Washington in May of 1863, O'Sullivan joined Gardner. O'Sullivan's work for Gardner included copying maps for the Union Army's strategic use, as well as making a variety of views of the war including individual and group portraits of military members and civilians engaged in the war, views of camps, forts, bridges, railroads, buildings, earthworks, towns, fields and plantations, and of changes wrought by the war.

These photographs were published in *Catalogue of Photographic Incidents of the War from the Gallery of Alexander Gardner, Photographer to the Army of the Potomac,* 1863 and *Gardner's Photographic Sketch Book of the War,* 1865/1866. Some of O'Sullivan's most memorable photographs were of the battlefield dead. Perhaps his most famous, *A Harvest of Death,* made at Gettysburg in 1863 and published in *Gardner's Photographic Sketch Book of the War,* shows a field littered with bloated Union corpses. A mounted soldier and the distant hills blur out of focus in the background. Instead of using a standard eye-level viewpoint, O'Sullivan has placed his camera close to the ground, bringing the viewer nearer to the dead men. This low vantage point also causes the battlefield to appear to rake steeply upward, filling more of the picture plane. Rather than aggrandize the heroics of war, O'Sullivan forces the viewer to confront the reality of the war's casualties. Including this powerful image, O'Sullivan made a total of forty-four negatives of the 100 published in *Gardner's Photographic Sketch Book of the War*, most of them landscape views of architecture including forts, bridges, railroad stations, churches, homes and tents employed by the army during the war.

Beginning with his field photography during the civil war, and continuing into his survey photography, Timothy O'Sullivan made glass plate collodion negatives. This method, also known as wet-plate because of the process of coating the glass with wet collodion just prior to exposure in the camera, was particularly difficult when employed in the field. The coating process (as well as the need to develop the negative immediately after

exposure) required field photographers to travel with portable darkrooms, or dark tents. In order to make large photographic prints, large glass negatives were needed, and traveling across the countryside by wagon with chemicals, large wooden cameras, and many sheets of glass made the process of photography quite burdensome by today's standards.

Throughout his career, in addition to single views, O'Sullivan made stereographic views of his war and survey subjects. These stereographs, which were collected widely in Victorian America, display two nearly identical images side-by-side, mounted on a small card.

Designed to imitate human binocular vision, they are best seen in a special viewer, called a stereoscope, which blocks out peripheral vision and creates the illusion of a three-dimensional image. Since these images are created with a special camera featuring two lenses separated by the same distance as human eyes, O'Sullivan had to travel with even more photographic equipment in order to make stereographic views.

In 1867, O'Sullivan was appointed to the Geological Explorations of the Fortieth Parallel by Clarence King, the United States Geologist in Charge. The survey had two explicit concerns: to study the natural resources along the Union and Central Pacific Railroads, and to document the geology of a section of the West one hundred miles wide from the Sierra Nevada Mountains to the Rocky Mountains. Unstated, but implicit in the goals of the survey, was that this research would help to promote the future development of the region by white settlers. This meant identifying possibilities for economic development, recording the local flora and fauna, evaluating the opportunities for mining, and assessing Indian hostilities. For King, as a geologist, this survey was also an important opportunity to produce not just a geological section, but a geological history, which would support his fervent belief in the concept of Catastrophism. This theory asserted that geological features of the earth's surface were created by a series of catastrophic and violent events, such as floods and earthquakes, rather than by slow evolution. King intended for O'Sullivan's geological photographs to illustrate his survey report, and therefore to visually demonstrate Catastrophism.

O'Sullivan had his photographic supplies shipped ahead, and then traveled to San Francisco by way of the Isthmus of Panama. Once there the party gathered in Sacramento, California, and set out on July 3, 1867. The going was arduous—King's men endured steep, snowy mountain passes, hot desert basins, and rough rivers. Most of the men caught malaria, O'Sullivan being one of the few to avoid it. While little has come down to us in O'Sullivan's own words, one of the rare written records of a survey expedition is a story that was published in *Harper's New Monthly Magazine* in September 1869. The article, entitled "Photographs From the High Rockies," does not mention O'Sullivan by name, but scholars believe the story relates his exploits on King's survey. In one colorful episode the article recounts how the photographer's boat became lodged against some rocks while descending the Truckee River, which flows from Lake Tahoe in California to Pyramid Lake in Nevada. Concerned that the boat would be dashed to pieces by debris crashing along in the rough water, O'Sullivan stripped off his clothes and dove into the raging river. From the shore, he maneuvered ropes to free the boat and brought it to safety. This story suggests the danger and adventure that were an inherent part of exploring and photographing the rugged Western country for members of the nineteenth-century survey expeditions like King's.

The first season, in 1867, O'Sullivan photographed in Western Nevada and made his now-famous and otherworldly image of the tufa domes in Pyramid Lake. The King party spent that winter in Virginia City and Carson City, Nevada, and in the former O'Sullivan made photographs of the gold and silver mines, several hundred feet under ground. Not only were conditions unbearably hot, with temperatures reaching more than 130 degrees Fahrenheit, but the darkness of the mine shafts required O'Sullivan to use a magnesium flare to make his exposures. Despite these difficult circumstances, he produced many photographs of miners and the interior of the mines. In 1868, O'Sullivan continued to work in Western Nevada, and also photographed Mono Lake, California, and the Snake River and Shoshone Falls in southern Idaho. O'Sullivan returned to Washington D.C. in the winter of 1868-9 to print his first survey photographs, which were used internally but not published. In fact, throughout his career as an expedition photographer, O'Sullivan never printed in the field. He made negatives as he traveled, and only saw his results later, when he printed back in the East. Also upon his return to Washington D.C. in 1868, O'Sullivan began his courtship of Laura Virginia Pywell, whom he would later marry. By May of 1869 he was back in the West, on his third survey season with Clarence King, photographing the mountains near Salt Lake City, as well as northern Utah, and southern Wyoming.

In January of 1870, during a lull in the surveying while King waited to see if future appropriations would be forthcoming, O'Sullivan photographed on the Atlantic side of the present-day Isthmus of Panama (then the Isthmus of Darien, in the State of Panama in Colombia). This position with a Navy Department survey, whose mandate was to identify a canal route, yielded photographs of the ship and crew, along with some views of native Indian villages, coastline and architecture. The region's dense foliage and the high humidity, however, prevented the topographical views that were the survey's goal. After

The J. Paul Getty Museum, Los Angeles

seven months, O'Sullivan returned to the United States and was replaced by the Navy with photographer John Moran. The change in personnel has caused confusion in attributing the Panama photographs, resulting in many Moran photographs being credited to O'Sullivan.

Lieutenant George Montague Wheeler hired O'Sullivan in September of 1870 to join his survey of the American Southwest, with permission from King, who maintained O'Sullivan on his payroll. Wheeler's expeditions were different from King's in several ways: Wheeler's survey was the only military expedition of the four major expeditions to be conducted in the West, and unlike King, Wheeler appreciated the value of photographs in the promotion of the survey itself. The survey's goals were similar to King's: to prepare accurate maps, document the physical features of the land, find sites for roads and military operations, assess the population and disposition of the resident Indian peoples, and evaluate the geology and vegetation as to their usefulness to settlers.

In May of 1871, O'Sullivan set out from Halleck Station, Nevada with Wheeler's crew, but because he had more seniority in Western surveys than the other explorers, O'Sullivan was often entrusted to head up side trips apart from Wheeler. Lieut. Wheeler led even more arduous expeditions than O'Sullivan had experienced with King. In their first season the survey team endured tremendous heat crossing Death Valley, and Wheeler often forced extended marches that lasted more than a day. The most challenging part of the trip involved traveling more than 200 miles up the Colorado River to the Grand Canyon. The party was divided into three boats: one headed by Wheeler, another by O'Sullivan and a third by Grove Karl Gilbert, the geologist on the expedition. The difficult journey took more than 30 days in all, and in the process Wheeler's boat was destroyed, along with many of his survey notes. Despite the physical challenge of the ascent, O'Sullivan was able to make photographs of the river canyon and of the crew, including the Mohave Indians who accompanied the survey

team. This first season with Wheeler also included an exploration of the mining districts in Nevada, and a period photographing in Northern Arizona. At the end of the survey season, O'Sullivan returned to Washington D.C. to print the season's work.

During the 1872 season, O'Sullivan returned to work with Clarence King photographing in Nevada, Utah, Wyoming and Colorado, but by 1873 was back with Wheeler. The intervening winter allowed O'Sullivan to print two sets of King survey photographs which were sent to the 1873 World's Fair in Vienna, along with other printing for both the King and Wheeler expeditions. On 11 February 1873, while in Washington D.C., O'Sullivan married his longtime sweetheart Laura Virginia Pywell. That year he spent the season in Arizona and New Mexico, making images of the Grand Canyon, and taking perhaps his most famous survey photograph, an image of the White House Ruins in Canyon de Chelly. The Indians settled near Santa Fe and in Arizona also became a primary subject that season. The winter of 1873–4 was again spent in Washington D.C. printing for both King and Wheeler, and in May O'Sullivan began producing official sets of images from Wheeler's survey, which were comprised of both large format and stereographic views. In July of 1874 O'Sullivan embarked on what would be his last season of photography in the West. He began in New Mexico and Colorado photographing Indians and the countryside for Wheeler, and then took a solo trip to a site he had photographed many years before: Shoshone Falls in Idaho. These would be O'Sullivan's last photographs in the West.

Once again the winter found O'Sullivan printing in Washington D.C. but this time that work continued through the middle of 1876. After that little is known about O'Sullivan's work; in 1878 he appears in the Washington D.C. directory as the partner of another photographer, William J. Armstrong, but it seems that venture did not last long. He was on the payroll at the United States Geological Service under King temporarily in 1880, and was the photographer to the U.S. Department of the Treasury from November 1880 to March of 1881, but retired with tuberculosis of the lungs. In September of 1881, O'Sullivan returned to his parents' home in Staten Island, too ill to take care of himself. On 18 October 1881, O'Sullivan's wife died of tuberculosis in Washington, D.C. and he traveled to attend her funeral there, returning to Staten Island. On 14 January 1882, Timothy H. O'Sullivan died on Staten Island, also from tuberculosis, at the age of 42.

REBECCA A. SENF

Biography

Timothy H. O'Sullivan was born in 1840, probably in Ireland, to Jeremiah and Ann O'Sullivan. His family emigrated to the United States in 1842. In 1861 and 1862 O'Sullivan photographed the Civil War for Mathew Brady, but spent the rest of the war working for Alexander Gardner. His war photographs were published in *Photographic Incidents of the War from the Gallery of Alexander Gardner, Photographer to the Army of the Potomac* and Gardner's *Photographic Sketch Book of the War,* 1865/1866. In 1867 he was appointed to Clarence King's Geological Explorations of the Fortieth Parallel and photographed for King in 1867-1869 and again in 1872 in California, Nevada, Utah, Wyoming, Colorado, and Idaho. O'Sullivan spent six months of 1870 with the Darien Expedition, photographing in present-day Panama, but the wet weather and heavy foliage hampered much successful work. That same year he was hired by Lieutenant George Wheeler to participate in his explorations, eventually known as the United States Geographical Surveys West of the One Hundredth Meridian. Between 1871 and 1874, O'Sullivan spent three seasons photographing for Wheeler in California, Nevada, Arizona, Colorado, Utah, and New Mexico. During his time with the western surveys, most winters were spent printing negatives made during the exploration season. 1874 marked his last year photographing in the West, after which he returned to Washington D.C., where he continued to work, including a brief job with the United States Treasury Department in 1880–1881. He left the government position just five months after beginning, due to tuberculosis, from which he died on 14 January 1882, at age 42.

OEHME, CARL GUSTAV (1817–1881)

German instrument maker and photographer

Carl Gustav Oehme was born in Berlin in 1817, and trained as a mechanic or mechanical instrument maker. He is reported as having visited Paris in 1840 where he met Daguerre, and learned the rudiments of the daguerreotype process from him, returning to Berlin in 1841 where he was one of the first artists to exhibit daguerreotypes in Germany.

While in France, he met fellow German L. Philipp Graff (1814–1851), an optical instrument maker and later professional photographer, and Graff also contributed daguerreotypes to the 1841 exhibition. Oehme and Graff went on to become two of the most important early photographers in Berlin.

Oehme opened a studio in Berlin in 1843 at No. 20 Jagerstrasse, from where, trading as Gustav Oehme, he produced daguerreotype portraits for many years. He was still using the process into the later 1850s.

Some sources suggest that he also operated a portrait studio in Hamburg 1854/5, but this has yet to be confirmed.

Oehme's surviving daguerreotypes, predominantly 1/6th plate size, evidence masterful control of soft yet directional lighting, and a sensitivity towards posing which gave his group portraits a natural appearance which belies the long exposures necessary.

JOHN HANNAVY

OGAWA KAZUMASA (1860–1929)

Japanese photographer

Ogawa Kazumasa (the characters used in his given name are also read Kazuma or Isshin) was born August 15, 1860, in present-day Saitama prefecture, near Tokyo. He was the second son of Harada Shôzaemon, a samurai and retainer of the Matsudaira clan, and his wife Miyoko. At the age of three Ogawa became the adopted son of Ogawa Ishitarô, a common practice in nineteenth-century Japan.

Ogawa had a strong interest in English, and was first introduced to photography around age 13 through his English tutor, a British missionary. Around the same time he also had a chance to visit the studio of Uchida Kuichi, then the premier photographer in Tokyo, which further piqued his interest. Ogawa became familiar with the wet collodion negative process while serving as an apprentice to the photographer Yoshiwara Hideo for six months during the mid-1870s. In 1877, just seventeen years old, he opened his first photography studio in Gunma Prefecture with a second-hand quarter-plate camera that he used to take carte-de-visite portraits. Despite the limited availability of quality photographic chemicals and supplies, it appears that this studio was quite successful. However, Ogawa closed it in 1880 and resolved to go abroad to further his photographic knowledge.

Ogawa made his way to the United States as a sailor on an American frigate, spending eighteen months in Boston and Philadelphia in 1883–1884. He studied portraiture, carbon printing and plate making, and collotype in Boston. In Philadelphia he studied dry plate techniques and manufacturing with John Carbutt, who developed the first commercial dry plate negative. Ogawa sent news of the latest advances in American photography back to Japan, where they were published in *Shashin shimpô* (*Photographic News*), Japan's first photography periodical. He also shipped dry plates, which were just starting to be used in Japan around this time. The information he conveyed to other Japanese photographers experimenting with dry-plate technology was instrumental in helping them successfully master the technique.

After returning to Japan, Ogawa established a studio in Tokyo in 1885 called the *Gyokujunkan*, and thereafter rapidly became involved with a number of innovative photography-related businesses and projects. Ogawa had several appointments and commissions that gave him access to an unusually wide range of subjects. In 1886 he was appointed photography instructor for the army, in a division that was then part of the Land Survey Department. In 1888 he participated in a survey of Japanese cultural assets under the auspices of the government. His affiliations with the military and the government enabled him to photograph such varied subjects as the Sino-Japanese War, the Russo-Japanese war, the aftermath of the Boxer Rebellion, the palace buildings of the Forbidden City, Beijing, and antique sculpture, paintings, and architecture of ancient temples in Kyoto and Nara. His style was also varied, ranging from straightforward documentary photographs to beautifully composed artistic images that prefigured a modernist aesthetic.

Perhaps even more noteworthy than the diversity of his subject matter, however, was his influential role in developing photographic printing techniques within Japan and in promoting a domestic photographic

industry. In 1888 Ogawa, Kajima Seibei, and William K. Burton, an amateur photographer and a professor of engineering at Tokyo Imperial University, formed the *Tsukiji Kampan Seizô Kaisha* (Tsukiji Dry-Plate Manufacturing Company), one of Japan's earliest commercial dry-plate manufacturers. Although it folded several years later, Ogawa continued to support other domestic dry-plate companies. He then established Japan's first photoengraving company, *Ogawa Shashin Seihanjo* (Ogawa Plate-Making Shop) in 1889. Through the Ogawa Shashin Seihanjo, he became a prominent publisher and produced numerous books featuring high quality collotype images. Ogawa himself took many of the photographs. Among the earliest items published by the Ogawa Shashin Seihanjo was Japan's first art magazine, *Kokka* (National Essence), still in production today. *Kokka* focused on traditional Japanese art and early issues reproduced Ogawa's classic images of Japanese Buddhist sculpture taken as part of the 1888 survey of cultural assets.

Significantly, Ogawa's books were largely directed towards a Western audience, and consequently he played an enormously important role in exposing Japan to the West as it emerged from two and a half centuries of isolationism. Most of his publications included English language captions and information, sometimes combined with Japanese text; many were so popular that they were printed in multiple editions. Typical topics were scenic or general themes that appealed to Westerners' curiosity about Japan. Some sample titles are: *Illustrations of Japanese Life*, with collotypes of people engaged in various daily activities, issued in multiple editions between 1892–1918; *The Charming Views in the 'Land of the Rising Sun* (1904), with 174 black and white photographs covering all areas of Japan including Formosa (Taiwan) and Korea; and *Photographs of Japanese Customs and Manners*, with several editions published around 1900. Flowers were another common subject and Ogawa released titles such as *Lilies of Japan* and *Chrysanthemums of Japan*. The full-page color collotypes of flowers he contributed to the multi-volume work *Japan, Described and Illustrated by the Japanese*, published by J. B. Millet Company in the late 1890s, are among his best-known work. And of course there was the perennially favorite theme of geisha. In 1891, Ogawa was commissioned to photograph 100 local geisha to celebrate the opening of the *Ryôunkaku* or "Asakusa Twelve Stories," an amusement center in the tallest building in Tokyo. These images as well as other portraits of geisha were incorporated into various editions released over the next decade, including *Types of Japan, Celebrated Geysha of Tokyo* (1892); *Celebrated Geishas of Tokio* (1895); and *Geisha of Tokyo* (multiple versions, 1898–1902).

Ogawa's other activities included being a founding member of Japan's first amateur photography association, *Nihon Shashinkai* (the Japan Photographic Society) in 1889. The same year he established a second version of *Shashin shimpô* (the first version, mentioned above, had ceased publication in 1884) and served as editor until 1896. He became the first Japanese photographer to be nominated as a fellow of the Royal Photographic Society of England in 1895, and was the first photographer appointed as a member of the Japanese Imperial Art Academy in 1910.

Ogawa was well regarded during his lifetime, widely recognized for his innovation in establishing new photographic technologies in Japan. Based on his influence on the Japanese photography industry, the many activities in which he was involved, and his reputation as a superb photographer, Burton described him as "the greatest authority on photographic matters in his country" (Burton, 1894, 185). In 2004 he continues to be regarded as a pivotal figure and a pioneering entrepreneur in Japanese photographic history. His work is in the collections of Nagasaki University and the Tokyo Metropolitan Museum of Photography.

OLIE, JACOB (1834–1905)

An animated nineteenth-century amateur photographer in Amsterdam

To Jacob Olie photography was a pursuit which he practised intensively in his youth and again in later life after an interlude of 25 years. Olie was originally trained as a carpenter and took lessons in drawing and in theoretical

subjects at a private technical school. At the age of 16 he joined the Maatschappij tot Bevordering der Bouwkunst (Society for the Advancement of Architecture) and in 1855, he and a small group of kindred spirits founded the society Architectura et Amicitia, a debating club where the international magazine portfolio brought news of developments in the arts, the natural sciences and technology. It was in these circles that Olie received further theoretical training and his wider cultural interests were shaped. He translated sections of E.E. Viollet-le-Duc's *Entretiens sur l'architecture* and lectured on *Grammaire des arts du dessin* by Charles Blanc, former director of the Paris École des Beaux Arts. During the years he also participated succesfully in many competitions for artistic architectural designs.

The first time the word 'photography' was mentioned at one of the society's meetings was by Olie in 1857. He cited a report from a Dutch periodical about the Architectural Photographic Society that had been set up in London with the aim to provide its members with reasonably priced photographic illustrations of 'noteworthy' buildings from all countries. The matter came up once again, but Olie received little response among his fellow members for his proposal to collaborate with the English and exchange photographs for measured drawings.

For architects the photograph and the drawing were not comparable media. For someone like Viollet-le-Duc, drawing was a higher form of seeing, despite the importance he attached to photography as an aid in restoration. However, at the weekly art reviews more and more photographs were shown. In 1859 Olie brought along a series of stereoscopic views of Amsterdam by Pieter Oosterhuis. Shortly thereafter, he began himself experimenting with the art of photography.

Olie probably took his first photographs in the summer of 1861, only a few months after he had started his career as a teacher of architectural drawing at the technical school. At that time there were enough publications available with technical instructions for would-be photographers. In his notebooks Olie copied recipes for collodion, which he had taken from E. Robiquet (*Manuel théorique et pratique de photographie sur collodion et sur albumine*, 1859) and A.A.E. Disdéri (*L'Art et la Photographie*, 1862), among others. Olie built his own camera, a simple model, similar to the earliest daguerreotype cameras, which could take glass plates of 10.5 × 12.8 cm which he cut himself from window glass.

That first summer Olie explored the utterly familiar world of the busy dockland and industrial area where he was born and where he still lived among his extended family of craftsmen, ship-builders and timber merchants. Here he took scenes not normally recorded by commercial photographers: a ship under construction, a mast-makers yard, or views taken from the deck of a ship.

In 1862 Olie equipped his camera with a new lens of sharper definition and took up portraiture, a genre which he had never attempted as a draughtsmen. He made more than 150 portraits of his family, friends and acquaintances, sometimes capturing them in their own environment, and on other occasions against an artificial backdrop of cloths, rugs and props, like those used in the professional portrait studio. Sometimes Olie moved his darkroom equipment to friends and relatives who lived in the city centre and photographed from their attic windows. In some cases the views he made from these high vantage points can be fitted together to breath-taking panoramas. They provide a unique and highly personal portrait of Amsterdam's city centre. Unlike his drawings, Olie never submitted his photographs to exhibitions, but in 1864 and 1865 he presented his albumen and salted-paper prints to his colleagues at an Architectura et Amicitia meeting. Soon after, he abandoned his photographic experiments for many years.

Olie would only return to photography after his retirement as headmaster of the technical school in 1890. By then, he was a 56-year-old widower with four young children ranging from four to eleven years of age. He still used the same camera but fitted with a new lens. Olie built a number of ingenious cassettes which he could load at home with ready-made dry-gelatin plates of 9x12 and 13 × 18 cm. In the intervening years, his interest in photography had not waned. Olie gave slide shows for his pupils and others audiences with the magic lantern. The teacher in him recognized the educational potential of the picture machine and it may well have inspired him to produce his photographs specially for it.

Between 1890 and 1904 Olie took over 3600 photographs, most of them portraying the city of Amsterdam, including street scenes and residents and workers in their own surroundings. Amsterdam was in the process of rapid transformation and Olie recorded construction works at different stages of completion, moving about the building sites freely as he knew the architect, the client or the building contractor. Often his views are not topographical in the strictest sense, but the city serves as a backdrop for public events—military parades and balloon lift-offs, visits by dignitaries and ship launchings. He continued to display a predilection for high viewpoints in this period, even when it was no longer strictly necessary.

What fascinated Olie was the new architecture within its urban context. Unlike some artists of his day, he was not charmed by decay. Although the painter-photographer G.H. Breitner and Olie were both admirers of Amsterdam's beauty, they produced quite distinct bodies of work. While Breitner reinforced the shabbiness of the old districts and evoked the dank atmosphere of decay,

Olie composed views in which old and new fused into an organic whole. Olie's photography is also very different from that of the younger generation of pictorial photographers who sought to render the 'soul' of the city in atmospheric photographs. Employing refined photographic processes, they would often blur the city's contours in their hand-crafted prints. In contrast, Olie's photographs are lucid images of a tangible world.

After the turn of the century, Olie began to use a modern, hand-held camera which could take several 9 × 12 cm glass plates. It gave him a new mobility and allowed him to work in a more casual manner. Olie and his family were zealous hoarders. Besides the thousands of photographs, negatives and drawings he left behind, a veritable mountain of personal material has been preserved. The Amsterdam city archives purchased this rich legacy from his heirs in two portions, in 1959 and 1990.

Anneke van Veen

Biography

Jacob Olie was born on 17 October 1834 in Amsterdam, from a long line of raftsmen and whalers. Trained as a carpenter and an architectural draughtsman, he taught drawing at the first technical school in Amsterdam from 1861 on, and in 1868 became its headmaster. As a member of the leading architectural societies in the Netherlands, he studied zealously architectural and art history and played an active role in the debates on architectural theory and the concepts of form. He practised and demonstrated his skills in drawing and design in many competitions. In 1861 Olie started to photograph with a daguerreotype-model camera which he had built himself, using wet-collodion plates. The next four years he portrayed the dockland and industrial area where he was born and still lived, choosing unusual subject matter. He also made many portraits of his family, friends and acquaintances, and used their homes in the city center to set up his darkroom equipment and photograph the views from their windows which in some cases can be fitted together to large panoramas. Pressure of work forced him to abandon his pursuit. After his retirement in 1890 Olie took up photograpy again, this time on industrial dry-gelatine plates. Until the age of 70, Olie worked at fever pitch, producing some 3600 photographs of Amsterdam, outlying areas, and the wide surroundings. He was particularly interested in the transformation of the capital into a modern city, focussing on new architecture as an organic part of the urban context. He never exhibited his photographs, but projected them as lantern slides to a wide audience. Jacob Olie died in Amsterdam on 25 April 1905. His rich legacy is kept at the Amsterdam city archives.

OOSTERHUIS, PIETER (1816–1885)

Topographical and industrial photographer of the Netherlands

When the artist Pieter Oosterhuis took up photography he had passed the age of 35, newly married moreover, and determined to maintain his family from the earnings of his Atelier Photographique et Daguerréotypique.At last, he had come out of the shadows of his father, the successful painter and illustrator Haatje Pieters Oosterhuis. At the time of the opening of his first studio over 240,000 people were registered in Amsterdam, while the number of studios was only six, which was very few compared with cities like Hamburg and Berlin. This reveals a sense of adventure and a talent for entrepreneurship in Oosterhuis, which impression is intensified by the fact that he was probably one of the very first to apply the stereo technique in the Netherlands.

Stereo photography had been presented to the Dutch public for the first time in 1855, at the International

Exhibition of Photography in Amsterdam. The overwhelming success must have inspired Oosterhuis to introduce the novelty in his portrait studio and to apply it also to topography. This brought out the best in him. The Dutch cityscape would become one of Oosterhuis's major genres for the next 25 years. The genre of the topographically precise cityscape is rooted in a long-standing north-Netherlandish tradition in drawing and printmaking. Oosterhuis photographed the views which topographical artists had depicted before him. Restricted to a picture plane of barely seven by seven centimetres, he succeeded in composing remarkably powerful images by adapting skilfully the proven compositional schemes.

There was a growing public for Oosterhuis's stereographs. Increased tourism and a greater urge to travel made the publication of stereoscopic views a profitable undertaking. In the early years Oosterhuis did not experience much competition from his own countrymen who catered for the local market. The Parish publisher Alexis Gaudin & Frères issued the series *Hollande* in 1858 with 71 views of Amsterdam, Rotterdam, The Hague, Haarlem and Dordrecht. These cities were linked by rail from 1847 and every tourist took them in on his tour of the Netherlands, in pursuit of the landscapes portrayed by famous Dutch 17th-century masters. In the following years, Oosterhuis had the tourist trail in the provinces of Holland and Utrecht entirely to himself, uncontested even by the French company of Adolphe Braun, whose son Gaston did not visit the Low Countries until 1864.

After a short-lived collaboration in 1858 or 1859 with an Amsterdam bookseller and publisher, Oosterhuis published the bulk of his stereographs himself. No publisher is given on his large collection of almost four-hundred views, sold as *Vues de Hollande* in the early 1860s. Following the introduction of the larger cabinet size for portraits in 1867, Oosterhuis brought out new series of cityscapes. He continued to make them until the end of his career and after his death his son Gustaaf carried on. From the 1870s on virtually all professional photographers made tourist views. To withstand this fierce competition Oosterhuis felt compelled to produce extensive photographic coverage of Amsterdam and other places in order to diversify his supply.

By that time Oosterhuis's career as a portraitist had come to an end. In 1869 he sold the establisment and devoted himself entirely to his topographical series as well as to a new branch of the profession. December 1858 saw the appearance of the first Dutch publication to be illustrated with "a photograph from nature": inside the *Praktische Volks-Almanak* an albumen stereograph by Oosterhuis was pasted, showing Dam Square in Amsterdam. Following the *Revue Photographique* of 5 March 1858 the author of the accompanying article quotes the example of a New-York engineer who contracted a photographer to record the daily progress of building projects spread throughout the United States. The photographs furnished the engineer with all that he needed "to direct construction from a distance." And, the author asked rhetorically: "Would a Dutch photographer be capable of an achievement like this?"

October 1861 Oosterhuis began photographing the excavation work for a new lock near Amsterdam. It was the first assignment of its kind in the Netherlands, soon followed by a second in the remote province of Zeeland. A bill of 1860 established a nationwide railway network at public expense. To the newly emancipated group of civil engineers it brought a whole new field of activity and a chance to distinguish themselves in prestigious projects. These developments contribued to the decision to systematically document the construction of public works with the aid of photography, culminating in 1869 in a ministerial decree to make this practice compulsory.

Between 1861 and 1884 Oosterhuis undertook twelve large assignments commissioned by central government departments. He found himself gazing down on immense construction sites, where he had to familiarize himself with a new landscape photography. The *Tijdschrift voor Photographie* devoted ample space to Oosterhuis's Zeeland photographs in 1864 and 1865 and praised Oosterhuis's "artistic sense." The nature of the industrial assignments demanded a larger format than was customary for tourist photography. Oosterhuis worked with a variety of cameras, ranging from a camera for plates measuring roughly 18 × 26 cm on his first assignments, to the largest which produced images of over 32 × 42 cm. His fellow photographers admired the outstanding sharpness and the "wide field of vision" of these landscapes, which were taken with an orthoscopic lens on dry collodion plates. Oosterhuis was well-known for his immense precision, never exposing more than one single plate for each commissioned view point.

Like all photographers of his generation Oosterhuis was forced to diversify. He worked also on assignments from the industry, private societies, and the Amsterdam local authorities. At the International Photographic Exhibition of 1877 in Amsterdam, where he was awarded the Gold Municipal Medal, he submitted engineering photographs, landscapes and cityscapes, "views and cloud studies," and dry plate negatives, in addition to art reproductions in carbon print and silver print. Two years later, no less than 64 photographs by Oosterhuis were incorporated in the *Patriotic Album*, a "welcome greeting" from the nation to Princess Emma, King Willem III's young bride. After this milestone in his career, the latter years of his life were less prosperous. Oosterhuis suffered from tuberculosis and his youngest son Gustaaf became more active. After his father's

death, Gustaaf continued the firm under the name "P. Oosterhuis" until 1936.

ANNEKE VAN VEEN

Biography

Pieter Oosterhuis was born on 20 January 1816 in Groningen, the son of an artist. Trained as a painter by his own father, he took up photography in the early 1850's. In 1852 he opened the sixth daguerreotype studio in Amsterdam. Four years later he marketed his first stereoscopic views on glass and on paper. Until his death Oosterhuis published his cityscapes "in their thousands," initially as stereographs, later as cabinet cards, establishing himself as the *homo topographicus* of the Netherlands *par excellence*. In addition to these tourist photographs, Oosterhuis worked on engineering assignments from the central government. During more than twenty years he photographed nationwide the modern landscape and geometric forms of railways, railway bridges, station buildings, canals, locks, and docks under construction. He developed a vocabulary for these landscapes which bears a striking resemblance to French, British, or even Russian engineering photographs of the period. By his contemporaries he was esteemed the first among the Dutch landscape artists. As a painter he was a member of the artist association Maatschappij Arti & Amicitiae, but later he joined the Amsterdam Photographic Society. In the 1870's Oosterhuis regularly published articles on technical issues in the photographer's magazine *Tijdschrift voor Photographie*. At the 1877 Exhibition of Photography in Amsterdam Oosterhuis was awarded the Gold Municipal Medal. After his death on 8 June 1885, his youngest son Gustaaf (1858-1938) continued the firm.

OPPENHEIM, AUGUST F. (active 1850s)

German photographer

It is conjectured that the German photographer August Oppenheim was born in Dresden. Around 1852 he was instructed in the art of photography and, more specifically, in the calotype method, by Gustave Le Gray. A year later, during the course of a photographic tour, he visited Greece and recorded the antiquities, with the aim, as he wrote, "to give to those who had not been fortunate enough to see these monuments with their own eyes a clear idea of them, and to others pleasant memories." Details of this journey, as well as of the difficulties he encountered, he published in the periodical *Lumière* (issue 6, April 1853). His intention was to publish, on his return to Dresden, a three-volume work. In the end, this was limited to two volumes under the titles respectively of *Die erhaltenen griechischen Tempel auf der Akropolis* and *Details der Akropolis*. These photographs of his were finally included in *Atheniensiche Alterthümer*, published in 1854. An important honourable mention was awarded to him for the photographs he exhibited at the Industrial Fair in Munich.

ALIKI TSIGRILAOU

OPTICS: PRINCIPLES

The ability to manipulate light dates back to ancient times. The understanding of the nature of light, which involved debates over whether it is composed of waves or particles, began in the 1500s and 1600s. The discovery of and the elaboration of principles needed to design optics with confidence began in the early 1800s.

It seems quite likely that reflections in calm lakes and ponds were seen and wondered at since the dawn of human existence, perhaps millions of years ago, but no trace remains. The earliest optical devices we have found are stone and obsidian mirrors from the Bronze Age in Europe and the Middle East. It is likely that at about the same time people noticed their reflections in the blades of metal swords, axes and armor if they were highly polished. Flat mirrors reflect light at the same angle as it is incident at, and the formation of an image takes place in the eye of the beholder. A mirror can concentrate light if its surface is made concave. There are Greek accounts of Archimedes' "burning mirrors" being used to ignite the sails of Roman ships in battle, using concentrated solar energy. These mirrors were made of polished metal. A helmet or breastplate, being convex on its outside, spreads light and, if of high enough quality, forms a reduced-scale, wide angle image, rather than a concentration of light or a magnified image.

Transparent materials transmit light and can also manipulate it. We find glass jewelry which spreads light into colors, a property called dispersion, from the Bronze Age on, and this was undoubtedly long predated by the discovery that natural crystals such as quartz, calcite, amethyst, and emeralds, created colorful dispersal and multiple reflections of light. And again going back to early human times our ancestors saw and must have wondered at the colors of mother-of-pearl, rainbows, sun-dogs, lunar halos and other natural phenomena.

Small apertures in opaque surfaces when illuminated from one side will form images on a surface placed on the opposite side. This phenomenon was remarked in classical Greek times, dating back to 250 BC. It allows

one to safely view a partial solar eclipse in shadows and images cast on the ground by a leafy tree.

All these phenomena can be explained based on the nature of light and its behavior in different materials and at material boundaries. If a material is internally uniform in density and transparency, then light travels through it in straight lines and only changes direction, or refracts, at the boundary to another medium. At each boundary the path direction changes, and the angle of change (with respect to a perpendicular to the surface at the penetration point) is called the angle of refraction. If the surface is flat, the light entering it at a given angle is refracted the same amount everywhere on the surface. If the surface is curved, then the angle of refraction varies over the surface. If the shape is part of a sphere, the piece is said to be a lens and it can focus or defocus light, depending on whether the surfaces are convex or concave. (It should also be noted that at each boundary between different materials a fraction of the light is reflected: for glass and air it amounts to about 4%, and can give rise to multiple internal reflections inside lenses or rear-surface mirrors.)

The angular amount of refraction of a material is measured by a number unique to each material, called the index of refraction, the ratio of bending in a material to that of empty space, which is set equal to one. Air and other low-density gases have indices of refraction just a bit larger than one. Water at sea level has an index of refraction of 1.33, natural crystals, glass and plastics generally fall in the range 1.25 to 1.8. Some relatively exotic composition glasses have indices of refraction well over 2.5, which means lenses made out of them can be of thinner material and still bend light as much as thicker lenses made of lower index glass. (An aside: Einstein's relativity shows that, in the presence of matter, space itself curves and thus light's path in space is curved proportionate to the distance and density of that matter. It shows up in astronomy in curved arc images of distant galaxies seen around massive foreground galaxies. This effect is ignored in classical optics and so far has found no application in conventional photography!)

Lens making became a profession in the late renaissance in Europe. The Dutch optician, Snell (1580-1626), discovered and published a short mathematical relation for the bending of light in 1626, by sending light beams through glass surfaces of varying shapes and indices of refraction and carefully measuring the angle of incidence of the light as it struck the glass, and then the angle it was deviated to inside. He also measured the angles at the light ray's emergence on the far surface, into the air.

Snell's law is: $n_1 \sin \theta_1 = n_2 \sin \theta_2$.

In words that is: the index of refraction of light in the first medium times the sine of the angle of incidence at the boundary is equal to the index of the light in the second medium times the sine of the angle of refraction in the second material. The unprimed numbers are the numbers in the first medium, the primed numbers refer to the second medium. The Greek letter theta (θ) refers to the angle in degrees. Recall that the sine of an angle is a trigonometric property and can be found in mathematical reference tables or calculated by hand or computer. Since by its definition, the sine of any angle between zero degrees and 90 degrees is somewhere between 0 and 1, and since the index of any ordinary transparent material is greater than one, a light ray entering glass from air will be bent to a smaller angle than the angle of incidence it had at entry. When a ray leaves the denser material, passing from glass to air, the ray will bend back to a larger angle.

Snell's law was empirically derived. It can be derived theoretically using the electromagnetic wave theory of light founded by James Clerk Maxwell in the 1860s, and also by Fermat's principle of least time of travel. The latter idea relies on the fact that the index of refraction is not only a measure of bending strength but also the ratio of the *speed* of light in a material to that in empty space.

Snell's law and a little further work led to a useful formula, still applicable with certain restrictions, for describing practical optical systems. It is called the lens maker's formula:

$$1/\mathrm{fl} = (1/\mathrm{OD}) + (1/\mathrm{ID}).$$

The OD is the distance from the object in question to the center of the lens, the ID is the distance from the lens center to the focused image, and fl is the focal length, the distance from the lens center to the focused image when the object is at infinity. The focal length is also, by definition, one half the radius of curvature of the lens surface. It should be noted that this formula can be repeatedly applied to follow light through a series of lenses. With proper observation of positive and negative sign conventions it can also be used to study mirrors. The restrictions are that the lens have a shallow curvature, or equivalently that it has a very long focal length compared to its diameter. And light rays are assumed to travel in straight lines except when they cross material boundaries. This is called the Thin Lens Approximation. The lens maker's formula is a shortcut of use in deciding where an image will focus for an object at a given distance using a lens of known focal length, or for a quick design of a simple optical system. This formula also can be used to get the image magnification, which is the ratio: M= ID/OD.

Aside: Fresnel (1788–1827) in the early 1800s garnered a large prize fund from the French Academy of Science by designing a very thin lens, for use in lighthouse lights. These were used successfully for that purpose but now find much larger use as lenses for

theatrical spotlights, in camera viewfinder focusers, and also as novelty wide-angle lenses for automobile rear windows. Think of taking a set of nested concentric circular cookie-cutters and slicing a lens into a series of rings. Then shave off the bulk of the glass in the rear, leaving only the front curvature. Cement the resulting rings to a thin flat sheet, and the result is like a Fresnel lens (which is actually molded). This is a really thin lens!

Using the Thin Lens Approximation and simple geometrical rules, it is possible to quickly draw the principle light paths in a lens system. For each lens, a light ray down the system axis (a perpendicular through the lens center) travels straight on. A ray parallel to the axis, emerging from an off-axis point of the object as if it came from infinity, is bent by the lens to pass through the rear focal point, and a ray passing from the same object point through the front focal point (at an angle) emerges from the lens parallel to the axis (note the symmetry!). Where the latter two rays cross is the point where the original point of the object is imaged. In cases where the image rays converge to a focus, the image is termed real.

If, in leaving the lens, the rays only diverge, then an image can only be seen by the use of an additional lens, say that in your eye, and the image is called virtual. Convex lenses and concave mirrors can give real or virtual images, depending on whether the object is closer or farther than one focal length away from the optic. Concave lenses and convex mirrors yield only virtual images.

Snell's Law, which describes the refraction of light, along with the law of reflection (the angle of incidence equals the angle of reflection), can be applied at each point of a boundary surface to predict the path of light rays as they pass through. By doing this step by step at all points (or a sample) of a surface of known shape, one can follow a ray of light through a system of any complexity, and in reasonable detail. This process is called ray tracing, and until the advent of computers was carried out by hand. There some complications to this process, however.

First, the index of refraction of any real transparent material varies with the color (wavelength or frequency) of light. This effect is called dispersion, and explains why prisms are able to spread white light out into the visible spectrum. In general the index is greatest in the blue and diminishes continuously into the red and infrared. Mirrors do not suffer from this problem. This effect causes any lens to send blue rays to a different focus point than green or red ones. The result is called chromatic aberration, and results in color fringes surrounding images of objects with sharp edges, such as the Moon. It was discovered in the middle 1700s that this problem could be removed by sandwiching together two lenses of different indices of refraction, one convex and the other concave, carefully choosing their focal lengths, to make the dispersion of the second approximately cancel that of the first. These pairs are called achromatic lenses. All modern lenses for cameras and telescopes are achromats.

Second, every lens or mirror has a natural limit to resolution caused by the wave nature of light, called the diffraction limit. Waves bend around any edge, straight, curved or jagged. This is termed diffraction. Light does this and this results in fuzzy shadow edges (visible under careful examination) and also fuzziness in the whole image. The larger the opening of the lens or mirror, the less important this is and the sharper the image. The longer the wavelength of light (the redder it is) the worse the effect. This diffraction limit can not be evaded in conventional optics.

The diffraction effect can actually be put to use, however. A simple round pinhole carefully made in an opaque sheet will give a real image on almost any size surface behind, at almost any distance. What you gain in areal coverage and depth of focus you sacrifice in speed and exposure time. In conventional optics (lenses or mirrors)the aperture is wide and concentrates a lot of light. In pinhole cameras, just a tiny amount of light passes through. A conventional "fast" lens might have a focal length to diameter ratio ("f/stop" or "speed") of f/1.2 or f/1.8. The speed of a pinhole is usually f/150 or more.

Aside: A more efficient way than a pinhole to use diffraction to manipulate light and form an image is a second invention of Fresnel: the zone plate. Fresnel found an exact formula to compute the widths of transparent gaps between and widths of concentric opaque rings to form a lens based on diffraction. A zone plate looks just like a bullseye, but it is a mathematical construct.

There are also distortions of image shape due to lens or mirror shape. If the surfaces are spherical then off-axis rays do not focus at the same distance as on-axis ones. Spherical aberration, along with comatic aberration (images at the edge of the field of view spread out into fan "tails" like comets), barrel distortion and pincushion distortion (rectangular objects have "swollen" or "collapsed" images, respectively) along with chromatic aberration all have to be reduced to make an optical system produce high quality images. With the use of ray tracing in modern computers all of these problems can be solved.

Compound lenses have been designed for many different purposes. Perhaps the two greatest challenges are to find excellent wide angle lenses, and to find zoom lenses which maintain focus and image quality, along with maximum speed at every magnification. Again computers have allowed many different solutions to these problems.

If one surface of a compound optical system can be made to change shape microscopically and the image sharpness can be sensed instant by instant, you can use computer control to integrate this information and "sculpt" the flexible surface to make ultra sharp images in real time. Such star "de-twinkling" systems ("rubber" mirrors) are now available for astronomers and can make earth-based telescopic images almost as sharp as those made from Earth orbit. But they are not yet available for ordinary commercial cameras. However, overall motion compensation ("de-jiggle") is here in binoculars and some digital cameras. It may not be long before it appears in film cameras too.

Holography, the making of 3-dimensional images using laser light, can use or dispense with lenses and mirrors to achieve focused images. The images are formed by preserving the distance, brightness and color information carried by light waves, in the form of microscopic interference patterns, which are recorded on super-high resolution emulsions. Only laser light has the color purity and wave orderliness to form stable interference patterns, and all motion must stop for the duration of the exposure, down to a millionth of an inch, to avoid blurring out the interference pattern.

Holograms can, however, be made of small moving objects if the laser can emit a very intense short flash. Holographic large-scene snapshots are not yet on the horizon.

ORIENTALISM

The term Orientalism was particularly used in the 19th century often as a facet of Romanticism to refer to the depiction of the Near and Middle East, primarily by western artists. Images of history, everyday life, monuments, landscapes, portraits, etc. depicting the life and culture of the geographic region that included modern day Turkey, Syria, Iraq, Iran, the Arabian peninsula, Jordan, Israel, Lebanon, Egypt, Libya, Tunisia, Algeria, Morocco, and sometimes modern Greece, Albania, and Sudan, constituted the realm of Orientalism.

In the 19th century the lure of the exotic, the mystique of the lands of the "Arabian Nights," the "Other" of unseen landscapes and unexperienced cultures, and the adventures of travel to new frontiers, all contributed to the growing popularity of Orientalism in painting, sculpture, and photography. Eugène Fromentin wrote in 1859, "The Orient is exceptional…it escapes general laws…This is an order of beauty which, having no precedents in either literature or art, immediately strikes us as appearing bizarre. All its features appear at once: the novelty of its aspects, the singularity of its costumes, the originality of its types, the toughness of its effects, the particular rhythm of its lines, the unaccustomed scale of its colors…It is the land of…inflamed landscapes under a blue sky, that is to say brighter than the sky, which constantly leads…" (Eugène Fromentin, *Une Année dans le Sahel*, ed. Elisabeth Cardonne, Flammarion, Paris, 1991 (1859) pp. 184–85.)

Orientalism frequently implies travel, in actuality, or simply from one's armchair, evoking deep seated colorful and/or steamy reveries, that inspired artists as they attempted to trace the trails that led to new geographic vistas, and to new realms of the imagination. The Orient was to become "unveiled" in images that were both accurate and inauthentic as artists and photographers worked "in situ" and in studio settings, often conflating dream and reality, truth and fiction.

In more recent years writers such as Edward Said in his 1978 *Orientalism* or Linda Nochlin in her 1989 essay, "The Imaginary Orient" (in *The Politics of Vision: Essays on Nineteenth Century Art and Society*, New York, 1989, 33–59) have argued that the Orient was a "creation of the West" and that many images represented aspects of Western domination and imperialism. Thus, in viewing "Orientalist" photographs, it is important to consider issues such as: why and how various photographs were taken; the role of individual and national power; the role of large format images, albums, and postcards; Colonialism and Post-Colonialism; documentary, propaganda, and artistic elements.

One of the most important publications in the early development of Orientalism was the French government's *Déscription de l'Egypte* (Paris 1809–22), 24 volumes illustrating the monuments, people, flora, and geography of Egypt following Napoleon's campaign in Egypt. Writers such as Flaubert, Chateaubriand, Théophile Gautier, and Pierre Loti all visited the Near and Middle East and incorporated "Oriental" themes and elements in their writings. With the advent of photography in 1839, the latter part of the 19th century saw increased demands for albums and images of the "alluring" Orient.

Improved means of transport and organized tourism also caused an increase in the market for photographic images of the Orient. The advent of steamships made it possible for the middle classes to travel to distant shores. In 1841 Thomas Cook began his organized tours. A full Mediterranean tour took passengers to the

Egyptian pyramids, the Biblical sights of the Holy Land, the classical antiquities of the Aegean and to Istanbul. The Hamburg-American Packet (Hapag) Company merged with North German Lloyd in 1857 to become Hapag Lloyd, launching its own grand tours to the East. The Orient Express began in 1883 and by 1889 had extended its retail service to Istanbul. New travel guidebooks were produced for the increased tourism, and international trade exhibitions of the 19th century also focused attention on the Orient. The opening of the Suez Canal in 1869 brought further improved conditions for travel and allowed photographers easy access to Oriental lands.

Among the first to travel to North Africa, shortly after the invention of the Daguerreotype in 1839, the painter Horace Vernet went to Egypt and the Holy Land to photograph, accompanied by the daguerreotypist Fréderic Goupil-Fesquet. Daguerre had predicted that the intensity of Egyptian light would help produce an image more quickly. The first daguerreotype taken in Egypt by Fosquet in October 1839, was titled "The Harem of Mohammed-Ali in Alexandria." (It actually only showed a half-open door and two guards.) The subjects of "Woman" and "Other" were to become a popular, as elements of the exotic, sexual, and decadent, were incorporated into many photographs.

Photography became a significant travel aid for artistic, archeological and geographic expeditions. In 1849–51, Maxime Du Camp accompanied Flaubert on his trip to Egypt and published some of his images in 1852 in an important album, *Egypte, Nubia, Palestine, et Syrie*. Several of the painter Jean-Léon Gérome's expeditions to the East included a photographer—his brother-in-law Albert Goupil in 1868, and Auguste Bartholdi in 1855. Bartholdi, perhaps better known as a sculptor, recorded both monuments, such as his "Colossi of Memnon" 1855, as well as aspects of their day to day travels.

The largest group of travelling photographers came from France, the second largest from England. Other European countries such as Italy, Germany and Austria and the United States had relatively few photographers travelling to the area in the early days of photography. There were few "local" photographers, in part due to religious restrictions, forbidding the making of "graven images." The first local photographers thus to open up shops were primarily Christians.

The relative prosperity in France and England during the middle of the 19th century allowed for more frequent travel to the Orient. The French government, in particular, encouraged Orientalist studies and often financed exploration trips. Maxime Du Camp and Auguste Salzmann were among the first to receive such support, followed by Louis de Clerq, Louis Vignes, and Théodule Dévéria. Government survey missions from England were fewer than from France but the British tended to spend years rather than months surveying and photographing. Significant were the military expeditions of the Royal Engineers, in particular, the Ordnance Survey of Jerusalem (1864–65) and the Ordnance Survey of Sinai (1868–69) with James MacDonald as official photographer. The Palestine Exploration fund was established in 1865 and an American Palestine Exploration Society was founded in 1870. The first American expedition under Dr. Selah Merrill arrived in Lebanon in 1875. Tancrede Dumas of Beirut was the official photographer for that mission.

Religious mission groups also often had photographers. As example, James Graham, lay secretary of the London Jews Society, came to Palestine for four years and was an active photographer there. In general, according to Nissan Perez, in *Focus East*, British photographs tended to be more objective while the French images tended to contain more mystery and emotion. "If the British in their truthful images denuded the Orient from its silken veil of Arabian Nights fantasy, the French wrapped it even more and made it more mysterious, more sensual—a project of pure Western fantasy and imagination. With an eye for detail and daring composition, French photographers [such as Teynard] reflected in their images the spirit of the places rather than the stark reality..." (Nissan Perez, *Focus East: Early Photography in the Near East (1839–1885)*, New York, Harry Abrams, 1988, p. 83)

Technical advancements in photography also had an effect on the type of photographic images produced. Initially the French daguerreotype and the British process, the calotype or talbotype, were employed. The latter system often produced quite atmospheric prints. These processes were overtaken by the wet collodion process that enabled Francis Frith to produce his beautiful large 16 × 20 inch negatives beginning with his first trip to Egypt in 1856. This process allowed for much faster exposures, often four to five seconds versus the calotype exposures which could be two minutes or the daguerreotype which could take as long as twenty minutes. The wet process gave way to the dry collodion process by 1875. Plates could then be prepared in advance and developed when appropriate. The development of gelatino-bromide emulsions in 1871, that were factory produced and exported from factories in Britain, France, and Germany to places such as Port Said in Egypt in the 1870s, was also significant. Innovations in lens design such as the 1886 Rapid Rectilinear lens further reduced exposure times and distortion in the image. These technical advancements made it possible for commercial photographers to better market their images and for photographers to set up photographic studios. In Port Said, the commercial market was initially dominated by Hippolyte Arnoux who had a floating darkroom on

Fenton, Roger. Reclining Odalisque.
The Metropolitan Museum of Art, The Rubel Collection, Purchase, Lila Acheson Wallace, Anonymous, Joyce and Robert Menschel, Jennifer and Joseph Duke, and Ann Tenenbaum and Thomas H. Lee Gifts, 1997 (1997.382.34) Image.

the Suez Canal, and the Zangaki Brothers who had a horse drawn mobile darkroom that actually appeared in a number of their images. Arnoux photographed the building site of the Suez Canal, and was known for his various studio portraits. Images such as his albumen prints "Odalisque, Egypt" c. 1880, and "Portrait of a Women," c. 1880, both using the same model against an alluring painted backdrop, are archetypal images of the exotic, seductive woman, that some studios fostered through the staging of such images.

The British Francis Frith was probably the first "entrepreneur" photographer to establish himself as the producer and promoter of large scale scenic and architectural photographs of the distant Eastern lands. Frith traveled to the Middle East three times between 1857 and 1860 and became the owner of the successful photographic-view company, F. Frith and Co., the largest such company in England. Frith's exquisitely detailed photographs record a world, often far off the beaten tourist track—that was in subsequent years to become vastly changed by the effects of archaeology, tourism and the politics of conflicting nations. One sees, for example, "Frith's Boat on the Nile," as its triangular sails pierce the quiet Nile and its silent sculptural, rocky shores; or "Cairo: The Mosque of the Caliph El-Hakim" where Frith shows the viewer the ancient mosque (990–1003), in ruins by the 1450s. Frith's framing of the majestic tower in a central arch form brings majesty and dignity to the monumental structure. In the foreground Frith has kept several people to show scale and local color. During much of his travelling, Frith dressed in "native dress"; a well-known self-portrait shows him in Turkish costume. Back home in England, the Victorians were enamored with foreign "costumes" that were picturesque and belonged to the middle and upper classes of any given country. Frith's book production in 8¾ × 6½ inch formats, contained beautiful albumen prints. From 1858–1862 his titles included, *Egypt and Palestine Photographed and Described by Francis Frith*; *Cairo, Sinai, Jerusalem*, and the *Pyramids of Egypt: A Series of Sixty Photographic Views by Francis Frith*; *Egypt, Nubia, and Ethiopia: Illustrated by One Hundred Stereoscopic Photographs;* and *Egypt, Sinai and Palestine, Supplementary Volume* (4 volume series).

While Frith's photographs were usually based on actuality, the Oriental photographs of Roger Fenton, comprising a suite of approximately 50 works, were studio based, from his London Albert Terrace studio. Fenton had traveled to the Crimea in 1855 on commission from the publisher, Thomas Agnew, and support from Queen Victoria to photograph the Crimean War effort. In so doing, Fenton provided one of the first extensive photo documentations of any war, and so collected many objects and fabrics that he was to use in his Oriental studio studies in the late 1850's. These images were not authentic, but were widely accepted by a public that sought the exotic and sensual, that was "safe" to view through the distance provided by the photographic image. In his 1858 "Pasha and Bayadère" one finds the elaborate details of patterned draperies, rugs, tables, and vases, and dress in a well articulated triangular composition of the three main characters on Fenton's stage set. Upon careful viewing, one can see there are actually strings holding the young woman's

hands, rhythmically placed above her head for the long exposure.

Other significant studios, established in the Middle East, included the Maison Bonfils, Abdullah Freres, Sébah and Joaillier, and Lehnert and Landrock. Félix Bonfils studied photography initially with Nièpce de Saint Victor. With his wife Lydia, who took studio portraits while he photographed throughout the Middle East, Bonfils established a successful business in Beirut, beginning in 1867, the first French photographer to relocate to the region. In 1871 he submitted prints of Egypt, Palestine, Syria, and Greece to the French Photographic Society and received its medal. His son, Adrian, who had mastered Arabic, took over the Maison Bonfils in 1885 when his father died. While many of the studio's images are posed, the photographs nonetheless are both documentary and artistic representations of 19th century Oriental cultures and monuments, that are important to consider in studying this era and region.

The Abdullah Freres were three brothers of Armenian origin who were particularly noted for their photographic work in Istanbul, often photographing royal guests in Istanbul. They also served as official photographers to Sultan Abdul Aziz in 1863, and later to Sultan Abdul Hamid II. For a brief period from 1886–1888, Kevork and Housep Abdullah established themselves in Cairo. The brothers sold their studio to Sébah and Joaillier in 1899.

Pascal Sébah initially worked in collaboration with Henri Béchard. Sébah received medals at International Exhibitions in Paris, Vienna and Philadelphia. With such success he opened a second studio in Cairo in 1873. In 1884 Policarp Joaillier became his partner in Istanbul. Noteworthy in Sébah's career was his collaboration with the Turkish painter Osman Hamdi Bey, whom he met in 1873. Sébah took photographs of models according to Bey's specifications for Bey's paintings and also experimented with light and shade. In his paintings, Bey often reacted to the cliché of the Oriental woman as sex object. Sébah also photographed models in traditional Turkish dress for an important album and Ottoman exhibition in Vienna in 1873.

Rudolph Lehnert, born in Bohemia (part of the Austrian-Hungarian Empire) in 1878, made his first trip to Tunis in 1903 and fell in love with the country. In 1904 he opened a studio with his friend, Ernst Landrock from Saxony. The two were captivated not only by the exotic beauty of people and places of North Africa, but also wished to capture a purity they felt was rapidly disappearing. From 1904–1930 the two worked closely. Their photographs of the Ouled Nail tribe in and around the Bou Saada oasis are particularly striking. During World War I their studio was confiscated by the British. In 1920 they founded a new company, Orient Kunst Verlag, and in 1924 they restarted their commercial enterprise in Cairo. By 1930, Lehnert returned to Tunisia where he died in 1948. The business they founded still continues in Cairo today, selling postcards and reproductions at 44 rue sherif Pasha.

In response to some Orientalist representations of Middle Eastern life by Western photographers that were perceived to be more fiction than fact, the Ottoman Sultan Abdul Hamid II, at the occasion of the 1893 World's Colombian Exposition, presented fifty-one photography albums to the National Library of the United States (now in the Library of Congress). The ornate albums containing 1,819 photographs by various Istanbul photographers emphasized reform and modernization. One sees for example, images of the elaborate Dolmabahçe Palace, constructed in 1856 that contains Eastern and Western architectural elements, or photographs of factories, docks, libraries, or a group of girls in a girls school, in simple uniforms, their heads uncovered.

By the 1890s the larger prints of some of the above photographers or photographers such as Francis Bedford, Robert Murray or Antonio Beato, had begun to become less popular. Such was in part due to the development of the PZ print, produced by Photoglob, Zurich. The process referred to as photochromy produced delicate, fairly accurate colored images. Not color photography, the process involved the use of collotype photolithography with a solution of asphaltum of ether, and involved as many as sixteen printings of different colors. This color process was applied to postcards, which became most popular when new postal regulations in 1894 allowed pictures to be mailed on postcards. And by 1900 the invention of the box camera brought competition to the staged Orientalist image, both large and small, as the family snapshot gained increase popularity.

Yet the impact of Orientalist photography still continues as the complexities of fact and fiction, dream and reality, continue to be studied. As Amelia Edwards wrote in 1892, "It may be said of some very old places as of some old books, that they are destined to be forever new…Time augments rather than diminishes their everlasting novelty…" (Amelia Edwards, *Pharaohs, Fellahs and Explorers*, New York, Harper and Brothers, 1892, 3).

OTTEWILL, THOMAS & CO.

The Ottewill company has long been recognised as one of the best quality manufacturers of cameras and photographic equipment of the 1850s and 1860s. The Ottewill double folding camera is reputed to have been the inspiration for Lewis Carroll's poem *Hiawatha's Photographing* (1857). Carroll's camera was made by Ottewill and supplied to Carroll by the London firm of R. W. Thomas of Pall Mall.

The business of Thomas Ottewill was established in 1851 and as such can be considered as one of the earliest British specialist photographic manufacturers. The business was listed first at 24 Charlotte Terrace, Copenhagen Street in Barnsbury, London, subsequently expanding to numbers 23 and 24 for the remainder of the firm's existence. The *London Post Office Directory* first records the firm from 1854 as Daguerreotype Apparatus Manufacturers, a listing which was expanded to Photographic Apparatus Manufacturers from 1856, until the firm's disappearance circa 1866.

The firm was listed as Ottewill & Morgan in 1855 before adopting the title Thomas Ottewill & Co from 1856–63. The following year it became Ottewill, Collis & Co until it was last recorded in the directories in 1866, although from other sources the firm seems to have remained active until 1868. The firm claimed in 1856 (*Photographic Notes*, 1 November 1856, np) to 'have erected extensive workshops adjoining their former shops, and having now the largest manufactory in England for the make of Cameras, they are enabled to execute with dispatch any orders they may be favoured with.' The firm exhibited 'a Monster camera made by Mr Ottewill upon Capt. Fowkes' plan' at the Photographic Society's 1858 exhibition.

An 1865 advertisement (*Yearbook of Photography* 1865, adv) stated that the firm was photographic apparatus manufacturer to the governments of 'England, India, Italy, Switzerland, the Colonies, etc' and that a fresh infusion of capital, together with a general knowledge of the photographic art would allow it to supply every article connected therewith of first quality'.

The firm advertised regularly throughout its existence in the *British Journal Photographic Almanac* and *Yearbook of Photography,* the *Journal of the Photographic Society and Photographic Notes*. The firm's reputation was exhanced by the double folding sliding camera that it started making from the early 1850s. The design was registered formally on 25 May 1853 and attracted much favourable comment in the photographic press. The *Journal of the Photographic Society* (December 21 1853, 149) stated of the design that 'there is none which more fully combines the requisite strength and firmness with a high degree of portability and efficiency.' The design remained available into the 1860s. Other cameras advertised by the firm were equally innovative. Ottewill produced Captain Francis Fowkes's camera (British provisional patent number 1295 of 31 May 1856) in teak for the British government and an Improved Kinnear-pattern camera in 1859 that he claimed was the first to introduce a swing back. They also produced Frederick Scott Archer's folding camera which has been registered in 1854. As with other manufacturers Ottewill produced boxform cameras in single lens and stereoscopic versions as well as studio and portrait cameras from the early 1860s. The firm claimed to have been the first to introduce the swing back in 1859. In 1860 the firm produced a miniature camera clearly inspired by Thomas Skaife's Pistolgraph of 1859 made from mahogany which was mounted on a box that contain all the parts.

Lewis Carroll recorded in his diary for 18 March 1856 that 'we [Reginald Southey who taught him to take photographs] went to a maker of the name of Ottewill… the camera with lens etc will come to just about £15.' The camera was delivered on 1st May. Carroll's £15 did not include the chemicals and associated processing equipment which probably came separately from R W Thomas of London.

The Ottewill firm supplied and advertised cameras and photographic equipment under it's own account. It also supplied several well-known London firms with cameras to be re-badged under their own name, including the firm of Ross who were primarily lens

manufacturers. In an 1867 advertisement Ottewill & Collis state '15 years manufacturers to Ross the Optician. Mr Collis having had upwards of 13 years experience in Mr Ross's establishment.' Ottewill also employed Patrick Meagher who went on to successfully establish his own firm in 1860.

Most of Ottewill's cameras can be criticised for their lack of innovation, but there is no faulting the very high quality of craftsmanship with which their cameras were made and a contribution to British camera making which, in the words of the *British Journal Photographic Almanac* of 1898 (p 640) 'may be regarded as the source to which the best school of English camera-making traces its origin'.

OTTOMAN EMPIRE: ASIA AND PERSIA (TURKEY, THE LEVANT, ARABIA, IRAQ, IRAN)

The discovery of photography was publicly announced in the Ottoman Empire on 28 October 1839, the news appearing in the government newspaper *Takvim-i Vekayi*, published in Istanbul in Turkish, Arabic, French, Greek and Armenian.

The spread of photography in the lands of the empire was pioneered by numerous travelers, writers, archaeologists, artists and architects (Özendes, 1995, 26).

On 21 October 1839 the French painter Horace Vernet (1789–1863) and the daguerreotypist Goupil Fesquet (1817–1878) sailed from Marseille to photograph the sights of the East. They arrived in Syria on 30 October and in Alexandria in November. In Egypt they found that Pierre Gustave Joly de Lotbiniere (1798–1865) had preceded them and was photographing on the banks of the Nile. From Egypt they traveled by caravan via Sinai to Syria, visiting Palestine, Tyre, Saida, Deir El Kamar, Damascus, Jerusalem, Nazareth, Beirut and Baalbeck, before travelling to İzmir on the Aegean Sea, arriving on 8 February (Özendes, 1995, 85).

Joseph Philbert Girault de Prangey (1804–1892), a student of Islamic architecture, visited the Middle East between 1842–1845 taking Daguerreotypes of Islamic buildings and monuments. These pictures were published in *Monuments Arabes d 'Egypte de Syrie, et d 'Asie—Mineure dessinés et mesurés de 1842 à 1845* in Paris in 1846 (Özendes, 1995, 96).

Excursions daguérriennes: Vues et monuments les plus remarquebles du globe 1840–1844 published in Paris by Nicolas Paymal Lerebours contains 114 photographs taken by Fesquet, Lotbiniere and Prangey (Özendes, 1995, 96).

The French writer Maxime du Camp (1822–1894) arrived in İzmir in May 1843, and after visiting Ephesus and other sites in the region traveled to Istanbul, and from there to Greece, Italy and Algeria. Du Camp's illustrated account of this journey entitled *Souvenirs et Paysages d 'Orient: Smyrne, Ephése, Magnésie, Constantinople, Scio* was published in Paris in 1848 (Özendes, 1995, 98).

Ernest Edouard de Caranza, a French physics and chemical engineer who worked in Imperial Gunpowder Factory (Baruthane-i Amire) since 1839, took many Calotypes in Istanbul between 1852–1854 and presented an album to the Ottoman palace. During this period he was given the title of royal photographer (Özendes, 1995, 107).

Alfred Nicolas Normand (1822–1909), who visited Istanbul in 1852, took Calotypes in which composition took precedence over technique (Özendes, 1995, 108).

A photograph of Péra taken by the Irish aristocrat John Shaw Smith (1811–1873) in 1852 is the earliest known combination of two negatives (Özendes, 1995, 108).

Jacob August Lorent (1813–1884) traveled to North Africa in 1858 and documented Arab culture, publishing his photographs in *Egypten, Alhambra, Tlemsen, Algier: Photographische Skizzen* in Mannheim in 1861 (Özendes, 1995, 148).

Francis Frith (1822–1898) arrived in Egypt in September 1856, and the photographs he took were exhibited in England in 1857. The same year he traveled to the Middle East and traveled through Palestine and Syria until May 1858. His photographs of both journeys were published in *Egypt and Palestine Photographed and Described*. In late summer 1859 Frith returned to Egypt and from there traveled to Sina, Petra, Palestine, Syria, Damascus, Jerusalem, Beirut and Jaffa, photographing İzmir in 1860. The same year he established Frith and Co., which became Europe's largest producer of photographs. His own portrait in Turkish costume is on the first page of his album entitled *Egypt, Sinai and Palestine*, which is illustrated by 37 photographs (Özendes, 1995, 149).

The British landscape photographer Francis Bedford (1816–1894) accompanied Edward Prince of Wales on his journey to Turkey and the Middle East in 1862, and in 1863 his photographs appeared in *Tour in the East; Photographic Pictures of Egypt, The Holy Land and*

Pesce, Luigi. In the Mosque of the Damegan/The Eunuchs. *The Metropolitan Museum of Art, Gift of Charles Wilkinson, 1997 (1997.683.21) Image © The Metropolitan Museum of Art.*

Syria, Constantinople, The Mediterranean, Athens, etc published in London by Day & Son (Özendes, 1995, 154).

In 1862 A. de Moustier traveled through Anatolia taking photographs, which were used to illustrate the 15 volume *Le Tour du Monde* published in 1864 (Özendes, 1995, 156).

Tancrede R. Dumas, who founded a studio in Beirut in 1860, took photographs in Istanbul in 1866 (Özendes, 1995, 162).

L. Fiorillo of Alexandria and G. Lekegian of Jerusalem are noted particularly for photographs of their own localities (Özendes, 1995, 82).

Travelers to this region mainly took photographs of eastern cities, so different from their western counterparts, ancient ruins, the pyramids of Egypt and Muslim cemeteries (Özendes, 1995, 44)

James Robertson (1813–1888), who worked as an engraver at the mint in London between 1833–1840, was employed in Istanbul from 1841, after the Ottoman government decided to modernize the Imperial Mint. He and Felice Beato (1825–1903) photographed Malta in 1850, and Greece, the Balkans and Anatolia in 1851. In 1853 Robertson's photographs were published as *Photographic Views of Constantinople* by Joseph Cundall in London, followed the next year by *Photographic Views of Antiques of Athens, Corinth, Aegina etc,* again by the same publisher.

After the Crimean War broke out between the Ottomans and Russians in 1853, first France and then, in March 1854, Britain, joined the war as allies of Ottoman Turkey. Roger Fenton was commissioned to photograph the war, and with his horse-drawn cart inscribed with the words "Photographic Van" he took over 360 photographs in 1855. When Fenton became ill and returned to England, Robertson and Felice Beato went to the Crimea in August 1855, and took over sixty photographs of Sivastopol, Malakoff and Balaklava during the last months of the war.

Beato traveled to India in 1857, China in 1860 and Japan in 1862. Robertson closed his studio in Istanbul in 1867, but evidently remained there fore another decade, since the last medallion that he designed for the Ottoman Mint is dated 1876. In 1881 he went to Japan, where he died in 1888 (Özendes, 1995, 89).

Carlo Naya (1816–1882) opened a studio in Péra, Istanbul, in 1845. Upon the death of his brother Giovanni in 1857, he returned to Italy and settled in Venice (Özendes, 1995, 100).

As western travelers became more familiar with the Islamic countries, they began to photograph local people as well as monuments, streets and markets, and this led to the emergence of local studios in the major cities of the Ottoman Empire (Özendes, 1995, 44).

In Istanbul studios began to be established from the 1850s, mainly along Grand' Rue de Péra, in the district where westerners working in the city congregated (Özendes, 1995, 35).

The first Ottoman studios were established by Armenians and Greeks, since although there was a portrait tradition in court circles, Islamic orthodoxy frowned on representation of the human figure and Muslims were reluctant to be photographed. Armenians were skilled artists and artisans, famed particularly as pharmacists,

chemists and goldsmiths. So Armenians with the knowledge of chemistry required for the Daguerrotype process, and who moreover studied this subject at the Murad-Raphaelyan School in Venice were among the first Ottoman photographers (Özendes, 1995, 21).

The Ottoman Greek photographer Basile (Vasili) Kargopoulo (1826–1886), who opened his studio on Grand' Rue de Péra in 1850, created a valuable documentary record of the time with his photographs of Istanbul and daily life in the city. He was awarded the title of royal photographer by Sultan Abdulmecid (r. 1839–1861), a position he held for many years, and was also private photographer to Sultan Murad V (1840–1904 r. 1876) (Öztuncay, 2000).

Fascination with the Orient began with the Turqueries fashion in the 16th century, when diplomats and travelers had their portraits painted wearing Turkish costume. In the 18th century the Istanbul embassies of principal European countries employed artists to do paintings and drawings of Turkey, Middle East and Egypt to satisfy the curiosity of friends and colleagues back home. In the 19th century the floodgates of Orientalism opened.

Although photography was supposedly the opportunity to see the 'real' Orient rather than artists' interpretations, photographers created scenes that perpetuated the preconceived European image of the Orient.

Westerners were fascinated above all by eastern women, and in response to this demand photographers generated a new category of photographs with titles like 'A Turkish Woman' or 'Young Turkish Girl' In fact it was out of the question that any Muslim woman would have sat for such photographs, and the women portrayed were generally foreigners or local prostitutes. When photographers had trouble finding models they even resorted to dressing up men in women's clothing. Although their faces are veiled, close scrutiny of eyes, hands and thick ankles reveals the deception (Özendes, 1999, 9, 160).

Pascal Sébah, (1823–1886), who opened his photographic studio, *El Chark,* on Postacılar Street in Péra in 1857. In 1873, he opened a branch studio in Cairo, and exchanged some negatives with H. Bechard, who had been working in Cairo since 1870. Each set their own signatures to the other's negatives.

After Pascal Sébah's death his studio remained in business, and in 1888 when Policarpe Joaillier became a partner, the name El Chark was changed to Sébah & Joaillier. This firm became the foremost representative of Orientalism in photography.

When Kaiser Wilhelm II (1859–1941) visited Istanbul in 1889, he was photographed by Sébah & Joaillier, and the firm was awarded the title of photographers by appointment to the Prussian court (Özendes, 1999).

Vichen Abdullah (1820–1902) began his photographic career touching up photographs for Rabach, who had opened his Istanbul studio in 1856. In 1858, when his younger brother Kevork (1839–1918) returned from studying at the Murad-Raphaelyan School in Venice, they and another brother Hovsep (1830–1908) took over Rabach's studio. The new firm became known as Abdullah Fréres.

In 1863 a portrait of Sultan Abdulaziz (r. 1839–1876) taken by Abdullah Frères earned them the title of royal photographer.

In 1886 at the request of Khedive of Egypt Tevfik Pasha, the Abdullah brothers opened a branch in Cairo.

They closed down the branch in Cairo in 1895, and at the end of 1900 sold their studio to Sébah & Joaillier (Özendes, 1998)

Nikolai Andreomenos (1850–1929) took a job touching up photographs at the Abdullah brothers' first studio in 1861 and took this over in 1867. He then opened a branch in Péra and became one of the photographers who won entry to the palace, giving lessons in photography to crown prince Vahdettin, later Sultan Vahdettin (1861–1926 r. 1918–1921) (Özendes, 1995, 164).

In the early 1870s Guillaume Berggren (1835–1920) opened a studio on Grand' Rue de Péra and took what are considered to be the loveliest contemporary images of Istanbul. He was decorated by the Swedish king Gustaf V (1858–1950) during his visit to Istanbul in 1885. When Berggren died his niece had all his photographic equipment buried with him in the Swedish cemetery in Istanbul (Wigh, 1984).

Felix Bonfils (1831–1885) opened a studio in Beirut in 1867. His son Adrien (1861–1929) joined the studio in 1878, and continued to work as a photographer for a decade after his father's death in 1885 (Özendes, 1995, 174).

Bogos Tarkulyan (?–1940) acquired his photographic training as assistant to the Abdullah brothers. In 1890 he opened his own studio, which he named Phébus, and became known as 'Phébus Efendi' (Mr. Phébus). Tarkulyan was also a skilled artist, and became the first Ottoman photographer to color photographs (Özendes, 1995, 175).

Ottoman studio owners prepared graphic designs incorporating the decorations they had received from the Ottoman sultans and European rulers, and medals they had won, and these were sent to the Bernhard Wachtl firm in Vienna to be printed on the back of mounts for Carte-de Visite and Cabinet sized photographs (Özendes, 1995, 65).

Photography came to be very widely used during the reign of Sultan Abdulhamid II, who used it as a way of keeping up with events around the empire without leaving his palace. By appointing photographers to record events and institutions all over the country, Sultan Abdulhamid became the principal patron of photography in Ottoman Turkey. When it was decided to pardon a

large number of prisoners to commemorate the 25th anniversary of his accession to the throne, he had photographs taken of the inmates in prisons throughout the country.

In 1893 the sultan sent photograph albums to the president of the United States and the monarchs of Britain and France to promote the country's image (Özendes, 1995, 28).

In the nineteenth century photography was added to the curriculum of the Imperial School of Military Engineering. Graduates in art from this school who had become photographers were employed to teach the new subject. Among them were Ali Rıza Bey (?–1907), Ali Sami Aközer (1866–1936), Captain Hüsnü Bey (1844–1896) and Ahmed Emin (1845–1892).

Ali Sami Bey, one of the military photographers appointed by Sultan Abdulhamid II, took photographs documenting the 1898 state visit of Kaiser Wilhelm II, who from Istanbul traveled to Jerusalem. Ali Sami Bey presented an album of these photographs to the sultan. Garabet Krikorian of Jerusalem also took photographs of the kaiser's journey (Özendes, 1989).

Adjutant Major Mehmet Hüsnü (1861–?), Bahriyeli Ali Sami and Fahrettin Türkkan Pasha (1868–1948) were among the photographers graduated from other military schools who were employed by the palace (Özendes, 1989).

Baghdad's most eminent photographer Z. G. Donatossian took photographs of every official inauguration, while Sadık Bey's photographs of Mecca were the first of the holy city ever to be taken (Özendes, 1995).

In Persia the first Daguerreotype was a portrait of 13 year old Prince Nasar-od-din Mirza taken during the reign of Muhammed Shah Qajar (r. 1834–1848) by the Russian diplomat Nikolaj Pavlov in 1842.

A photographic laboratory established in the royal palace by Muhammed Shah reflects the growing interest in photography, which had been introduced by western visitors to Persia. This laboratory could be described as the first official studio (Tahmasbpoor, 2004).

Albania

Three generations of photographers from the Marubbi family represent the core of the history of photography in Albania. The first, Pjetër Marubbi (1834–1903) or Pietro Marubbi, an architect, painter, sculptor and photographer, was born in Piacenza, Italy, and as a member of Garibaldi's movement, came to Albania where he in 1864 founded the first studio for photography in the town Shkodra. The Studio Marubbi, as it was printed on the reverses of his cartes-de-visite, which worked until 1890, was specialized both for portrait-making and for photographic documentation of the famous marketplace (bazaar) in Shkodra. With remarkable success and greatest attention he documented city-scenes, as well as the scenes of fishermen's lives. When shooting landscapes, he chose the panoramic aspect, whilst in documenting the scenes of old urban settlements he sometimes boldly shortened the perspective. Some carte-de-visite portraits by Pietro Marubbi look like salt prints, but they are made on albumen paper. Many are hand-colored and varnished. Marubbi published some of his photographs on life and customs in Albania in the magazine "Illustracione Italiana." Later on, in the 20th century, his photographs were often used as illustrations in many books about Albania. They were motives on the first postcards and many other reproductions.

The second generation of Marubbi photographers is represented by brothers Mati and Kel Kodheli, Pjetër Marubbi's adopted sons. It was Kel who took over the Studio, because Mati died young (1862–1881). Kel Marubbi (1870–1940) documented, as a good reporter, all the important events and persons involved in the movement for liberation of Albania from the Ottoman Empire. Especially important are his reports about the mountainous regions where he took photographs of anonymous peasants and shepherds as well as interesting folklore types. Around 1900, the Studio Marubbi was, according to the print reverses on the photographs, the official photographer for the Montenegrin royal family Petrović in Cetinje.

Kel's son, Gegë Marubbi (1907) who had continued his father's work, gave the entire collection of negatives from the Studio Marubbi, with a span of almost hundred years (1864–1952), to the Albanian Country. In 2005, UNESCO and its Italian-founded PASARP program started the process of digitizing about 240,000 negatives, glasses and films of this collection.

Kolë Idromeno (1860–1939), one of the leading painters of realism, had also a studio for photography in Shkodra. He printed numerous postcards, notably in Austria and Germany at the turn of the century.

Bosnia and Herzegovina

According to the latest research, the oldest existing photograph was taken in Sarajevo in 1855, and its author was Georg Knežević. It is a photograph of a bride and bridegroom (Jaša and Gavrilo Jelić), who were both from families of tradesmen, and were thus members of the middle class in a society that was still feudal. Georg Knežević was a traveling photographer, who worked first in Budapest, then Novi Sad, Segedin, Belgrade, Sarajevo and finally in Zadar. He combined the form of carte-de-visite with paper negatives printed on salted paper when making portraits in his improvised atelier, but in his senior works he used wet plates and albumen paper. He regularly visited Sarajevo for longer periods of time, of which a number of private collections of photographs give evidence. Although he was a traveling photographer, Knežević wrote his name, surname, profession and location both on the back and on the front of his photographs in Cyrillic letters.

During the insurrections in Herzegovina in 1875–1878, came a traveling photographer named Silvio S. Maskarić from Dubrovnik. He made many portraits of the insurgents, as well as of the refugees who found shelter in Dubrovnik's surroundings. Beside wet plates, he also used the ambrotype technique.

With the arrival of the Austro-Hungarian army in 1878, many traveling and official photographers came to the area. Traveling with the army, their photographs were often of executions and other military subjects but they usually lack the signature of their authors.

The first permanent studio for photography was opened in Sarajevo by Anton Shadler who came from Vienna in 1878. Another photographer, František Franjo Topič came to Sarajevo as a representative of the Viennese Court Art Institute C. Angerer and Goshl. He was very active as an outdoor photographer until 1905 and he published many photographs in the official annual of Provincial Government "Bosnian" (Bošnjak).

The National Museum (Zemaljski muzej Bosne i Hercegovine) was founded in 1885 and from 1891 it published its illustrated "Annual" (Glasnik) with photographs of Ćiro Truhelka, the director of the Museum and of A. Weinwurm, photographer. In the book "Durch Bosnien und die Herzegowina kreuz und quer" (Through Bosnia and Herzegovina along and across), Berlin 1897, an eminent number of Weinwurm's photos was included.

At the end of the 19th century, there were many photographers in Bosnia and Herzegovina from all the countries within the Austro-Hungarian Monarchy: G. E. Abinum, Emanuel Buchwald, Ignaz Lederer, A. Viditz, Stefan Ossko and A. Hoiger working in Sarajevo, Ottmar Rebaglio and Johan Patzelt in Banja Luka, Anton Kuzcento in Livno, Julius Zenter in Brčko, Vladimir Merćep in Bileća and Cisar Leopold in Bosanska Krupa.

The first amateur photographer and mountaineering reporter was doctor Radivoje Simonović from Sombor, who climbed Herzegovina's mountains in 1888, and some of his photographs were published in the magazine "Nova Iskra" (New Spark) from Belgrade.

Bulgaria

The first photographers in Bulgaria were foreign traveling photographers that came in the middle of the 19th century. They were mostly French, Austrian, Hungarian and German. The oldest existing photograph was made by a traveling photographer in 1851 in the town Šumen, and it represents an orchestra founded by Mihail Šafran, an immigrant from Hungary and participant of the revolution of 1851.

Before he founded the most prominent studio for photography in Sofia in 1878, Anastas Karastojanov (1822–1880) was the court photographer of the Crown-Prince Mihailo Obrenović in Belgrade under the name of Anastas N. Stojanović, as it was printed on the reverses of his cartes-de-visite from 1863. Being a participant of the Bulgarian national revival (Vazrazdane), he made dozens of portraits of the prominent insurgents. He also used the wet plates technique when he documented the spectacle organized in the streets of Belgrade on the occasion of the 50th anniversary of the Obrenović dynasty and of the uprisings for the liberation from Turkey. His sons Ivan and Dimitar had continued the work at the studio "Braća Karastojanovi" in Sofija, and it had been prosperous from 1878 until the middle of the 20th century.

Ivan Stojanov Papazov-Zografov, learned to paint icons at the Holy Mountain, first, and around the year 1860, he began making photographic portraits as well as icons in Panaguriste. Because of the fact that he participated in the April's insurrection, he and his wife received the capital punishment, and his studio for photography was destroyed. We can judge his work only by a remaining family album with photographs. Stojan Karaleev was also both a painter of icons and a

photographer. He learned to paint icons in Kiev where he also bought a photo-camera around 1870.

Nikifor Nenčev Minkov (1838–1928) gained his first knowledge of photography in Rumania, and around 1860, he founded a photographic studio in Istanbul under the name of "Nikifor Konstantinopol." During the Russian-Turkish war of 1876, he took panoramic overviews with military troops and scenes of life behind battlefield.

Toma Hitrov (1840–1906), together with Josif Buresh opened a photographic studio "Slavjanskata Svelopisnica" in Sofia around 1890. He made portraits, of which the best ones are those of the cabinet format, but he also photographed everyday life in the streets of Sofia. His portraits of contemporaries (insurgents, prominent writers, scientists and intellectuals) are very direct and sincere, and they show the author's keen sense for analyzing characters. He remained faithful to the wet plates technique until the end of the 19th century. He was one of the first photographers who systematically documented the landscapes and locations where the key events of the Bulgarian insurrection took place. At the beginning of the 20th century, his daughters Ivanka and Bojka took over the studio. They learned photography in Dresden and Berlin.

Many foreign photographers had their permanent studios in bigger Bulgarian towns, only after the liberation, that is to say, at the end of the 19th century. Some of which are the following: M. Wolf, Fr. Bauer, O. Markolesko, M. Rekhnitch, J. Buresh, V. Velebni, F. Grabner, M. Kurtz, etc.

The Collection "Portraits and Photos" kept in the National Library St. Cyril and Methodius in Sofia, consists of over 80.000 photo documents.

Macedonia

In the second half of the 19th century, came a number of traveling photographers from Serbia, Bulgaria, Turkey, Greece and Austria to the regions of today's Macedonia. Authors that are truly essential for the development of photography as well as for cinematography are beyond doubt brothers Yanaki and Milton Manaki.

The Manaki Brothers were born in a small village Avdela, Kostur area, Greece. They started to work together in 1898. During this time Yanaki (1878–1960) was a drawing professor in the high school in Yoanina, where he opened his photo studio with his younger brother Milton (1882–1964). In 1905 they moved their studio to Bitola and opened their well-known "Studio for art photography." In that period, Bitola was an important political, economic and cultural center for the Balkans. At the invitation of King Karol the First, they took part in the Big World Exhibition in Sinaia-Romania in 1906. They won a Gold medal for their photo collection and received the title of court photographers of His Majesty Karol the First.

Their unique skills and artistry attracted many outstanding Balkan personalities, including Prince Mehmed, later to become the sultan of Turkey, King Karol I of Rumania, as already mentioned, and many of the legendary insurgents of the Macedonian revolutionary units of the uprising against Ottoman's empire.

The photo-legacy of the Manaki Brothers with 18.513 negatives, of which 7.715 are glass plates, is kept at the Macedonian State Archive, Regional Dept, Bitola.

Serbia

The work of Anastas Jovanović (1817–1899) belongs to the pioneer age of the calotype process in the Balkans, with more than 800 paper negative and 500 paper positive pieces, kept in the City's Museum in Belgrade. In his *Autobiography*, he described in detail his first encounter with daguerreotype and calotype in Vienna where he was from 1838 as student at the Academy of St. Ana and later, as photographer and lithographer, until 1859. According to J. M. Eder, an Austrian historian of photography, Anastas Jovanović practiced calotype as a member of the group around Anton Martin, the author of the book *Repertorium der Photographie* (1846/8). As many of Jovanović's portrate calotypes are dated 1850, it can be asserted that they were part of the preparations for the publication of *Spomenici Serbski* (Serbian Memorials), a series of lithographs of intellectuals, writers and prominent personalities from the young Serbian state. The portrait genre stands out in Jovanović's photographic opus not only because it greatly outnumbers all other motifs, but also because of its exceptionally high artistic merit. His decision to use close-ups helped him span the distance between his Voigtlander camera and the model.

The legacy of Anastas Jovanović includes paper negatives of the streets and squares of old Vienna as well as the fortress of Petrovaradin on the Danube and the Library of Belgrade photographed by Petzval's portrait lens in 1850, so that parts at the corners of the paper remained unexposed. He photographs outdoor scenes as panoramic overview, but searching for dynamic light-and-dark relations. The body of Jovanović's calotype works contains some still-lifes, interiors and reportages about historic events, such as the withdrawal of the Turkish army from the Belgrade fortress in 1867. Photographs of the exteriors that Jovanović made later on indicate that he, with the process of wet plates, adopted the conventional style of photographic approach.

The public in Serbia could read about the invention of daguerreotypes in *Magazin za hudožestvo, knjižestvo i modu* (The Magazine for Art, Literature and Fashion) already in 1839. Another magazine, "Srbske narodne

novine" (Serbian Popular Newspaper) states that Dimitrije Novaković made the first daguerreotype of the city of Belgrade. Serbian press reports about another domestic author—Milija Marković, a clergyman, who learned the technique from a German traveling photographer Adolf Deitsch in 1850. Josif Kappilleri, traveling daguerreotyper, came to Belgrade in 1844, and Florian Gantenbein came from Switzerland to open a permanent studio in Belgrade in 1860.

The appearance and publishing of collections of photographs in the format and outfit of cartes-de-visite coincided with the incline of the first Serbian dynasty: Obrenović's. Early studios of cartes-de-visite portraits, as Richard Musil and Mirić, Panta Hristić, Anastas Stojanović, Đoka Kraljevački, Aleksa Mijović, Milan Jovanović and others, introduced the international language of Disderi's portrait into Serbian photography. Their work is no different from the work of foreign photographers such as Nicolaus Stockmann, Moric Klempfner and Lazar Lezter.

The value of documentary approach becomes particularly apparent during Serian-Turkish war 1876–1878. Ivan Gromann, a Russian photographer, made a series of photographs in the wet plates technique about the scenes of war as well as fragments of everyday life in the south of Serbia. His intention was to perceive and document reality in its totality.

OVERSTONE, LORD (1796–1883)

English patron

Samuel Jones-Loyd, first, and only, Baron Overstone, was an influential banker, a collector of Italian, Dutch, and French old-master paintings, and a munificent patron of the arts. He was one of the organizers of and lenders to the Manchester Art Treasures exhibition of 1857. His place in nineteenth-century photographic history is due to his connection with Julia Margaret Cameron and her family, to whom he provided substantial long-term financial support, in large part because of the friendship he had formed at Eton College with her husband, Charles Hay Cameron.

It was Mrs. Cameron's habit to give albums of her work to members of her family and to famous men whom she admired, like Sir John Herschel and George Frederick Watts, both of whom sat to her. As a likely acknowledgement of the largesse that had underwritten her photographic endeavors, on August 5, 1865, Mrs. Cameron gave Lord Overstone an album containing 111 photographs that she had made in the previous eighteen months, beginning with some of her earliest images. She indexed them in three categories: "Portraits," "Madonna Groups," and "Fancy Subjects for Pictorial Effect." Inevitably, Overstone became one of her sitters, but not until 1870.

GORDON BALDWIN

OWEN, HUGH (1808–1897)

As a photographer, Hugh Owen is now chiefly remembered for his photographs of the objects exhibited at the Great Exhibition of 1851 (otherwise known as Exhibition of Works of Industry of All Nations) and for being the first photographer to photograph a cornfield (an achievement since early emulsion usually rendered

yellow as black). Little is known of Owen's early life except that he was born in 1808. He was an accountant and the Chief Cashier for the Great Western Railway, employed by Isambard Kingdom Brunel. Owen even lived for a while, in and apartment in the Temple Meads building, above the railway's offices. He was married twice—the first time at St. Mary's Redcliffe Church to the daughter of Thomas King a Master of the Society of Merchant Venturers—and it is known that he had at least one child (a daughter).

It is not clear how or when Owen first became interested in photography, but most accounts have him making photographs by 1847. In a letter to W.H.F. Talbot written in March of 1845, Owen requests a sample of Talbot's calotype process and says that he as "for some time practiced the process on Silver." This statement implies that he was familiar with the dagurreotype process before learning the rudiments of photography on paper. It has also been suggested that Owen once worked with another Bristolian photographer by the name of John Bevan Hazard in the 1850s, though further research needs to be done to determine the exact nature of their collaboration.

In 1851 Owen, along with the French photographer C.M. Ferrier, was "elected by his peers" to make 155 photographs for the Executive Committee of the Great Exhibition. The photographs were intended to illustrate the Reports by the Juries and the prints were to be made by Nicholas Henneman using Talbot's salted paper process. Concern over the quality of Henneman's printing though led the majority of the prints to be produced in France under the supervision of Robert Jefferson Bingham who had also taken several of the pictures. It was an ambitious project and the first known attempt to photograph the contents of an exhibition and thus represents an important watershed in the history of catalogue publishing. Surviving prints from this body of work show that in some instances Owen chose to photograph the object in isolation, as we can see for example in *Camel Gun*, where the gun and its elaborately decorated saddle are set against a dark background. There are no clues about how the gun was displayed, what other objects surrounded it, or how it would have appeared to the viewers who paraded through the Crystal Palace in 1851. The photographs seem to have been meant more as a kind of inventory rather than a souvenir of the exhibition itself. Approximately one hundred and forty bound sets of the reports were made and were distributed to Queen Victoria, the Exhibition Commissioners, the British Museum and "a few other institutions."

The city of Bristol was also commonly featured in Owen's photographs. One of his earliest photographs was of the shops of the Corn Exchange on Narrow Quay. Dating from the 17th century, the building was demolished in 1849 and was one of several examples of historic architecture in Bristol that Owen sought to record and preserve through photography. A number of these photographs were exhibited in London at the Society of Arts exhibition in 1852 and the Photographic Institution in 1853. These images reflect the almost documentary style with which he approached his subjects. Heavily influence by the Pictureseque tradition, he also photographed scenes from the countryside around Bristol including waterfalls, quarries and "ruins" as we can see in a work titled *The Bishop's Palace*. Probably photographed in the late 1840s or early 1850s only two decades after the Bristol riots of 1831 that had been the cause of the building's destruction. Given his position as an employee of the Great Western Railway, it is no surprise to find that Owen also photographed trains—and in particular one that had gone of the rails—as can be seen in the photograph titled *Bristol and Exeter Railway No. 20*. Several of his photographers were later copied and made into lantern slides and then were eventually turned into postcards featuring the city of Bristol and its environs.

Owen was also one of the founding members of the Calotype Club in 1847. The majority of his photographs are salted paper prints made from paper negatives (except for a few prints he made while trying out the wet-collodion process). Although he experimented with the wet- collodion process, his distaste for the medium (apparently he was irritated by the staining of his fingers by the collodion mixture) led him to abandon photography around 1855.

Photography was not Owen's only hobby. He was obviously very interested in the historic sites of Bristol and was made a Fellow of the Society of Antiquarians. In 1873 he published a book titled *Two Centuries of Ceramic Art in Bristol* and was considered an expert in the field.

Although somewhat a forgotten figure within the history of photography, Owen is considered to be the master of early photography in Bristol. His contributions to the history of early photography in England are only beginning to be re-discovered. His photographs were often left unsigned but occasionally bear the letters HO. Owen's work can be found in public collections around the world but the largest collection appears to be in the Bristol Records office. He died in 1897.

P

PACHECO, JOAQUIM INSLEY (c. 1830–1912)

Portuguese painter and photographer

Born in Cabeceiras de Basto, Portugal, in about 1830, landscape painter, watercolor artist and photographer Joaquim Insley Pacheco learned the daguerreotype method from Frederick Walter in Ceará, Brazil, before studying under Mathew B. Brady and Jeremiah Gurney in New York. He also used the ambrotype and platinotype methods and was "an apologist of photopainting." Pacheco in 1854 founded a photographic studio in Brazil originally called Pacheco & Son (later Insley Pacheco) and returned to the US to photograph the Civil War (1861–1865). Renowned for his portraits, he was a favorite of Emperor Pedro II. Appointed Imperial Photographer on December 22, 1855, and dubbed a Knight of the Royal Order of Christ, Pacheco won over 16 medals for works shown at the Imperial Academy and national and international exhibitions. He took part in the 1862 London Exhibition, the Expositions Universelles of 1867 and 1889 in Paris, the Vienna Universal Exhibition (1873), the Philadelphia Universal Exhibition (1876), the Buenos Aires Continental Exhibition (1882), and the Chicago Exhibition (1893) among others. His photographs won honorable mention in Vienna, first prize at the Oporto International Exhibition in Portugal (1865) and a gold medal at the Louisiana Purchase Exposition (1904). He died in Rio de Janeiro in 1912.

SABRINA GLEDHILL

PAINTERS AND PHOTOGRAPHY

Artists from the time of the Renaissance relied on optical devises such as the camera obscura as an aid to create landscapes, interior views, still-lifes and portraits. The way that a camera records a view differs from how our eyes see the same scene. The camera image perspective is perceived differently, and the images are in sharper focus. Painters using the camera obscura knew this, and used this forerunner of the camera to meticulously render objects, and to represent depth and dimension on the flat surface of canvas.

With the invention of the daguerreotype, the image captured by the camera was no longer fleeting. It now had the same permanence as a painting and could be framed, stored in a case and shared with others. Some artists and critics feared that photographs would eventually replace painted portraits and landscapes. Samuel F. B. Morse (1791–1872), who brought Daguerre's process to the United States in 1839, believed that "Art is to be wonderfully enriched by this discovery. How narrow and foolish the idea which some express that it will be the ruin of art." Morse was obviously correct, and during the second half of the nineteenth century, photography influenced artists both self taught and academically trained, in styles as diverse as Folk Art, Realism, and Impressionism.

Portrait Painting

The public began to look at paintings in new ways as a result of the photographic images that were available to them after 1839. Daguerreotypes provided likenesses that made the work of itinerant artists appear less true to life, and they were less expensive than painted portraits. The growing interest in daguerreotype portraits resulted in a reduced interest in miniature portraits in the 1840s and 1850s, and some painters of miniatures began to earn a living hand coloring daguerreotypes. Not every artist abandoned miniature painting. John Henry Brown (1818–1891) of Lancaster, Pennsylvania, did not even take up the art of miniature painting until the 1840s. He relied heavily on daguerreotypes as an aid in creating

his miniatures which he sold for between $100–$250 to wealthy patrons in Philadelphia. This was significantly more that the three to six dollars charged for painted daguerreotypes.

While some artists stopped painting portraits as a result of the competition of daguerreotypes, most artists painting life-sized portraits quickly found ways to use the new technology as a tool to assist them in the creation of their work. Photography was recognized as an aid to the making of portraits by both Itinerant portrait painters in New England capturing the likeness of local inhabitants, and the Academically trained artists in Europe painting portraits of world leaders. Painters such as Horace Bundy (1814–1883), who found their clientele by traveling from town to town in New England, frequently advertised portraits painted from both photographs and daguerreotypes (*Horace Bundy Broadside*, March 1851, Dodge & Noyes Printers, New Hampshire Historical Society, Concord). Advertisements show that portrait artists made use of photographs in a numerous ways. They used daguerreotypes to paint portraits of deceased family members, or as a visual aid that eliminated long sittings for the subjects of the painting. Some artists, such as the Itinerant artist Erastus Salisbury Field (1805–1900) created group portraits of large families from several photographic images of both living and deceased family members (*Ruben Gilbert Puffer Family*, c. 1857–650, courtesy Stephen P. Putter Family on loan to Historic Deerfield, Inc.). This type of photo-montage, painted in oil by Field or watercolors by other anonymous painters, often had the sitters appear much too small for the room they inhabited (Unidentified Photographer, *Campbell Family*, ca. 1870 albumen print photomontage with watercolor, George Eastman House, museum purchase).

Photographers and academic and self taught artists began to paint over enlarged photographs in the 1850s. In 1856 Mathew Brady was advertising "large portrait photographs printed on canvas and colored with oil paint." David Acheson Woodward (1823–1909)**,** a portrait painter and art instructor, patented a solar camera in 1857 that used light from the sun and copying lenses to enlarge a small negative onto large photographically sensitized paper or canvas. Many artists did not simply paint the photograph, but would use the photograph as a starting point, changing the background of the room, the pattern of fabric, style of the clothing, or expression of the face of the sitter. Erastus Salisbury Field who was experimenting with a variety of ways to use photographs in his work must have been familiar with D. A. Woodward's solar camera. Field, in his portrait of an *Unknown Woman* c. 1855, (formerly titled *Clarrisa Field*, oil on paper adhered to canvas, Museum of Fine Arts, Springfield, Massachusetts) took an enlarged photographic image on paper (photograph on file at the Museum of Fine Arts Springfield) and pasted it onto his canvas and then painted directly over the paper. Woodward brought his technique to Europe in 1859 where he influenced many painters including the French artist Leon Cogniet (1794–1880) who he met in England. Cogniet used Woodward's invention to paint the full length portrait of *M. Magne* over a photograph by Andre-Aldolphe–Eugene Disderi. *Phot-pientre* was the term used by Disderi to describe his process of printing enlarged images on canvas. Cogniet also created several preliminary sketches of the subject—so the photographic image was only one step used to complete the portrait. Almost a decade after Woodward's trip to Europe, Isaac Rehn's method of creating solar photographs was described in the *Philadelphia Photographer*, June 1868. The article reports that he prepared the canvas by brushing on a mixture of zinc white, egg albumen, ammonium chloride and silver nitrate. Most painters did not own a solar camera, but could obtain canvases with photographic images by sending negatives through the mail to photographers such as Albert Moore of Philadelphia who would enlarge the negative onto paper or canvas.

Political portrait paintings were more widely available as a result of photography. Portraits of American leaders such as Abraham Lincoln, Henry Clay, General Grant, John C. Calhoun, and Daniel Webster were in great demand for display in public buildings and in private parlors. Mathew Brady's Studio was a source for many of these photographs. Artists such Chester Harding (1792–1866), George P. A. Healy (1813–1894), George Henry Story (1835—1923)**,** and Thomas Sully (1783–1872) all used photographs to paint political portraits. George Healy's *The Peacemakers* (White House Collection) painted in 1868 shows a meeting that took place three years earlier. Healy used life sketches he made of Lincoln in 1862 and Brady's studio photographs of Lincoln, General Grant (1864, Library of Congress), General Sherman and Admiral Porter to paint this scene.

Landscape Painting

By the late 1840s, landscape artists began to alter the way they painted as a direct result of their exposure to landscape photographs. The ways that landscape painters were influenced by photography is wide-ranging. Calotypes and Collodion prints that blurred leaves on trees and placed areas of light and shadow into flat plans influenced Jean Baptiste Camille Corot's (1796–1875) paintings. Corot was part of a group of painters and photographers working in the forest near Arras, France. This group tended to prefer romantic naturalism which presented the spirit of nature in vague forms and soft focus. The photographer Adalbert Cuvelier and the

de Gaillard, Paul. Portrait of a Woman Seated in Profile.

painter/photographer Constant Dutilleux were among this group.

Later in the nineteenth century, the United States Geographical and Geological expositions often included both painters and photographers, and they influenced each others work. The painter Thomas Moran (1837–1926) and photographer William H. Jackson were on the same exposition to survey the Yellowstone region in 1871, and Moran at times used photographs taken by Jackson in his paintings During the 1880s, photographers Timothy H. O'Sullivan, William H. Jackson, A. J. Russell, Jack Hillers and Edward Muybridge frequently relied on the framing devices of trees and mountains used by Hudson River School artists like Thomas Cole and Frederick Church. Hillar and Muybridge often sought out high vantage points in which to set up their cameras so they could offer an above ground view like those often found in Hudson River School paintings (John Hillar *Mouth of Zion Park*, c. 1872–73, albumen print, Denver Public Library.) Muybridge also manipulated his prints in the darkroom in order to express the aesthetic of landscape paintings.

Albert Beirstadt (1830–1902) was among the first American landscape artists to be influenced by photography. He was familiar with the large western photographs of Carleton Watkins (exhibited December 1862 at Goupil's gallery in New York) and Watkins' work encouraged him to go to Yosemite Valley. The work of Watkins and other landscape photographers most likely caused Albert Bierstadt to paint his landscapes from new vantage points with altered perspectives. Previously, Beirstadt had followed a tradition of landscape painting that placed the viewer's eye level well above ground. Imitating the new photographic views, Beirstadt began to paint landscapes from the ground level looking off to the base of mountains that soar above the viewer as in *Looking up the Yosemite Valley* (Haggin Museum, California). The other type of landscape view that

Bierstadt adopted from photography can be seen in *Thunderstorm in the Rocky Mountains*, 1859 (Museum of Fine Arts, Boston, gift of Mrs. Edward Hall and Mrs. John Carroll Perkins). In this work he placed the foreground, middle ground and distance all below eye level at the lower portion of his canvas. The way that Bierstadt painted the large rocks in *Thunderstorm in the Rocky Mountains* may also have been influenced by stereoscopes that brought dimension to objects in the foreground. Beirstadt's accurate rendering of geological and botanical forms leads viewers to believe that real scenes are represented in his paintings. His landscapes, were however idealized views that relied on truthful details.

The art critic John Ruskin (1819–1900) was interested in how photography could bring truthfulness to fine art. He studied daguerreotypes of architecture and landscape views in an attempt to capture their detail and tonal qualities within his own drawings. The Pre-Raphealite Artists, whose work he championed, used photographs as an aid in creating their paintings. Ruskin's writings, however, encouraged artists to paint from nature and only use photographs for drawing or studies. As time past, he grew even less enthusiastic about photography's role in painting, and wrote in 1868 that "I knew everything that the photography could and could not do;—I have ceased to take the slightest interest in it."

Impressionist Painters and Photography

Impressionist artists had a close association with photographers. In 1874, the conservative judging at the French Academy exhibitions prompted Claude Monet (1840–1926) and other Impressionists to exhibit their works independently in the studio of the photographer Nadar. French and American Impressionist artists, noted for painting out of doors (*en plein air*) using loose brush work, relied on photographs to understand the placement of forms, to capture particular times of day, and the changes of light and shadow on figures and the landscape.

The American artist Theodore Robinson (1852–1896) noted that "Painting directly from nature is difficult as things do not remain the same; the camera helps to retain the picture in your mind." Robinson first used photographs to create crayon portraits in the 1870s. He continued to use photographs as an aid in painting portraits and landscapes during his years in Giverny with Claude Monet. Robinson often used a grid on his cyanotypes or albumen prints as a guide to transfer the composition onto canvas. He stated that "I must beware of the photo, get what I can of it and then go." While transferring the photographic image on to canvas, he freely made alterations such as removing or repositioning objects and figures. Robinson's paintings *At the Fountain,* also entitled *Josephine in the Garden*, c. 1890, (Canajoharie Library and Art Gallery) was one of a series of paintings created after photographs of this subject (c. 1890, cyanotype, Terra Foundation for the Arts, Gift of Mr. Ira Spanierman, C1985.13). His oil on canvas of *Two in a Boat*, 1891 corresponds to his albumen print of the subject (Terra Foundation for the Arts, Gift of Mr. Ira Spanierman, C1985.1.1). Robinson used a grid on the photograph as an aid to transfer the forms of the boat and figures onto canvas, but omitted one of the boats that did not suit his sense of composition when he was painting the subject.

Nineteenth century painters were working from photographs that provided tonal variations, but no information about color. Impressionist artists used photographs in the same way they used pencil sketches. Impressionists usually remained faithful to the colors they recalled from direct observation. They had to rely on nature, their imagination and their talent as painters, to transform the photographs they used into paintings.

Portrait and landscape photographers often framed their subjects following traditions found in painting. Impressionist painters however, noticed that many photographs taken by amateurs did not follow these traditions and showed major figures, not framing devices, at the edge of the picture. This is demonstrated in many of Edward Degas' (1834–1917) paintings including *Carriage at the Races*, c. 1873 and *Bouderie*, 1873–1875. At times photographs captured awkward poses and cut off figures at the edge of the picture. Edward Degas noticed these images and began to purposely paint figures at the edge, rather than center of the canvas.

Degas' accurate copying of photographs also resulted in a new somewhat distorted perspective in some of his works. His paintings, at times, show large foreground figures and a much smaller scale for figures only a bit further away. This exaggerated perspective could be found in all styles of painting copied from photographs. It was often a point of criticism, and was even the subject of a Nadar cartoon in 1859 that ridiculed the exaggerated foreshortening and impossibly large shoes of a seated figure with his legs outstretched towards the viewer.

Nude Studies Used by Painters

Nude photographs were used by artists as studies for painted figures. Eugene Delacroix and (1798–1863) Gustave Courbet (1819–1877) were both drawing and painting nudes from photographs by the mid 1850s. Eugene Durieu, and Julien Vallou de Villeneuve were among the many photographers in France providing nude studies to painters. Paul Cézanne used a photograph of a nude male for his painting *The Bather,* c. 1885 (Museum of Modern Art). In this painting, Cézanne transformed a photographic image of a nude male in a

static pose standing on a rug (Unknown photographer, Museum of Modern Art) into a walking figure in a landscape.

The American realist painter Thomas Eakins took photographs of nude models for his paintings, and provided his students with nude studies of himself and others. The nude figures in his paintings *Arcadia,* 1883 (Metropolitan Museum of Art) and *Swimming*, 1885, (Amon Carter Museum, Fort Worth, Texas) were created by copying figures from photographs. Sometimes Eakin's combined individual nude studies such as his photograph of Susan Macdowell Eakins, c. 1883 (Pennsylvania Academy of Fine Arts) into larger figure groups within a landscape setting.

Motion in Photographs andPaintings

Impressionist artists copied the blurred images caused by the movement of figures and slow exposure times in order to express motion in their paintings. This can be seen in Robinson's painting *Gathering Plums*, 1891 (Georgia Museum of Art, University of Georgia, Eva Underhill Holbrook Memorial Collection of American Art) where the artist faithfully copied the blur caused by the movement of the plum pickers hands.

Exposure times of 1/50th of a second were possible as early as the late 1850s. The reduced exposure time allowed for instantaneous photographs of city life. By 1861 the London Stereoscopic Company was boasting that their photographs showed horses legs and walking figures "without a blur." Stereoscopic photographs often showed these snapshots of city life with walking figures in poses not traditionally found in art.

Edward Muybridge's instantaneous photographs influenced a number of painters in the 1880s. Muybridge's 1872 commission to photograph race horses in motion resulted in photographs that contradicted what had been depicted in paintings, and lead to his open criticism on the way that Realist artists such as Rosa Bonheur (1822–1899) painted horses. The actual motion of a running horse's legs was recorded by Muybridge placing a bank of cameras along the race track and taking a series of stop action photographs. The photographs revealed that all four hoofs actually left the ground, but not in a way actually depicted by painters. By the 1880s Muybridge was lecturing and using lantern slides to compare his photographs of horses in motion to famous paintings he felt did not accurately represent the horse's movement.

Edward Degas (1834–1917) and Thomas Eakins (1844–1916) responded in different ways to this new visual information. Eakins took a scientific interest in animal locomotion and his painting *May Morning in the Park* shows horses trotting in front of a carriage in a manner demonstrating the influence of Muybridge's photographs *The Horse in Motion Abe Edgington trotting* (photographic print on card, The Library of Congress) and *Lizzie M trotting, harnessed to sulky, Animal Locomotion pl 609.* (1884–86). Muybridge's book *Animal Locomotion* included human motion which also intrigued Eakins. The American Realist artist was particularly interested in how muscles in the human body worked and used sequential photographs of figures walking to gain insight into how to paint a figure in motion.

Both Degas and Eakins, not only studied Muybridge's photographs, but also took their own photographs of figures in motion. Degas was particularly interested in painting ballet dancers and photographed them to better understand how they moved. Paintings such as *Carriage at the Races*, c. 1873 (Boston Museum of Fine Arts), and Eakin's *May Morning in the Park*, convey motion through the accurate rendering of the horses' legs and also by positioning the subjects at the edge of the canvas to show that they are traveling across a landscape that continues beyond the picture's edge.

More to Discover about Individual Artists and Their Use of Photographs

Painters found many ways to use photographs in combination with preliminary sketches or to replace pencil studies for paintings. Both Impressionist and Realist artists drew penciled grids on their canvas to aid copying photograph images onto canvas. The French artist Jules-Meuenier projected glass lantern slides on to his preliminary drawings which he then transferred to canvas. Eakin's also traced projected images onto his canvas. Other artists, including Eakins, used a pantograph that allowed lines traced on the photograph to be transferred in a different scale onto canvas.

While most painters in the second half of the nineteenth century found some use for photographs as an aid in creating their work, they did not always openly admit to their reliance on photographs to their public and art critics. During the 1880s, artists including Eakins and the French Realist Pascal Aldolphe-Jean Dagan-Bouveret (Photograph of the artist working at Ormoy from a model on *The Pardon in Brittany*, 1886, Metropolitan Museum of Art, Archives dela Haute-Salone, Vesoul, France) went so far as to pose for photographs depicting them painting from a live model, when they in fact had relied heavily on photographic studies to create the painting. Conservators and art historians looking closely at nineteenth century paintings, artists' letters and journals will continue to uncover information about how photographs were used by individual artists.

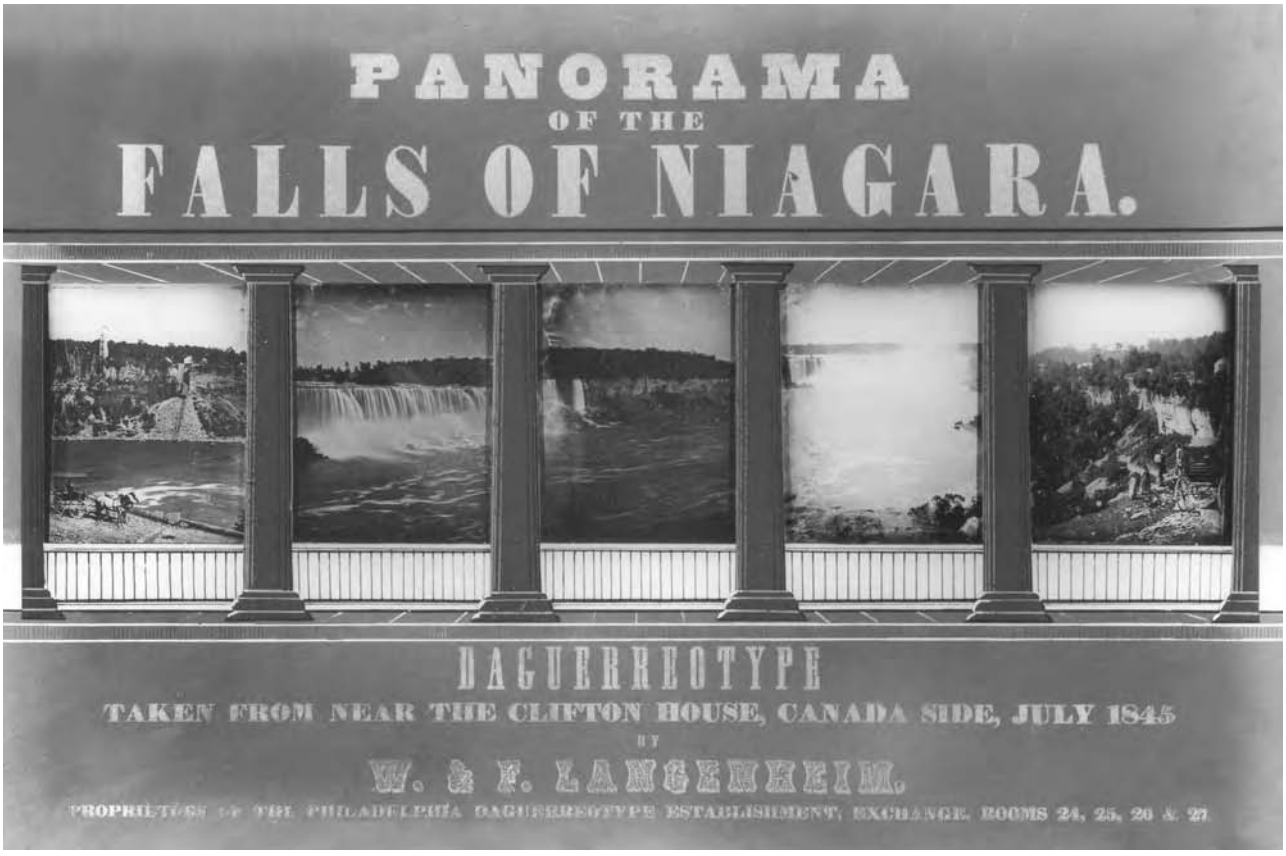
PANORAMIC PHOTOGRAPHY

Since its birth, photography sought to compete with human vision by the reproduction of reality; with the panorama, it succeeded in exceeding it. The panorama indicates, in photography, an image of the broadest possible angle of vision (up to 360°); it thus exceeds the extent covered by an ordinary lens (50°) and that covered by the human binocular vision (approx. 160°). It follows in the fashion of the painted panoramas presented in specially built rotundas, whose prototype was patented by the Scot Robert Barker in 1787 and who knew a great vogue in the first half of the nineteenth century. The painters also had the idea to use photography to save time in the realization of their painted scenes. One of the most famous examples is the The Siege of the Malakoff by Colonel Charles Langlois, made of 14 plates, created in 1855 and inaugurated in 1860 on the Champs-Elysées. To help in the project, he was assisted in the photography by Leon Méhédin and in the printing by Frederic Martens.

A photographic panorama can measure a few centimeters or several meters, and consist of only one or several assembled prints. It is obtained by means of a «wide angle» lens or from an ordinary lens assembled on a special apparatus. The nineteenth century distinguished four categories of panoramic images: panoramas of views, consisting of a lengthened image, carried out with only one lens and in only one take; panoramas formed of the juxtaposition of several views; panoramas realized by a mobile lens allowing the coverage of an angle of 150° (since 1845); and panopticons, views embracing a complete horizon or more (since 1890). Initially, the juxtaposition of several prints proved to be an effective means to widen the field of vision; but the photographers were not satisfied with this type of properly pictorial representation. The photographic panorama acquired its autonomy thanks to the invention of special apparatuses known as panoramic.

On June 23, 1845, Frederic Martens, who in the 1830s created engraved panoramas of the large towns of Europe then towards 1840 created engravings according to daguerreotypes for the Lerebours' *Excursions daguerriennes*, presented at the Academy of Science the first panoramic room for daguerreotype; this room, known as also Mégascope, was marketed by Lerebours. The principle is as follows: an ordinary lens laid down on a pivot traverses all the points of the horizon according to a horizontal movement produced by a crank; this objective makes it possible to take photographs of 12 × 38 cm, very clear on the surface, embracing an angle of 150°. The daguerreotype marries the cylindrical curve of a drum; thanks to this curve, the points most unequally distant are brought to the surface of the plate, which is rectified after the shot is taken. The clearness of the image is due to a vertical narrow slit at the bottom of the box which follows the objective in its movement; this slit lets only the central rays act on the sensitive layer. An expensive and cumbersome device, being able to produce only daguerreotypes, this apparatus was dedicated to a restricted use.

In 1848, Napoleon Garella, a mining engineer in Algiers, eager to apply panoramic photography to his work, obtained two tests rectified with its "planopanoramic," "rectilinear" apparatus, which did not require bending the plates of daguerreotypes: the sensitive plate turned with the lens, which allowed the use of plain negatives. In 1850, Peuvion adapted this device to negative glass. The field of vision covered by this type of apparatus is of 180°, that is to say half of a view. In 1856, Martens Schuller, nephew of Martens, reached a similar result starting from the invention of his relative, by applying the principle of the revolving unit of Garella to the ap-



Langenheim, William; Frederick Langenheim. Panorama of the Falls of Niagara.

paratus of his uncle. This apparatus includes a lens of 15 cm focus, turning on itself. The sensitive glass plate must follow the lens in its movement while being maintained constantly in relation to him and equal distance. Instead of the lens alone, all the camera turns around the pivot fixed under the axis of the objective thanks to a mechanism of casters. The frame carries the glass plate in a carriage to casters and turns too. The plate presents thus successively all the parts of its surface at the narrow slit. The rotating movement can be regulated by means of a mechanism or be directed by hand, which makes it possible to prolong or decrease the installation according to the light. The apparatus can thus carry out a whole review; very clear iamges are obtained. The disadvantages of this apparatus are the slowness of the preparation of the glass plates, their weight and their brittleness.

In 1858, Garella improved his first apparatus, resulting in a type close to that of Martens Schuller. The same year, Ross manufactured in London an apparatus designed by Sutton, for curved plates and provided with an angular large objective of 120°. In the 1860s, the inventions multiplied. In 1862 the patent of the pantoscope of Johnson and Harrison in London was registered, for plates with collodion; to the exposition of the Société française de photographie of 1865, Brandon exhibited a panorama taken on top of the Saint-Jacob Tower in Paris, with this apparatus. In 1865, Martens, who continued to improve his invention, obtained a view on only one negative, of a great clarity. In 1867, the Abbé Rolin presented at the SFP a panoramic apparatus allowing the creation of several partial shots forming a panorama, on the same plate.

In these first three categories of images the principal photographers of the years 1850–1870 illustrated themselves, who saw in the panorama a technical challenge; one could see many examples of them in the exposures (panoramas of cities, of mountains) signed Baldus, Bisson, Braun, Gray (scene of Châlons), Marville for France, Hill and Adamson for the United Kingdom. In addition to insistence on the effect of the illusion produced, criticisms generally commented on the homogeneity of the tone and the connection between the prints. The World Fairs, which emphasized the wonders of nature and the richness of the colonial empires, and which resorted to the new medium, exhibited many panoramas. In 1851, Martens was distinguished at the Great Exhibition in London for his panoramic images on

albuminous glass. In 1855, he showed at the Exposition Universalle, Paris views of the Alps (on this occasion, the critic Ernest Lacan called him the "photographer of the mountains") in particular a panorama of Mont Blanc composed of fourteen prints and one of the Geneva Lake, "one of those scenes in front of which one stops seized by surprise and admiration" (Louis Figuier). In spite the many panels repainted, the sight of Mont Blanc was appreciated for its smoothness: "Nothing is more admirable nor more imposing than this panorama. One recognizes there the feeling and the key of a consumed artist, and, as for the exactitude of the details, it is enough to have an idea of it, to compare the photographic tests, placed around, with the parts of the drawing which reproduce them. Not a stone was forgotten, not a piece of ice has escaped the scrupulous hand of the artist "(Ernest Lacan). In 1855 also, the Bisson brothers exhibited a 150 cm-long image of Paris. Baldus, using the apparatus of Garella, showed a picture of Mount-Gilds with the lake Chambon, 130 cm long, and a picture of the interior of the arenas of Arles, both discussed by critics. At the 1867 Exposition Universalle, the Abdullah brothers showed a panorama of Constantinople that was 220 cm long.

One could also see panoramas at the exhibitions of the Société française de photographie. In 1859, Sinigaglia, photographer of Padua, exhibited a picture of Venice in ten prints, almost four meters long. In 1861, Jeanrenaud, who used the apparatus of Sutton, exhibited a panorama of Thoune, which Lacan considered to be full of charm and harmony. In 1861, Baldus showed a Panorama of Tuilleries and the Louvre, which offered a view of two hundred degrees, about which a critic said that it " is beyond imagination, almost inducing dizziness" (Ladimir). In 1865, Gueuvin exhibited two panoramas of Paris taken from the Tower Jacques Saint, each forming an angle of 180°, taken with the apparatus of Koch and Wilz; Gaudin noted that they seemed to have been taken from a single viewpoint after the juxtaposition of different negatives, so that the junction was successful. In 1869, Koch and Wilz presented panoramic pictures obtained with their apparatus: a panorama of Paris capturing seven bridges, a great panorama of Meudon, Bellevue, Sevres.

The panorama had various scientific applications, like the technique of the photogrammetry of Colonel Laussedat around 1850–1853 (land surveys and soldiers). Paul Perier, who had percieved the views of the Alps de Martens not through photography, "but a kind of geological plan, a work of geographer or engineer" (1855), seemed to foresee the work of Aime Civiale, who provided panoramas of mountains to the best scientists, and more particularly geological, without artistic claim. He showed some at the SFP; in 1863, he showed a circular panorama close to Monte Moro and a panorama of l' Oberland; one of them measured eighty centimeters high and four meters long.

It was necessary to await the manufacture of flexible film in gelatino-bromide in the 1880s to see panoptiques appear (complete view). In 1883, Moessard invented the cylindrographe, patented in 1889 (same principle as Martens): two prints were necessary to obtain a whole panorama. In 1889, the apparatus of the Benoist brothers made it possible to obtain a complete view on glass.

The most important invention was, in 1890, the Cyclograph of Damoizeau. A camera is assembled on a swivel slide on a circular plate. A frame with rollers containing two reels of films allows a compact device and a reduced format of the apparatus as a whole. A clockwork motor rotates a cylinder containing the film, and the same clockwork motor rotates the camera. The same mechanism thus activates the rotation of the apparatus and the unfolding of the film in opposite direction, which makes it possible to produce images of great clarity. The clockwork is at variable speed, involving a more or less long rotation. A meter indicates the quantity of film available. An lens of 50 cm focus requires a 30 cm length plate and can produce a panorama of 3,14 m. It allows the use of lenses of different focuses and thus the creation from views of considerable length. This apparatus is characterized by its perfection and its simplicity of operation. It was shown with the Colombian Exhibition of Chicago in 1893 and taken again by Sheldon to the United States.

In 1895, Ducos du Hauron discovered the principle of the Microcosm (a silver plated ball reflects the image on to a flat plate or film). In 1899, Louis Lumière invented Photorama which made it possible to see the views of panoramic images and take pictures at the same time (systems of drums). Photography then exceeded the limits of the field of ordinary vision by showing on only one image what the human glance can see only while moving. The image becomes the ground of infinite investigations, out of the reference mark of the traditional prospect. From a faithful search for reproducing reality, this photographic technique leads to going beyond this reality.

PANUNZI, BENITO (1819–1894)

Nothing is known of his whereabouts before he arrived in Argentina.

He was a painter and architectural draughtsman, and is known to have taught drawing. The first national census (1869) records him as an Italian, 50 years old, single, a photographer with a studio at 55th Cuyo Street, Buenos Aires. The studio was named "Fotografía Artística."

He published country views, mostly from Buenos Aires and surroundings, accompanying them with a nice paper folder (583 mm by 430 mm), titled: *Fotografía Artística—Album de Vistas y Costumbres de Buenos Aires*. The images then were bound in albums.

The earliest known dated photograph is from 1868 (the seventh one), so, usually it is supposed that he started keping records not too before 1866. Usually he received, wrongly, the authorship of a small and crude album *Vedute di Buenos Aires*.

Excellent copies of his works are kept in Archivo Audiovisual de Venezuela—Biblioteca Nacional and private Argentine collections.

ROBERTO FERRARI

PAPER AND PHOTOGRAPHIC PAPER

Paper has played an essential part in photography initially in the late 1830s and 1840s as a support medium for both the negative and positive, and increasingly from the 1850s, as the principal means of producing a positive, on commercially produced photographic papers. During the initial period the quality of the paper was crucial to the end result while later on it was mainly a support to new photographic emulsions and printing processes being developed.

During the period up to the early 1850s, paper for photographic use was usually selected and coated by the photographer, although some retailer's such as London's Horne, Thornthwaite and Wood offered pre-iodised, waxed and albumenised papers. All the manuals of the period and instructions to amateurs gave clear advice on selecting paper for photographic use.

W.H. Thornthwaite writing in 1853 stated: 'There are various kinds of paper I have found well suited for the purpose, but that manufactured expressly by Turner, the blue wove of Whatman, and the positive paper of Carson Frères, of Paris, appear to produce the best results.' He continued: 'those sheets only are to be employed which are of an even texture and free from specks and water-marks; these specks should be carefully avoided, as they are generally small particles of iron left in the substance of the paper during the process of manufacture, and which, brought in contact with any salt of silver, speedily produce a brown stain on the paper of considerable size. The suitableness and quality of the paper is best ascertained by holding each sheet opposite a strong light, either of a window or lamp, and when approved a pencil mark should be made on one side of each sheet for the purpose of distinguishing it when required.' Thomas Sutton in his *Calotype Process* (1855) recommended Hollingsworth paper for negatives which he had specially made for the purpose of negatives. He described it: 'It is truly excellent, giving intense blacks, fine definition and beautiful half-tones. It improves by age; and, in fact, it is not in first-rate condition until it has been made for a year or two'.

These statements make a number of wider points about papers. There was general agreement that English papers were preferable to those of foreign manufacture. W.H.F. Talbot and his employees used J. Whatman Turkey Mill papers made at Hollingsworth's Mill at Maidstone, Kent, and R. Turner's Chafford Mill was also recommended. English papers were generally sized with gelatine while foreign papers were sized with starch leading to a better quality and improved light sensitivity through the organic compounds present in gelatine, a fact which was realised later and made use of.

The quality of the weave of the paper and effect on wet strength and finer 'grain' of the paper was crucial in producing more detailed negatives and chemical cleanliness all had a bearing on the quality of the final image. J.B. Hockin in his *Practical Hints on Photography* (1860) recommended English papers for Calotype photography and French paper, notably that made by Canson Frères, which was sized with starch, as being best for the waxed paper process.

There were other requirements for printing papers and other preferences amongst contemporary writers. Sutton stated that 'the paper commonly employed for positives is that manufactured in France by Messrs Canson frères' and he preferred the heavier weight although it was, he said, more inclined to chemical spotting than the lighter weight. He expanded on this by saying that the papers manufactured by Turner and Whatman although more sensitive than the Canson frères had a courser grain leading to poorer definition in the final Calotype print.

Hockin describing the printing of collodion negatives detailed what was required from the paper: 'that it be fine and close grained, with a very smooth surface, and sufficiently permeable to the liquids employed, without being rendered by them prone to be readily torn during the long series of washings and manipulations to which it is to be subjected. It should also be free from any "water-mark," and most especially free from metallic or other particles which induce ineradicable defects in the pictures.' Different qualities were required from the

paper depending on whether it was to be used simply as salted paper or as albumised and salted. For the former Hockin recommended English paper (Towgoods) and for the latter foreign papers only were suitable, the result of their being sized with starch which 'confers upon them a certain permeability by the very glutinous liquid, without detracting much from their strength or rendering them bibulous.'

Gustave le Gray writing in 1853 on the waxed-paper process stated that very thin paper from Lacroix or Canson Frères was required for making waxed-paper negatives. This was expanded on by Roger Fenton, an acknowledged practitioner of the process, who stated that the 'beauty of the results depends much upon a judicious selection of [paper].' Fenton noted that Whatmans and Turners paper were recommended for their firmness and evenness of texture but that their gelatine sizing limited their suitability for photography. Paper from the Whatman mills from 1832–1838 was preferred as it was thinner and less highly sized and was 'much used by the French, who say that it gives better halftones, and supports the action of the gallic acid for a longer time.' Fenton recommended thin Chanson paper despite it being prone to iron spots which was sensitive, being sized with starch, one side was smooth and made from courser rags than the Whatman paper which gave it greater strength. Lacroix paper was similar in quality but with less spotting although slightly coarser.

In summary the three main paper processes, the Calotype and waxed-paper for negatives and printing paper each required different qualities from paper with the former more suited to English papers and the latter two to European papers.

The appearance of the collodion negative on glass from the early 1850s saw a rapid decline in the use of paper negatives and from the 1860s the major use of paper in photography was for the production of photographic postives. Increased commercialisation of photographic printing, the preparation of sensitised papers on a large scale and new processes affected the paper requirements through the rest of the nineteenth century. With the ready availability of pre-prepared printing papers the early range of papers tested and prepared by photographers was reduced to those available commercially which by the end of the century had expanded to large range of types, surfaces and weights.

The printing out process with paper made light sensitive through silver nitrate and salt goes back to pre-1839 experimenters and was used by Talbot and Herschel in 1839. These silver chloride papers remained the dominant type over silver bromide papers throughout the century because of their stronger blacks. The coating of paper with albumen to produce finer prints by overcoming the grain and porosity of paper was described by Blanquart-Evrard in 1850. Once and twice albumenised papers superseded starch and gelatine-filled silver chloride papers which had been introduced in the 1850s. Albumunised papers remained popular until the 1890s.

Experimentation and the development of permanent emulsion printing papers was advanced by the work of G. Wharton Simpson who developed collodio-chloride silver emulsion printing process, later called the celloidin process. This work was complimented by the work of J.B. Obernetter (1840–1887) of Munich who was the first to manufacture collodio-chloride papers on a commercial scale. The paper was claimed to have greater definition and permanency over the albumen papers that it gradually displaced. Colonel Abney in a paper read before the Photographic Society described gelatine chloro-citrate papers which led to their subsequent commercial manufacture.

The rise of the amateur photographer using dry plates and later rollfilm encouraged a demand for permanent and easily workable printing papers. By 1890 gelatino-chloride silver emulsion papers (aristo papers) and collodio-chloride silver papers (celloidin papers) had almost completely displaced the earlier albumen and starch papers.

The other principal photographic paper is use during the later nineteenth century was gelatine silver bromide paper. In 1874 Peter Mawdsley of the Liverpool Dry Plate Company described the possibility of using gelatine silver bromide papers for photographic printing which he believed was 'destined to play a most important part in the future of dry plate photography.' (*Yearbook of Photography* 1874) He manufactured such papers commercially emphasising their sensitivity and matt surface which was suited to over-painting. Mawdsley met with limited commercial success and it was Sir Joseph Swan (1823–1914) who in 1879 was granted British patent number 2968 for photographic printing paper coated with bromide of silver. The patent noted that the paper could be employed in a long band and prints made as the band advanced allow for large runs of prints to be made. Swan emphasised the short exposure in weak artificial light that would ensure successful results for the amateur.

Factories manufacturing silver bromide papers opened in France by E Lamy at Courbevoie and in Britain by Mawson and Swan, Morgan and Kidd and Marion & Co amongst others. Silver bromide papers, being more sensitive than the better quality silver chloride papers, as a medium for rapid printing with artificial light and for enlargements was rapidly adopted from 1880. To meet this demand emulsion coating machines for paper and plates were developed in Germany, Britain and the United States. Matt surfaced silver bromide papers were introduced from 1879 using starch paste instead of

gelatine and the Eastman Kodak Company introduced it's own matt papers which it called 'platino' from 1894. Matt papers displaced the more usual glossy papers for commercial and artistic photography although glossy papers were used in certain areas because of its greater resolution of detail.

Automatic printing machines were also developed the first of which was patented in 1883 by Schlotterhoss in Vienna. By the mid-1890s mass-production of photographic postcards using silver bromide papers was commonplace. Between 1895 and 1913 Arthur Schwartz's Neue Photographische Gesellschaft in Berlin had produced 40 million metres of photographic paper.

Silver chloride and silver bromide papers were not the only photographic paper in use. Other photographic printing papers using variants on the basic silver chloride and bromide formulae and new papers extended a demand for papers and commercial manufacture.

Gelatine silver chloride positive paper was first described by Eder and Pizzighelli in 1881 and large scale manufacture started from late 1882 by Dr. Just in Vienna. Leon Warnerke in London started the production of gelatine silver chloride paper in 1889 appreciating the warm tones compared to the cold tones achieved with silver bromide paper. Increased appreciation of gelatine silver papers and the marketing of such papers by the Eastman Kodak Company under the Velox tradename led to the dominance of this type of paper in the twentieth century.

Gelatine silver bromo-chloride emulsions for prints were described in 1883 and a range of papers was marketed in Britain under the Alpha tradename from the later 1880s and by Ilford Ltd under the clorona name and by other European manufacturers.

Self-toning papers which incorporated gold chloride or platinum were manufactured from the 1890s to improve the final colour of the print from the typical reddish colour to a more acceptable sepia to brown prints. Two new processes in the 1870s led to the development of a new range of papers. William Willis's (1841–1923) platinotype process patented in 1873, 1878 and 1880 led to the commercial introduction of a range of platinum papers manufactured for the trade and amateur use through his Platinotype Company. He also developed the palladium process requiring palladiotype paper and a silver-platinum paper, satista. These also saw commercial success.

The other area that saw the commercial development of new papers was the introduction of pigment processes. Swan's transfer process of 1864 was developed commercially by the Autotype Company which manufactured and sold pigment papers exclusively. The gum bichromate pigment process, popular from the mid-1890s also allowed companies to produce special papers and other transfer processes such as bromoil moved paper away from a purely sensitised base.

The 1870s and 1880s saw a short-lived return to paper being used as negative support in an effort to develop smaller and more portable cameras suitable for amateur use. Leon Warnerke in 1875 produced dry collodion silver bromide films on chalk coated paper which could be stripped. This was not successful but the idea was resurrected by George Eastman in 1884 who developed a paper film using a specially developed coating machine which he patented in 1885. The sensitised paper roll was used in an Eastman-Walker roll holder and attached to the back of a camera. The grain of the paper was intrusive and was replaced by a stripping film where the paper served as a temporary carrier for the emulsion layer which was transferred to a glass plate after development. The introduction of celluloid from 1888 as a carrier for photographic emulsion in 1888 quickly superseded paper roll film, although glass remained the main support for professional photographic emulsions until the 1960s.

The use of paper throughout the nineteenth century saw a move away from the paper being critical to the effectiveness of the process to one where the paper was primarily a carrier for a silver halide photographic emulsion and, later, non-silver emulsions and pigments, leading manufacturers to develop increasingly specialist surfaces and weights of photographic paper for increasingly specialist or aesthetic ends.

PARKER, JOHN HENRY (1806–1884)

English publisher and photographer

John Henry Parker, publisher and bookseller from Oxford became Director of the Ashmolean Museum, Oxford, in 1870, published *The Manual of Archeological Terminology* (1836), and *The Manual of Gothic Architecture* (1849). After he came to Rome in 1863, he founded the British and American Archaeological Society of Rome in 1865 and carried out several excavations on behalf of the Pope. He became convinced that photography was a more accurate method of recording

than drawing and was the first to demonstrate the use of photography in archaeology and to use magnesium lighting for photography by artificial light. From 1866 onwards he commissioned the Italian photographers, Giovan Battista Colamedici, Carlo Baldassarre Simelli, Francesco Sidoli, Filippo Lias, De Bonis and Filippo Spina as well as the Canadian, Charles Smeaton, to document the 'Antiquities of Rome from the Classical Age to 1600.' In 1869 his catalogue had 1500 images and by 1879 boasted 3391 which he published in reproductions, issued in 12 parts from 1874–1878 as *The Archaeology of Rome.* A set of actual photographs was offered in 1879 as *A Catalogue of Three Thousand Three Hundred Photographs of Antiquities in Rome and Italy*. The majority of the plates however were lost in a fire in 1893 and there are only three nearly complete sets of the photographic prints known, one is at the British School at Rome.

Alistair Crawford

PARKES, ALEXANDER (1813–1890)
English inventor

Alexander Parkes, the originator of over eighty patents during his career, covering a range of inventions in metallurgy, rubber, vulcanisation, and plastics, was born in Birmingham, the fourth of eight children, and would eventually have twenty children of his own—eight by his first wife, twelve by his second.

Parkesine, the invention for which bears his name, was the first plastic material based on cellulose nitrate, and was introduced during the 1862 International Exhibition in London. As such, it predated and predicted the massive plastic industry which has emerged subsequently. Indeed, Parkes anticipated many of the uses to which cellulose-based plastics might eventually be applied.

Four years later, in 1866, he established The Parkesine Company to market the material, and an alternative to rubber, or the gutta-percha and shellac-based thermoplastics which were then in vogue. The company was based in Hackney Wick in London.

Despite the great expectations Parkes had for his new material, The Parkesine Company ceased manufacture after only two years, and closed with significant debts. Parkes had anticipated being able to market the material at a price of less than a shilling per pound, a target which proved unachievable.

His work, however, laid the foundation for the modern plastics industry. The American John Wesley Hyatt introduced the most significant product based on cellulose nitrate, with the development in 1863 of *celluloid* on which photography for so long depended.

John Hannavy

PATENTS: BRITAIN AND EUROPE

Britain's first patent relating to photography was granted to the patent agent Miles Berry on behalf of Louis Jacques Maude [*sic*] Daguerre and Joseph Isidore Niepce, junior, on 14 August 1839 for the daguerreotype process. Richard Beard, who had licensed Daguerre's process, was granted the next in June 1840 for an improved camera with internal mirror and improvement to operating the process. The third was granted to William Henry Fox Talbot for his calotype process. The 1840s saw only eleven photographic patents being granted.

The Great Exhibition of 1851 acted as a catalyst for reformed patent law as manufacturers and patentees sought greater protection and attempted to meet increasing competition from the United States, although the resulting Act only partially met their demands. In comparison with the American system Britain's patent process left much to be desired for patentees. The Patent Law Amendment Act of 1852 reduced the cost of a single patent for the United Kingdom to £25 (plus renewal fees) from a previous minimum of £310 and the application process was simplified. The number of photography patents increased. The 1850s saw 185 classified by the Patent Office as photography, the 1860s 273 and the 1870s 213. The 1883 Patents, Designs and Trade Marks Act further reduced the cost of a patent and simplified the application procedure and during the 1880s 750 photography patents were recorded with the next decade, the 1890s showing 1778. The Patent Office photography classification included some subjects that were not strictly photographic such as emulsions and stands and some patents that might be seen as photography were included in other classifications such as advertising and printing.

Unlike the American system, under the British patent system there was no requirement for the applicant to show novelty and many patents were simply variants on existing designs rather than novel designs of apparatus, chemical processes or applications of photography. The two Patent Acts of the nineteenth century each coincided with significant changes to photographic technology which led to significant increases in the number of patents being applied for and in the areas in which patentees were applying for patents. The 1860s, for example, saw a significant number of patents relating to photographic printing and photo-mechanical printing processes and the latter remained strongly represented until the 1890s. In the 1880s and 1890s patents for roll holders were widespread, as were those for shutters and studio and flash illumination. In the 1890s as new technology began to coalesce into practical applications kinematography patents started to appear regularly and from 1896 Röntgen, or X-ray photography, was represented for the first time.

In Europe there were different patent systems operating which offered varying degrees of protection to the patentee. In France the modern patent system was established by 1844 and consisted of a simple registration system with the state remaining an active participant in managing both the patents and their exploitation. An inventor could choose between a patent or offering an invention to the government in returned for an award from a special fund. Until 1902 patent specifications were not published although the original application was available for inspection. In Germany unified national patent legislation was passed in 1877 which established a central office for granting patents. Government policy was intended to encourage economic development and in some areas, such as chemical products patents, were prohibited. The government encouraged the diffusion of patent information by publishing claims and specifications before they were granted. From 1891 a *gebrauchsmuster* offered a parallel but weaker system of protection through a registration system.

Elsewhere in Europe two countries took a view that patents were not morally acceptable. The Netherlands reinstated a patent system in 1912 and Switzerland in 1888 mainly as a response to international pressure.

Japan, as part of its modernization policy during the mid and late nineteenth century, sent an envoy in 1886 to examine the European and American patent systems. As a result the first national patent law was passed in 1888 copying many features of the American system which were considered superior to the various European systems, although it placed many restrictions on patentees. A new law was passed in 1899 after Japan signed the Paris Convention which brought it into line with the convention and extended patent protection to foreigners.

Despite some serious deficiencies in its patent process the British patent specifications record some of the key developments in photography. Some notable patents include the Woodburytype process (number 2338 of 1864 and others), the platinotype process (number 2011 of 1873) and the Kodak camera (number 6950 of 1888). Many other British patents are unlikely to have ever been produced commercially. Several innovations that one might have expected to be patented were not, the most significant being Frederick Scott Archer's wet-collodion process which he published and made freely available in 1851 ensuring a wide-spread and rapid adoption compared to the patented daguerreotype and calotype processes. Both of those were robustly defended through the law courts.

PATENTS: UNITED STATES

In order to encourage improvements in the applied arts, the United States government in 1790 gave inventors (citizens and non-citizens) temporary, exclusive rights to profit from their inventions. The purpose was to promote public good through individual ingenuity; the incentive was the guarantee of ownership and attendant profits. Patent rights, however, were limited. The original Patent Act of 10 April 1790 fixed the term of U.S. letters-patent for inventions at no more than fourteen years; in 1861 it was expanded to seventeen years.

In spite of the protest mounted by some in the photographic community who believed that photography could only be advanced by the free exchange of ideas, most involved in the business understood that the costs associated with patent rights were an inevitable part of doing business. However, exclusive patent rights were frequently challenged, especially if the patentee defined his invention so broadly that others could easily be accused of infringement. And patent holders who insisted upon substantial fees sometimes found themselves outfoxed by others who circumvented their patent rights by inventing slight modifications, for which they too could apply for and receive a patent.

Particularly contentious was the fourteen-year controversy surrounding three patents issued in 1854 to James A. Cutting. In one of these patents, *Improvement in Compositions for Making Photographic Pictures* (11 July 1854, No. 11,266), known as the bromide patent, Cutting had modified Frederick Scott Archer's collodion process to include bromide, which made film more light-sensitive and thus speeded up the process. Since the patent included all wet-plate photography, it would be hotly contested by the full photographic establishment who saw it as a threat to the progress of photography, collodion being a new and important medium for making both positives and negatives.

Some of the most important photographic patents of the hundreds that were granted in the nineteenth century are the following. The first U.S. Patent in photography was issued in 1840 to Alexander S. Wolcott for his *Method of Taking Likenesses by Means of a Concave Reflector and Plates So Prepared as that Luminous or Other Rays Will Act Thereon* (8 May 1840, No. 1,582). His reflector shortened the time of exposure in the camera when taking a daguerreotype. Ann F. Stiles was the first woman to be issued a photographic patent. Her invention, a *Case for Daguerreotype-Pictures* (22 January 1850, No. 7,041), consisted of a tube-like case in which one could view a small daguerreotype through a magnifying lens. Albert S. Southworth was issued a patent for a *Plate-Holder for Cameras* (10 April 1855, No. 12,700), which allowed the photographer to prepare one plate then slide it into place for multiple views in rapid succession, or for stereoscopic views on one plate. Edward J. Muybridge received two patents for an *Improvement in the Method and Apparatus for Photographing Objects in Motion* (4 March 1879, Nos. 212,864 & 212,865) for instantaneous photography, where the subject is in rapid motion. George Eastman's patent for a *Method and Apparatus for Coating Plates for Use in Photography* (13 April 1880, No. 226,503), transformed photography from wet plate to dry plate by making commercial gelatine dry plate affordable. His machine could spread gelatine emulsion easily and uniformly over glass, and eliminated the early problems with the process.

Patents were not only issued for photographic methods, but also for albums, cases, stereoscopes, cameras, stands, head rests, burnishing tools, printing frames, plate holders, photographic backgrounds and baths, etc. Whereas many patents saw their way to manufacture or use, others were quickly abandoned or never realized.

PAUL, ROBERT WILLIAM (1869–1943)

English inventor and electrical engineer

Born October 3, 1869, at 3 Albion Place, Highbury, North London, and active in Britain's early motion picture industry, Paul had following a technical education and employment with the electrical instrument makers Elliott Bros, Strand, started his own business in 1891, at 44 Hatton Garden. Asked by two Greek entrepeneurs to make copies of the Edison Kinetoscope motion picture peepshow machine, he realised that the design had not been patented in England and started making examples on his own account. Introduced to photographer Birt Acres, their resulting camera for 35mm film provided motion pictures for Paul's kinetoscopes. Subjects taken by Acres in 1895 included The Derby (the oldest surviving English film), Rough Sea at Dover (screened in New York in April 1896), and several comic scenes. After an acrimonious split with Acres, Paul made a successful film projector, the Theatrograph, and a new camera. Films included A Soldier's Courtship, shot on the roof of London's Alhambra Theatre. Paul built a studio and continued producing motion picture machines and films until leaving the changing industry in 1910, to concentrate once again on electrical engineering. He died March 28, 1943, at Twickenham, England.

STEPHEN HERBERT

PEASE, BENJAMIN FRANKLIN (1822–1888)

American engraver, studio owner, and photographer

One of eight children, Benjamin Franklin Pease was born November 17, 1822, in Poughkeepsie, New York, to Dudley Pease, and Sara Rilley. According to the family genealogy, Benjamin was considered an artist as a young adult and by 1846 he was engaged as a wood engraver.

Pease arrived in Lima, Peru, ca. 1852, and a published advertisement states that he purchased a daguerreotype studio at 14 Plateros. Sometime around 1855 he married Peruvian Mercedes Ramírez and together they had eighteen children, though not all the children survived.

He operated successfully for several years at the

Plateros location in Lima during a time the city was experiencing extensive population growth and economic change. This period also brought about more photographic competition. Pease moved his studio sometime around 1859 to a street level location, 182 Plateros, the same building in which Emilio Garreaud had his studio. Historian Keith McElroy, who has complied extensive biographical information on Pease, characterized Pease's daguerreotypes as "straightforward studio portraits... [that] meet high standards, and he served a distinguished clientele, including presidents, intellectuals, and socialites."

In order to compete in the burgeoning photographic community, in addition to his daguerreotypes, Pease began to offer the public ambrotypes, various kinds of hand painted images, and photographs on paper. By all accounts he remained successful. But this success was eventually overshadowed by yet another technological advancement, the carte-de-visite. In the summer of 1856 Benjamin Pease and his family left for Europe. The control of his studio was left to D. David Vargas and D. Fuljencio M. de Urgarte.

Benjamin Franklin Pease returned to Peru ten years later and operated an establishment that made and sold shoes, sewing machines, and other items. He died in Pisco, Peru, in 1888.

MICHELE M. PENHALL

PECK, SAMUEL (active 1840s–1850s)

American inventor and photographer

Samuel Peck was instrumental in the introduction and initial development of the thermoplastic union case in the early 1850s, and thus responsible for the first application of molded plastic to photography.

After spending his early years as a grocer, Peck is listed as an early daguerreotypist operating a studio in New Haven, Connecticut, from the mid 1840s until early 1852, by which time he was also making leather daguerreotype cases, probably in partnership with the Scovill Manufacturing Company. His first patent, issued in April 1850, was for an improved holder for daguerreotype plates during buffing.

Peck's first patent for a thermoplastic composition case (US Patent 11,758) was issued on October 3, 1854, and by the following year, the partnership with Scovill had been formalised into a new company known as Samuel Peck & Co.

Over the following six years, Peck's company, along with rivals A P Critchlow, and Littlefield, Parsons & Co., was highly influential in the popularisation of the thermoplastic case. Peck, however, is believed to have left the company in 1857.

His engagement with photography and case-making was relatively short-lived, and he developed further careers, first as a music-hall proprietor, and then as an undertaker.

He is believed to have died c.1879.

JOHN HANNAVY

PENCIL OF NATURE, THE

Despite its limited initial audience, *The Pencil of Nature* was an epoch-making publication, both technically and aesthetically. Published in six instalments between 1844 and 1846 by William Henry Fox Talbot, it was a luxurious work that constituted the first true photographic book, incorporating in quarto format a total of twenty-four pasted-in original calotype prints (whereas earlier, daguerreotype-based publications had used engraved reproductions), and setting a model for later similar productions by Talbot and others. The subjects ranged from artwork to houseware, scenes in Talbot's Lacock Abbey estate, and English monuments. The prints, of various sizes, were produced at Talbot's Reading Establishment by Nicolaas Henneman and assistants, and pasted in along with a frontispiece, prefatory notes including a "brief historical sketch of the invention of the art," picture titles and lengthy captions in ornate type. The *Pencil of Nature* was sold by subscription, the price of instalments varying with the number of prints (from twenty-one shillings for Part II with seven prints, to seven shillings six pence for three prints in the last parts). Although nearly three hundred copies were produced of the first instalment, interest later dropped and fewer than one hundred were made of the last one. This small printing—a paradox for a book considered to be an ancestor of mass illustration—accounts for the rarity of extant full sets, fortunately supplemented by facsimile editions. Despite its limited circulation, however, the *Pencil of Nature* achieved Talbot's goal of illustrating his invention of a "new art"—an art indeed so novel that Talbot had to warn readers that the plates were produced "by the mere action of Light." It was not only a technical feat, but an ambitious attempt at giving artistic and aesthetic status to the calotype and, more generally, photography. Many of the pictures reflected a heritage of fine arts, and the caption for Plate VI, "The Open Door," explicitly linked its "common" subject—a barn door with tools on either side—to "the Dutch school of art." Thus, the *Pencil of Nature* almost single-handedly created the pictorial tradition in photography. This artistic bend, however, went beyond a generic affiliation with the fine arts, and the caption for Plate VI, as others in the book, should not be read as mere prophecy. More fundamentally, the *Pencil of Nature* enacted an aesthetics and practice of photography that

were strongly rooted in the subjectivity of its author. A number of the pictures illustrated a private (and even aristocratic) realm, which Talbot's texts construed as the antithesis to the universalist, Republican discourse that surrounded photography in France. In the *Pencil of Nature*, photography triggered fancy, as exercised especially in the activities of reading, writing, and more generally playing with signs; it engaged the reader's curiosity as a novel kind of sign itself. Thus fulfilling the concerns voiced in the preface, the *Pencil of Nature* succeeded in establishing—in contrast to the utilitarianism of the daguerreotype—an alternative definition of photography as "pencil of nature," i.e. the playful art of applying the "mere action of Light" to a singular, human creation.

PENN, ALBERT THOMAS WATSON (1849–1924)

The son of a family of shoemakers originating in Northamptonshire, Penn was born in Street, Somersetshire on 30 March 1849. Leaving home before the age of twelve, by 1865 he had arrived in Ootacamund, the South Indian hill station in the Nilgiri range west of Madras. During his first decade as a photographer in India, Penn appears to have worked closely with the firm of Nicholas Brothers (later Nicholas and Curths), before establishing his own studio in Ootacamund in 1875. From 1871 Ootacamund had served as the seat of Government for Madras during the hot season and the influx of European visitors to the hills, swelling the resident population, assured the photographer a steady market: for the last quarter of the 19th century, the Penn studio was the most successful photographic business in the Nilgiris, producing a comprehensive record of the town and surrounding hills in work that is often reminiscent of the picturesque style of Samuel Bourne. Penn also made an important documentation of the 1877 famine in South India and an extensive record of the hill tribes of the Nilgiris, in addition to supplying illustrations for a number of published works. He came back to England with his wife in 1911, but returned to South India after the First World War and died at Coonoor in the Nilgiris on 19 October 1924, where he is buried in the Tiger Hill Cemetery.

John Falconer

PENROSE PICTORIAL ANNUAL

From its first issue in 1895 as *The Process Work Year Book* Penrose's Annual, as it was more generally known for nearly a century, provided a review of progress in photo-mechanical and printing work and in its early years offered a unique source of examples of different photo-mechanical printing processes.

It was initially published by A W Penrose & Co which had opened a Photo-Process Stores at Upper Baker Street, London, and was edited by William Gamble (1864–1933) the partner in the firm responsible for the process engraving side of the business. He also edited Penrose's *Process Work*. From 1897 the annual was printed and bound by Lund Humphries of Bradford who in 1909 acquired an interest in the publication when they took over as publishers. Gamble emphasised in 1898 that Penrose saw the annual as more than simply a commercial venture, it was designed to promote photo-mechanical printing more generally.

Gamble had felt the need for an annual review which would give engraving firms the opportunity of showing specimens of their work. In the annual these were pages that were supplied directly by those firms as printing blocks or as printed sheets which enabled the annual to be produced and sold at a price that was significantly lower than its actual costs of production. No payments were made to photographers as the annual considered that an appearance in its pages constituted an introduction to editors and publishers. The specimen pages were supplemented by an editorial surveying progress over the previous year and articles on techniques and materials. In the early years these included many authors from photography such as Bolas, Brothers, Waterhouse, Sanger Shepherd, Chapman Jones and Horsley Hinton. Advertising pages at the rear of the book included catalogues from Penrose and firms from the printing, process and photographic trades. Gamble aimed the annual at 'the editor, publisher, author, artist, photographer, printer, engraver, paper maker, ink maker, binder…'

In 1896 the annual became *The Process Year Book. An Illustrated Review of Photo-Mechanical Processes.*

Penrose's Annual. The next year Gamble in his editorial emphasised that the annual's primary object was the exposition of British work. In 1898 it was subtitled 'a review of the graphic arts' which it retained until its demise and *Penrose's Pictorial Annual* was included on the masthead for the first time. The annual found a ready market and the early volumes quickly sold out. During the early 1900s it further expanded its pagination with more illustrations and articles.

By the 1920s as photo-engraving techniques became static the scope of the annual was expanded to include articles on printing and after Gamble's death in 1933 the new editor Richard B Fishenden further widened the scope to include modern art and experiments in creative colour photography. The annual failed to appear in 1914, 1917–19, 1941–48 and 1963. During its final years, publication was irregular and the last volume, number 74, appeared in 1982.

PERCY, JOHN (1817–1889)

English physician, photographer, and inventor

John Percy was born on March 23, 1817, and studied medicine in Paris and Edinburgh where he qualified as a doctor in 1838. An early enthusiast for photography, he is believed to have first experimented with the medium in 1844, using Talbot's calotype process.

He later studied mineral sciences, was elected a Fellow of the Royal Society in 1847, and took up a teaching post (later Professor of Metallurgy) at the newly opened Government School of Mines and Science Applied to the Arts (now Imperial College) in London's Jermyn Street in 1851. There he was assisted by John Spiller with whom he would subsequently take and exhibit photographs using Archer's collodion process. Their joint work appeared, in the 1857 Photographic Exchange Club album, and the 1857 exhibition of the Photographic Society.

Amongst Professor Percy's many scientific innovations was a means of extracting silver from photographic paper waste.

Surviving images point to him showing an early interest in stereoscopy and the Wheatstone Reflecting Stereoscope, producing images for this instrument contemporaneously with Roger Fenton and others.

In the year of his death, 1889, he was awarded the prestigious Albert Medal for, as the citation read 'his achievements in promoting the Arts, Manufactures and Commerce, though the world wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy.'

JOHN HANNAVY

PERIER, CHARLES-FORTUNAT-PAUL CASIMIR (1812–1897)

French amateur photographer

Charles-Fortunat-Paul Casimir Perier was one of the quintessential "gentleman amateurs" of early photography. The son of Casimir Perier, Prime Minister of France (1831–32), Perier helped manage the family's vast industrial and financial interests, although his avocation was in art collecting and connoisseurship. He acquired important collections of Dutch and Barbizon painting, and his taste for realism extended to the new art of photography. While evidently not a member of the earlier Société héliographique, Perier was a founding member of the Société française de photographie, which he served as vice-president. He photographed with paper and collodion negatives, and participated in the international exhibitions of the 1850s, in which he showed virtually all genre of subject matter, very little of which is known today. His work is rarely discussed in the early literature, perhaps in part because he was himself one of the era's few photography critics, writing lengthy and sensitive reviews in the *Bulletin de la Société française de photographie*. These articles also promoted Perier's own, sometimes polemical views, such as his argument that photography must be accepted as a fine art, albeit of secondary rank. Perier's photographic activity declined in the 1860s, as he turned more interest to writing on the French Salon and art in general.

LAURIE DAHLBERG

PERINI, ANTONIO (1830–1879)

Italian photographer

Fortunato Antonio Perini was born at Treviso in 1830. From the early 1850s he devoted himself to photography and in 1853 he was given official permission to practise as a photographer by the Venetian government. In 1854 he started to collaborate with Carlo Ponti, who collected and sold views of Venice by various photographers. In 1855 Perini showed an album of Venetian views at the Exposition Universelle, Paris and in 1856 he presented a similar album at the Universal Exhibition of Brussels. He took photographs of the solar eclipse on 15th March 1858. On 10th February 1859 he opened a shop

in Venice, next to the San Marco tower. He became very well-known for his professional skill, mainly for his photographs of works of art. In 1862 he won a prize at the International Exhibition in London with an album of 110 albumen prints representing the miniatures of the Grimani Breviary, a famous religious book kept in the Marciana Library in Venice. In 1878 he published his last work, an album of 24 albumen prints of the miniatures of Attavante Fiorentino. In his last days he wrote a letter to his friend Carlo Naya in favour of the proposal by Carlo Brogi of Florence, for a law defending the intellectual and artistic rights of photographers. He died in Treviso on 21st August 1879. His 1872 Vesuvius pictures still survive in the private Italian collection, P. Becchetti collection, Rome, and they are also published.

SILVIA PAOLI

PERMANENCY AND IMPERMANENCY

> Photographs need not, of necessity, fade" wrote Robert Hunt (1857), and "where they do fade, blame rests with the photographer, who has not bestowed the required care in giving them permanence… and if the pictures are toned with gold instead of sulphur, photographs are as permanent as water colour drawings.

That statement was made at a time when the fading of photographs had threatened to undermine the whole future of photography. Far from being the permanent record of nature drawing herself, photographs were becoming seen as being as transient and temporary as the light which originally created them.

The issue of fading was of such widespread significance in the early 1850s, and its causes so little understood, that a letter on the subject appeared in the first issue of the *Journal of the Photographic Society*. The writer, identified only as J.G.M., asked if

> there is any known method by which a positive photograph, prepared only with an ammonio-nitrate of silver solution, may be prevented from fading, or by which it may be revived, having faded; I have one in this latter condition taken about a year ago, and of which the details are certainly becoming obscured, the dark parts being much lighter.
>
> It was done in winter, during rain, and in a much warmer latitude than this.

The assumption that the weather conditions during the taking of the negative might have had some impact on the resulting permanence or impermanence of the print, demonstrates how limited was the average photographer's understanding of the chemistry involved in photographic production.

The editor's recommendation, that a solution of hydrosulphuric acid might restore the image, would have produced only a temporary improvement. Sulphur in the image would, in time, be identified as one of the many factors that contributed to impermanence.

Within two years of this letter appearing in print, the Photographic Society of London, increasingly aware of the mounting scale of the problem, established a committee of photographers and chemists to explore the problem. Their remit was "to take into consideration the Question of the Fading of Positive Photographic Pictures upon paper." The so-called "Fading Committee" chaired by Roger Fenton, was made up of many of the eminent figures of the day, its work funded by a donation from Prince Albert.

While Fenton may have held the chair, the project was led by the eminent chemist T. F. Hardwich. The brief for Hardwich's team had, in effect, been established while the salt print was pre-eminent, but the introduction of the albumen print in the early 1850s had exacerbated the problem. The greater concentration of chemistry within the more impermeable structure of the albumenised surface layer of the print had increased rather than reduced the problems caused by continuing chemical reactions after the processing cycle had been completed. Albumen prints were much harder to wash than salted paper prints, and the chemistry contained within the emulsion more complex. The methodology used by Hardwich to determine the causes and effects—in what was the first scientific study of its kind—established the principles upon which the effects of aging on photographs would be determined for many years. His experimental methodology is still held up as an exemplar.

Almost since the dawn of photography, fading had been recognised as an issue, but not one which appeared to afflict all photographers equally. While Talbot and Henneman had experienced significant fading problems with many of the production runs of prints made by Henneman at the Reading printing establishment in the mid 1840s, prints made by Hill and Adamson in Scotland had not exhibited such difficulties.

There were a number of differences in the manner in which the prints had been made. Henneman had observed that the print colour was 'improved' as the fixing bath aged—due in fact to increased levels of sulphur in the fixer—and thus elected to fix his prints in increasingly old hypo baths. Hill and Adamson, preferring the use of a more dilute, but always fresh, fixer, did not encounter the problem. While Henneman gave limited washing to the completed prints—thus inefficiently removing the complex thiosulphates from the paper thickness—Hill and Adamson washed for up to twenty four hours. While Henneman's shorter wash might have proved reasonably effective in warm weather with warmer water, in winter with cold water it would have

failed to significantly reduce the level of contaminants which would, in time, cause fading. The impact of cold water washing on albumen paper was even greater, with the cold water reducing the permeability of the albumen even further.

The practice of using aged fixers continued until the mid 1850s, recommended by many writers as a means of producing a print colour which was consider more 'pleasing.' It is remarkable that such a deleterious effect was directly as a result of *a positive decision* by photographers.

It was not until 1855 that the importance of fresh fixer and effective washing were widely publicised and understood. The understanding came, in part at least, from the scientific investigations of Alphonse Davanne and Jules Girard, published at about the same time as the 'Fading Committee' in London was undertaking its own exploration.

The most effective solution to the longer term fading of prints came from the combination of efficient fixing and washing, with gold toning, which greatly reduced the effect of sulphur on the image structure. The 'gold bath' became an almost universal stage in print production, but in spite of it, the effects of sulphur in the atmosphere over the past century and a half has bleached the edges of a significant proportion of Victorian prints, both on salt paper and albumen.

While gold toning may have arrested the lightening of the developed tones in an albumen print, no counter was ever discovered for the yellowing of the highlights, caused by the combined effects of light and pollution on complex silver/albumen salts which remained within the paper's image-carrying layer. While intensifiers were produced to 'redevelop' faded images, they could not be used on prints which exhibited this yellowing, as they effectively developed the highlights as well, introducing a buff 'fog' into the highlights.

Questions over image permanency led, in part, to the evolution of printing processes which were not exclusively dependent upon the conversion of silver salts to metallic silver. Carbon, platinum, and pigment processes all resulted in prints which were impervious to the effects of air-borne pollution, and which at the same time expanded the repertoire of the creative printer.

Other permanent printing processes grew out of the quest for methods which would facilitate print production on a truly commercial scale—such as Woodburytype, Autotype, and others—and the introduction of ink-based lithographic and gravure processes.

PERSPECTIVE

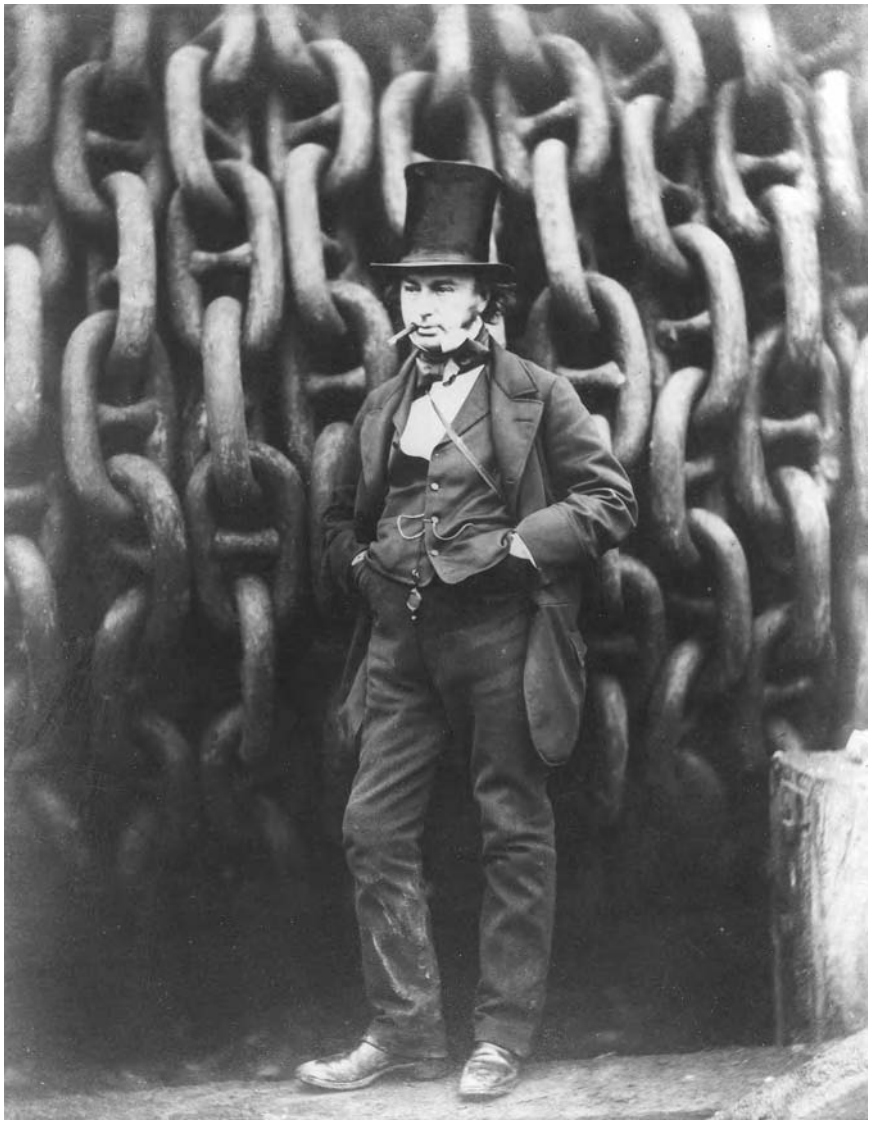
In photography, as in art, there are generally accepted to be two forms of perspective worthy of consideration–linear perspective and aerial perspective. The importance of both was clearly and distinctly understood from the earliest days of the medium.

Linear perspective—sometimes referred to as *isometrical perspective* by nineteenth century practitioners—is the phenomenon by which the spatial aspects of the three dimensional world in which we live are recognized by issues of apparent visible scale. The distance that we perceive in three dimensions is conveyed and visibly recreated in two dimensions by our recognition and understanding of those changes in scale. Thus, an object that appears smaller in a photographic print or a painting is read as being further away from the eye or the camera lens from a similarly sized object that is reproduced larger.

Aerial perspective—the term was coined by Leonardo da Vinci—has, on the other hand, long been understood as the enhancement, or otherwise, of the sense of distance conveyed in a picture by the effect of haze, smoke or water vapor in the air.

While the former implies distance by the convergence of lines towards a notional vanishing point, the latter uses the reduced distinctiveness of objects farther from the lens to imply their distance from the viewer.

The conditions which produced marked aerial perspective were not always seen as being advantageous to the photographer. Especially in the 1850s, when the pursuit of technical excellence was seen to be of greater importance than effect, aerial pollution was seen as a distinct problem, especially in cities where the smoke



Howlett, Robert. Isambard Kingdom Brunel Standing Before the Launch. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Harriette and Noel Levine Gift, 2005 (2005.100.11) Image © The Metropolitan Museum of Art.*

from coal fires combined with moist air to limit the occasions on which the atmosphere was quite clear.

Edinburgh, Scotland, was known as 'Auld Reekie'—literally 'old smokie'—because of the combination of damp air and smoke from fires. Thus, in a lecture to the Photographic Society of Scotland in 1856, the amateur photographer and advocate of le Gray's waxed paper process, Dr Thomas Keith, lamented the persistent effect of aerial perspective on his pictures:

> I am quite satisfied that the commonest cause of failure arises from the paper being exposed in bad or indifferent light, especially in town, where the atmosphere is much adulterated with smoke. I never got a good picture where there was the slightest trace of that blue haze which smoke produces between the camera and the object.

Yet, it is the spatial effect of that aerial perspective which gives many of Keith's pictures their character. The same is true of Roger Fenton's beautiful study *The Terrace and Park, Harewood House*, where, thanks to the haze of a Yorkshire summer, the picture reads as a series of planes, like the layers of a stage set, each lighter and less distinct than the one before it, receding into the distance.

It is, arguably, the impact of moisture in the air that enhanced the effect of aerial perspective in European photographs, and gave the work of European pioneers a quality distinctively different from the work produced in drier climates. In order to assess the likely final appearance of a photograph, photographers were encouraged to consider the scene without color, and thus to assess the tonal impact of aerial perspective. In *The Practice of Photography —A Manual for Students and Amateurs*, 1855, Philip Henry Delamotte suggested:

A black mirror, such as is used by artists, will be found useful in making choice of a view, as, by neutralizing the colours of objects, it more nearly exhibits the resulting photographic effect.

That was, of course, only partly true, due to the

limited color sensitivity of the materials then in use. The black mirror more truthfully exhibited the sort of tonal relationships which would be created on a panchromatic material—something that was still decades in the future. The blue sensitivity of calotype, waxed paper and wet collodion actually exaggerated the impact of aerial perspective, lightening the middle distance and distance more than was apparent to the naked eye, due to the increased blueness of the light which reached the camera from those distances.

In photography, linear perspective is a function of the relationship between the focal length of the lens, and the lens to subject distance. If the lens to subject distance remains constant, then so does perspective even if the focal length of the lens is changed. If, however, a wide-angle lens is used, and the camera is moved closer to the foreground subject, then the relationship changes and a distortion is introduced. That distortion appears to change perspective, and has been an issue which has had to be confronted and addressed ever since lenses were first used as an aid to drawing.

Early illustrators using the camera lucida as an aid to drawing quickly recognized the change in spatial reading, which a short focal length lens gave to them. Such effects are visible in the railway illustrations of John Cooke Bourne in the 1840s, who, for example, would later take up the camera himself as the photographer on the construction of Charles Vignoles' bridge over the Dneiper in Kiev. Users of both the camera lucida and the camera obscura had long understood that unless their instruments were level, a distortion caused by changes in vertical perspective would ensue. Talbot and his circle recognized this problem early on in the history of photography—where the tendency to tilt the camera upwards to include the topes of buildings introduced a horizontal perspective effect which we know today as 'converging verticals.'

In a letter to Talbot in June 1839, quoted in Schaaf (2000), his uncle, William Fox Strangways, offered a criticism of his early photogenic drawings, with the observation:

> I wish you could contrive to mend nature's perspective—we draw objects standing up & she draws them lying down which requires a correction of the eye or mind in looking at the drawings.

Cameras would later be fitted with rising lens panels to correct this distortion, enabling the tops of buildings to be included while keeping the instrument perfectly level. Others asserted that the creation of a true or natural perspective was beyond the capability of the camera. Writing in the *Journal of the Photographic Society* in June 1853, John Leighton believed that the single photograph would always suffer from the fact that "linear perspective [appears] comparatively flat when contrasted with binocular perspective as exemplified in the stereoscope." That comparative flatness was in fact a realistic representation of perspective, not a distortion.

Many artists saw the perspective created by the camera lens as being as being a distortion, an unnatural reading of the subject. Yet, as would later be proved, the camera's perspective was entirely natural—it was the expansion of perspective which was commonplace in paintings which was false. The painter George Frederick Watts (1817–1904) believed that photography "has unfortunately introduced into art a misconception of perspective which is as ugly as it is false," and the American artist Joseph Pennell (1857–1926) was so disillusioned by the perspective created by the camera that he abandoned using photographs as reference.

For much of the second half of the nineteenth century, the lenses used in architectural and landscape photography were of relatively long focal length, requiring quite a substantial camera to subject distance in the case of churches and cathedrals. Such lenses—with a field of view of between 10° and 30°—were essential if large format images were to be created which exhibited the degree of sharpness demanded by early photographers. Until optical manufacturing techniques advanced sufficiently to eliminate spherical aberration, long focal length lenses were the surest way of achieving a perfectly flat image field across the entire plate area. The effect of that was to create a slight compression of perspective—the flatness about which Leighton, Watts, Pennell and others complained. By the end of the century, with wide-angle lenses offering fields of view of between 50° and 80°, photography was able to create the same sort of enhanced perspective so beloved of painters.

PERU

In September of 1839, a major Lima newspaper (*El Comercio*), offered its readers news of the new Daguerrean process. Peruvian engagement with photography was not far behind that of more affluent countries (an in some cases it was ahead). In July of 1842, Maximiliano Danti

opened the first photography studio in Peru while Berlin's first studio opened in August of 1842 (McElroy 1977). Photohistorian Keith McElroy notes that photographers active in Peru during the Daguerreotype era (1839–1859) were generally from France or the United States. While the former emphasized "art, current European style and good taste," the latter based their marketing on "speed, prices and technical proficiency" (McElroy 1979a).

Philogone Daviette was the second known daguerreotypist in Lima (1844) and possibly the first in Perú to offer postmortems. Jacinto Pedeville (Pedevilla) arrived in 1846 and is credited (along with Felix Salazar) with introducing albumen prints in Peru in 1853. Early North American daguerreotypists include J. M. Newland (also known as Juan Newman), active in Lima and Callao (1846) and Arequipa (1847), and Arthur Terry who managed a Lima studio between 1848 and 1852. After moving to Chile, Terry was in partnership with Cipriano Clavijo who was later active in Arequipa and Trujillo between 1860 and 1892.

The first known native-born Peruvian photographer Juan Fuentes was active in Lima beginning in 1856. His idea to photograph convicted criminals as an innovative record keeping device was eventually funded by the government. Other Peruvian-born photographers from that era include Felix Salazar who worked in Lima between 1854 and 1887. Salazar was in a succession of partnerships with other photographers (Richardson, Bouvier, Remorino, and P. E. Garreaud). Salazar also produced views of the Arequipa Revolution of 1867 and the great Arequipa Earthquake of 1868.

North American Benjamin Pease arrived in Peru in 1852 and bought the studio of compatriot Arthur Terry. According to McElroy, Pease "produced the most significant body of daguerrean plates and built the first of the grand [photography] salons in Lima" (1979b). Later, Pease successfully transitioned into the cdv era. In 1870 Pease took a series of photographs of the Mollendo to Arequipa railroad line whose construction was supervised by the noted engineer Henry Meiggs. Other arrivals from the United States included Henry de Witt Moulton (who had worked at the famed Gurney and Fredricks studio in New York) and Villroy L. Richardson. Both men had been contracted to work at the Pease studio. Later, they were both affiliated for a time with the studio of Pedro Emilio Garreaud.

Villroy Richardson opened his own studio in Lima in 1862. Richardson's well executed cdvs were much in demand as were his images of the Lima to La Oroya railroad line. In the 1860s he produced photomontages, placing political personalities on the bodies of animals and later produced a series of popular political caricatures on cdvs. When he did not heed government warnings to cease, Richardson was arrested and released only after his political favorite became President. Henry Moulton's negatives of Lima and most significantly, the Chincha islands (where fortunes in guano were harvested), were made into prints by U.S. photographer Alexander Gardner. The images appeared in *Rays of Sunlight in South America* (c.1865).

Ricardo Castillo first worked for the Richardson studio. In the late 1890s, Castillo operated the latter's studio in association with Ignacio Lecca, and later managed his own studio. Castillo produced carbon prints, photographed the mining area of Cerro de Pasco and documented portions of the destruction resulting from the War of the Pacific between Peru/Bolivia and Chile (1879–1884). Eugenio Maunoury opened his elegant studio in 1861 and is credited with popularizing the *carte-de-visite* in Peru. Manoury along with José Negretti and the major Lima studios had great success marketing cdvs of *tapadas* (women posing in *mantos* (shawls) and *sayas* (skirts) once worn by Limeñas during the colonial period and which signified flirtation). Maunoury's affiliation with Nadar in Paris was noted on his cdvs and the logo was later used by the famed Courret studio when it acquired Manoury's three studios in 1865.

The Courret brothers studio established in 1863, merits special attention due to "The quantity, quality and duration of its production" (McElroy, 1977). Eugenio operated the camera while Aquiles took care of the business details. In the 1870s, the latter left Peru and Eugenio managed the studio until around 1892 when he returned to France. The elegant Courret studio produced thousands of cdvs and cabinet cards, outdoor scenes of various cities (Lima, Callao) events (earthquake of Arica and Arequipa, Industrial exposition of 1869); and of the Oroya railroad line. According to McElroy, "It would be impossible to illustrate a history of Peru in the second half of the 19th century without including Courret portraits" (McElroy 1977). The Courret studio was transferred to Adolfo Dubreuil and a series of successors. Portions of the Courret Archive have been preserved.

Photographers in the provinces were able to maintain successful studios in various cities, especially in Arequipa which for a time prospered due to a large demand for alpaca wool. Ricardo Villalba (also spelled Villaalba) owned a studio in Arequipa during the 1870s. He produced cdvs, remarkable photographs of the Mollendo to Puno railroad line and views of Lake Titicaca. Felix Renaut, active in Arequipa between 1868 and 1874, produced cdvs and stereoviews. Miguel and Luis Alviña whose familial relationship if any, is not known, both worked in Arequipa in the 1860s. Luis also worked in Cusco in the 1870s and participated in an expedition to Paucartambo in 1873. Some of his albumen prints of that region's people have survived.

Carlos Heldt worked in Trujillo, Lambayeque and Arequipa between 1870 and 1890. Juan Manuel Anda was active in Tacna and other southern Peruvian locations between 1878 and 1910, where he specialized in studio photography. Toward the end of the 19th century, Charles Kroehle produced notable photographs of the Amazon region and its people, some of which were published in Miles Moss's book *A Trip into the Interior of Perú (1909)*. Kroehle's photos of Lima and its environs were published in A*lbum de Lima y sus Alrededores* (1900).

Frenchman Emilio Colpaert photographed various areas of Peru between 1859 and 1862 focusing primarily on ethnographic and archeological subjects. He also owned one of the first studios in Cusco (1862). His compatriot Pablo Emilio Garreaud opened a studio in Lima in 1856 with T. Amic Gazan. In 1862 Garreaud traveled to various locations in Peru, photographing views of and people in Cusco, Arequipa and the Altiplano. These were used to illustrate a major work, *El Atlas Geográfico del Perú* (1865). Pablo Emilio was the father of Fernando Garreaud who between 1898 and 1899 traveled throughout Perú documenting various regions for a national documentation project published as *Peru 1900*.

Late 19th century studio owners who enjoyed success into the 20th century include Rafael Colmenares active in Ayacucho, Lima, and Callao; Miguel Chani in Cusco; and Emilio Díaz and Max T. Vargas in Arequipa. Manuel Moral was active in Lima between 1884–1896, after which he sold his studio and went on to publish some of Peru's most important illustrated periodicals including *Prisma, Variedades* and *Ilustración Peruana*.

Climate, indifference and lack of resources have contributed to the loss of portions of the Peruvian photographic patrimony. Private collectors and some institutions can be credited with preserving important portions of this heritage. The history of Peruvian photography received its first major attention in the work of Keith McElroy who in 1977 conducted an in-depth study of 19th century Peruvian photography. In his study McElroy identified over 140 photographers. Since that time the number of articles, exhibitions and books on the subject has grown significantly. The latest and most comprehensive project was the exhibition held at the Museo de Arte in Lima and the Fundación Telefónica in Lima (2001–2002). The two volume catalog of the exhibition includes a detailed essay on the history of Peruvian photography, photographs showing the range and quality of Peruvian photography since its beginnings, and a directory of over 500 photographers active in Peru between 1842 and 1942.

PERUTZ, OTTO (1847–1922)

Otto Perutz was born on July 27, 1847, in Teplitz-Schoenau (Teplice, Czechia) to a family of industrial manufacturers, mostly in the textile industry. Little is known about his formal training, the first record being his installation as managing director at the Bayerische Aktiengesellschaft fuer chemische und landwirtschaftlich-chemische Fabrikate (BAG) at Heufeld near Munich which had been founded in 1857 under the supervision of the German chemist Justus von Liebig. The BAG worked on agrochemical substances and had no relation to photography. On April 13, 1880, Perutz bought the Chemische und pharmaceutische Produktenhandlung Dr. F. Schnitter & Co. in Munich, a merchant in photochemical substances necessary for wet plate processes. In 1882, Perutz came into contact to Johann Baptist Obernetter who had worked as a chemical assistant to Joseph Albert and his printing house and was licensed by Hermann Wilhelm Vogel to produce dry plates after his method of sensitisation with Eosin (orthochromatic plates). Introduced in August 1887, the Perutz plates were an instant success due to their rapidity and extended spectral sensitivity. The company grew quickly and concentrated on a number of different products: From 1893 it produced large format glass plates for the use in stained windows as in church houses, villas, or official buildings; these large format positives were developed and monochromically tinted in the company. From 1896, Perutz was the first company to produce glass plates for the Roentgen process of X-ray photography.

On July 1, 1897, Otto Perutz sold his enterprise to the Engelhorn family, then owners of large chemical companies like Boehringer (Ingelheim) and BASF (Ludwigshafen). He returned to the BAG where he became member of the board of trustees in 1902, a position he held until his death on January18, 1922. The managing director of the new Perutz company was Franz Mayerhofer, a modernist in many aspects. For the time of his direction, until 1922, Perutz had the most modern advertising, marketing, and product range of all German film and plate companies. In 1900 and 1902, two plates

which extended spectral sensitivity were launched which had been created in collaboration with Adolf Miethe, the successor of H.W.Vogel in Berlin, and Arthur Traube, then assistant to Miethe. From 1904 to 1910, Traube constantly worked with Perutz and developped a number of colour sensitive plates, preparing his own colour photography inventions which he was to market in his own company Uvachrome from 1910 onwards. Under the direction of Curt Engelhorn, from 1924 to 1938, Perutz managed to stay away from being swallowed by the I.G.Farben concentration, and survived as an independent film producing company until its integration to the Agfa-Gevaert holding in 1964.

ROLF SACHSSE

PETIT, PIERRE (1832–1909)

French photographer and studio owner

Pierre Petit practiced daguerreotype beginning in 1849 and was trained as photographer in Disdéri's studio. In 1858, he left to join Trinquart, with whom he opened the "Photographie des Deux mondes" the following year at 31, Cadet place, not far from the boulevard. In 1860, they opened a branch in and then, in 1861, they opened another in Marseilles. In 1859, Petit started to work with the immense project *Galerie des hommes du jour, portraits photographiés* (*Gallery of portraits of men of the moment*), headed by the critic Theodore Pelloquet, which had appeared in installments since 1861. These portraits were taken on whole plates and printed, which was then placed on Bristol-board paperboard. Accompanying each portrait was a biographical note about the person in the image. The professional singer Pauline Viardot, the journalist Alphonse Karr, the painter Eugene Delacroix, and many others appeared in this gallery. At the same time, Petit undertook a series of portraits of bishops, for which he received, in 1862, the title of "photographe de l'épiscopat français" (photographer of the French episcopate). He created a total of 25,000 portraits of ecclesiastics. He was also interested in the techniques of mechanical reproduction so much so that Poitevin granted the right to him to use his process, which guaranteed the better conservation of portraits.

Similar to his activity as a portraitist, Petit documented the Expositions Universalle. In 1855, he was part of the "Société du Palais de l'industrie" (Company of the Palace of Industry), which was set up by Disdéri, and was responsible for reproducing the various sections of the exposition. In 1867, he received along with the young assistant Bisson, an imperial commission for the exclusive control of reproduction of the overall pictures. Leon and Lévy were responsible for the stereoscopic views and Michelez for the reproductions of works of art. Petit worked in a private house built on the exhibition site. In 1875, he reproduced the collections of the Musée Dupuytren, totaling 85 plates. In 1878, he again photographed the Exposition(s) Universelle. He also made a report to the head office of Paris in 1870–1871 during the Franco-Prussian war and another on the construction of the Statue of Liberty in New York, between 1871 and 1886.

Petit worked with the Société française de photographie in 1875, but only took part in three of its exhibitions, 1859, 1861 (with Trinquart), and 1863, each time from various framed images. He presented portraits primarily, but also group portraits, studies of animals, an image of the Champs-Elysées, and reproductions of Roman frescos. His portraits were noted by critics, who regarded them as the best of their kind, even by the prestigious Francis Wey. The *Galerie des hommes du jour* was qualified on several occasions as "monumental."

Pierre Petit was appreciated by the critics and by the public for the direct aspect of his portraits which were simple on neutral background, and without decoration. Critics also praised his images for their natural poses, the frankness of the images, his skill to seize the character of the model while playing with the various shades of light, and for his irreproachable execution. Ernest Lacan was one of most laudatory in this respect, evoking the striking resemblance of his portraits: "He did not only reproduce the features of his models, he reproduced their true facial appearance" (*La Lumière*, August 13, 1859). Familiar with the parallels with painting, the critic compared the strength of the tone and the boldness of the parties captured in Petit's portraits to the works of the great Spanish painters. Ernest Lacan also compared him with Nadar, his principal competitor as portraitist on the Parisian scene. Francis Wey greeted the way in which he managed to release all the energy and the grandeur of the model and the critic Ladimir greeted his artistic feeling, his manual dexterity, and his capacity to represent intimate thoughts (*Le Pays*, June 24, 1861). More than the portraits of celebrities are his figures of children.

In 1862, Petit published the *Simples conseils ; manuel indispensable aux gens du monde* (*Simple councils; essential handbook with the society peoples*), a small work with a misleading title that moved away from the technical handbooks that were published then. This contained texts written on him by various critics as well as caricatures made of him which testify to his notoriety as a great part of his portraits were drawn from the calling card format which allowed a broad diffusion of them. To attract customers, Petit used the advertising space affixed to the buildings of his district, that announced his establishment to the passersby. One can see one of them on the street Laffitte by Charles Marville. A sign of his success was the expansion of his establishment on the rue Cadet in 1876. On this occa-

sion, Ernest Lacan described it like "a true museum," with a gallery lit by transparent photographs on glass, like stained glass (*Moniteur de la photographie*, November 16, 1876).

Even if he illustrated in other genres, Pierre Petit remains particularly well-known as a portraitist. His career, like those of Disdéri or Nadar, is a perfect illustration of the popularity of the photographic portrait and of the prosperity that of some large professional workshops knew, as true "temples of photography."

PETZVAL, JOSEF MAXIMILIAN (1807–1891)

Josef Petzval is widely recognized as the father of photographic optics, being the first person to apply mathematical computation to the design of a photographic lens.

Born in Spisská Belá—then in the Austro-Hungarian Empire but today in Slovakia—he studied physics and later mathematics in the Institutum Geometricum in Budapest, now part of Budapest University.

After graduation, with a doctorate in physics, he lectured part time at the Institutum, while also working as an engineer in Prague. In 1838, he moved to Vienna and took up the position of Professor of Mathematics at the University of Vienna, where he spent the next forty years. In the following year, he designed the rapid portrait lens which bore his name and which revolutionized photography.

His interest in photographic lenses is believed to have been triggered by a discussion with his friend and colleague Andreas von Ettinghausen, after the latter had returned from Paris where he had seen the daguerreotype demonstrated. Ettinghausen lamented the fact that exposures with the new process were too long to make portraiture a practical proposition, and Petzval embarked on research to see if the design of lenses could be improved to reduce exposures.

The result, computed before the end of 1839, and produced in prototype by early 1840, was an innovative design using two pairs of achromatic lenses that reduced exposure times by more than 95%. Daguerre's original camera used a lens with an effective aperture of f/16, while Petzval's alternative offered a fixed aperture of f/3.6.

Descriptions of the portrait lens, in early manuals, attest to its reliability and popularity. In the 1860s, William Lake Price described it as:

> A front crown lens of unequal convex curves, to which are cemented a double flint lens of unequal concave curves; the back combination is a crown lens of unequal convex curves and a concavo–convex flint lens at a little distance from it. For more than a quarter of a century this lens, without further changes in its construction than modification of its curves, has been ised not only for the class of pictures its name denotes but for a variety of others.

Petzval's design used two pairs of color-corrected lens glasses, their negative elements facing towards the centre, on either side of a large central space. It was the creation of the space between the pairs that achieved the desired result. That result was a combination which offered significant correction of chromatic aberration and coma, but like all such designs, suffered significantly from spherical aberration.

The design did not create a flat image field, and while this was not a major issue when used to make small daguerreotype portraits, it had severe limitations when it came to larger plate sizes, as definition and sharpness fell off significantly towards the edges of the plate. Given the small sizes of daguerreotype plates popularly used at the time, and the fact that enlargement of the photographic image was still decades in the future, the loss of edge definition was not immediately seen as a problem. A variation on the design later partially eliminated the problem, and allowed the lens to be used for architecture and landscape. It was, however, the portrait lens which achieved greatest significance in the evolution of photography and, accompanied by the considerably increased sensitivity of the daguerreotype plate which resulted from the chemical innovations of John Frederick Goddard, made portrait photography a practical proposition. Between them, these two men and their ingenuity effectively reduced exposure times from many minutes to just a few seconds.

Being of limited means, Petzval could only afford to patent his design within the Austro-Hungarian Empire, and agreed, for a single payment, to license the manufacture to Peter Wilhelm von Voigtländer, who produced the first commercially available lenses in 1840. One of the first cameras to be sold with the Petzval lens attached was Voigtländer's unique metal-bodied daguerreotype camera of 1841. About six hundred examples of this camera are believed to have been manufactured, but very few are known to have survived.

Petzval's relationship with Voigtländer deteriorated from 1845 when Petzval saw the success of the lens and realized that, apart from his original payment, he would not benefit from it. When Voigtländer subsequently moved his manufacturing facility from Austria to Germany, and outside the scope of Petzval's patent,

their dispute continued for many years. Voigtländer, however, went on to refine and develop the design, and his 'Orthoskop' lens—a direct derivative of the original design—achieved widespread success as a landscape lens.

Recognizing the shortcomings of the original lens, Petzval applied his mathematical skills to resolving the problems of spherical aberration, and in so doing, evolved a mathematical calculation to measure and predict the flatness of the resulting image field. The 'Petzval Condition' or 'Petzval Sum,' derived in 1843, became the standard method for quantifying this problem and resolving its effect. It is still in use today.

Petzval is also credited with the design of opera glasses, and therefore with contributions to the evolution of binoculars. He also proposed mirror reflectors for light bulbs, to gather and reflect a higher proportion of the available illumination, and made significant contributions to the worlds of mathematics, acoustics and physics.

However, a break-in at his house in Vienna in 1859 resulted in the loss of many of his manuscripts—several of them unpublished—and resulted in him abandoning his plans to publish definitive books on the subject of optics.

He retired from scientific pursuits in 1877, and died in Vienna in 1891.

CARYN NEUMANN

Biography

Born in Spisská Belá–then in the Austro-Hungarian Empire but today in Slovakia—Josef Petzval was one of six children. His father was a teacher and musician. Josef studied physics and later mathematics in the Institutum Geometricum in Budapest, now part of Budapest University, and after graduation, with a doctorate in physics, lectured part time at the Institutum, while also working as an engineer in Prague. In 1838, he took up the position of Professor of Mathematics in Vienna, where he spent the rest of his professional career, retiring in 1877.

An intensely private man, relatively little is known of his private life, and even his biographer Ludwig Ermenyi could offer little information. He is known to have married late in life—in 1869 at the age of 62—but was divorced four years later. In 1877 he moved to Kahlenberg of the outskirts of Vienna where he became a virtual recluse and died in 1891, largely forgotten and almost penniless. History, however, has not forgotten him.

PHILADELPHIA PHOTOGRAPHER

Under the editorship of Edward L. Wilson, *The Philadelphia Photographer* was established in 1864 with the sponsorship of the Philadelphia Photographic Society. Wilson had left business a year previous to work with the Philadelphia photographer Frederick Gutekunst. The journal was published twice-monthly, and distinguished itself from the New York journals by including a tipped-in photograph, varying from views, portraits and copies of engravings, in each issue. The journal included one of Edward Muybridge's views of Yosemite in 1869. In contrast to the more scientific concerns of *The American Journal of Photography* and *Humphrey's*, Wilson saw the *Philadelphia Photographer* as serving a more general readership, including the "novice, experienced artist or amateur." "No centre table is without its album, and no parlor wall entirely bare of photographs. Yet how few know how they are made; how to get the best or where; which are the best kinds; or how to sit and what to wear," Wilson wrote in the first issue. After 1869, *The Philadelphia Photographer* was the remaining independent photography journal and the most influential journal in the field in the last decades of the 19th century.

Writers for the journal included Matthew Carey Lea, chemist and scion of the Philadelphia publishing family, who reported on and evaluated photographic chemistry and wrote summaries of his reading of the British and European photographic journals. In 1864 and 1865, Coleman Sellers wrote a series "Letters to an Engineer, On Photography as Applied to His Profession" that traced the connection between industry and photography; he also profiled Dr. Thomas Kirkbride's use of the Lagenheim brothers' magic lantern slides displays at the Philadelphia Hospital for the Insane. Hermann Vogel regularly wrote a "German Correspondence" column for the journal and reported on photographic events in Europe beginning in 1865; during the 1870s, John Towler, former editor of *Humphrey's*, wrote a regular column as well.

Technological and chemical reporting in the journal ranges from wet and dry plates to discussions of magic lantern slides, stereographs in the 1860s and 1870s. In the 1860s, the journal published articles titled "Photography as a Moral Agent" and "Photography and Truth." Wilson and his writers weighed in on discussions of artistic view photograph in the 1870s, promoting the artistic visions of photographers and their medium, recommending in 1871 that Henry Peach Robinson's *Pictorial Effect in Photography* was the standard-bearer in photographic literature. In the 1880s the journal gave

regular coverage to the burgeoning amateur movement and camera club outings as well as discussed half-tone printing, highlighting the tensions that remained at the end of the decade between artistic and scientific interests in photography.

Wilson also published *The Magic Lantern* (1874–1885) and the annual digest *Photographic Mosaics*. He also wrote and published a number of books, *The Philadelphia Photographer* absorbed *Photographic World* in January 1873 and *Photographer's Friend* in 1875. The journal was continued as *Wilson's Photographic Magazine* and published monthly in New York from 1889–1914.

Alongside the technological information profiled in its pages, social and cultural historians have looked to the journal to trace attitudes toward and responses to 19th-century photography, among them Sara Greenough, Peter Bacon Hales, Mary Panzer, Barbara McCandless, and Alan Trachtenberg.

PHILOSOPHICAL INSTRUMENTS

The term "philosophical instrument," despite being in popular use, was never clearly defined but was in general use during the eighteenth century through to the mid-nineteenth century. From the 1850s the term gradually fell out of favour and was not replaced. Philosophical instruments were generally used to explore and demonstrate in either an academic or popular way the basic principles of natural philosophy, or science.

Scientific instruments played an increasing role in scholarly study and working life from the middle ages. Accurate measurement and calculation was essential for navigation, manufacturing and construction, and trade and commerce and through the sixteenth and seventeenth centuries this need lead to the development and refinement of instruments such as back-staff, octant and sextant for navigation; compasses, levels and theodolites for surveying; and scales, weights and rules for commerce. These were developed out of practical need and represented the everyday trade of instrument makers.

From the mid-seventeenth century experimentalism had superseded theories about the natural world based on Greek thought and grand hypotheses. Francis Bacon had shown that experimentation, observation and careful records could be used to make scientific deductions and this new methodology was taken up by the Royal Society in London. The major centres of scientific learning in Europe began teaching experimental philosophy using practical apparatus. Popular demonstrations and lectures rapidly spread across Europe and America. Their effect was to stimulate the demand for the commercial manufacture of philosophical instruments for demonstration and teaching purposes. The basic design of most instruments varied little into the twentieth century.

Although many of the instruments were used for demonstration and teaching purposes many, such as telescope and other optical devices also had a practical aspect to them and were sold by instrument makers to a wider public and for practical commercial and business use. During the later eighteenth and early nineteenth century, many makers described themselves as 'optical and philosophical instrument makers' rather than mathematical instrument makers, chemical manufacturers or specialised makers of, for example, spectacles or scales. A number of firms associated with early photography used this description of their business. Philosophical instruments were produced in a range of qualities as, for example, simple brass 'student' microscopes through to elaborately-decorated gilt and silver finished microscopes for use by royalty, confirming their dual use as instruments for scholarly use and as home entertainment.

Although the definition varied slightly philosophical instruments were originally understood to demonstrate mechanics, magnetism, pneumatics, hydrostatics and hydraulics, electricity, heat, sound and light. Meteorological instruments were also included.

Mechanical models were used to demonstrate various mechanical effects including gravity, forces, inertia, momentum, inertia and levers and pulleys. Steam models were produced from the early nineteenth century of different types of engine and engineering tools such as cranes and mills.

Magnetism and the compass were essential for safe

navigation and natural magnets or lodestones were used to demonstrate the power of magnetism.

Pneumatics, the study of air and gases, and especially the creation of a vacuum led to the development of air pumps from the late seventeenth century.

Hydrostatics. This was the name given to apparatus used for demonstrating all effects involving water. This ranged from model diving bells that made use of pressure to move a model up and down a water-filled cylinder, to the Tantalus cup demonstrating the siphon, to elaborate fountains and the use of water under pressure. Instruments such as the hydrometer were developed to measure specific gravity.

Electricity was studied extensively during the eighteenth and nineteenth centuries and machines were developed to produce electricity and then to store it. Static electricity was studied and machines produced in the later eighteenth century culminating the Winshurst machine that used two counter-rotating glass disks to generate static electricity to produce an electric spark. Many electric devices were used as forms of popular entertainment. Geissler tubes were glass tubes containing a high vacuum which contained gases that glowed when electricity was passed through them. The discovery of electric current lead to the development of measuring instruments such as the electrometer and galvanometer and storage methods such as the Leyden jar.

Heat—apparatus was developed to show that some materials expand and contract under heat, that mirrors could be used to focus heat and the nature of heat as an energy form which lead to the development of Crooke's radiometer.

Sound demonstrations in the eighteenth century were limited with the principal experiment showing that a noise disappeared in a vacuum. In the nineteenth century work into tuning forks and resonance lead to the development of the telephone and phonograph.

Meteorological instruments. The refinement of the principal meteorological instruments occurred during the eighteenth century with the thermometer to measure temperature; the hygrometer to demonstrate humidity in the air; and barometer to measure air pressure.

Light—which had most relevance to photography—was studied through apparatus designed to demonstrate and make use of scientific discoveries. Early studies traced light through different media such as water, the use of mirrors and light through lenses and prisms. Microscopes and telescopes made use of the development of advances in lens design and the understanding of refraction and reflection of light. Mirrors appeared as Claude Lorraine glasses for drawing, and in different forms to view anamorphic drawings. The camera obscura made use of lenses, mirrors and the camera lucida used a prism, to aid drawing. The zograscope, stereoscope, magic lantern and kaleidoscope all derive from optical study.

Allied to this was the study of the eye and how it worked with the brain. The demonstration of persistence of vision was shown through the thaumatrope, phenakistiscope, zoetrope and praxinoscope.

Other areas of optical study also developed instruments such as the polariscope and polarimeter which made use of the discovery of polarisation. The spectroscope allowed chemical composition to be determined through the study of emitted light. According to Turner the spectroscope 'contributed more to modern science than any other instrument'.

The development of instruments to study and demonstrate scientific principals lead to a rapid increase in scientific knowledge during the nineteenth century and a growth of scientific instrument makers who produced the standard demonstration instruments as well as their own variants and entertainments based on scientific principles. In 1701 there were 151 instrument maker's working in the British Isles which had increased to 837 by 1851. It was from the group of 'optical and philosophical instrument makers' that the first photographic retailers and specialised photographic manufacturers emerged in the early 1840s and 1850s.

PHILOSOPHICAL MAGAZINE

Using the relatively new printing technology of stereotyping, the *Philosophical Magazine* was launched in 1798 by Alexander Tilloch (1759–1825):

> the grand Object of it is to diffuse Philosophical Knowledge among every Class of Society, and to give the Public as early an Account as possible of every thing new or curious in the scientific World, both at Home and on the Continent. ('Preface,' *Philosophical Magazine,* 1, 1798)

Initially, the journal was in competition with another recently-founded periodical, William Nicholson's *Journal of Natural Philosophy, Chemistry and the*

Arts, but the *Philosophical Magazine* absorbed this in 1813. In 1822, Tilloch took the printer Richard Taylor (1781–1858) into partnership as both editor and co-proprietor in the face of increasing commercial competition. This move proved successful, and after Tilloch's death in 1825, leaving Taylor sole owner and editor, the *Philosophical Magazine* (known throughout its many permutations affectionately as '*Phil. Mag.*') managed to absorb Thomas Thomson's *Annals of Philosophy* in 1826 (when its editor Richard Phillips became co-editor) and David Brewster's *Edinburgh Journal of Science* in 1832, when Brewster became the third editor of the amalgamated *London and Edinburgh Philosophical Magazine and Journal*. A Dublin editorship was created when the eminent chemist Robert Kane (1809–90) was invited onto the editorial board in October 1840.

As W.H. Brock and A.J. Meadows have written:

> one estimate suggests that 64 per cent of all nineteenth-century scientific periodicals were commercially published rather than issued as the official journals of learned societies. Such journals served an important number of functions. They speeded up publications at times when the proceedings of scientific societies appeared intermittently or only once or twice a year … Such journals also provided intelligence of science in foreign journals for those who read no foreign languages or who had no access to large libraries. They also aired controversies or allowed space to issues involved in new research programmes; they accepted for publication the minor and even trivial research with which learned societies could not be bothered, thereby continuing to cater for the popular and cultural (and often provincial) images of science during a time when it was undergoing the rigor of specialisation. On the other hand, such journals often accepted for publication original findings or theoretical speculations that were considered unorthodox by the societies. In this respect they kept the scientific societies on their toes, broke their monopolies, and made them less authoritarian and cliquish than they might have been. (Brock and Meadows 1984, 93)

Before the specialist photographic journals became established, the *Philosophical Magazine* provided a ready forum for early papers discussing the emergence of the new science. For instance, one of those of the pioneer photographer, W.H.F. Talbot, read before the Royal Society but then not submitted to its prestigious journal, the *Philosophical Transactions,* appeared in the *Philosophical Magazine* in early 1839. Other important papers relating to photography in 1839 included ones by Sir John Herschel and John Towson; subsequently in 1840, John William Draper discussed daguerreotype portraits, and Antoine Claudet published his method of speeded-up daguerreotype development there in August 1841, having discovered it in May. Herschel published a variation of a paper published earlier in the *Philosophical Transactions* in February 1843, while George S. Cundell wrote about the calotype in May 1844, and in December that year, George Shaw and Dr Percy published 'On some photographic phaenomena' (Gernsheim 1984, 137–9). However, as the nineteenth century progressed, the *Philosophical Magazine* became increasingly specialized, and by the last quarter of the century it had become almost entirely a journal composed of physics articles.

PHILOSOPHICAL TRANSACTIONS

The Royal Society of London is deemed to have been founded at an informal meeting at Gresham College in the City of London on 28 November 1660, shortly after the restoration of the Stuart monarchy in the person of the king, Charles II. 'On 15 July 1662', wrote Marie Boas Hall:

> a formal Charter of Incorporation was enacted for 'the Royal Society', while in April 1663 a second charter denominated it 'Regalis Societas Londini pro Scientia naturali promovenda', the Royal Society of London 'for improving naturall Knowledge'. It is thus the oldest continuous scientific society in the world still operating under its original charter, and its principal publication, the *Philosophical Transactions*, is the oldest continuous scientific journal. (Hall, 1984, ix.)

The *Philosophical Transactions of the Royal Society of London* first appeared in 1665, with beginnings that upon closer scrutiny were turbulent but ground-

breaking; however, by the early nineteenth century, the Society was beginning to reform itself. Under the forty-two year presidency of Sir Joseph Banks it had epitomised the gentlemen's club leisurely investigating a wide range of curiosities; after his death in 1822, it began to transform itself into a rigorous and disciplined body pursuing the increasingly professionalized sciences, across social boundaries. The twice-annually published *Philosophical Transactions* followed this self-reforming trend, and as the main publication of what was effectively the nation's independent academy of science, was treated with considerable respect.

Only a handful of important scientific papers relating to the emergence of photography were published in the *Philosophical Transactions*, all within the first decade of photography's genesis. This apparent paucity can be explained by the comparative rapidity with which other commercially-produced periodicals, such as the *Philosophical Magazine*, could produce a publication. Also, the emergence of journals dedicated exclusively to photography in the early 1850s meant that the writers, assured of an interested audience, in due course went elsewhere. But amongst the important papers which appeared in the *Philosophical Transactions*, the pre-eminent scientific journal of the English-speaking world, were several by Sir John Herschel (FRS from 1813), one of which was awarded the Royal Society's Royal Medal; this was published in 1840 and in it he divided photography into positive and negative images for the first time, mentioned his experiments with photography on glass, the use of hyposulphite for fixing, and the necessity for achromatic lenses for correct delineation. An earlier paper, read before the Society in March 1839, was mislaid until recently. Other significant photographic papers were published in the *Philosophical Transactions* by Robert Hunt and Antoine Claudet; two papers about the application of photography to recording instruments were placed there by Sir Charles Brooke and Sir Francis Ronalds.

PHILPOT, JOHN BRAMPTON (1812–1878)

English photographer

Born in England, John Brampton Philpot resided in Florence from about 1850 until his death in 1878. In 1856 Philpot made thirty calotypes which record the sculpted figures of the Tuscan "pantheon" in the exterior niches of the Uffizi. A series of 28 calotypes of Florence date from the same period, for four of these were exhibited in 1856 at the Photographic Society of Scotland in Edinburgh. Also in the 1850s Philpot produced facsimiles of drawings in the Uffizi in connection with a proposal to compile an inventory of the collection. Baedeker mentioned this aspect of Philpot's production in his 1877 Handbook for Northern Italy, listing Philpot's business as one of the principal photographic establishments in Florence: "Philpot & Co., Borgo Ognissanti 17 (reproductions of Uffizi drawings)."

Graham Smith

PHOTO-CLUB DE PARIS

In the 1880s, photographic technique and practice evolved, it became easier to take pictures, thanks to the introduction of the Gelatino-bromide process. This invention permitted an industrialization of photography. Lots of people bought a camera and photographed—for most of all—their family life and their entertainments.

Likewise, the institution had to follow this fundamental change. Scientific members of photographic societies and long time users tried to make recognize photography not only as a leisure but as a new subject of research.

Following the techniques simplification, a new type of amateurs emerged. Born for almost all of them during the 1850s, they were not particularly involved in chemistry. Along with it, a new kind of gathering, the Photo-Club de Paris created in 1888 after an article in the newspaper "L'Amateur photographe," was entirely dedicated to the amateurs, and not only to the scientific community, which was the main audience of the Société française de photographie. The Photo-Club had a real program : it was struggling to make photography recognized as an art and to give a real status to the creators. It corresponded to a new expectation that the established institutions could not satisfy.

However, one of its most important initiators, Maurice Bucquet, searched for acknowledgement of the

institution with distinguished members of the other photographic societies like Doctor Etienne-Jules Marey (the famous physiologist), Doctor Dujardin-Beaumetz and Albert Londe (already member of the French photographic society and the Société d'Excursions des Amateurs photographes: Excursions Society of the photographic Amateurs).

As the other guilds, the Photo-Club de Paris gave to its members the possibility to use a new modeling and development workshop, a chemistry laboratory dedicated to the tests, a library next to a reading room and other places to meet every month and to participate to the projections sessions.

In order to "show to the other photographic societies that the Photo-Club de Paris take an important part in the general toil" ("montrer aux autres sociétés qui s'occupent de photographie la part que le Photo-Club de Paris prend dans le labeur général," in *Bulletin du Photo-Club de Paris*, 1891, 9), the amateurs' association published between 1891 and 1902, the *Bulletin du Photo-Club de Paris* in which members could find a transcription of the photo-club's life: communications about techniques as well as artistic considerations, descriptions of novelties like new cameras or chemistry methods for development or pictures treatments and summaries of foreign researches. This publication had to sustain the debate and to claim the position of the Photo-Club. In 1903, the *Bulletin* became independent and turned its name into "La revue de photographie."

Thereby, the association took a central role in the diffusion of a new trend considered as the first artistic photographic movement. Beginning with the book of Peter Henry Emerson, *Naturalistic Photography for Students of the Art*, published in 1889, Pictorialism opened a new avenue for photographers. The Pictorialists saw the excursionist's and the family practices only as entertainment, whereas they treated their pictures with particular processes. Using printed techniques such as gum bichromate or oil transfer, they searched to give to their photographs drawing effects considered as the best way to make recognize photography as an art. But soon, two esthetics appeared, the vaporous one and the detailed one. A dispute to choose the best one followed.

To distinguish them from the excursionists, members of the Photo-Club de Paris took part to the international exhibition of 1892, the "first international exhibition of photography and related arts" ("Première exposition internationale de photographie et des arts qui s'y rattachent"), and soon organized the "First exhibition of photographic art" ("Première exposition internationale d'art photographique du Photo-Club de Paris) in 1894, from the 10th of January to the 30th of January, closely modeled on the French artistic Salon. The academic painter Léon Gérôme even presided the jury from 1895 to his death in 1904.

The creation of the Photo-Club de Paris was part of a worldwide movement, along with the Wiener Camera Club in Vienna, the Linked Ring based in London and the Camera Club of New York. These associations accelerated the internalization of the photographic institution, promoted the International Union of Photography, creating links between societies. The pictorial movement used their luxurious publications to diffuse their esthetics, works and researches.

In France, members of the Photo-Club de Paris and the most representative members of Pictorialism were Léon Robert Demachy (1859–1936) and Emile Constant Puyo (1857–1933). These charismatic leaders theorized the esthetic and wrote many articles published in different newspapers. They met each other at the Photo-Club in 1895. Less prominent figures included René Le Bègue and Henri Fourtier.

Very involved in printed technique, Demachy was one of the first to employ the gum bichromate already used by Alphonse Poitevin (in France) and John Pouncy (in Great Britain) in their own research during the 1850s.

He spread his method thanks to several articles and illustrated lectures in Paris, Brussels, and London. He was also a specialist of the bromoil process. These printed techniques made photographs look like drawings, gave them an artistic touch and permitted the interpretation of reality.

With the public recognition, first during the Exposition Universelle of 1900 in Paris, came the time of the suspicion about pictorialism. Some photographers and critics underlined its lack of creativity and innovation: the vogue of etheral and vaporous photography vanished with the birth of the "straight photography."

However, the Photo-Club de Paris' position about the artistic photography remained the same, always represented by amateurs. With the First World War, the association became less and less powerful but was still headed by one man, Constant Puyo (Demachy stopped his practice during the war) who still approved the same esthetic. In 1924, it became the responsibility of the French photographic Society to continue to organize photographic exhibitions.

The life of the Photo-Club de Paris had always been bound with the first artistic photographic movement. Its influence disappeared with the death of the pictorialist approach and the death of Puyo in 1933 marked its last activities.

PHOTOCHROM PROCESS

The Swiss process

This beautiful photomechanical process was worked out by one of the oldest printing and publishing firms in the world, Orell Füssly, of Zurich, Switzerland, funded in 1504 by Hans Rüegger. The firm still exists, along with Photoglob AG, founded by the former "Art Institute Orell Füssly" in 1889 for the worldwide distribution of photochrom pictures. Using up-to-date technology, they are currently the leading postcard publisher in Switzerland and their range of printed products include city maps and coffee-table books.

The descendants of Orell Füssly did not keep details of the trade secrets associated with the 19th century Photochrom process but a modern investigation by Dr Bruno Weber confirmed what many had been saying all along. The process was lithographic in nature and made use of a light-sensitive material first used by Nicéphore Niépce in 1814: asphalt, also known as bitumen, which can be dissolved in benzene and thinly coated onto a grained litho stone. When the coating is dry it can be exposed under a continuous-tone negative and after an exposure of 10 to 30 minutes under the summer sun (several hours in winter) the parts of the image that were protected from the light by the dark areas of the negative will remain soluble when subjected to a solvent such as turpentine. The rest of the image will remain on the stone and can be made ready to receive a greasy ink that will create a visible image that can then be transferred to paper.

While the above photographic system sounds simple, adapting it to the production of full color reproductions would be a different matter. The man who made this happen was Hans Jakob Schmid (1856–1924), a lithographer from the Swiss town of Nürensdorf. One can only imagine the difficulties involved in printing six to fifteen colors from a single black and white negative. One stone was required for each color. A registration system had to be designed that was so efficient that even today one needs a magnifying glass to discover minute imperfections in the printing process.

Very large editions of town views were made by this process, which can be classified as a form of screenless lithography. The Zurich Central Library currently houses about 10,000 Photochrom landscapes and city views given by the "Art Institute Orell Füssly" between the years 1891 and 1914.

The first photolithographic polychrome prints were made in 1886. At that time this new printing technology was referred to as "photo-chromo printing process." After 1888 it became known as "photochrom." It was also known under the name of Aäc.

Photochroms have almost the appearance of natural color photographs, although under a magnifying glass they will show a delicate grain pattern. Single illustrations printed in Switzerland, Germany and the US often have a characteristic caption in gold lettering along the base of the print, with a serial number and "P.Z." for Photochrom, Zurich.

In the UK the process was exploited by the Photochrom Company Ltd, which also used a different spelling for its name and its products: Photochrome (sic). Their large illustrations did not carry the P.Z. initials but did show a serial number. We do not know how active the English firm was but of the many Photochrom(e) Company illustrations that appeared in the *Penrose Annual*, all but one, in Vol. 9 (1903), were in fact conventional half-tone relief engravings.

There were other successful photolithographic operations including the Frey process invented by Frey & Söhne, of Zurich. This was acquired by Hudson & Kearns in Britain but never successfully exploited by them. There were also variants by Photostone, Wetzel & Naumann, Müller & Trüb, Schulz, etc.

In 1897 the Photochrom Co. of Detroit, USA, was created after William A. Livingstone (of The Detroit Photographic Company) went to Zurich to obtain exclusive U.S. rights to the Photochrom process which they used to print color postcards, beginning in 1898. In 1905 the company name was changed to the Detroit Publishing Company. From 1907 they also used Phostint as a trade name. The firm was active in the production of color printing until 1931. Much of the company's archive is now housed at the Library of Congress, in Washington, D.C. The collection includes over 25,000 glass negatives and transparencies as well as about 300 color photolithographic prints, mostly of the eastern United States. The collection includes the work of a number of photographers, one of whom was the well known photographer William Henry Jackson (1843–1942). Other parts of the collection are housed at the Colorado Historical Society (Denver, Colorado) which has approximately 13,000 images, primarily glass plate negatives of views west of the Mississippi. Their collection also includes vintage photographs, Photochrom prints, postcards, and the Detroit Publishing Company's negative record log. The Historical Society also has one of Jackson's diaries from the 1870s.

The Henry Ford Museum & Greenfield Village (Dearborn, Michigan) has approximately 18,000 vintage photographs, 9,500 postcards, and 2,500 Photochrom prints from the Detroit Publishing Company.

Photochrom was later adapted to offset lithography and produced excellent screenless color lithographs in various art books published between WW I and WW II (e.g., Gottfried Wälchli: Martin Disteli Romantische Tierbilder, Zürich/Leipzig, Verlag Amstutz & Herdeg, 1940). The last Photochrom operator, Frédéric Wälti, retired at the age 81 as recently as 1970.

The French Process

The Swiss photochrom process should not be confused with the similarly named multi-color process introduced by Léon Vidal in France in 1872. The "photochrome," often anglicized "photochromy," was first seen in the photographic exhibition at the Palais de l'Industrie in Paris in 1874. The prints were much like chromolithographs, except that the base illustration (key plate) was a photograph usually printed by the woodburytype process.

In other cases, the colors were applied in sections (selected manually) made by the carbon transfer process. These photochromes, never achieved the realistic effect of the Swiss process but they were suitable for printing reproductions of crowns, diamonds, and other precious objects from the Louvre and other French institutions. Fine examples can be seen in Paul Dalloz' *Trésor Artistique de la France, 1ère série,* (Paris, Moniteur Universel, 1883).

PHOTOGALVANOGRAPHY

The name of this photomechanical process came from Duncan C. Dallas, at one time manager of the Patent Photo-Galvanographic Company, a short-lived printing and publishing firm set up for the exploitation of an English patent granted to Paul Pretsch (1808–1873), an Austrian photographer and inventor.

Paul Pretsch arrived in London in 1854 and took out an English Patent, No. 2373, dated Nov. 9, 1854, for "Improvements in producing Copper and other Plates for Printing" In the following year he formed the Patent Photo-Galvanographic Company with a number of partners, including Roger Fenton (1819–1869), as the chief photographer.

Commencing in December 1856, they published a serial portfolio, *Photographic Art Treasures, or Nature and Art Illustrated by Art and Nature.* This was the first photographically engraved reproductions of works of art. There were five issues published, each containing four plates, the last publication appearing in early 1857. Their *intaglio* process, which was the first to utilize the reticulation of gelatin, was based in part on W.H.F. Talbot's 1852 photoglyphic engraving patent and produced plates often heavily retouched by hand engravers—a common practice in the printing industry at the time. Nevertheless, many of the plates were exceedingly good, considering the state of the printing technology at the time.

At a meeting of the Photographic Society of London in June 1856, Pretsch exhibited specimens of his work in various stages and read an interesting paper on "Photogalvanography, or Engraving by Light and Electricity," in which he explained the principles and applications of his process, founded on the peculiar properties of animal glue (gelatin) mixed with chemical ingredients so that it can be made to swell or shrink to produce images that could be turned into intaglio plates. In the course of discussion Pretsch stated that the granular appearance of the matrices was due more to the formation of silver chromate rather than to the iodide (*Phot. Journal,* vol. 3, 58). This chemically induced granularity is interesting and indeed questionable as more recent methods of photogalvanography and collotype printing used the effect of elevated temperature during the drying stage of the matrix.

In the same journal (vol. 5, 1859, 109 and 132), there is a reprint of another paper by Pretsch on "Photography subject to the Press," in which he gives his reasons for abandoning the etching methods of photo-engraving used by Talbot in favor of the photo-galvanographic and gave a short sketch of his method, stating that the granulation was a distinctive feature of it, and was indispensable for the reproduction of any tint by a printing plate. There is another paper on "Photo-galvanography, or Nature's Engraving" (vol. 6, 1959, 1) illustrating with a plate from a negative by O.G. Rejlander, "I pays," which is interesting not only as a good specimen of the process, but also because it is an early example of the process of *aciérage*, by which the electrotyped plate was coated with iron and so was made capable of yielding the large number of copies required (3,000) instead of having to prepare a number of duplicate plates or make a transfer to stone for inferior photolithographic results. A description of the aciérage process is given by F. Joubert, the inventor, in the same number of the journal.

Notwithstanding Pretsch's remarkable skills and inventions, much of his career, and the progress of photography and photomechanical printing in general, were harmed by W.H.F. Talbot's intransigence when it came to negotiating the licensing of his patents. A study of Talbot's correspondence, now made possible thanks to Larry J Schaaff's *The Correspondence of William Henry Fox Talbot* project, reveals a dark side to this otherwise well regarded inventor as we see him displaying an incredible level of greed and lack of respect for Pretsch's efforts. In early 1857 Pretsch was forced to abandon his publishing activities with the photogalvanic process following a lawsuit by Talbot. Despite this he kept improving his processes, notably for relief (block) printing, and maintained contact with Talbot, sending him specimens of his new methods and begging him for permission to exploit his new inventions. The following, from a letter Pretsch sent to Talbot, June 1, 1861, shows the level of desperation facing the Austrian inventor.

> Sir,
> I have been informed by Mr. Hogarth that you intend to postpone the conclusion and settlement of our affairs till your return from the Continent. I must confess that this would be too much for my means which are now utterly exhausted;—the transactions with yourself and Mr. Hogarth have been carried out since February (four months), and before that time since several years I have been living on my own resources, but which are now perfectly exhausted, and at an end without any hopes of being renewed. I do not suppose that it is your intention, to torture me;—I think I have not deserved such degrading pains for my hard labour and unceasing skillfull work.
>
> I have therefore to request most urgently the favour of you, that you may make your decision at once, whatever it may be.—Last Friday night has been forwarded to you the draft draught of the indenture with suggestions for your approval. I beg therefore to send your reply to this as soon as possible, and I rely at least in this instance on your reasonableness and impartial kindness.
>
> I enclose the impressions of two blocks which I have latterly finished. Both of them are *absolutely untouched by the graver*.
>
> Expecting very soon your kind reply, permit me to remain_Sir_Your very obedt. Servt
>
> Paul Pretsch

Despite many such efforts, his plea was not met favorably.

At the Exhibition of 1862, in London, he exhibited half-tone photogalvanographic plates in intaglio and in relief, and obtained the only medal awarded for that class of work. He did a good deal of work in illustrating the *Journal of the British Museum*, but found it, however, difficult to get on in London, and after a serious illness he returned to Vienna in 1863. He was taken on again in the Imperial State Printing Office, but his health had broken down and he made no further progress in perfecting his methods. In 1873 he died of cholera.

Others improved photogalvanography under the names of *helioplasty, leimtype photo-electrotype, swelled gelatin* and *wash-out processes*. It was employed in England almost exclusively by A. & C. Dawson, who styled themselves otherwise the Typographic Etching Company. It was in all essentials identical with the original Pretsch process. It had considerable merit, but was hopelessly expensive and slow compared with the other methods.

PHOTOGENIC DRAWING NEGATIVE

In 1834, William Henry Fox Talbot invented a light-sensitive paper that he named "photogenic drawing

paper." For the next ten years he used it to make his "photogenic drawings," by exposure to sunlight in contact with flat, semi-opaque objects, such as leaves, lace, clichés-verres, or printed pages—a type of image now called a photogram. In August 1835, using the same sensitized paper, Talbot succeeded in making the first camera photographs in silver, which he referred to as "Views taken with the camera obscura. The pictures … represent the scene reversed with respect to right and left, and also with respect to light and shade." It was not until 1840 that Sir John Herschel proposed the noun "negative" for such a photograph having a reversed tonal scale, but neither he nor Talbot ever used the expression "photogenic drawing negative," which has been coined in recent times to distinguish a camera negative recorded on photogenic drawing paper.

Talbot choose the finest rag paper available—customarily, the gelatin-sized writing-paper from John Whatman's Turkey Mill in Maidstone, Kent. He immersed each sheet for a few minutes in a dilute (ca. one per cent) solution of sodium chloride (common table salt), then, after blotting the sheet dry, he brushed one side of it with a strong (ca. 18 per cent) solution of silver nitrate. The result was to precipitate silver chloride within the fibres of the paper, according to the chemical reaction:

ILLUSTRATION

$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$

silver + sodium —> silver + sodium
nitrate chloride chloride nitrate

The high concentration of silver nitrate ensured that an excess of this substance was retained within the paper—a condition that Talbot had found essential for light-sensitivity. The paper was usually dried in front of a fire. Upon exposure to sunlight for a few minutes, it turned a rich purplish-black, due to the formation of metallic silver in a finely-divided state, according to the photochemical reaction:

ILLUSTRATION

$light + AgCl \longrightarrow Ag + {}^1/_2Cl_2$

UV + silver —> silver + chlorine
light chloride metal gas

The chlorine evolved was rapidly absorbed by other constituents of the sensitized paper, otherwise it would have reversed the reaction. This is the silver chloride printing-out process, in which the silver image is formed entirely by the action of light; consequently, it has very low sensitivity compared with development processes. In contrast to the ease of making photograms with "photogenic drawing paper," it proved barely sensitive enough to yield negatives in a camera obscura, which had to be small, with a lens of large aperture to maximise the brightness of the image. Even so, exposures of about one hour were required, and the subjects had to be brightly sun-lit. Talbot's earliest known photogenic drawing negative—of the sky seen through a latticed window at Lacock Abbey—is dated August 1835. This, and other photogenic drawings, were first exhibited to the public at the Royal Institution on 25 January 1839, when Michael Faraday announced Talbot's invention.

After exposure, photogenic drawing paper remains sensitive to light owing to the unchanged silver chloride. In February 1835, Talbot discovered that the obliteration of his images could be prevented by treatment with a saturated (32 per cent) solution of sodium chloride, or a solution of potassium iodide; the former rendered the silver chloride much less light-sensitive, and the latter converted it to inert silver iodide, so that his photographs could conveniently be viewed in daylight. These were the first fixing processes: chloride-fixed specimens were often reddish-brown in the shadows and tended rapidly to acquire a characteristic pale lilac "veil" over their highlights, which Talbot found quite attractive; iodide-fixed images showed primrose-yellow highlights due to the colour of silver iodide. Both types of photograph remain somewhat light-sensitive, however, and cannot be exhibited without risk of perceptible damage. It has been estimated that a light exposure of only 3–4 hours under the most stringent gallery illumination of 50 lux, may cause a just-noticeable change in a halide-fixed photogenic drawing.

In January 1839, Sir John Herschel discovered the more effective "hypo" method of fixing—or "washing out" as he more accurately described it—using sodium thiosulphate (then known as "hyposulphite of soda") to dissolve out the residual silver chloride entirely. Photogenic drawings fixed by this means are stable to light, but if the sodium thiosulphate itself has not been fully washed out of the paper, they may fade severely owing to the slow conversion of image silver into yellowish silver sulphide:

ILLUSTRATION

$2Ag + Na_2S_2O_3 \longrightarrow Ag_2S + Na_2SO_3$

silver + sodium —> silver + sodium
metal thiosulphate sulphide sulphite

In March 1839, Talbot made the first use of silver bromide in photography—an important innovation for which he does not receive full credit. His "common photogenic paper" was treated with a ten per cent solution of potassium bromide to convert the silver chloride into silver bromide, and then coated with excess silver nitrate, to yield a more sensitive paper. Talbot privately called this his "Waterloo paper," and employed it with some success in his cameras until the use of photogenic drawing paper for negative-making was totally eclipsed,

in September 1840, by his pivotal discovery of the much faster calotype development process. Nonetheless, Talbot's recipe for "common photogenic drawing paper," which was not restricted by patent, continued to be universally used until ca.1855 to make positive contact prints from camera negatives; such positives, then called "re-transfers" or "copies," are today referred to as salted paper prints. Thiosulphate-fixation rapidly became the preferred method, although Talbot himself persisted in the use of halide (i.e., chloride, bromide, or iodide) print-fixation for some years, possibly due to an aesthetic preference for the interesting colours that the process generated, compared with the uniformly dull brown of the thiosulphate-fixed images.

The camera exposures for making photogenic drawing negatives were lengthy—typically, one hour—during which interval the sun moved relatively through an angle of 15 degrees of arc; consequently, in any sunlit scene, the areas of shadow were diminished and their hard edges diffused, while the reflections from highlights were multiplied. Photographs printed from photogenic drawing negatives often display a softness of modelling that is quite different from the chiaroscuro qualities seen in the much faster calotype process. Talbot's photogenic drawing negatives made in 1839–40 recorded the luminosity of his scenes with a delicacy that is quite inaccessible to the instantaneous vision of the human eye, and the modern camera.

PHOTOGLOB ZURICH/ORELL FÜSSLI & CO.

Photochromy is a lithographic printing process for disseminating photographs via colour printing off several stones, a combination of collotype and chromolithography for the production of "photolithographic polychrome half-tone images." The process consists of the direct photographic transfer of an original negative onto litho and chromographic printing plates and is most commonly known by its commercial name of "photochrom."

Whilst Lemercier had experimented with an analogue process in the 1860s, and Vidal's process enjoyed limited dissemination in the 1870s, neither enjoyed commercial success Breakthrough occurred in the mid-1880s when a lithographer in Zürich, Switzerland experimented with the process successfully enough for Orell Füssli & Co., then a leading firm of banknote and map printers, to decide to incorporate it into its development and manufacturing plans. The first photolithographic polychrome half-tone prints produced by the firm in 1886 were always subsequently described as the firm's own invention, while the identity of the actual inventor was never mentioned in the firm's catalogues or other publications. The unheralded inventor was in fact Hans Jakob Schmid (1856–1924), a lithographer from Nürensdorf. He worked at Orell Füssli and Co. from November 1876 onwards, initially as a lithographer, then as a machine minder. After an experimental phase, a patent application was filed for the new process in Austria-Hungary on 4 January 1888.

Due to the business acumen of Heinrich Wild-Wirth (1840–1896), partner in the firm since 1873 with his brother Paul Felix, and, from 1890, chairman of the board, the photochrom process was widely disseminated and achieved unparalleled success in the market for colour photographs. The trading company Photochrom Zürich, founded in 1888 to exploit the process, incorporated the collotype printers and publishers Schröder & Co. in 1895. The company thereafter traded as Photoglob Co. (since 1974 Photoglob AG) and is still active, especially in the postcard business, as a subsidiary of Orell Füssli Graphische Betriebe AG. The Photochrom Co. Limited was established in London in 1896 as successor to the London office of Photochrom Zürich, set up in 1893. An identically named subsidiary in Detroit produced and marketed photochrom prints in America,

with the collaboration of William Henry Jackson. The photochrom market transformed the firm into an international concern.

The photochrom production process required the participation of four different specialists: photographer, chromolithographer, stone-polisher and planographic printer. The grained litho stone was coated with a thin layer of bitumen purified in ether and dissolved in benzene. On this light-sensitive surface, a reversed photographic half-tone negative was firmly applied, with the sensitized side face down. By means of exposure to daylight, lasting 10 to 30 minutes in summer, up to several hours in winter, the bitumen would harden in proportion to the action of the light, rendering it insoluble to normal solvents. Then the lithographer or photochrom operator washed the bitumen matrix in various acid-free turpentine solutions, soaking off the soft bitumen in proportion to the amount of exposure the plate had received. The matrix was then retouched painstakingly with cotton wool tabs or a badger's hair brush, in the tonal scale of the particular colour, strengthening or softening the tones as required. The gradation of the positive bitumen image could be strongly influenced by this manual procedure.

Following the chemically worked transformation of the photographic half-tones into the grain structure of the stone surface, the polisher treated the developed image with finely powdered pumice stone, for grinding the surface grain smooth. Readying the layer for subsequent etching remained a long guarded commercial secret. The prepared stone, with its highly resistant etching surface, was, according to this method, degreased with a solution of 1° to 3° nitric acid, as for normal litho stones, the image area repulsing the acid, then washed clean, dried, coated with moisture-bearing gum arabic, and dampened. After the fatty lithographic colours had been applied by roller, the stone was then ready for printing off. Each tint required a separate stone bearing the corresponding retouched image, and each print was usually the product of at least six, and as a rule between 10 and 15 tint stones, and thus an equal number of pulls through the press. An initial print run of "upwards of 150 to 200 impeccable prints" (*Photographische Correspondenz* 1888, 498) soon increased; individual print-runs are unknown, but probably amounted to several thousand prints by the early 1890s.

Photochrom prints subsequently became the object of an extraordinary collecting cult, rivalling stereo views as the favoured proxy souvenir of the armchair traveller. The photochrom operators' standard output consisted of landscapes and cityscapes, the colour range of which sometimes proved to be either too muted or too harsh in the early years, but then settled down to present all corners of the globe in a uniform photochrom style of characteristically slightly hazy watercolour tints. Photochrom Zürich was early on offering more than Swiss views—by 1891 it was supplying views of the Riviera, the Rhine valley, Italy, France, and Britain. The company was soon sending its own photographers out throughout the continent to take views of sites and monuments. In January 1896, the company's stock included 3,000 European subjects. A standing exhibition was opened in central Zürich "to give everyone the opportunity to view our whole picture collection and, on that basis, put together a travel itinerary."

Around this time the scope of the collection was broadened to include views from North Africa, Turkey, Syria and Palestine, India, Russia, and the United States, later Central and South America, adding Persia in 1911, alongside China, New South Wales, and New Zealand. The "P.Z." logo in gilt lettering on each print, standing for Photochrom and Photoglob Zürich, together with a caption and inventory number, served as an instantly recognisable trademark.

Prints were available in seven sizes, the majority in sizes II (16 × 12 cm.) and III (21 × 27 cm.). The mounts were available in six different designs: black with bevelled gilt edges, olive with broad gilt ruling, plain light grey with the print recessed, grey matt frame, washable enamel mount on laminate base, and on glass. An ideal photochrom library for the systematic collector in 1899 included a solid oak cabinet, with compartments designed to house 34 albums of 200 prints each—a total of 6800 prints.

Photochroms may be considered to constitute a significant achievement in printing technology wedded to dynamic marketing in the field of popular landscape imagery. After the First World War, which brought an end to the cult of this type of collecting, Orell Füssli's main output consisted of poster printing and high value art reproductions in the photochrom process. The last photochrom operator retired as recently as 1970. Orell Füssli Verlag AG is now a leading multi-media publishing house headquartered in Zürich. The trading arm Photoglob AG specializes in the distribution of maps, albums, illustrated works and guide books of Swiss interest.

About 10,000 unmounted photochrom prints are housed in the print collections of the Zurich Central Library, an annual donation by the Art Institute Orell Füssli and its subsidiary Photoglob Co., from 1891 to 1914, of that year's complete output.

PHOTOGLYPHIC ENGRAVING

Photoglyphic Engraving is an early process of photogravure invented by William Henry Fox Talbot (1800–1877), but one that was rapidly superseded by the Talbot-Klic process of 1879. Talbot's first photomechanical invention, "Improvements in the art of engraving, in which photographic processes are used" (English. Pat. No. 565), was recorded in 1852. Talbot had discovered the light-sensitivity of a mixture of potassium dichromate and gelatin. He was the first researcher to publish the fact that chromated gelatin becomes insoluble after exposure to light and loses its capacity of swelling in cold water.

He applied this principle to a printing process that made use of dichromated gelatin coated on a steel plate prepared for engraving. When dry, the gelatin coating was exposed to sunlight under a positive image. After exposure, the parts of the gelatin coating that were not exposed to light were dissolved in hot water, leaving a relief image. The plate was then ready for etching with bichloride of platinum, which was poured over the plate. This solution would first attack the thinner parts of the gelatin relief and would leave a depression in areas that were protected from light by the positive image. This depression could be filled with ink like any intaglio plate (etchings, line engravings, etc.) and the resulting image could be transferred onto paper with a printing press.

One can easily imagine that Talbot's first results were suitable for line reproductions. For the production of prints that produced the shades of a real photograph he invented a primitive form of half-tone screen: *photographic veils*. To quote from the patent abridgement, "To produce the effect of engraved lines or of uniform shading, the image of a piece of folded gauze, or other suitable material, is impressed upon the gelatin prior to the image of the object required being formed. Plates of zinc or lithographic stones are also readily engraved by this process." Nevertheless, Talbot himself admitted that his first photomechanical invention did not succeed in reproducing photographs with a full range of tones.

In his follow-up patent of 1858 (No. 875), he introduces new modes of etching. With the first method the picture is no longer washed, but as soon as it is removed from the copying frame it is covered with pulverized copal or other resin. This fine powder is then heated over a lamp, which makes it melt and stick to the plate. When the plate has cooled it is etched by means of a nearly saturated solution of perchloride of iron in water; the etching being accomplished in consequence of the perchloride solution penetrating the gelatin wherever the light has acted upon it, but refusing to penetrate those parts upon which the light has sufficiently acted.

Once again, we see an idea borrowed from traditional printmaking. In this case, it is the old aquatint etching process invented in the 1760s by J.B. Le Prince (1734–1784). With this intaglio process a full scale of tone is obtained by etching a multitude of extremely small pockmarks in a random manner on the printing plate. Niepce de Saint-Victor had documented the use of the aquatint grain in his *Traité Pratique de Gravure Héliographique* (Paris, 1856, 44).

In another variant of the etching process, the exposed picture is washed in warm water before receiving the resin powder. Another method made use of an electrotype etching. Specimens of Talbot's new processes appeared in *Photographic News* in 1858 as reproductions of photographs of Spain, France and elsewhere by Soulier and Clouzard. William Crookes, the publisher of *Photographic News*, was quite impressed by Talbot's new invention:

> We have recently been favoured with the inspection of some new photographic prints, or to speak more correctly, PHOTOGLYPHIC ENGRAVINGS, executed by a new process, the result of experiments made by Mr. H. Fox Talbot. By means of his invention common paper photographs can be transferred to plates of steel, copper, or zinc, and impressions printed off afterwards with the usual printer's ink. The plates engraved by this mode are indeed beautiful in themselves as photographs, and will bear strong microscopic inspection, the most minute detail being given with astonishing fidelity. They are free from many of the imperfections which were so evident in former attempts, and the manner in which the half-tones are given is really wonderful; the specimens are of various subjects, showing the perfection which can be obtained in any branch of pictures. Even in these copies the detail is so fine that when a powerful microscopic power is brought to bear on them, we are enabled to trace the names in the shops in the distance, and easily read the play-bills in the foreground, and this in a picture only a few inches square, while the minuteness in architectural subjects is most remarkable. In a view of Paris there is all that can be desired in half-tones, and the perspective is almost as good as in a photograph.

The new invention was named "Photoglyphic Engraving" by Talbot and led to a considerable amount of activity among experimenters. It eventually evolved in what became known as the Talbot-Klic process, which was introduced in 1879, two years after Talbot's death.

This process is also referred to as heliographic etching with chromated gelatin process, photographic

etching, photoetching; photoglyphy and photoglyptic engraving.

PHOTOGRAMMETRY

Photogrammetry, the art of making measurements from images, synthesizes the science of mathematics and the technology of photography. The development of photography in the 19th century, which is the embodiment of projective geometry, led to widespread development of photogrammetry for topographic and architectural measurement by the end of the century.

The mathematical basis of photogrammetry is projective geometry; initial work in this area was done by Lambert (1728–1777), with Poncelet's 1822 treatise providing a broad basis for later development. Projective geometry is a generalization of standard Euclidean geometry, with the basic axiom being that parallel lines meet in a point. This describes the properties of central perspective, in that parallel lines imaged by a lens appear to meet at the vanishing point.

Given this mathematical basis, mapping was first attempted using freehand perspective drawings from multiple viewpoints. In 1846, Aimé Laussedat (1819–1904), a captain in the French Army, experimented with freehand perspective drawings for mapping of the Pyrenees. Discovering the limited accuracy and detail from using freehand drawings, he experimented with the *camera lucida*. The camera lucida used a four-sided prism to project a view of the scene onto the drawing paper, where it could be traced by the operator. After several improvements to the device and the development of graphical techniques to produce the final map, Laussedat produced drawings of the façade of l'Hotel des Invalides in 1849 and a topographic map of the fort du Vincennes in 1850. He named this technique *iconometrie*.

The development of photography at this time provided another method of generating perspective views, although Laussedat realized that existing cameras would not be suitable for mapping purposes due to their narrow fields of view and lack of calibrated orientation. He therefore commissioned the Paris instrument maker Brunner to construct a camera to his specifications in 1859. The camera had a 50cm focal length lens and used glass plates with a 27×33 cm format. The internal camera geometry was established by *fiducial marks* exposed on the plates, which allowed the reconstruction of the position of the plate relative to the principal point (intersection of the optical axis with the image plane). The first topographic map was produced in 1861 depicting the village of Buc and covering approximately 200 hectares. This and other successful mapping demonstrations led to the establishment of a French military mapping unit using Laussedat's equipment and techniques.

Albrecht Meydenbaur, a German architect, realized the potential of photography for documenting and measuring buildings. Understanding the limitations of the cameras of the time, he designed his own camera which combined stable imaging geometry with a measuring circle from a surveying instrument. His *phototheodolite* was tripod-mounted and had a wide angle lens with a 105° field of view and a 25cm focal length, imaging onto a 30×30 cm and later 40×40 cm format glass plate. Leveling screws maintained the image plane in a vertical position, thereby simplifying the graphical reduction of the data. Later versions were designed to be collapsible, to ease transportation, and with a lens which could be vertically shifted to better record buildings.

Meydenbaur's initial experiments were performed in 1867 in Freyburg-on-Unstrut, where he photogrammetrically documented the town church and topography. In a paper describing this work he introduced the term "photogrammetrie." While military applications were unsuccessful, the detailed metric information derived from his photographs proved valuable for architectural documentation. His work led to the formation of the Royal Prussian Photogrammetric Institute, whose goal was the photogrammetric documentation of German cultural monuments and which still holds a large archive of Meydenbaur's photographs.

Ignazio Porro (1801–1875), an Italian surveyor and instrument maker, developed a panoramic camera for mapping in 1858. By mechanically scanning a narrow field-of-view lens he obtained a wide field of view without the accompanying lens distortion. However, data reduction from the panoramic imagery could not

be done using the standard graphical methods; Porro therefore invented the *photogoniometer*, a telescope placed at the optical center which measured the angles at the camera position between objects in the scene. The telescope used the same type of lens as the camera, thereby canceling out the effects of lens distortion in the measurement. Later rediscovered by Koppe, this Porro-Koppe design principle has been widely used in photogrammetric equipment.

The latter part of the 19th century saw widespread adoption of photogrammetry for topographic mapping in many different countries. The first textbook on photogrammetry was published by Carl Koppe in 1889.

Data reduction was initially accomplished using graphical methods similar to those used in standard surveying. Instruments were designed to automate the operations involved in drafting, using mechanical joints to reproduce the projection through the lens. However, these approaches had the shortcoming of requiring identifiable points in each image, a difficulty for topographic mapping.

The introduction of stereoscopy and the invention of lens and mirror stereoscopes pointed to a different approach to the problem, although the first instrument to use stereoscopic viewing was not introduced until 1896 by Deville in Canada. Based on a Wheatstone mirror stereoscope, the instrument was not geometrically rigorous and was difficult to use since it required that the operator simultaneously view the stereo model through half-silvered mirrors and a physical point in the stereo space.

One of the biggest issues in applying photogrammetry to topographic mapping was the lack of a suitable viewpoint, especially in flat or wooded terrain. Laussedat conducted experiments with Tournachon (Nadar) in 1858 on using photographs from balloons, although the wet collodion process used was difficult to accomplish in a balloon. With the introduction of dry plates balloon photography became more practical and military reconnaissance operations became widespread. However, mapping presented further problems, including covering wide areas and determining the position and orientation of the photograph. Wide area coverage was achieved by using panoramic cameras or by using multiple synchronized cameras at different viewing angles. Camera position was determined using known photo-identifiable points or geometric figures on the ground, while mechanical devices were used to maintain the camera axis in a vertical orientation.

Aerial photography from kites also became common, using trains of kites carrying stabilized cameras. Cameras could be lowered to change plates without lowering the kite.

PHOTOGRAMS OF THE YEAR (1888–1961)

Photograms of the Year began as the November 1894 issue of the British journal *Photogram*. In the inaugural issue, the editors wrote of their hopes for a separate, more fully realized volume the following year. Devoted to photography "as a means of artistic expression fully up-to-date," the stated aim of the publication was to review exhibitions in England and the United States and reproduce a representative selection for critique. Henry Snowden Ward and Catharine Weed Barnes Ward, editors of the *Photogram*, started the annual. Both had extensive experience as photographers, writers, and editors of other photograph magazines, and their names were well-known in photographic circles in the United States and England. They knew many influential photographers and writers, and were able to engage people like A. Horsley Hinton, editor of the British journal *Amateur Photographer* and author of several books on photography; writer and master of the gum-bichromate process, Robert Demachy and Alfred Stieglitz, leader of the American Photo-Secession, to write articles.

The annual emerged out of the photography movement known as pictorialism and art photography that began in the last decade of the 19th century. Until World War I, the title positioned itself in the center of that movement in Europe and the United States and played a secondary role in the dialogue about the nature of artistic photography stirring the photographic world at

the time. The audience for the journal was the serious amateur photographer who wanted to perfect his craft, and aspired to make a photograph situated within an artistic tradition. The reviews made a point of aesthetic analysis, and in the first issue, the Linked Ring exhibition was lauded for showcasing expressive photographs that eschewed technique over purer artistic aspirations. In these early years, the annual reported on the latest artistic developments, and followed the careers of the major international figures—with news and reproductions of works by important British photographer H.P. Robinson**,** pioneering American Alvin Langdon Coburn, venerable Baron Adolf de Mayer and newcomer Edward Steichen. Exhibitions large and small were covered, along with the groundbreaking salons at the turn of the century, including the Photographic Society of Philadelphia Salons and the Photo-Club de Paris. This focus on exhibitions would remain throughout the life of the title. As the annual was published in Great Britain, the yearly Royal Photographic Society exhibition and other British displays were covered, along with reports and analysis of the year's exhibits in Europe, the United States, Canada, Australia, South Africa, and Japan. With the exception of a few lead articles on more general topics, the body of the journal was given over to geographically centered assessments of the state of artistic photography and critiques of the numerous reproductions published in every volume. The editors also opened the pages to works from readers for review.

The annual remained devoted to pictorial photography and the salon movement for close to 70 years. As the international art world changed, and pictorial photography was no longer considered the most progressive form, the emphasis of the periodical shifted to the myriad small photographic societies that cropped up in every major metropolitan area as well as smaller cities and towns. These groups kept the pictorial photography movement alive in the 20th century. In 1961, the title changed to *New Photograms*, and contained the expected reviews of exhibitions worldwide and analysis of individual works. But the editor gently criticized pictorial photography for being somewhat conformist and lacking in vitality. He announced an expansion of content to embrace less conventional aspects of the genre, including photojournalism and more experimental works. Curiously, this was be to the last volume.

PHOTOGRAPHIC AND FINE ARTS JOURNAL, THE

The Photographic Art Journal was published between 1851 and 1860 in New York City by Henry Hunt Snelling; the journal was retitled *The Photographic and Fine Arts Journal* in 1854. The publication was the second photographic trade journal produced in the United States (following behind the *Daguerrean Journal*, later *Humphrey's Journal*), and offers insights into the development of the daguerreotype to the age of collodion in the United States, with particular focus on New York City in the age of Mathew Brady.

The journal's view of photography aligned it more with the fine arts than the scientific approach to photography advanced in the pages of *The American Journal of Photography* and *Humphrey's*. "Photography," Snelling wrote, was viewed "too much as a mechanical occupation...In too many instances men enter into it because they can get nothing else to do; without the least appreciation of its merits as an art of refinement, without the taste to guide them and without the love and ambition to study more than its practical applications." Such a narrow interest neglected both the sciences "drawing, painting and sculpture, sister arts, a knowledge of which [would] elevate taste and direct the operator into the more classical walks of his profession," Snelling wrote in the first issue of 1851. He wrote of his concern with the moral elements of the daguerrean art but the journal also serialized technical manuals like Philip Delamotte's *The Practice of Photography* and Désiré van Monkhoven *Photography on Collodion*.

Like its contemporaries, the journal relied on reprints to fill its pages, drawing widely from publications as diverse *as Hunt's Merchant's Magazine*, the *London Art Journal* and *La Lumiere* on such topics ranging from forgery to photographic chemistry. A series of unsigned

articles, "Photographic Galleries of America," which profiled commercial studios in Philadelphia, Washington, New York, Baltimore, Cincinnati, and Richmond in the mid and late 1850s is particularly useful for the photographic historian. Writers for the journal included Marcus Aurelius Root, the Philadelphia daguerreotypist, who published early excerpts of *The Camera and the Pencil* in its pages, and New York daguerreotypist and photographer Nathan G. Burgess.

While publishing the journal, Snelling met Edward and Henry Anthony and later became the general manager for their photographic supply business, E. and H. T. Anthony and Company. Snelling was also a photographic publisher, reprinting Delamotte's manual and T.F. Hardwich's *Manual of Photographic Chemistry*, originally published in London. Snelling himself authored *The History and Practice of the Art of Photography* (1849), *A Dictionary of the Photographic Art* (1854) and *A Guide to the Whole Art of Photography*, a gallery start-up manual (1858). Snelling sold the journal to Charles A. Seely, editor of the *American Journal of Photography* in 1860, and was subsequently less of a presence in the photographic press, although he continued to write for *The Philadelphia Photographer* and *Anthony's Photographic Bulletin* in the 1870s and the 1880s.

The journal is a frequent source of information for Robert Taft's *Photography and the American Scene* (1938, reprint 1964). Alan Trachtenberg cites the journal in his cultural history of the daguerrean era in *Reading American Photographs: Images as History, Mathew Brady to Walker Evans* (1989) and Mary Panzer, in *Mathew Brady and the Image of History* (1997), draws on Snelling's view of daguerreotypes in her cultural and photographic history of Brady's New York.

PHOTOGRAPHIC EXCHANGE CLUB AND PHOTOGRAPHIC SOCIETY CLUB, LONDON

During the 1850s, the exchange of photographs between some early practitioners became formalised. Two clubs are referred to as the Photographic Exchange Club and both were instigated in 1853: the Photographic Exchange Club (1853) and the Photographic Society Club (1853). Among other organisations, which advertised photographic exchanges, were the Liverpool and National Photographic Exchange Club (1856), the Architectural Photographic Association (1857) and the Amateur Photographic Association (1859).

The aim of the earliest clubs was to enlarge the portfolios of amateurs throughout Great Britain who had limited leisure to devote to photography. Clubs for the exchange of prints, such as etchings, already existed and distribution was made possible by the postal service.

Photographic exchanges achieved rapid popularity because of the large number of positives that could readily be obtained from a negative.

The Photographic Exchange Club was advertised first through the pages of *Notes and Queries*, a fortnightly, antiquarian periodical edited by one of the club members, William John Thoms. The Photographic Society Club was established from within the newly formed Photographic Society of London (later RPS) and publicised in the *Journal of the Photographic Society*. In both clubs, the first issues of photographs did not take place until 1855. Some photographers participated in both exchanges.

The Photographic Exchange Club appears to have begun as an antiquarian exchange. A printed leaflet (RPS Collection, NmeN) contains a list of members and the rules of the exchange. Initially, there were twenty-one members, but ultimately twenty eight members took part in one or more exchanges. The members were Francis Bedford, W. G. Cambell, A. B. Cotton, Francis Edmond Currey, Philip Henry Delamotte, Hugh Welch Diamond, Thomas Damant Eaton, Joseph James Forrester, George Glossop, Robert Howlett, Edward Kater, John Dilwyn Llewelyn, Robert Wilfred Skeffington Lutwidge, Thomas George Mackinlay, John Richardson Major, Thomas Lukis Mansell, Sir William Newton, Lady Caroline Nevill, Lady Augusta Mostyn (nee Nevill), John Percy, Henry Pollock, Arthur Julius Pollock, William Lake Price, Henry Peach Robinson, Alfred Rosling, George Shadbolt, William John Thoms, Peter Wickens Fry was listed as a member but did not take part in the exchange.

The cost of membership was 10 shillings per annum to cover expenses. John Richard Major was secretary and treasurer. Every member sent him the requested number of copies of the same un-mounted image and he compiled and posted out a complete set of different prints to each of them. In some cases the recipient incorporated these prints into their own albums (Pollock album, Arnold Crane Collection, Getty), others mounted them on individually in a portfolio (Eaton Collection, Norfolk Record Office). Only two sets of bound exchange clubs prints are known to exist. They are the 1855 and 1857 Exchange Club albums of Lady Augusta Mostyn, which have printed title and content pages (IMP/GEH), and of Henry Peach Robinson (RPS/NmeN).

The photographic exchange operated by the Photographic Society Club produced a typographically printed album with pasted-in photographs in a limited edition of about 50. The Chiswick Press imprint and typographic design suggests that Joseph Cundall, publisher and club member was actively involved. As well as a printed title and photographer's name, each print was accompanied by technical details, such as lens aperture and exposure time, and a page of poetry or prose. Benjamin Brecknell Turner was the first secretary of the Photographic Society Club exchange, nominally, he was succeeded by Philip Henry Delamotte. Forty-four photographers contributed to the 1855 album and thirty-nine to the 1857 album.

The contributors to one or both albums were J. Anthony, A. Batson, F. Bedford, Sir J. Coghill Bart., C. Conway Jr., J. Cundall, F.E. Currey, H. W. Diamond, P.H. Delamotte, R. Fenton, J.J. Forester, G.B. Gething J. J. Heilman, T.H. Hennah, F. Horne, R. Howlett, A Kerr, Rev. J. Knight, J.D. Llewlyn, R.W.S. Lutwidge, Mary E. Lynn, Rev F S Marshall, Count de Montizion, T.G. Mackinlay, J.R.Major, J.R. Major D.D., J.L. Mansell, W.W. Nichol, Lord O'Fitzgerald, Dr Percy, Lieut Petley, W.C. Plunkett, A.J. Pollock, H. Pollock, L. Price, O.G. Rejlander, G. Shadbolt, J.Stewart, G Stokes, W.J. Thoms, H. Taylor, A. Rosling, B.B. Turner, W.E.Vivian, H. White. Operational details and costs are yet to emerge, but remaining copies of the album were available at 10 Gns (£10 10s).

The two early photographic exchange clubs set national standards for the production of photographs and they established image types for the rest of the nineteenth century. Both these exchange clubs ceased to operate after 1858. With the commercialisation of photography, many of the first generation of practitioners stopped photographing. One group, including Delamotte, Fenton and Lake Price proposed a commercial exchange, the Photographic Association (Ltd), with shareholders and management salaries. Some became members of other exchanges, Shadbolt become Vice-President of the North London Photographic Association, and, in particular, several joined the Amateur Photographic Association, which was to become the main mechanism for the exchange of photographs during the 1860s.

PHOTOGRAPHIC JEWELRY

Jewelry that contains an image rather than a stone combines decoration (jewelry) with function (an image of a loved one). Photographs began replacing cameos and miniatures beginning with daguerreotypes. The photographic method dictated the style of the jewelry. Daguerreotypes required a glass covering and appeared in traditional jewelry such as rings, pendants, lockets, and bracelets. Tintypes took a decorative form as suspender clasps and belt buckles. The history of photographic jewelry spans from the daguerreotype to the present.

Worn by men, women, and children photographic jewelry lent itself to a variety of settings depending on sex and age. Women generally selected pins, lockets, rings, bracelets, and even coat buttons including matched sets of bracelets, earrings, and necklaces. Men favored keywinds (used to wind watches), watch fobs, rings, cuff links, stick pins, and coat buttons.

Before the late nineteenth century, all of these pieces were custom-made for specific clients with unique images. Individuals interested in owning one could purchase it directly from a photographic studio or have a jeweler insert the picture into a setting. It took skill to create the item so that the image was not damaged when set into the piece. Jewelers created specially made pieces, using precious metals and marketed them to affluent clients. Costume jewelry settings made of brass also existed. With the advent of mail order catalogs in the late nineteenth century customers could choose photo garter buckles, belt buckles, charms and buttons to show off paper prints or tintypes usually covered with a piece

of protective glass. Abraham Lincoln used a tintype portrait button for political campaigning.

J.B Dancer's development of microphotography in the 1850s created a new trend—stanhopes. A microscopic image could be included in any item including jewelry. When held to the light, the magnifying glass peephole allowed for viewing. Most stanhopes feature multiple scenes of tourist locations.

Queen Victoria popularized photographic jewelry as a symbol of mourning when she wore pieces adorned with Prince Albert's image after his death in 1861. Most mourning pieces of photographic jewelry contain a reminder of the deceased. In the period 1861–1880 photographs appeared in lockets and brooches with a swiveling compartment to hold swatches of hair or clothing. Photographer William Bambridge of Windsor created some of the first pieces worn by Queen Victoria. She also ordered a set of nine gold lockets from Garrard & Company, possibly for her children. Dancer designed a mourning ring for Queen Victoria that contained a photograph of Prince Albert attributed to John Jabez Edwin Mayall. The Queen wore jewelry with Albert's image for the rest of her life, choosing a photographic bracelet for the Diamond Jubilee.

Most of the images included in jewelry are portraits. Usually these individuals had a familial relationship with the owner of the piece. Today, most of these images are nameless and separated from the original family. Identification of the image is possible based on several factors: the type of photographic image; clothing worn for the portrait; and jewelry setting. The photographic method establishes a creation date for the piece, but not necessarily a timeframe for the image. Since different settings faded into and out of fashion, the style and type of jewelry determines when the piece was fashionable. Costume assigns a narrower span of dates based on clothing details. Any locks of hair, handwriting samples, fabric swatches, or other types of insertions behind the picture can help identify the subject of the piece. It is important to be careful when establishing a date for a piece of photographic jewelry. Later images could be set into older pieces of jewelry or vice versa. Examine the jewelry and the image thoroughly before deciding on a time frame.

Since photographic jewelry is collected both as jewelry and as photography—the two linked by their setting, it is not unusual to find the jewelry without the image. Early collectors often discarded the unidentified image. The value of a piece of photographic jewelry depends on the type of image, the metal used, whether it includes hair or other evidence, and the rarity of the setting. Lockets and pins are common with rings and keywinds the most unusual. Today, photographic jewelry is very collectible and difficult to locate.

PHOTOGRAPHIC NEWS (1858–1908)

The *Photographic News* was an important agent in the popular dissemination of photographic knowledge. It commenced publication as a weekly journal on September 10, 1858, selling for 3*d*. unstamped or 4. stamped. The first issue consisted of twelve pages of text and six pages of adverts. Unlike the pre-existing photographic journals, the *Photographic News* was not the organ of any of the London or regional photographic societies.

The success of the *Photographic News* was a product of the growing number of professional practitioners in the late 1850s. As the introductory address of the second volume claimed, "the *News* has done what other journals of similar character failed to do; made photography a subject of interest to the public generally" ("Preface" iv). The range of subjects covered by the journal made it more lively and readable than its principal competitor, the *British Journal of Photography*. It quickly established a successful format that was to last until the mid 1880s. In these years it also produced an accompanying publication, *The Yearbook of Photography and Photographic News Almanac*. The main areas covered by the journal were technical improvements and instruction; notes and queries; critical reviews of literature and exhibitions; trade gossip; and reports from the photographic societies of Britain and Europe.

The first editor of the *Photographic News* was William Crokes, a distinguished chemist who was also

secretary of the Royal Institution. After January 1860, the journal was edited jointly by Thomas Piper and George Wharton-Simpson. Simpson remained as editor until his sudden death in 1880, having also become sole proprietor of the journal in 1860. It was under Simpson's imprimatur that the *Photographic News* was the leading photographic journal. Simpson provided excellent reports of international developments in photography and introduced many contributors who subsequently became well-known photographic figures. These included Henry Peach Robinson**,** A.W. Vogel and Colonel Stuart Wortley. After Simpson's death, the journal was taken over by H. Baden Pritchard, the head of the photographic department at the Royal Arsenal, Woolwich. Pritchard introduced the illustration of photographs and the *Photographic News* is a significant historical record of early forms of photomechanical reproduction.

The *Photographic News* was at its most influential from the late 1850s to the mid 1880s. During this period, its readership was predominantly made up of professional photographers. It was the increasing ease with which photography could be carried out, combined with the corresponding increase in the number of amateurs, which meant the alteration and subsequent slow decline of the *Photographic News*. In 1884, Pritchard died and Thomas Bolas became editor. In 1891, Pritchard's widow sold the journal to T.C. Hepworth, who attempted to make the journal much more attractive to amateur photographers. In 1892, it changed proprietors for the final time and reformatted itself as primarily a paper for amateurs. Trade gossip gave way to a weekly competitions and pictorial analysis. Subsequent editors were E.J. Wall (1897–1902), Richard Penlake (1902–1906) and F.J. Mortimer (1906–1908). The journal finally ceased publication in 1908 when it was amalgamated with the *Amateur Photographer*.

PHOTOGRAPHIC NOTES (1956–1867)

Edited by Thomas Sutton (1819–1875) the 'indefatigable experimenter and journalist' (*British Journal Photographic Almanac* 1876, 22) *Photographic Notes* appeared on 1 January 1856 and ceased publication in 1867 when it merged in February into *The Illustrated Photographer* which started publication that same month. During the early part of its life it was associated with Blanquart-Evrard who wrote occasionally for it, and with whom Sutton worked, and it became the house journal for the Manchester Photographic Society, Photographic Society of Scotland and Birmingham Photographic Society. The editorial content of *Photographic Notes* reflected the preferences and prejudices of its editor and Sutton was not afraid to voice opinions that other contemporary publications would not—notably against the Photographic Society of London.

The first numbers of *Photographic Notes* appeared in January and February 1856, published in Jersey by Sutton and Blanquart-Evrard from St Brelade's Bay, Jersey where Sutton was resident and ran his own photographic printing works. The publication was more successful than Sutton had anticipated, for a second edition of these numbers was published on 1 May 1856 in a 'remodelled' form 'suppressing two or three articles of minor importance.' A third edition was also published of numbers 1 to 4. Throughout the earlier period of the journal, revised or combined editions of particular numbers were issued.

Sutton described the journal as being ready to report the proceedings of photographic societies in the United Kingdom; to include notices of matters relating either to the theory or practice of photography; at the service of the professional and amateur photographer; to include extracts from foreign journals; and leaders that will contain a resume of the photographic views and a discussion of the photographic topics of the day. He concluded 'in offering our own opinions, we wish it to be understood that we invite discussion'.

In issue 5 of 25 April 1856 Sutton reported that *Photographic Notes* had 'obtained a circulation more than half that of the Journal of the Parent [the Photographic of London] Society.' The May issue reported that it had been adopted as the journal of the Photographic Society of Scotland and in June that the Manchester Photographic Society had adopted it. The Birmingham Photographic Society adopted the journal from early 1857. Monthly publication was stopped in favour of fortnightly publication on the 1st and 15th of the month from 1 September 1856. With issue 13 of 15 October Sutton reported that circulation had 'received a sudden increase' and that numbers 3 and 11 were out of print and that 4 and 12 nearly so. He would be reprinting back numbers and increasing the print run.

Sutton did not include material already published in other British photographic journals, principally the *Liverpool Photographic Journal* (later the *British Journal of Photography*) and the *Journal of the Photographic*

Society and in October 1857 attributed the success of *Photographic Notes* to the fact that it did not copy articles and the demise of the *Photographic Record* and *Liverpool Photographic Journal* to copying. He claimed to address the 'whole class' of British photographers and not certain sections. He did include material that he consider useful from French and American journals on occasion and by early 1858 was making arrangements to distribute *Photographic Notes* to America.

The contemporary view of the *Photographic Notes* is best summed by J Trail Taylor writing in the manuscript journal *The Photographer* and reproduced in *Photographic Notes* (15 June 1857) 'Photographic Notes, from the beginning, has occupied a high place' and reflects the individuality of the editor 'who is everywhere present from the title page to the closing advertisement. He writes as he thinks, and his honesty may be relied on, for the he seems ever ready to retract what he finds erroneous.' For this reason *Photographic Notes* provides a useful alternative to contemporary debates and issues and in it's early years it's frequency gave it a topicality not enjoyed by its rivals.

PHOTOGRAPHIC PRACTICES

Photography in the 19th century was very much a practice, from the studio or the photographic van to the card album and photolithographic publication. The following presentation will concentrate on practices involving the use of photographs, a vast topic in view of the formidable spread of photography in the 19th century.

The 19th century viewed, appreciated and used photographs not just as images but as objects. Because of the amount of investment, technique, and effort that was required to produce a satisfactory and durable photograph, and because the overwhelming majority of photographs produced were portraits, photographs were treated not just as valuable images but as precious objects, especially in the early days. This was particularly true in non-reproducible processes such as the daguerreotype and its later imitation the ferrotype, or tintype. The daguerreotype, nicknamed "silver plate," sometimes hand-colored and often gilded, was inherently a precious object, and visitors to some of the more ambitious daguerreotype "galleries," such as Mathew Brady's in New York, regularly described them as fairy-like, glittering palaces. More commonly, daguerreotypes and tintypes, because they were single images with hard metal bases, usually small, and generally portraits, invited procedures of preservation and exhibition that tended to define them as both relics and ornaments. Thus the finished daguerreotype or tintype would be framed and inserted in a wallet or case, often decorated on the outside and lined with red or purple velvet inside. This made it possible to mail the picture or to carry it along, as soldiers often did, but also to display it and treasure it, in the same fashion as miniature paintings had been earlier. In the era of the daguerreotype, when obtaining a portrait of oneself or of one's family or friends was a rare and a costly occurrence, and since such portraits had a very strong sentimental value, likenesses of loved ones were prized objects that expressed a combination of feeling, novelty, and prestige, as indicated by early daguerreotypes with sitters holding another daguerreotype portrait. Daguerreotypes were shown in the sitting-room, sometimes carried to formal occasions, but also sent as gifts to far-away friends and relatives, even across oceans, and the action of opening the case added solemnity to the experience of seeing a face that might not have been known beforehand. From 1840 on, the business of daguerreotype frames and cases was one of the most successful and creative activities deriving from photography. Although the demand for cases faded with the decline of the daguerreotypes in the 1850s, it picked up again with the popularization of the tintype. Historian Robert Taft reported a case of an American manufacturer receiving an order in 1862 from a single operator for 3000 gross of these cases. A cheaper form of presentation for tintypes was to mount them in envelopes with a window for viewing the picture. A related practice, although rarer and more status-conscious, was to insert miniature daguerreotype portraits of beloved ones or spouses in various kinds of jewels, such as pocketwatch cases and brooches. All of these practices amounted to a kind of framing, by which the emotional appeal of the picture was at the same time highlighted and confined. Similarly, and in keeping with the constant 19th-century association of photography with the memorializing of the deceased, portraits of loved ones in daguerreotype, and then in tintype as well as in photographs transferred onto ceramic bases, were often placed on graves, and patents for the fastening of such effigies on tombstones were taken out starting in the 1850s. These ritualistic, almost religious, uses were also common with paper photographs later in the century, as is evident from mentions of them in novels such as Thomas Hardy's *Jude the Obscure* and especially Marcel Proust's *Remembrance of Things Past*, where the ordinary seductions of photographs are

a recurring motif. As a whole, however, the private cult of photographs was only the most visible aspect of a very general tendency of 19th-century culture to treat photographs as objects.

The case of paper prints obtained by the various negative-positive processes deserves special attention, because they were the most common kind of photographs after 1855, and because they would naturally seem to function more as images and less as objects. They too were nonetheless subject to the logic of objectification, partly because, like daguerreotypes, they remained rare and precious possessions, but partly also because they seemed almost too immaterial to function culturally without some sort of "hard" environment. First of all, finished prints of any quality were rarely left unmounted. As if a paper photograph had been too thin or too fragile an object to exist on its own, it was systematically mounted, usually on cardboard, but sometimes on wood or glass. The typical professional mount was not just a material base, but also functioned as a marker, serving to integrate the pictures in social and cultural networks. Very often mounts included the name and location of the studio or of the organization the photographer belonged to, as well as some decorative lining or frieze along the edges of the picture, while the back might present more information about the studio, quippings from the press, or advertisements for other businesses; in the case of commercial or archival views, captions and information about places would also be included. Large, deluxe, or specially significant prints would be framed and displayed, like daguerreotypes, while the more common photographs were kept in boxes and, of course, albums, which were sold by many specialized businesses. After 1855, the mass production of carte-de-visite portraits and stereographic views induced specific procedures of storage and display, and encouraged collecting and exchanging practices that spread quickly through the upper classes of society; the relative uniformity of formats and mounts was something like a standard, facilitating filing and circulation. The

very concept of the carte-de-visite as a kind of visual identity card engendered the related concept of the card album with slots of uniform size for sliding in cards, and by 1880 socially prominent families would often have collected enough cards to fill several of these 100- or 200-card albums. Similarly, the standardized format of stereoviews was intended to fit in popular stereoscopes and special boxes, which might typically hold fifty stereoviews, a number that is probably indicative of the extent of an ordinary stereo collection in a well-to-do urban household around 1875. Amateur photographic clubs developed in some cases as arenas for exchanging, comparing, and discussing stereoviews and other pictures; the same would be true, around 1900, for illustrated postcards, which in many ways continued the tradition of 19th-century photographic collections, while introducing photography into the realm of private correspondence. Finally, one of the more significant types of photographic object produced in the 19th-century was the photographically illustrated book, a category that actually covered a wide array of techniques and practices, from hand-made and hand-captioned single-copy photographic albums to full-fledged publications including photographic prints or, more commonly, photolithographs. Although photographic books are not the subject of this entry, it is worth mentioning here that the whole association of photography and paper, from William Henry Fox Talbot's research on, was geared precisely at making photographs that would be compatible with the space and economy of books and more generally printed matter, thus emphasizing their iconic, iconographic, and informational dimensions, as opposed to their materiality and their exhibition value as separate objects. At the same time, the urgency and difficulty of this association of photography with the book also hinted back at the resilient materiality of photographs, a factor one needs to take into account in order to understand more generally why so much of 19th-century photographic practice tended to treat photographs as objects.

One of the typical features of 19th-century photography is that it nourished the desire of producing a total illusion of reality—of replacing real things with images that were as life-like as possible—with a still primitive state of technology, which could only produce this illusion by resorting to and often paradoxically foregrounding its own infrastructure of objects, materials, and tools. Some of the more obvious examples of this paradox are panoramic photography, magnesium lighting, and especially photosculpture, a pre-holographic technique that was devised as early as the 1850s and that consisted of sculpting, with the help of a pantograph, from several photographs of a given subject taken at different angles. The three-dimensional illusion was more ordinarily realized after 1860 by stereophotography, and in this case also all the paraphernalia that surrounded the production as well as the contemplation of stereoviews functioned as a framework for the rapturous experience of seeing "solid pictures" or "sun sculptures." According to Oliver Wendell Holmes's famous dictum, with stereography "form is henceforth divorced from matter," and "matter as a visible object is of no great use any longer, except as the mould on which form is shaped" ("The Stereoscope and the Stereograph," 1859). The "mould," in this case, included the mounted cards and every aspect of their production, as well as the stereoscope itself, and the various implements used to store and transport the cards. Another striking illustration of photography's materiality is the fact that glass remained for much of the century, and into the 20th, the dominant base in negative-positive processes. The glass processes perpetuated preciousness, weight, and fragility as inherent characteristics of photography. Meanwhile, the unfeasibility of enlargements called for a scale of equipment, production space, and transportation that, with the increasingly large formats practiced by landscape photographers especially, could only emphasize the "hardware" aspect of the medium, and therefore its visibility as a technology, as opposed to its semantic and artistic dimensions. The materiality of photographs, however, was not just the result of technological constraints; rather, it should be seen as a cultural framework that governed much of the technological evolution itself, as is shown by countless 19th-century experiments on adapting photographs to virtually every type of base or surface, a spectacular example being the cyanotypes on cloth used by American home quilt-makers after 1880. Although "blueprint" quilts served memorial functions, it often seems that the production of photographic objects—i.e., the actual transformation of images into objects—was a goal in itself, beyond whatever social uses may have been intended. As a result, although photography as an abstract entity was called upon as a tool of truthful illustration, decoration, or commemoration, the very diverse objects it was produced with and applied to consistently advertised the parallel or parasite message of its own technicality and materiality.

After the realm of private practices, comparable observations may be made about many 19th-century institutional practices wherein the acquisition, accumulation, and conservation of photographic archives seem to have obeyed a self-justifying logic, whether or not actual utilitarian or documentary benefits can be ascribed to these archives. Strictly commercial interests, such as those of railroad companies and early tourist businesses, would justify investments in photography as a tool of illustrating landscape and thus promoting a firm's service. In the United States, the major railroad companies sometimes outfitted a special photographic car that served as an exhibition and sales room for views

of scenes along the way. Similar justifications can be adduced for the photo-sessions and group picture opportunities that started to appear after 1860 in organizations of every kind, from army regiments to school faculties, for which photography provided collective or corporate visual identities. At the same time, however, vast quantities of photographs were produced and accumulated with little ascribable justification under the aegis of armies, government agencies and other educational, scientific or medical organizations. Collections such as those of French and British expeditionary photography to the Middle East and the Far East, or those of U.S. surveys in the American West, are often loosely labeled "documentary." Yet beyond the general notion that they reflected colonial or strategic motivations, it is often hard to account precisely for their purpose, except by suggesting that the constitution of a photographic archive was a self-justifying practice, or a sign of modernity and technicality, which was as such suitable to illustrate the efficiency of the organization that produced it. Such archives were routinely described to budgeting authorities in terms of numbers of items secured, as opposed to informational content. Most of these photographic collections never reached the general public, or were only briefly and partially shown at exhibitions. In some cases, however, as with some of the U.S. federal surveys of the American West after 1865, photographs and especially stereographs were distributed or sold to the public, and special services were created to that effect, in response to an explicit public demand. Whether or not they were distributed, however, these large photographic collections induced procedures of archiving, cataloguing, serializing, captioning, describing, and in some cases publishing, which are historically significant as such, for they amounted to early systems of photographic documentation. Such documentary ventures contributed to making photography a customary adjunct to almost every undertaking of description, identification and analysis of visible phenomena, to the extent that around 1880 the photographic representation of many subjects had become an integral part of their cultural perception. This perception was often framed by and limited to one particular image which tended to function as an icon, as in the case of portraits of great historic figures (Queen Victoria, Napoleon III, Abraham Lincoln, Victor Hugo, etc.) that were also carried in engraved form by illustrated magazines and even reproduced as postage stamps. But it was no less common for photographic representation to emphasize accumulation, multiplicity, and seriality. Thus, the abstract concept of photography as an apparatus of truthfulness was enacted either through the treasuring of memorable icons or through the accumulation of many different views, but both practices reflected an aspiration to obtain total depiction of the visible world.

Yet for a variety of reasons, one of them being that no single photograph or collection of photographs could produce the total view that the idea of photography seemed to promise, many 19th-century photographic practices embodied the opposite assumption that photographs as such were incomplete messages, semantically deficient, particularly because lacking in context. The photographically illustrated book was only one major example of practical and discursive apparatuses that served to endow photographs with meaning, and which consistently surrounded the apparition of photographs in social life. Mounts with imprinted serial numbers, captions, and decorative motifs, and the ideal picture collections that they referred to, were more common manifestations of a general practice (which in fact predated photography) of anchoring visual messages in textual and more generally cultural contexts. Thus, the scope of large-scale institutional ventures such as the expeditionary photography campaigns already mentioned could only be legitimized by ascribing the thousands of photographs gathered to didactic, memorial or scientific purposes, even though as noted above the mere achievement of these large collections appears to have served as de facto justification in many cases. In these large-scale documentary ventures, pictures were often made or presented in serial form (for instance in albums, sets of stereoviews, or descriptive catalogues that were used for marketing prints), emphasizing a requirement for descriptive exhaustiveness that nonetheless remained a utopia. Many procedures of photographic description, such as multi-plate panoramas and grouped views of the same subject from different angles, answered the same concern for a totalizing depiction, while at the same time acknowledging failure to achieve it and denying the sense of self-containment that would, in the 20th century, be associated with a great photograph. In more specialized uses such as police and medical records, the specific methodologies of picture-taking, filing, and comparison that were devised in the late 19th century aimed at bringing out clues or signs that photographs of a more lay kind, or considered in isolation, would not convey. Meanwhile, in many ethnophotographic collections the actual documentary content was largely if not exclusively a function of captioning and commentary. Exhibitions of photographs, especially in the context of world fairs, often grouped them by process and then by topic or geographical area, rather than by author or style, and thus they interpreted pictures not on formal or even strictly technical grounds but in relation to what they represented, and to what in 20th century art-historical terms would be considered external categories. It should also be remembered that for most of the 19th century photographs were structurally incomplete with respect to the printed media, which could not incorporate them

without transferring them into some printable form. 19th-century photographs had little or no public life in their original photographic appearance (except on stereocards), and instead they were reproduced in engraved or lithographed versions that more often than not, and even with semi-automated processes, transformed the visual message and impregnated it with specific intentions. Conversely, this technical incompleteness also meant that photographs were like raw materials, usable for any purpose, and transferable onto any base, from chromolithographs to magazine engravings to postage stamps. Finally, it is known that an artistic echo to these technical procedures was found in the practice of many painters, sculptors and even writers, who (whether or not they welcomed photography amid the sphere of art) used photographs as studies or preliminary sketches, i.e., as documents that were at the same time deficient as works of art and useful (sometimes even essential) to the creation of works of art.

In sum, the diversity, ingenuity and intensity of 19th-century photographic practices may reflect, in part, the primitive state of a technology that did not yet lend itself quite so easily to the universal uses that it seemed destined to fill. More fundamentally, however, these practices registered the oscillation of 19th-century culture between a fascination that led people to magnify and sometimes to multiply the brilliant realism of photographic images, and a reticence, or perhaps a mere lack of familiarity with the workings of photography, which caused attitudes of restraint and an urge to control or frame its power.

PHOTOGRAPHIC RETAILING

From the outset, the emerging profession of photography had two distinct but associated requirements—a market place for pictures and a source of equipment and materials. Thus a photographic retail marketplace emerged catering for both requirements—outlets for the supply of the latest in equipment and chemistry, and a shop window for the photographs themselves.

Many early retailers of photographic equipment were optical instrument makers—the Parisians Charles and Vincent Chevalier made Daguerre's first experimental cameras, while Alphonse Giroux et Cie manufactured and marketed the first commercially produced daguerreotype outfits in 1839. The absence of any patent control over the design of daguerreotype cameras, however, meant that within a very few years other French manufacturers—including Chevalier and Nöel Marie Paymal Lerebours—were producing and marketing almost identical instruments at prices much lower than Giroux's original 600 franc outfit. Giroux reportedly sold all his original production run of outfits within the first few days after Daguerre's announcement of the process. That the inventor and a manufacturer/retailer should work so closely together at the dawn of a new medium may seem surprising, but Daguerre was always convinced of the success of his invention, and Giroux was related to Daguerre's wife.

Giroux had pre-sold a number of camera outfits to Berlin art-dealer Louis Sachse who had intended to become Germany's first recorded photographic retailer. He retained one of the outfits for his own use. Gernsheim (1982) recounts that, in the event, there was a delay before Sachse could sell the cameras, and was beaten to the market place by a few days by nearby optician Theodor Dörffel who had manufactured his own apparatus, and significantly undercut the Giroux/Sachse price. Dörffel's outfit—but without a lens as these were in very short supply—went on sale on 15th September 1839.

The Giroux camera was the first to be marketed and used in many European countries—at least two thousand are believed to have been sold—but was very quickly copied locally, the replicas and later improvements driving prices down by the dawn of the 1840s. The names of many of these early entrepreneurial retailers have not been preserved.

In Great Britain, J.T. Cooper, a London chemist with premises at the Royal Institution became the first person to retail papers for William Henry Fox Talbot's photogenic drawing process—with a month of Talbot's announcement of his discovery on January 31, 1839—while Ackermann & Co, a print-seller with premises at 96 Strand, London, became the first supplier in Britain to retail a complete outfit for making photogenic drawings, at a cost of one guinea. Additional supplies of paper could be purchased separately for two shillings.

In London, the business of Horne & Thornthwaite first emerged about 1841, becoming Horne, Thornthwaite & Wood from 1844, developing into a major force in photographic retailing in England, both through their premises in London, and, from the mid 1850s, through extensive advertising in the emerging photographic press.

By the mid 1840s, Richard Willats, a chemist and optician, was importing Lerebours' cameras from France into Great Britain, and even working with the French manufacturer—suggesting modifications and improvements to the design. Within a few years, the firm of T & R Willats became one of London's leading retailers of photographic materials and equipment, and the publisher of both original, and English translations of, several pivotally important early photographic manuals.

In London, one of Willats' major rivals in the photographic market place, George Knight & Sons, also published instruction manuals as well as supplying materials.

The back pages of instruction manuals often carried advertisements for the leading retailers of the day—offering the photographer a ready directory for everything photographic. Thus, for example, at the back of the 1855 edition of Philip Delamotte's *Manual of Photography*, Andrew Ross offered a wide range of cameras and lenses from his Holborn premises, as well as papers and chemicals; Horne & Thornthwaite invited readers to send for their catalogue; Dinneford & Co listed all the necessary chemicals for the preparation of wet collodion, and waxed paper; Halifax and Co. of Oxford Street, and Howard George Wood of Cheapside both offered a range of British and French papers; and Knight & Sons advertised Voigtländer's lenses.

In Manchester, England, John Joseph Pyne, originally a chemist, opened his first 'Photographic Depot' in the mid 1850s, retailing equipment and 'photographic materials from France, Germany, and America.

It is an interesting feature of early British photographic advertising that foreign goods were sold as if they had a certain advantage over locally produced equipment and materials—in London, photographer J.J.E. Mayall originally advertised his studio as the American Daguerreotype Gallery, while in Liverpool, John Atkinson advertised heavily the imported equipment and materials available from Atkinson's American Photographic Stores. Atkinson imported Scovill products—for which he was the sole English agent in the 1850s, Peck's union cases. Skelling's American Ambrotype Varnish, and 'American cases, matts and preservers in a hundred varieties' as well as a range of French products including Jamin-Darlot camera lenses.

American retailers were similarly heavy in their promotion of British and especially French products.

In America, the most notable pioneers in photographic retailing included the Scovill Manufacturing Company which had started retailing daguerreotype plates in the closing weeks of 1839, and Edward Anthony, who opened his first studio in New York in 1841 selling daguerreian apparatus and supplies as well as taking portraits. By 1846 Scovill had established a large retail outlet in New York and reportedly had become the largest manufacturer and retailer of daguerreotype plates in America. In 1847 Anthony moved exclusively into manufacture and retailing and, in 1854, published the most comprehensive catalogue of photographic equipment and materials yet produced.

Anthony's *Comprehensive and Systematic Catalogue of Photographic Apparatus and Materials, Manufactured, Imported and Sold* was prefaced with the promise that "Those who purchase of him do so from the original manufacturer, and not at second hand, or from a jobber." Not strictly true, of course, as Anthony sold a wide range of imported goods for which he was not the manufacturer—including cameras by Chevalier and by Voigtländer, blue skylight glasses, and leather daguerreotype cases from France and Great Britain.

By the early 1860s, the expanding retail market for photographic equipment and materials in New York City was dominated by four companies—Scovill, Anthony, Holmes Booth & Hayden, and J. W. Willard & Co. But there were many more retailers—the advertising at the back of the John Towler's 1864 manual *The Silver Sunbeam* occupied almost thirty pages, and demonstrated just how competitive the market place had become.

With the advent of dry plates, and of manufacturers producing plates and papers commercially, a separation gradually occurred between manufacturers and retailers, and by the late 1870s, the idea of the photography shop—destined to become a familiar sight in every town as a one-stop source of everything needed to practice either as an amateur or professional—had been established.

Early retailers of photographic images included George Lovejoy's bookshop and library in Reading, England, where images by Henry Fox Talbot and Nikolaas Henneman were sold in the 1840s.

For many years, the print shop, the bookshop and the stationers was the most usual outlet for photographs. As people travelled throughout Europe and the Americas, specialist shops, often set up by the photographers themselves, were opened to cater for the demand for photographs fuelled by a growth in tourism. The route of the Grand Tours of Europe included many locations where large format images could be purchased, and when touring in the Middle East became popular, retail premises appeared along the banks of the Nile, amongst them outlets for the works of the Félix and Adrien Bonfils, the Zangaki Brothers, Antonio Beato, Pascal Sebah and others.

Bookshops along both European and Middle Eastern tourist routes increasingly catered for the well-off visitor, with expensively produced albums of photographs. Photographically illustrated albums, as well as single unmounted prints, of such locations as Florence, Pompei, and Rome in Italy, the architectural treasures of Ancient Greece, and the treasures of the Nile were all available by the late 1850s. Italian photographers such as Alinari, and Brogi, both in Florence, catered for the art lover, selling both large format prints and cartes-de-visite of the treasures of Italy's most famous cities and galleries.

In America, as the country was opened up to tourists, the same pattern emerged, with souvenir photo booths opening at all the major attractions. One of the first was at Niagara Falls, where in the early 1850s, Platt D. Babbitt established an outdoor facility, photographing visitors against the dramatic backdrop of the Falls, but also selling 'off the shelf' scenic views as well.

When the Crystal Palace building was removed from the Hyde Park site in London and rebuilt at Sydenham, photographers Negretti & Zambra opened a retail outlet within the building for photographic souvenirs of a visit to the exhibition complex. By 1855, and the opening of the Exposition Universelle in Paris, the idea of selling photographic souvenirs at exhibition sites was well established, and Parisian photographer André Adolphe Eugène Disdéri formed a company specifically and exclusively to make and retail souvenir photographs—daguerreotypes, stereo daguerreotypes and paper prints.

Subsequent exhibitions and world fairs all had a photographic franchise, selling souvenirs of the visit, a pattern which continue past the end of the century to this day.

By the mid 1850s, the distribution of the finest images from several of the leading photographers of the day was already being handled by well-established art dealers. In London, P & D Colnaghi had established themselves as early promoters of photography, and with Thomas Agnew of Manchester co-marketed Roger Fenton's Crimean War photographs in Great Britain. Those same images were distributed and marketed in New York by Williams & Co., and in France by Parisian photographer and print-seller, Félix-Jacques-Antoine Moulin, from his premises at 23 Rue Richer.

Colnaghi's entry into the photographic retail market was belatedly reported in *The Art Journal* in 1857, which reported:

> In addition to the other departments of their extensive and very complete establishment, Messrs P. and D. Colnaghi have just completed the requisite arrangements for the productions of photographs of the highest class and of the largest size and also in every possible vartiety. We have been able to examine many of these photographs and their excellence justifies our pronouncing their appearance as a new era in art.

Colnaghi also handled the distribution and marketing of some of Fenton's photographs of the treasures of the British Museum, but in his business dealings with the museum authorities in the 1850s, Fenton introduced a number of innovative marketing approaches, including an agreement to produce negatives without charge in return for the right to sell prints himself, made after the museum's orders had been fulfilled. This culminated in the establishment of a sale kiosk in the museum foyer, where images were sold to the visiting public by Fenton's staff. The success of this venture, in addition to substantial print orders from the museum trustees themselves, kept a number of staff at Fenton's printing establishment occupied.

They later also marketed many of the works of Julia Margaret Cameron, both in large format prints, and in the increasingly popular carte-de-visite size.

The popularity of the carte-de-visite and the stereoscope turned even relatively small photographic portrait studios into retail establishments, with the rise of the album fuelling demand for images from the catalogues of leading producers such as Mayall, the London Stereoscopic Company, Nadar, and others. E.H.&T.Anthony also became distributors of cartes, with their catalogues being retailed from studio outlets throughout America and Europe.

Many studios stocked and retailed portraits of European royalty, American presidents, stars of stage and music hall, and other celebrities.

With poor copyright protection for photographs, however, many of the sales thus achieved did not benefit the original photographers, with copies rather than originals being offered for sale. One of the first to establish what is now recognised as 'image rights' and thus benefit financially from the sale of his 'likeness,' was Tom Thumb, who controlled the marketing of pictures of himself and his family.

For much of the 19th century, the photographic exhibition served as a successful retail outlet for images, with exhibition catalogues from the early 1850s giving a price for each image on display.

By the early 20th century, however, the retail market for photographic images had largely been transferred to the picture postcard.

PHOTOGRAPHISCHE CORRESPONDENZ

Between 1888 and 1938, the *Photographische Correspondenz* undoubtedly was the most renowned magazine in photographic sciences. Any invention or scientific photographic progress mentioned in this magazine meant that it was a validated device or process. This was due in part because of its behind the scenes editor Joseph Maria Eder, then the foremost source and teacher in photographic sciences to the degree that the quality of this paper's articles had a canonic character. Before publication, any method offered, process introduced, or industrial operation presented was tested by Eder in his laboratories at the Viennese Hoehere Graphische Lehr- und Versuchsanstalt [Higher Institute of Graphic Arts and Reproduction Technology] which he founded in 1888. The shift of the magazine into photographic science was not only due to his influence but to the competition of a number of other magazines, too, which also concentrated on the publication of Fine Art imagery.

Photographische Correspondenz started in 1864 as a periodical from practitioners to practitioners. The first editor, Ludwig Schrank organized exhibitions and wrote papers for an equally sound practice in economy and arts. Fixed to ideals of craftmenship, the magazine focused on composition, lighting, posing, and the different genres of photography. Fine Art was discussed in its practical aspects, from the discussion of printing processes to questions of the copyright for photographs. From 1888 on, not only the contents of the papers changed but the illustrations and photographers as well. Any important scientist in the German speaking world who something to contribute about photography did it in *Photographische Correspondenz*, from the archeologist Heinrich Schliemann to the physicist Ernst Mach, and a number of other unnamed astronomists. The quality of these articles culminated in the first decade of the 20th century when Theodor Scheimpflug and others published their researches for the first time in Photographische Correspondenz.

Portrait photography in the studio was the main interest of the editors and authors in the first decades of *Photographische Correspondenz.* Printing technology seemed to be the main concern in the years to follow mirroring itself in the prints accompanying the periodical itself: After 1888, most of the images were produced in Eder's school, and often new technologies of both lithographic and autotype processes were used for one issue or another. The experimental characteristic of the print preparation allowed for artistic experiments o, and therefore a number of important Fine Art photographers published their works in *Photographische Correspondenz* like Hugo Henneberg, Wilhelm von Gloeden, Heinrich Bachmann, Robert Demachy, Hugo Erfurth, Hermann Clemens Kosel, and Fred Boissonas. The contrast of the scientific approach in the articles, a bourgeois habitus in the news, and a slow approval of aesthetic developments mark the overall appearance of this magazine.

Undoubtedly too, *Photographische Correspondenz* had a number of strong competitors in the world, and in German language as well: The *Photographische Rundschau*, under direction of Richard Neuhauss, mostly managed to publish international articles in German translation earlier than *Photographische Correspondenz*, and from 1900 onwards there were a number of good periodicals exclusively devoted to Fine Art Photography, which surpassed *Photographische Correspondenz* in aesthetic quality by far. But there was no other magazine in German language that had the earliest news of scientific developments, than *Photographische Correspondenz.*

PHOTOGRAPHISCHE RUNDSCHAU

The magazine *Photographische Rundschau* was launched in Vienna in 1887. Its subtitle read 'Centralblatt fuer Amateurphotographie. Organ des Club der "Amateur-Photographen" in Wien' and displayed clearly the aims of this new addition to the world of photographic periodicals. The *Photographische Rundschau* was among the earliest magazines specifically produced for amateurs, for non-specialists in both art and science. The first editors of the periodical were Carl Srna and Carl Schiendl, who was replaced from issue No. 5 by Charles Scolik, then a well-known author on photography.

With the second year the *Photographische Rundschau* moved from Vienna to Halle on Saale, to the publishing house of Wilhelm Knapp, one of the first specialists in photography. With volume 8, 1894, the magazine not only changed the title—*Photographie Rundschau. Zeitschrift fuer Freunde der Photographie*—and its editorship but shifted towards a broader understanding of photography at all. Richard Neuhauss, the new editor, was a renowned scientist in photo chemistry but had firm roots in the fine art photography movement as well. The publication now was lavishly illustrated with at least four pages of perfect prints in different techniques, mostly phototypes or heliotypes, often enough even three-colour prints.

With volume 19, 1905, the magazine was united with *Photographisches Centralblatt* from Vienna but kept its subtitle and hosted a trifolium of editors: Richard Neuhauss, Fritz Matthies-Masuren and Hermann Schnauss. Fritz Matthies-Masuren was a painter and fine-art photographer, and as an art critic he gained enourmous influence on the German scene short before World War I. In 1907, Neuhauss vanished from editorship in favour of Robert Luther, and Schnauss was replaced by Otto Mente; both were lecturers in photo-chemistry and gave the magazine a more scientific note. By 1912, volume 26 of the *Photographische Rundschau* was united with volume 49 of the *Photographische Mitteilungen* to become *Photographische Rundschau und Mitteilungen* as which it was published for the next 32 years (and counted as the older one). If one credits the later magazine *Fotografie*—the official GDR publication in amateur photography—as the subsequent follower of the earlier periodical, the *Photographische Rundschau* has existed for exactly 103 years, up to 1990.

The long history and the number of changing editors set light to the social role the *Photographische Rundschau* played. It was the earliest amateur periodical in German language but it contained larger parts of scientific news as well as messages from clubs and congregations. The main reason to subscribe this magazine, at least after 1894, was its perfect illustration with photographs from masters of the art. Later, there were more luxuriously illustrated periodicals like the *Sonne* or the *Kunst in der Photographie*, but it was the *Photographische Rundschau* where young followers of the art could see images by important professionals. Accompanied by lengthy debates on the pros and cons of printing processes, by long critical essays on exhibitions and contests, the magazine secured its reader with the information necessary to take part in most of the photographic affairs in Germany.

And the *Photographische Rundschau* even set sails for one phrase, maybe by incident: In August 1905, the Belgium fine art photographer Alexandre published an image in this magazine, showing a number of soldiers on horses in a hollow valley, under the title 'Avantgarde im Hohlweg' (Avantgarde in the defile). Six years before Guilleaume Apollinaire's first use of the word avantgarde in the context of fine art, the *Photographische Rundschau* seems to have contributed to the critic's vocabulary.

ROLF SACHSSE

PHOTOGRAPHS OF THE GEMS OF THE ART TREASURES EXHIBITION (MANCHESTER, 1857)

A major concern of mid-Victorian Britain was the relationship between art and industry. One of the key movements in this debate was The Exhibition of the Art Treasures of the United Kingdom held in Manchester in 1857. The site of the exhibition was the Manchester Cricket Club's ground at Old Trafford. It was opened by Prince Albert on the 5th May 1857 in the presence of Queen Victoria, remaining open for 142 days and closing on the 17th October that year. In retrospect, this exhibition was one of the most spectacular art exhibitions of the nineteenth century.

At the time, Manchester was at the centre of Britain's industrial heartland. A French social commentator of the period on visiting the great mill town of Manchester in 1835 was appalled by what he found: 'A sort of black smoke covers the city…. Under this half-daylight 500,000 human beings are ceaselessly at work…. From the foul drain, the greatest stream of human industry flows out to fertilise the world.' (*Journeys to England and Ireland*, 1835).

The main exhibition hall was a vast iron and glass

structure not unlike a railway shed with a decorative brick façade designed by local architect Edward Salomons. Inside, the walls and ribs of the galleries were decorated by the firm of Crace of London and each column bore the gilt monogram of the show: 'ATE.' The main hall was flanked by two picture galleries while the whole layout resembled a cathedral with a transept and a massive organ at the far end. Watercolours and photographs were displayed on a balcony, and the Indian collections were tucked into a gallery on one side of the organ.

The exhibition brought together some sixteen thousand works of art, including paintings by Duccio, Michelangelo and Rembrandt, Renaissance maiolica and glass, medieval metalwork, treasures from the English East India Company, as well as modern sculpture, paintings, watercolours and photographs. The organisers used three compelling arguments to persuade lenders: the idea of educating the masses, the promotion of British wealth, and the ultimate incentive, royal patronage.

Photography was represented by 597 examples of which 247 were portraits. It included the work of such names as Francis Bedford, Roger Fenton, Gustave Le Gray, John Dillwyn Llewelyn, John Mayall and William Lake Price. Oscar Rejlander's *Two Ways of Life* was hung at the exhibition and a print purchased by Queen Victoria for Prince Albert. Contributing photographers from the Manchester area included James & Robert Mudd and Alfred Brothers.

In 1853 Philip H. Delamotte recorded the various stages in the reconstruction of the Crystal Palace at Sydenham and photographed the Royal Family there in 1854 and 1855. Delamotte was later awarded the photographic rights for The Exhibition of Art Treasures. Alfred Brothers was asked by the Manchester print dealer Thomas Agnew to take photographs of the opening of the exhibition that was attended by Queen Victoria and other members of the Royal Family.

More than one million visitors came by road or rail to the Old Trafford site. On a single day the show was seen by the Duke of Wellington, the Bishop of Oxford, Florence Nightingale and the painter David Roberts. The exhibition gave hundreds of thousands of working-class Victorians a glimpse of a world beyond the factory and the pub. For many, 1857 marked the start of 'a noble era in which Art took Industry by the hand, and gave her all she needed to command the world' (*The Art-Treasures Examiner*, 2).

PHOTOGRAPHY AND REPRODUCTION

While photography can be defined as a reprographic process, and thus all images created are reproductions, one of the great applications of the medium during the second half of the 19th century was in the reproduction of manufactured objects and aspects of the natural world and its phenomena.

Photography redefined the concept of facsimile and objectivity throughout the second half of the 19th century and the medium was exploited across a wide range of applications where accurate reproduction was required. In order to achieve this, photography needed to overcome a number of technical barriers. The first was the ability to reproduce fine linear detail and replicate tonal ranges in order for a monochromatic photographic image to 'look like' an original subject. The other challenge was to act as an intermediary to capture and then reproduce colour in printed form. Both of these were achieved in a number of stages during the 19th century though it was the 20th century that saw their eventual full flowering.

The 19th century saw photography become fully integrated and inextricably linked to 'ink on paper' printing. Photographic illustration accompanying printed text had started as early as 1840 with the five photomechanical heliogravures in Berres' *Phototyp nach der Erfindung des Prof. Berres in Wien.* By the end of the century photography—largely through industrialized photomechanical processes—was illustrating publications distributed across the entirety of human activity. Thus photography distributed the reproduced world through a number of channels; as loose photographic prints in a wide variety of formats; as photomechanical prints and as illustration to printed texts.

Photographic formats included the stereoscopic view, and the lantern slide, both modifications to existing technology. Sir David Brewster (1781–1868) invented the first practical stereoscopic camera in 1849 and this '3-D' format quickly became popular, being used to reproduce subjects including topographical views, sculpture, architecture and sets of genre scenes representing stories depicted through pictorial narratives. Current events such as wars, and natural disasters including floods, fires, train-wrecks, and earthquakes were enormously

popular subjects and distributed through international networks. The format was commercially exploited well into the 20th century.

William and Frederick Langenheim of Philadelphia patented their photographic lantern slide process in 1850 and called it the 'Hyalotype.' This photographic format had enormous impact both as a form of entertainment and for learning. The dual projection of 'slides' was exploited by 19th century art historians to form a cornerstone of the discipline's 'comparative' methodology. Both this and the stereoscopic format were pivotal moments in the development of visual perception.

The reproduction of two-dimensional graphic art encapsulated a number of the dimensions of 19th century photography. This ranged from engineering, architectural and technical drawings and maps through fine art engravings and old printed texts, to oil paintings. Photography was also used to reproduce itself, as in the case of photographic copies of unique Daguerreotypes. Another dimension here was the rise form the 1860s of photographic 'piracy.'

Photography was applied to technical drawings in fields such as architecture and civil engineering. By 1847 the engineer Isambard Kingdom Brunel (1806–1859) was using the Daguerreotype for professional purposes. He sent Daguerrotypes of his engineering drawings to prospective railway builders across Europe. By the 1850s Brunel was using photography as a contractual tool during the construction of his vast ship the *Great Eastern,* built at the yard of John Scott Russell (1808–1882) at Millwall on the River Thames. From the 1860s most major civil engineering projects were being documented photographically. By the 1870s there was wide spread use of photolithography to reproduce architect's and engineer's drawings.

Photolithography was also used to reproduce important historical texts ranging from Shakespeare's original folios to William Griggs's 1871 reproduction of the Mahabhasya (an authority on Sanskrit grammar), consisting of some 4674 pages. This was carried out for £6000 less than the estimate for a manual tracing of the original manuscript. Between 1899 and 1903 Griggs produced the sixty plates for one of the landmarks of 19th century colour photolithography, George F. Warner's *Illuminated manuscripts in the British Museum.* Such applications underline aspects of photography's role in 19th century scholarship.

The use of photography to reproduce maps became well established by the 1860s. In the late 1850s Colonel Sir Henry James, (1803–1877) director of the Ordnance Survey Office in Southampton, introduced his photoplanographic process called Photozincography. The function of the Ordnance Survey and the politics involved in its funding dictated that the primary application of this process lay in its reproduction of maps. James regularly pointed out that Photozincography reduced the cost of map making by several thousand pounds a year. However, James also used Photozincography to reproduce historical and illuminated manuscripts in the British national collections, the chief example of which was the 11th century Domesday Book published by the Ordnance Survey Office between 1861 and 1863.

Both Daguerre and Talbot considered the reproduction of the fine and decorative arts and architecture a key application for their respective photographic processes. Talbot's experiments in particular covered a wide range of the fine and decorative arts. From engravings, printed texts and paintings, through porcelain, glass to sculpture. These subject matter were used within his landmark publication *The Pencil of Nature* (1844–1846).

Technical innovation in 19th century photography was also connected with a number of reproductive applications of the medium. For instance, the limited spectral sensitivity of photographic emulsions caused problems for the reproduction of polychrome objects such as oil paintings. In the late 1870s Gaston Braun (1845–1923), the son of the great photographic publisher Adolphe Braun (1812–1877) of Dornach, exploited developments in photochemistry to create orthochromatic collodion-bath plates to reproduce paintings in the Prado Museum, Madrid and the Hermitage, St Petersburg. These photographs caused considerable astonishment in the photographic and art world but since Braun kept completely silent about his system, it could not be adopted by other companies, thus permitting Braun et Cie to achieve pre-eminence in this specialised field However, orthochromatic (also known as isochromatic) film was not sensitive to the entire visible spectrum and it was not until 1902 that Professor Adolph Miethe and Dr Arthur Traube, of the technical college in Berlin-Charlottenburg, discovered that by using a red-violet dye, subsequently called 'ethyl-red,' it was possible to produce truly panchromatic plates and thus to correctly register in monochrome the colours of the visible spectrum in their proper tonal relationships.

The principles of colour photography had been largely established by James Clerk Maxwell (1831–1879) in the 1860s. Charles Cros (1842–82), another pivotal figure in the history of colour photography, produced colour photographs of paintings by the entrepreneurial and controversial avant-garde artist Edouard Manet (1832–83). One of these photographs was used by the collector of Impressionist art Ernest Hoschedé (1837–1891) for the cover of his review *Impressions de mon voyage au Salon de 1882* (A. Tolmer, Paris, 1882). However, during the 19th century the use of photographic colour reproductions were frequently the result of a combination of photographic and manual processes. One of the more complex of these 'hybrid' processes was the *photochromie* of Léon Vidal (1834–1906), which combined chromolithography

and the Woodburytype photomechanical process. Since Vidal primarily reproduced works of fine and decorative art —rather than scenes from nature—it was difficult for the observer to determine the resulting accuracy.

Throughout the 19th century, the manual transcription of photographic originals to form a variety of graphic illustrations to place. This to a degree masks the medium's impact. While the *Illustrated London News* prominently credited those illustrations that were after photographs, other publications did not. One of the primary reasons for manual transcription was one of speed and cost. Publications working within strict timescales exploited cheap labour to create graphic illustrations based on photographs. The rise of photomechanical processes—particularly during the 1870s—greatly increased photographic reproduction during the last two decades of the 19th century. However, it is not always easy to identify such productions. Simple line drawing illustrations were frequently not credited as being produced by photomechanical processes. At the other extreme, from the early 1870s the French engraver Amand Durand (1831–1905) produced a series of 'facsimile' heliogravures of drawings, etchings and engravings by the Old Masters which were so accurate that it was reported that a 'distinguishing mark' had been placed next to his 'deceptive copies.'

Photographic reproduction was applied to a number of areas of 19th century science. Light and colour theory and astronomy were greatly aided by the introduction of photometry and the work of William de Wiveleslie Abney (1844–1920).

Medical photography provided the capability to document and reproduce diseases, abnormalities and clinical conditions. These ranged from such as diseases of the skin, through surgical procedures to Dr Hugh Welch Diamond's photographs of the insane—taken from the late 1840s- that were also used to develop diagnostic techniques. Photographs frequently were transcribed into engraved medical illustrations. Thousands of photographs of pathological specimens and soldiers wounded in the American Civil War were used to provide illustrations for monumental six volume *The Medical and Surgical History of the War of the Rebellion* published in Washington, D.C., between 1870 and 1888.

The second half of the 19th century saw an explosion in scholarship in every conceivable academic discipline. Numerous societies and institutions were formed to represent these interests, whether in a professional and amateur capacity. Many of these not only formed photographic collections but also encouraged the photographic reproduction of pertinent objects and artefacts. In some instances 19th century local history and architectural societies joined with photographic societies to achieve their aims. The publications of these societies and illustrations were another channel by which photographic reproduction had a major influence on the dissemination of knowledge and the promotion of scholarship.

In the autumn of 1839 John Benjamin Dancer (1812–1887) made the first microphotograph on a Daguerrotype plate at 160X reduction. Photomicrography became increasingly used in the second half of the 19th century in fields such as botany and entomology. During the Franco-Prussian War of 1870, the microphotographs of the Frenchman Prudent René-Patrice Dagron (1819–1900) were exploited to provide a mail service to and from Paris while the city was under siege. Some 115,000 messages were allegedly transmitted in this way. Such uses also formed the early use of microphotography for purposes of spying and transmitting illicit messages, an application suggested by Dancer in the mid 1850s. In the 1880s Robert Koch (1843–1910) made microphotography a central tool of bacteriology. During the 20th century the microfilm became a key technology to distribute information and knowledge.

By the end of the 19th century, photography and photomechanical processes had largely eliminated the requirement for labour intensive manual printmaking methods for the production of utilitarian botanical illustrations. Related to this is the matter of the change in contexts. In the 1880s, the Harvard botanist Asa Gray (1810–1888) purchased large photographic prints taken by Carleton Watkins (1829–1916) on a California State Geological Survey, to augment the Gray Herbarium. Gray formerly acquired these images as botanical illustration, though today Watkins' images are primarily viewed within the context of their aesthetic value.

Photography was used to document manufactures and produce in-house records or advertising materials and illustrated catalogue for a wide range of industries. By the early 1860s photos replaced drawings in the china manufacturer Minton company pattern books. From the 1870s the Baldwin Locomotive Works of Philadelphia began publishing photographically illustrated catalogues.

During the last third of the 19th century photography began to have a significant commercial impact on the various components of the industry. The construction industry the works of architects, architectural masons, manufacturers of decorative fixtures and fittings, etc. were all photographically reproduced. In 1872, a critic writing on the industrial results of photography pointed to the savings being made through the efficient use of photography. "Does a builder require a number of metal brackets from Birmingham? Instead of having to incur the delay and expense of attending the transmission of a specimen from the manufacturer, he receives by return of post a photograph of the article wanted, and gives his order accordingly."

PHOTOGRAPHY AS A PROFESSION

The professional exploitation of photography came about surprisingly quickly after the daguerreotype became a practical proposition. The era of the professional began in the early 1840s with a few operators producing high price images for an elite few. The nineteenth century ended with photography as a major employer catering for a mass market, and with professional photographers establishing collectives and associations to protect their interests.

Those first sixty years of professional photography were punctuated with major 'firsts' and with the profession generating and nurturing most of the applications of the new medium which are taken for granted today. During that time, many thousands of photographic studios opened their doors. Very few of them survived for any length of time as a result of fierce competition, falling prices and a lack of business acumen.

The first photographers were, predominantly, artists and scientists who explored the potential of the medium out of curiosity and fascination. It was not until exposure times were reduced sufficiently to make portraiture a practical proposition that the photographic studio evolved. That the daguerreotypist could do in a few minutes what had taken the miniature painter hours or even days to complete immediately caught the imagination of those able to pay the not inconsiderable cost of having their likenesses made.

The dawn of professional photography in the United States was marked as 1840, and the New York *Sun* carried an account of the opening by Alexander S Wolcott and John Johnson of the world's first professional photographic studio on March 4:

> Sun Drawn Miniatures.– Mr A. S. Wolcott, No.52 First Street, has introduced an improvement on the daguerreotype, by which he is enabled to execute miniatures, with an accuracy as perfect as nature itself, in the short space of three to five minutes. We have seen one, taken on Monday, when the state of the atmosphere was far from favourable, the fidelity of which is truly astonishing. The miniatures are taken on silver plate, and enclosed in bronze cases, for the low price of three dollars for single ones.

This is believed to be the earliest publication of the cost of having a daguerreotype portrait taken professionally. Three dollars represented a week's earnings for the majority of Americans, clearly placing the daguerreotype in the same social stratum as the miniature painting.

The first photographic studio to be opened in France is believed to have been that of Nicholas-Marie Paymal Lerebours, which opened in late spring 1841. He had sold daguerreian equipment from his optical instrument shop at 13 place du pont-neuf in Paris, since taking over the business from his father in 1839. During his first year as a professional photographer he is reported as having taken around 1500 portraits. Other claimants for France's first studio include E. T. Montmirel, and Louis-August Bisson. Montmirel reportedly charged a minimum of ten francs per portrait in 1842, again the equivalent of a week's wages for the average worker.

Also in 1841 Lerebours wrote and published his *Derniers perfectionnements apportés au daguerreotype* and in the following year published his *Treatise on photography*, which sold eighteen hundred copies. A fourth edition appeared in 1843.

Richard Beard opened what is believed to have been Europe's first professional photographic studio at London's Royal Polytechnic Institution, on March 23, 1841, just a few weeks earlier than Lerebours.

Beard, who had initially paid £150 to purchase a licence to use the daguerreotype from Daguerre's English agent Miles Berry, later bought out all Berry's rights and effectively therefore gained control of professional photography in England. His patent control and resulting licensing policy, granting exclusive rights to practice the process professionally within defined geographical areas, arguably constrained the development and growth of professional photography in England for several years.

The Frenchman Antoine François Jean Claudet opened his first studio in London in June 1841, having acquired a licence direct from Daguerre. That set him uniquely outside Beard's patent control. Claudet's Adelaide Gallery prospered for many years, and in the early years especially, was the setting for some of the most significant improvements to the daguerreotype as far as the professional exploitation of photography was concerned. Claudet's chemical improvements considerably reduced exposures, and his other innovations included the painted studio backgrounds which became popular worldwide.

The media was keen to publicise the new medium, and many local newspaper stories were devoted to the opening of professional portrait studios. One of Claudet's former operatives, a 'Mr Edwards,' keen to escape the cost of Beard's English licences when he sought to establish his own professional studio, moved to Glasgow, and opened his own business in the city. *The Glasgow Herald* newspaper in March 1843 noted that

> Mr Edwards, a cadet of the Adelaide Gallery in London—which has turned out some of the very finest specimens of the art—has established his painting rooms (to speak in the old phrase) in a handsome saloon 43 Buchanan

> Street, erected for the purpose, so that the light of day, which acts to him the part of a pencil, may have free and uninterrupted access.

Initially there was insufficient demand for a full-time professional photographic studio, even in some large cities. Photographers had to have another source of income. That might be a bookseller, or even a print-seller.

Itinerant photographers opened temporary studios for a few days or weeks, then moved on to a new location. Their advertisements were remarkably similar on both sides of the Atlantic, separated only by time. In Washington, D.C., the *National Intelligencer* noted on June 30, 1840 that, "Mr Stevenson would inform the citizens of Washington and the District that he has taken rooms at Mrs. Cummings on Penn. Ave. a few doors from the Capitol where he is prepared to take likenesses by the daguerreotype every fair day from 10am till 4pm." Three years later, in the small Scottish town of Dumfries, *The Dumfries & Galloway Courier* announced on March 27, 1843 that Mr Edwards 'of the Adelaide Gallery in London':

> respectfully intimates his arrival in Dumfries, where he purposes remaining a few days, in the exercise of a profession which is altogether new in the South of Scotland. He has engaged apartments at Mrs Williamson's, Irish Street, where his specimens may be seen every lawful day from 10 to 4 o'clock. NB As Mr Edwards has pressing engagements in Russia, Prussia, &c., this may be the only opportunity of his being in Dumfries again, if ever, for a lengthened period of years.

While early professional interest was predominantly directed towards the daguerreotype, it was not exclusively so. Robert Adamson became Edinburgh's first professional photographer to use Talbot's calotype in early 1843. The *Edinburgh Review* noted in January of that year that, "Mr. Robert Adamson, whose skill and experience in photography is very great, is about to practice the art professionally in our northern metropolis." He opened his 'studio' in May of that year at Rock House on the Calton Hill, although the exposure times necessary required the photographs to be taken outdoors in the garden. Despite several daguerreotypists having operated in the city since before the end of 1841, Adamson remained, until 1846, the only professional photographer listed as such in the city's trade and street directories.

Nicholas Henneman, Talbot's assistant, also became a professional calotypist when he was appointed manager of the Reading printing establishment in December 1843, and took some of the images published in *The Pencil of Nature.* By 1848, with the Reading establishment closed, he was operating the 'Sun Picture Rooms,' the calotype studio Talbot had established the previous year in London's Regent Street.

The expansion of professional portrait photography was, understandably, driven by price. While the high price daguerreotype was the sole option, markets remained small and exclusive. The ambrotype widened those markets by providing a lower cost option to those who aspired to a cased portrait, but it was the advent of the carte-de-visite, introduced by André-Adolphe-Eugène Disdéri in 1854 which really established photography as a universal medium. With the carte-de-visite, photography no longer sought to emulate and imitate the painted miniature but, instead, evolved a new and uniquely photographic alternative, which itself created a market for albums, frames and the paraphernalia of portrait collecting.

Interestingly, while no specifically professional manuals were published, the 1850s saw the emergence of handbooks directed specifically towards the non-professional—recognition of the fact that the amateur needed to know less about the manipulation of the medium than his professional counterpart.

Not all so-called 'professionals' had any great understanding of the medium. Henry Mayhew, in his 1861 *London Labour and the London Poor* included as one of his case studies, a 'Photographic Man' who had been a fairground performer before turning to photography, a subject he knew nothing about. Relying on public ignorance of the workings of the photographic process, Mayhew's case study was just one of many con men, who sold poor quality 'sixpenny portraits' to their unsuspecting customers, often moving on to new locations before their disappointed customers could demand their money back. Relying on the fact that the poor seldom possessed good quality mirrors—and thus really did not know what they looked like—Mayhew's 'photographic man' even managed to sell customers portraits of someone else.

Such practices were in sharp contrast to the standards maintained by the great portrait studios of Southworth & Hawes**,** Whipple, Brady and others in the United States or Mayall, Claudet or Kilburn in the UK, and the great commercial photographers like Nadar or Hippolyte Collard in France, Roger Fenton**,** P. H. Delamotte, and others in Britain, or John Carbutt, Alexander Gardner *et al* in America. Indeed, the rapidly falling prices, brought about by the carte-de-visite, are often cited as a likely reason for Fenton's sudden abandonment of photography in 1862.

By the 1870s, the majority of the professional specialisms with which we are familiar today were in place. Portrait studios in their thousands produced cartes and cabinet photographs, while the expanding tourist market was met by output from professional photographer/publishers such as G. W. Wilson, Francis Frith, and James Valentine in the UK, Antonio Beato, the Zangakis, Bonfils and the Sebahs in Egypt, Adolphe Braun and others

in Europe, Bourne and Shepherd in India, the Bierstadts, Notman in Canada**,** and Carleton Watkins, William H Jackson and others in the United States.

Specialist industrial and architectural photographers emerged to photograph the many great construction projects of the Victorian era, aided by more sophisticated equipment, faster emulsions and greater consistency and reliability.

Photographic associations had, from the 1850s, been open to all who were interested in the medium, their meetings populated by amateurs and professionals alike. As the century progressed, however, the requirements of amateur and professional began to diverge. While the amateur was still concerned with experiment, with exhibition and with the interchange of ideas, the professional faced a widening range of challenges, not least of which were to do with copyright and the duplication and dissemination of images. The introduction of cheap methods of photomechanical reproduction of photographs made the resolution of these issues even more pressing.

Until the mid 1870s, the use of photographs as book illustration was easy to control, but with the advent of the Woodburytype, Autotype, and other pigment printing processes, it became easier and cheaper. Walter Bentley Woodbury's *Treasure Spots of the World* published in 1875—and often described as the world's first 'coffee-table book'—heralded the dawn of a potentially large new market for professional photographers.

Copyright laws throughout the first three decades of photography did not include the image, giving the photographer little protection against the commercial exploitation of his/her work by others.

In most countries of the world, by the end of the century, the concept of automatic copyright in a photograph was still decades in the future. In the UK, as copyright in an individual image had to be registered at Stationers' hall, and a small fee paid per image, few photographers exercised a right which they had enjoyed since the 1870s.

Once newspapers and magazines could reproduce photographs, the professional became open to frequent exploitation. Individually the photographer was powerless. Collectively, the profession could bring about change. Thus the century ended, and the 20th century began, with the formation of first professional associations in Britain and the United States.

PHOTOGRAPHY IN ART CONSERVATION

Over the centuries the restoration of works of art has been both a business, and a source of additional earnings for artists: Paintings, sculptures and buildings were often part of ritual, or other functional contexts, and often the preservation of such use value was considered to be of more importance than either the artistic value or the historical authenticity of a work of art. Thus, if artists could not preserve the piece by completing or repairing it, they were qualified to replace or remake the lost piece.

Along with the general status of works of art in society, the position of restoration changed during the 19th century: The authenticity of the pieces themselves started to rank higher, although it remained disputed how restoration as a profession should present itself: Theoreticians such as Violett Le Duc took the position that in cases of doubt, the reconstruction of historical monuments and works of art was necessary, while John Ruskin advanced the view that restoration was the most brutal form of destruction. This juxtaposition remained fundamental for debates on conservation well into the 20th century, for example in the disputes surrounding the preservation of monuments in which Georg Dehio and Alois Riegl took part. These controversies affected the work of the restorers.

Until well into the 19th century it had been the task of the artists' appointed gallery directors to restore the paintings within collections. Since the 1850s, restoration increasingly became a profession in its own right, one

which often collaborated with the developing academic discipline of history of art, appropriating and developing a scientific foundation for its practise.

Among the first to work in this field was Humphry Davy who around the same time conducted studies on substances sensible to light and inquired into pigments and papyri excavated in Pompeji, publishing his findings on the latter in 1819. The first laboratory for the scientific investigation and treatment of museum collections was founded in 1888 in the Royal Museum in Berlin, run by Friedrich Rathgen until 1927. Photography, now as then, is being used in restoration mainly for two purposes: on the hand it is used for documenting the inventory, and on the other it is applied to the study of works of art by scientific means and methods.

Arago was already aware of the importance photography could have for the examination of works of art when, in his speech in the Chamber of Deputies on July 6 1839, he drew the attention of the audience to the fact "that if photography had been known in 1798, we should now have correct images of a somewhat considerable number of emblematical pictures, of which the cupidity of the Arabs, or the fatal mania of certain travellers for destruction has for ever deprived the scientific world."

Even though for the moment, scientific documentation receded into the background, initial evidence of it can be found in the volume Egypte, Nubie, Palestine et Syrie published by Louis Desire Blanquart-Evrard in 1852: The work was primarily a commercial enterprise, but the photographs by Maxime Du Camp, illustrating the subject as prints on paper was pathbreaking for the further development of the architectural photography. Du Camp, for instance, had fellow travellers pose in front of the buildings in order to visualize the architectural dimensions. A year earlier, the French Commission des Monuments Historiques appointed photographers such as Edouard Baldus, Hippolyte Bayard und Henri Le Seq to document architectural ensembles in French cities before they were pulled down in the course of modernization. As a consequence of the 'Mission Heliographique,' photographers during the next years were more and more involved in similar enterprises: in 1855, the architect Jean Baptiste Lassous appoints Charles Nègre to document the restoration of the cathedral in Chartres, and Désiré Charnay is sent to Mexico in 1857 to photograph the ruins of the ancient indian cultures. At about the same time, similar initiatives were begun in several German cities: In Cologne, the building authorities ordered pictures to be taken of buildings due for demolition, and in Hamburg, Georg Koppmann was paid to document buildings of historical significance. In other places, such initiatives were triggered by private commercial or antiquarian interest: While Eugene Atget's photographs of the vanishing Paris, for a long time remained in obscurity, Fratelli Alinari in Florence produced and sold photographs with urban motifs. However, of more commercial interest and as well significant for restoration, were the reproductions of sculptures, paintings and graphic arts marketed by Alinari. Similar enterprises were undertaken by Adolphe Braun (Paris/Dornach), Josef Albert and Franz Hanfstaengl (Munich).

These firms systematically reproduced private and museum collections; the catalogue of the company of Adolphe Braun in 1887 offered tens of thousands of different works of art. With these commercial campaigns, a vast number of works were reproduced for the first time and thus were available for the stylistic comparisons necessary for tests of authenticity, the separation of 'hands' and for the purpose of establishing dates. Occasionally however, the commercial photographers caused work for the restorers than aiding them: Well into the 20th century, reproductive photographers exchanged recipies about how to treat paintings in order to obtain stronger contrasts and brighter colours. In particular, cooking oil and mixtures of albumen, sugar and glycerine enjoyed great popularity. To avoid such incidents and, moreover, to participate in the profitable business of reproducing works of art, some museums appointed

their own photographers: Already in 1855, the Louvre had pictures of its collection of antique sculptures taken by an internal photographer, and the prints were used not only for reference in the deeds, but sold to scientists and the interested public. In London the newly founded South Kensington Museum assumed the function of reproducing exhibits for the British Museum and the National Gallery since 1859; the Reproduction Room committed to selling the prints, but closed four years later because the museum's atelier was not able to cope with the demand.

At around the same time, photography was first used to document the work of restoration of artworks: The Munich chemist Max von Pettenkofer had developed a process for regenerating torn varnish, instead of the common practice of removing it from the paintings. To demonstrate the advantages of his process, he had a painting by Domenico Quaglio photographed by Josef Albers, first in 1859 and then again in 1864. The photographs showed a significant increase of fissures and dull spots in the varnish vanishing after the regeneration. Pettenkofer recommended exhibiting such photographs together with the paintings, a suggestion that had rarely been taken into consideration until recently. This kind of photography borders on its application as an analytic tool for restoration.

In the 1890s, Arthus Pillans Laurie used a stereo microscope to investigate the surface of paintings in order to find out which pigments were used by the old masters and to detect forgeries by analyzing the brush strokes; however he published most of the results only after the turn of the century. As well, Theodor von Frimmel used microscopes and photographs to understand the regularities of the formation of crackles in the paint; he published one of his photographsin his Handbuch der Gemäldekunde (1894). Raking light was systematically used for the investigation of paintings since the 1890s: with its help, traces of pentimenti and earlier versions could be detected. In the course of restoration of two portraits by Christoph Amberger in Braunschweig in 1892/93, subsequent alterations were discovered, changing the donors into saints; the findings were confirmed by later radioscopies. X-ray examinations of works of art were executed within months after Röntgen published his discovery in January 1896, indicating that lead paint absorbs the radiation.

Already in March 1896 the Frankfurt physicist Walter König had investigated paintings using X-rays. In the following years, a number of smaller publications referred to the new method of examination, which proved to be particularly useful for the verification of works of art. Around 1913, the Weimar roentgenologist Alexander Faber systematically researched the absorptions of different pigments used for paintings, and even though the general procedure was known at that time, in 1914 he was issued a patent for a 'Procedure for the determination of overpaintings in oil paintings and similar objects.'

Other photographic methods for the investigation of works of art in use today were not applicable yet in the 19th century. Since Hermann Wilhelm Vogel had developed the appropriate emulsions in 1873, infra-red photography was technically possible; for paintings, however, it has only been in use since the 1930s. On the other hand, while the sensitivity of photographic emulsions to ultra-violet rays has been known since the beginnings of photography; it became of practical value only after the invention of the mercury vapour lamp by Küch in 1906. Its first application for purposes of restoration was by P.R. Kögel who, with the help of this method, could decipher illegible palimpsests.

A curiosity in this context is the heliography of a painting by Vernet now preserved in the Harrach collection in Rohrau/Lower Austria: The canvas of the painting was penetrated by a bomb splinter during the revolutionary fights in Vienna in 1848. The hole, however, was not mended: instead, a small piece of cardbord with a note about the damage was mounted to the back of the painting, such that it was readable through the hole. In this state the painting was reproduced. The hole was mended only in the course of another restoration executed in 1961.

PHOTOGRAPHY OF PAINTINGS

The graphic reproduction of works of art has an extended and diverse history and photography followed the tradition in which the depiction of the fine and decorative arts bestows some kudos on the reprographic processes being used. Photography was invented at a time when a large and vibrant market in the reproduction of paintings was rapidly evolving. This market encompassed a wide range of sectors from highly expensive *de luxe*

Unknown (Photographer). Galerie Anglaise. *The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.*

engravings to cheap wood cuts used a loose prints or to illustrate cheap such as the *Penny Magazine*, first published in 1831, that produced 'a revolution in popular Art throughout the World.

Both Louis Jacques Mandé Daguerre (1787–1851) and William Henry Fox Talbot (1800–1877) appreciated the importance of reproducing works of art (including paintings, drawings, engravings, sculpture and decorative art) not only for proof of their respective photographic processes but also for their commercial application. Subsequently, during the 19th century art reproduction was to form a key and commercially very significant part of the photographic market. Until the 1870s, the photography of works of art (including paintings) was considered a standard advertised service offered by commercial photographers.

At the time of photography's invention a plethora of reprographic processes were available and by 1859 William John Stannard listed no less than 156 in his privately published *Art Exemplar*. These relief planographic processes were being exploited to meet the rising demand for loose graphic reproductions and the business opportunities offered by rapidly expanding and diversifying commercial markets. Throughout the 19th century, photography was to compete and interact with manual reprographic processes in the reproduction of paintings. Indeed this forms a significant part of the history of photography during the 19th centuy.

During the 1840s a variety of amateurs used the Daguerreotype to document paintings in their collections though the scale and scope may never be known. In parallel, commercial photography was being used to document public collections—or collections open to the public. In February 1848, Richard Beard, a leading London photographer, had been given permission to Daguerreotype paintings in the National Gallery in London and a month later a certain John Woolley asked 'permission to make copies of two or three pictures in this gallery by means of the Calotype Camera.' Such small but significant activities were being undertaken in many countries.

It is also known that during the 1840s leading artists had their paintings photographed. Jean-Auguste-Dominque Ingres (1780–67) was one of the earliest acclaimed contemporary painters to apply photography to document his work. In 1842 he had a Daguerreotype taken of his painting of Saint Peter destined for Santa Trinita dei Monti in Rome. This may have been to enable Ingres to have Daguerreotypes with which to teach his students. In 1848 Gustave Le Gray (1820–1884) Daguerreotyped the painting *Anacréon, Bacchus et l'Amour* by Jean-Léon Gérôme (1824–1904) exhibited at that year's Salon. In the 1860s Gérôme developed extremely close professional relationships with the photographer Robert Bingham (1825–70), regularly having his paintings photographed before being sold. Gustave Courbet (1819–1877) exploited photography to reproduce his paintings and had commercially available photographs produced of those paintings that were refused by the 1855 Salon. Photographers including E. Baldus, P.A. Richebourg, E. Carjat and C. Michelez all registered photographs of paintings by Courbet at the Dépôt legal in Paris.

The photography of painting was identified as significant by a wide range of influential photographers during the 1840s and was strategically used to further the cause of the revolutionary process. An album of Calotypes by David Octavius Hill (1802–70) and Robert Adamson (1821–48), presented to the Royal Academy of Arts in London in *c.*1848 included a reproduction of a painting entitled *The Dance* by William Etty (1787–1849).

However, the photography of paintings, like most applications of photography, was to scale up very significantly from the early 1850s. While most 19th century commercial photographers marketed themselves as generalists covering the general requirements of their customers across Europe and beyond, some created significant reputations for art reproduction. These included Fratelli Alinari of Florence, Adolph Braun (1812–1877) of Dornach, Robert Macpherson (1814–1872) and James Anderson (1813–1877) in Rome, Leonida Caldesi (1823–1891) an Italian working in London, Robert Bingham (1825–1870) the Parisian-domiciled Englishman, and Juan Laurent (1816–c.1890) and Charles Clifford (1819–1863) in Madrid; Hanfstaengl and F. Bruckmann in Munich; At the end of the century Frederick Hollyer (1837–1933) was renowned for his reproduction of paintings, particularly using the Platinum print process.

By the 1850s all aspects of the commercial art world including painters, sculptors, architects, engravers, art dealers and auction houses had adopted photography. The public sector in the form of museums also adopted the medium and in some instances appointed photographers. Charles Thurston Thompson (1816–1868) was one of the earliest of these and his career at the South Kensington Museum (now the Victoria & Albert Museum) during the 1850s and 1860s set an benchmark as he recorded the permanent collections, temporary loan exhibitions and ventured abroad to photograph in France, Spain and Portugal. It is significant that as early as the 1860s commercial photographers were complaining that museum 'in-house' photographers –such as Thurston Thompson—were given preferential treatment and were being heavily subsidised by Government departments that enabled them to undercut the prices at which they sold photographs. In Thompson's case this was largely due to the sappers from the Royal Engineers that were being used at South Kensington as part of the unofficial yet permanent photographic facilities.

By 1880 the South Kensington Museum held a collection of some 50,000 photographs acquired from a variety of sources and channels all over the world. Many of these were reproductions of paintings. Thompson also undertook commercial work photographing paintings on behalf of leading art dealers. In 1863 he was employed by the art dealer Ernest Gambart (1814–1902) on several occasions to photograph paintings that he was selling. These included *Shetland Ponies* and the *Ferry Boat crossing the Lake in the Highlands* by Rosa Bonheur (1822–1899), and *Derby Day by* William Powell Frith (1819–1909).

The photography of paintings was hindered by a number of technical problems during much of the 19th century. Levels of illumination were particularly critical. In the early 1840s Talbot had taken paintings outdoors into the cloister at Lacock in order to enable high enough levels of illumination for adequate camera exposures to take place and this practice continued for several decades. In 1858 the Raphael Cartoons were taken outdoors from Hampton Court Palace to be photographed twice in parallel, once by Charles Thurston Thompson and once by Leonida Caldesi. To the modern observer the general views photographed of this work being undertaken by Thompson and Caldesi are curious since the paintings have been placed upside down. This was to enable easier framing on the ground glass screen of the camera—the image on a plate camera always being vertically inverted from the actual view as seen by the human eye.

Many paintings are hung in ways that make their photography difficult or impossible. Paintings can be hung high off the ground. They can be hung in corners and thus have restricted illumination. In 1860 paintings from the Royal Collection at Buckingham Palace were removed to the London photographic studio of Caldesi, Blanford, & Co for photography to take place. From the 1850s some public museums and galleries built photographic studios to enable photography of paintings to take place.

To counter the challenges of instances where paintings could not be moved—such as wall frescoes—some photographers built scaffolds to position the camera at the paintings mid-point and thus remove any distortion. The most significant example of this was the use by Adolphe Braun et Cie. Of a movable scaffold to photograph Michelangelo's frescoes in the Sistine Chapel in Rome. These photographs, published in 1869 using Swann's Carbon print process and almost exclusively of details the fresco scenes, had a major impact on the study of these paintings and were greeted with universal acclaim.

While the use of mirrors to reflect light was known, artificial light sources were very rarely exploited in the photography of painting during most of the 19th century. Artificial light sources were very rarely used in the photography of painting during most of the 19th century the preference was for natural 'North' lighting in studios. One particularly significant early example of the use of artificial lighting to photograph paintings took place in the subterranean Early Christian Catacombs in Rome during the late 1860s and 1870s where magnesium light was used to illuminate the Early Christian fresco decora-

tion. These images appeared in the publications of John Henry Parker (1806–1884) dealing with the Roman and Early Christian archaeology of Rome.

One of the most prominent challenges to the photography of painting was the limited spectral sensitivity of black and white photographic materials that could not reproduce the full colour spectrum. This was of particularly apparent in the reproduction of paintings and frequently evidenced in religious paintings where the traditional blue colour of the Virgin Mary's cloak would be reproduced as a very light tone due to the photographic emulsions being oversensitive to blue thus making a very dark area on the negative—which in turn printed as a light tone in the photographic print. Some photographers 'retouched' their negatives of paintings to counteract the tonal imbalances introduced by the spectral sensitivity of the photographic emulsions they used. Others retouched the photographic print and then rephotographed the retouched photograph in order to create a second negative from which they might print more tonally accurate photographic prints. That photographers were willing to go to such lengths indicates the commercial value of the market for photographs of paintings during the 19th century and it is significant that it was the specialist photographic art reproduction company of Adolph Braun that developed and then introduced improved orthochromatic (or isochromatic) emulsions in 1878, fully panchromatic film being introduced in 1905.

Related to this technical limitation of 19th century photographic processes is the fact that during much of the 19th century photography was exploited to copy reproductions after paintings, such as engravings, lithographs and the like. Undoubtedly, the copying of achromatic engravings was a simple and thus extremely cheap form of copy photography. In some instances there were practical and economic reasons for photographers or publishers not being able to photograph directly from paintings. However, throughout the 19th century the engraving remained highly esteemed and thus photographs of important engravings after paintings were frequently seen as valuable in their own right.

Producing 'colour' photographs of paintings was addressed in a number ways. Firstly, was the hand colouring of monochrome photographs of paintings. An example of a hand coloured Calotype from the studio of Nicolaas Henneman dated to the late 1840s survives and the colouring of Daguerreotypes was also well developed by this time as photographers exploited the professional talents of miniature painters in new commercial fields. A significant market for coloured photographs developed and Vincent van Gogh (1853–1890), while working in the London office of the printseller Goupil, mentioned this in a letter to his brother in November 1873.

The development of hybrid reprographic processes was also an avenue that was explored to reproduce paintings in colour. Between 1864 and 1866 Jules Labarte's *Histoire des Arts Industriels au Moyen Age et à l'époque de la Renaissance* was published and was illustrated with two 'albums' containing 150 plates created by the Parisian printer Lemercier through a synthesis of photographic, lithographic, photomechanical and chromolithographic processes. However, few of the plates are of 'paintings.' Similarly, the Photochromie process of Léon Vidal (1834–1906) introduced in 1875 and which combined chromolithography and the Woodburytype photomechanical process was little used to reproduce paintings.

Colour photographic processes were developed as early as the late 1860s and paintings by Edouard Manet (1832–1883) reproduced at this time. Charles Cros (1842–1882), the inventor of one of the earliest colour photographic processes copied *Jeanne—Le Printemps*, Manet's portrait of Jeanne Demarsy, dated 1881–82. This photograph was used by Ernest Hoschedé (died 1892) for the cover of his review *Impressions de mon voyage au Salon de 1882* (A. Tolmer, Paris, 1882). Cros and Manet shared an interest in the problems of colour-printing technology and the reproduction of this painting was part of their experiments in colour photogravure.

Photographs of paintings were disseminated through a number of channels. Print dealers dealers formed a primary channel. In Florence, Fratelli Alinari formed an association with the print seller Bardi in the early 1850s. In the same decade the London firms of Paul and Dominic Colnaghi and Thomas Agnew & Sons commissioned and published photographs of paintings. Together these two dealers copublished one of the landmarks in the photographic reproduction of paintings *Photographs of the "Gems of the Art Treasures Exhibition," Manchester, 1857*. This title consisted of some 200 photographs—100 "Ancient" masters and 100 'Modern' masters—taken directly from the paintings. These photographs formed a milestone in 19th century art historiography in that it helped in the reattribution of a number of works by the Old Masters, often to the detriment of the owners who had perhaps sent a work of an 'Old Master' to Manchester only to have it returned as a copy or work of another, lesser artist. A contemporary review of these photographs also pointed to the democratisation of art; "These things bring Art nearer the reach of the poor man—to whom it will some day become, not mere furniture and wearying luxury, but hope and comfort, and prophecy and exhortation."

Colnaghi set up a photographic studio specialising in art reproduction and formed a professional relationship with Leonida Caldesi that prospered during the late 1850s and 1860s.

Throughout the 19th century stationers and book shops also provided a wide range of photographs for

purchase. Little research has been undertaken in the role of such outlets. However, they played a significant role in the distribution of photographs of works of art at a regional and particularly a local level. In parallel, purchasing photographs of paintings from printed catalogues remained common throughout the 19th century.

Some remarkable works were created using photographs of paintings. At the 1862 International Exhibition held in London, the Belgian photographer Edmond Fierlants (1819–1869), was reported to have exhibited two works, copies of orginals by Hans Memlinc (ca.1440–1494); a life-size replica of the *Shrine of St. Ursula*, with photographic reproductions of the painted panels (at £45), and the *Mystic Marriage of S. Catherine* (at £12. 4s).

A wide variety of photographic print formats were exploited for art reproduction during the 19th century. These ranged from thumbnail-sized prints, used as border decoration in photo albums, to the large Elephant format images of paintings in major European galleries published in portfolios by Adolphe Braun et Cie. In some instances a variety of different loose print sizes were available of the same image. The carte de visite from the 1850s and Cabinet from the 1860s were both used to document a wide variety of works of art including paintings. Paradoxically, examples of photographic stereoscopic views of paintings are also known, though given the two-dimensional nature of most paintings this format seems particularly inappropriate.

The photographic lantern slide, one of the cornerstones of the teaching of art history, was invented in the late 1840s and was beginning to have a significant impact in the teaching of art in Germany by the end of the 1870s. It was not until the 1960s that this format was abandoned in favour of the 35mm slide. It is also significant that black-and-white photographic slides remained predominant—particularly in German-speaking countries, since there were widely held beliefs that the "inaccuracy" of colour photography could distort the reproduction of the original painting.

The use of photography for the illustration of art books began in the 1840s and has proved to be one of the most significant applications of photographs of works of art. Talbot's Reading establishment printed the photographic illustrations to William Stirling's *Annals of the Artists of Spain* published in 1848. Although as few as 50 copies—25 each in quarto and octavo format—may have been produced, the publication was doubly important; firstly as the first photographically illustrated art history book and secondly that some of the illustrations were photographs taken directly from the paintings they represented, rather than manual intermediaries such as engravings or lithographs. British publishers such as Samson Low, Bell & Daldy, A.W. Bennett, Day & Son, Seeley, Jackson & Halliday and Bickers & Son were prominent as publishers of photographically illustrated art books during the 19th century and several thousand titles were published during this period. While many of these photographically illustrated books contained pasted in Albumen prints of paintings (or reproductions after them), by the end of the century photomechanical processes were almost exclusively used.

Though comparatively little appreciated in the 21st century, the 19th century photography of paintings formed a central position in the history of the medium during that century. This was from an aesthetic, technical and market development perspective. The impact on the history and study of painting is difficult to over estimate.

PHOTOGRAPHY OF SCULPTURE

The practice of drawing from sculpture—particularly from ancient sculpture—was a central element in the education of artists in Italy during the fifteenth and sixteenth centuries. Antiquities such as the *Apollo Belvedere*, the *Belvedere Torso,* and the *Laocoön*—after its rediscovery in January 1506—were fundamental to the figurative vocabulary of every Renaissance artist. Indeed, the study of sculpture complemented direct study of the human figure, and, in the case of the female figure, an antique *Venus* might serve as a surrogate for a live model. Life drawing and the study of plaster casts of sculpture remained at the core of every academic art curriculum in Europe and in North America throughout the early modern period.

Photography was presented as a new form of drawing, and so it is not surprising that sculpture became one of the primary categories of subject matter among the English and French pioneers of the new art. Nor is it surprising that plaster replicas of many of the works that had been important to the formation of Renaissance artists should also have had a formative influence on the early history of photography. In the 1840s the *Apollo Belvedere* and the *Medici Venus* were still considered to represent the Greek ideal of male and female beauty. Small-scale portable versions of these and other ancient

Lampue. Still Life of Sculpture and Architectural Fragments.

sculptures were popular souvenirs among visitors to Italy and were therefore natural and readily available models for early photographers. Life-size casts of the same works became essential elements in academic training in the fine arts. Photography was assimilated into this practice through the production of 'academies' for study by posing nude models.

In the first sentences of his commentary on the *Bust of Patroclus* in the first fascicle of *The Pencil of Nature*, William Henry Fox Talbot defined what was to become an important and continuing relationship between photography and sculpture:

> Statues, busts, and other specimens of sculpture, are generally well represented by the Photographic Art; and also very rapidly, in consequence of their whiteness. These delineations are susceptible of an almost unlimited variety: since in the first place, a statue may be placed in any position with regard to the sun, either directly opposite to it, or at any angle: the directness or obliquity of the illumination causing of course an immense difference in the effect. And when a choice has been made of the direction in which the sun's rays shall fall, the statue may then be turned round on its pedestal, which produces a second set of variations no less considerable than the first. And when to this is added the change of size which is

> produced in the image of bringing the Camera Obscura nearer to the statue or removing it further off, it becomes evident how very great a number of different effects may be obtained from a single specimen of sculpture.

In fact, sculpture featured prominently in Talbot's own repertoire almost from the inception of photography. In a memorandum of March 1840 he placed sculpture first among ten divisions by which he classified photogenic drawings, and notes of photographs he took in 1840 establish that many of those depicted sculpture. The *Patroclus* appears several times, and an *Apollo*, a *Venus*, an *Eve*, and four *Sabines* are also listed. In fact, more than a dozen negatives depicting a miniature version of Giovanni da Bologna's *Rape of the Sabine Woman* are known. Although Talbot photographed the *Patroclus* in the south gallery of Lacock Abbey, it was often the case that the sculptural subjects would be carried outside to be photographed in the grounds of the abbey, and in some instances it is apparent that the object is standing on grass. It is noteworthy, therefore, that *Diogenes*, a sculpture in the entrance hall of the Abbey, was one of the first subjects Talbot photographed after discovering the latent image. It is also significant that a small-scale replica of Antonio Canova's *The Three Graces* is the subject of a photograph that is being made in the well known panorama of Talbot's Printing Works at Reading.

Photographs of sculpture likewise appear in all Talbot's photographically illustrated books. The first of these, the *Record of the Death Bed of C. M. W.*, has as its frontispiece a plate depicting a marble bust of the deceased. The *Patroclus* is illustrated twice in *The Pencil of Nature*, first as plate V and again as plate XVII. Plate six in *Sun Pictures in Scotland* is a photograph of a sculpted effigy of Maida, Sir Walter Scott's favourite dog. The volume of *Talbotype Illustrations* that was published to accompany copies of Sir William Stirling's *Annals of the Artists of Spain* contains several photographs depicting works of sculpture.

Sculpture was also among the first subjects treated in the earliest history of photography in France. In 1838 and 1839 Louis-Jacques-Mandé Daguerre photographed still-life compositions that included statuettes and reliefs. One well-known daguerreotype representing a collection of shells and fossils is effectively a miscellany of sculptural objects. Sculpture was the principal category of subject matter in the body of work made by Hippolyte Bayard in 1839 and 1840. Photographs mounted in an album preserved in the Société française de photographie in Paris, for instance, show that he photographed some forty different plaster casts in this formative period. Bayard continued to photograph arrangements of sculpture during the 1840s and 1850s. Among these pictures is one beautiful composition in which five different casts form a figurative garland around a replica of the renowned *Venus de Milo*.

Bayard, Daguerre, and Talbot evidently recognised and exploited the fact that plaster casts, because of their whiteness and stability, provided ideal practical models for photography. However, Talbot's interest in the *Patroclus,* the *Sabines,* and the *Three Graces* may also have been stimulated by a wish to explore the possibility of depicting expression and movement. The *Patroclus* is an exceptionally animated sculpture, one that appears physically and spiritually alive. Giambologna's sculptural group, described in John Murray's *Handbook* of 1847 as "wonderful for its expression and its energy of action," neverthelesss stands patiently still for Talbot, enabling him to capture its violent torsion and turbulent energy. Similar points might be made with respect to Charles Nègre**'s** renowned photograph of 1859 depicting the sculptural group *Boreas and Orythia* in the Tuileries Gardens in Paris.

David Octavius Hill and Robert Adamson occasionally introduced works of sculpture into their portraits and subject pictures. In these portraits the sculpture alludes to the nature of the sitter, much as books do in Hill and Adamson's portraits of churchmen, and in this respect the sculpture serves as do the coins medallions, and statuettes that appear in Renaissance portraits by Bronzino, Titian, and others. A calotype of Elizabeth Rigby, for instance, portrays her with a plaster cast of a bronze by Pierre Philippe Thomire depicting two cupids fighting over a heart. This group is clearly appropriate to a portrait in which the sitter is depicted in a mood of romantic reverie. A colossal head entitled *The Last of the Romans* serves straightforwardly as an 'occupational' attribute in Hill and Adamson's portrait of John Stevens, the sculptor responsible for this work. This head functions more allusively in *The Morning After'He Greatly Daring Dined,'* a composition that is perhaps a lightly moralising sermon on the effects of intemperance. Transporting the sculpture to Rock House must in itself have been a considerable challenge. In a more serious vein, the sculptural tombs in Greyfriars Churchyard provide settings for compositions by Hill and Adamson that are in effect meditations on mortality.

In the spring of 1846 the Reverend Calvert Richard Jones made two negatives in Florence from Giovanni da Bologna's *Rape of the Sabine Woman*. These studies recall Talbot's earlier efforts to record his miniature *Sabines* and serve also a form of homage to Talbot. However, Calvert Jones's pictures of Giambologna's sculpture and a precisely contemporaneous photograph of Baccio Bandinelli's *Hercules and Cacus* are also instances of the employment of photography to document works of art for touristic purposes. Such images enabled the traveller—like Napoleon—to carry off 'trophies' of travel. Indeed, the first catalogue produced by the Fratelli Alinari consists entirely of architectural views and photographs of sculpture. Such photographs

also enabled the armchair traveller to experience these attractions without having to leave home.

The ritual of purchasing photographic 'spolia' became an integral part of the 'work' of tourism, and photographs of sculpture formed a significant portion of any representative collection of views of Florence, Rome, and Venice, for example. Among the innumerable photographers that supplied such portable records were—in addition to the Alinari—James Anderson, Adolphe and Henri Braun, Giacomo Caneva, Robert Macpherson, Carlo Naya, and Carlo Ponti. Photographs of ancient sculptures excavated in Rome during the pontificate of Pius IX contributed to the myth of the Papacy, as did the lavish photographic albums documenting the Vatican sculptures that Macpherson and the Brauns published in the 1860s. Working farther afield in the sphere of travel photography, including the photography of sculpture, were, for instance, Felix Bonfils in Athens and Constantinople; Maxime Du Camp, Francis Frith, John B. Greene, Félix Teynard in Egypt; Lous De Clercq in Syria; Auguste Salzmann in the Holy Land.

Travel photography and photography that was intended to document the history of art and architecture were closely related. In France in the early 1850s, Charles Nègre, Em. Pec, and Henri Le Secq recorded the sculpture at Chartres, for instance, in addition to photographing the cathedral itself. In England, Roger Fenton was employed in 1854 to document the ancient sculpture in the British Museum. After constructing a studio on the roof of the museum, Fenton set about photographing dozens of Assyrian tablets and other works of sculpture. In order to ensure that there was sufficient light, it was often necessary to have the objects carried out on to the roof itself, a practice that in turn required Fenton to devise ingenious ways of controlling and modulating the natural light; occasionally he would even dust the sculpture with powder to make the surfaces more conducive to photography. Between February 1854 and May 1856, Fenton and his assistants produced over eight thousand salt prints of sculpture. From these beginnings, the scholarly study of sculpture became inseparable from the history of the photography of sculpture, and understanding of particular works of sculpture was shaped in significant part by the character of the photographs that were available. Conversely, the interests and needs of art historians might affect the nature—general views and details—and particular viewpoints of the photographs that were made.

Sir David Brewster's invention in 1849 of the stereoscope made it possible to produce photographs of sculpture that more closely approximated the sensation of relief and volume provided by the subject itself. Sir David himself affirmed that such views would enable the student of sculpture to "avail himself of the labours of all his predecessors." He would "virtually carry in his portfolio . . . the gigantic sphinxes of Egypt, the Apollo, and Venuses of Grecian art, and all the statuary and sculpture which adorns the galleries and museums of civilized nations." Indeed, such images came to be perceived as accurate and true substitutes for the models themselves. As a result of the publication of millions of inexpensive stereoscopic prints and slides of ancient and modern statuary, sculpture was literally "photographed into . . . popularity."

Talbot's observations concerning the "almost unlimited variety" that is possible when photographing sculpture raises important questions concerning the nature of the relationship between the two media. In relation to the graphic arts and printing, for instance, photography is a reproductive process in which the correspondence between the matrix and the image appears relatively straightforward. For a start, the subject and the photograph are both two-dimensional. A photogenic drawing of an engraving or a leaf is a direct impression of the object made by the action of light. With sculpture, however, the relationship between the object and the image is exceedingly complex and is, as Talbot indicates, "susceptible of an almost unlimited variety."

Elements contributing to this variety are the three-dimensional character of the matrix, the changing nature of the sculpture's ambience, and the character of the photographer's intervention. Rather than being an impartial and objective impression of the subject, a photograph of a sculpture is a discrete image, one that is a visible record of dialogue between photographer and object, a dialogue that took place at a particular place and time. This dialogue may be affected significantly by the conditions under which the photographer is working and by the limitations of contemporary technology. In order to produce a satisfactory plate of Alessandro Vittoria's *St Jerome*, for instance, the Venetian photographer Carlo Naya left his camera standing in the Frari for several days.

That a photographer may take possession of a sculpture is illustrated by the famous series of photographs of Auguste Rodin's *Balzac* created by Edward Steichen in 1908. The ambivalent relationship between sculpture and photography was also recognised by Constantin Brancusi when he asked Man Ray to teach him how to make his own photographs. Underlying this request was Brancusi's experience of seeing a photograph of his work by Alfred Stieglitz. "It was a beautiful photograph, [Brancusi] said, but it did not represent his work. Only he himself would know how to photograph it." Even when the photographer is self-effacing, as the American art historian and photographer Clarence Kennedy intended to be, the image is inevitably a record of a dialogue between the photographer and the object.

PHOTOGRAVURE

An intaglio photomechanical printing process invented by Karl Klic (1841–1926) of Vienna in 1879. It was based on F.H. Talbot's photoglyphic engraving process of 1852. Intaglio refers to methods of printing in which the lines, dots, grain or other elements of the printing plate, are sunk in the plate so that the depressions are filled with ink for printing. Photogravure, aka. gravure, aquatint photogravure, dust grain photogravure or Talbot-Klic process, is the best known intaglio process. In capable hands, it can produce high quality images with a rich matt surface, on a wide variety of papers.

Common etchings, mezzotints and line engravings are also intaglio processes.

Photogravure is the ultimate facsimile process for the reproduction of etchings because the lines it reproduces are actually etched in the printing plate just like the original etching plate. Rembrandt's work has been the subject of more facsimile reproductions than any other artist's. Philip Gilbert Hamerton (1834–1894), in his book*, The Graphic Arts* (1882) provides an insight into the techniques used in France. On Goupil, "... [it] is a secret, and all I know about it is that the marvelously intelligent inventor discovered some means of making a photograph in which all the darks stood in proportionate relief, and from which a cast in electrotype could be taken which would afterwards serve as a plate to print from." On Dujardin "… he covers a plate made of a peculiar kind of bronze with a sensitive ground, and after photographing the subject on that simply etches it and has it retouched with the burin if required." And on Amand Durand, "He bites his plates like ordinary etchings; and when they are intended to represent etchings he rebites them in the usual way and works upon them with dry point, &c., just as an etcher does, but when they represent engravings he finishes them with the burin." He concludes, "The reader now perceives the essential difference between the Goupil process, in which there is no etching, and the processes employed by the héliograveurs, which are entirely founded upon etching."

Photogravure was popular with pictorial photographers at the end of the 19th century and in the early part of the 20th century. The most impressive use of this process was the production of Edward S. Curtis' 20 volume work, *The North American Indian*, each containing 75 hand-pulled photogravures and 300 pages of text, produced between 1907 and 1930. Alfred Stieglitz's Camera Work, which had 53 issues between 1903 and 1917, included 544 illustrations, 416 of which were photogravures. Alvin Langdon Coburn (1882–1966) produced the photogravure illustrations for his books —83 plates and over 40,000 prints.

Peter Henry Emerson (1856–1936) used platinum printing for his first book but learned photogravure, which he referred to as "photo-etching," a term a found more suitable to a medium of original expression rather than as a method of reproduction. His best known works include *The Compleat Angler, or the Contemplative Man's Recreation,* a two-volume work (1888, 54 photogravures) and *Wilde Life on a Tidal Water. The Adventure of a Houseboat and Her Crew* (1890, 30 photo-etchings).

Around the 1880s, Thomas Annan (1829–1887) entered into a partnership with Sir Joseph Wilson Swan and purchased the rights to use the photogravure process from the Imperial Printing Works in Vienna. His most impres-

sive work was published in photogravure by his second son, James Craig Annan (1864–1946), *Old Closes and Street—Glasgow, A Series of Photogravure, 1868–1899* (Glasgow, T&R Annan & Sons, 1900, 50 plates).

More recent efforts include portfolios of the photographs of Robert Mapplethorpe (1946–1989) and Eduard Steichen (1879–1973).

Aquatint photogravure is practiced today by a small group of artist photographers and printmakers. The early process did not meet the requirements of popular publications which required large print runs rapidly executed. The improvements have been too numerous to be discussed at length in the context of this article but we will mention the main inventions. It was the same Karl Klic mentioned above, who founded the Rembrandt Intaglio Printing Co., at Lancaster, England, in 1895, where the first rotary gravure (aka. rotogravure) process that made use of a doctor blade (to wipe the excess ink off the surface of the plate) and a cross-line screen was secretly exploited for many years. Printing from cylinders on paper fed from large spools reduced the cost of high-quality photogravures to a point where they began appearing in popular publication.

Although the square pattern of photogravure screens is normally associated with mass produced rotogravures, Austrian born Theodor Reich worked out a way to use a cross-line screen with a flat-plate gravure ca. 1897 and sold his invention to F. Bruckmann of Munich in 1903. The process was exploited under the name mezzo-tinto-gravure and was advertised in the Penrose Annual until at least 1927.

In 1904 the first rotogravure plant in America, the American Photogravure Co., started operation in Philadelphia. In 1910 the first example of the Rembrandt Intaglio color process appeared in a book, Colour Printing and Colour Printers, by R.M. Burch and C.W. Gamble. In the same year, Mertens introduced his Monochrome Intaglio Process, i.e., intaglio pictures combined with letterpress text. This method was popular until the 1950s. In 1913, Alfred Stieglitz' Camera Work published five duogravures in the April/July issue. These two- color gravures should not be confused with the duotone photoengravings advertised as "duogravures" which appeared in many books published by the Boston firm L.C. Page & Company during the years 1901 and 1925. In was not uncommon in those days for publishers to claim that the cheaper processes they used, including collotype, were photogravure.

Until fairly recently, the modern commercial process was called screen photogravure or rotogravure. In this process, the continuous tone positive and gravure screen were exposed in succession onto carbon tissue which was then mounted on the copper-plated gravure cylinder. A later form, where the plate is made flat and afterwards curved around a cylinder, was known as "plategravure" (ca. 1930s).

In an effort to remove one of the main difficulties of the original photogravure process, researchers have tried to replace the chemical etching step with other methods that involved "spark erosion" and laser engraving, the latter developed by Crosfield but abandoned in early 1990. The most popular method currently employed is based on the electromechanical engraving process invented by Hell in Germany in 1952. The Helioklischograph uses up to a dozen vibrating styli with diamond tips that peck out tiny pits in the copper surface.

PHOTOHISTORIANS

For several decades after the publication of the first photographic processes in 1839, and indeed for most of the nineteenth century, photography was primarily regarded as an invention. Its history, therefore, was predominantly written as the history of an invention, comparable as such to histories of the steam engine or the electric telegraph, and more often than not filled with the petty personal quarrels, as well as broad generalizations on the invention's utility, that attended such enterprises at the time. Accordingly, most of the first historians of photography were its scientific patrons, inventors, or early practitioners, and the histories they wrote were predominantly "technical," as they have often been called, or rather professional and promotional. After 1914, and more so after 1930, new brands of photohistorians emerged, some of them early collectors of photography's incunabula, but others from outside the ranks of the profession and even the realm of amateurs. Between 1930 and 1970 they gradually changed the perception of nineteenth-century photography, which came to be regarded more as a socio-cultural artefact, and also appreciated in artistic as well as financial terms. Starting in the 1960s and especially after 1970, the influence of art historians, museums, the art market, and art-historical models on photographic history became more marked, without extinguishing other approaches, especially those of collectors, by then more specialized, and cultural historians and critics, who challenged traditional art-historical assumptions while broadening even more the scope of photographic history.

The very first attempts at writing a history of photography were embedded in the very procedures of publication of the various processes that competed for recognition and influence, starting in 1839: thus François Arago's and, to a lesser extent, William H.F. Talbot's presentations to the French and British learned bodies contained some historical research on the origins of the invention. These accounts aimed, among other goals, at establishing the usefulness and even the cultural legitimacy of the invention. They were decidedly less technical than broadly scientific, and placed photography—envisioned as a discovery, even more than an invention—within a relatively long-term history of science. Thus Arago, while endorsing the claims of the French inventors Niépce and Daguerre, was the first to link their research to those of alchemists, as well as earlier (French) physicists, be it in order to better stress the magnitude of the inventors' achievement. Incidentally, it must be noted that Arago's choice to designate Daguerre and the daguerreotype—over Talbot, but also over Niepce—as the true beginners of photography caused, in France, a long string of priority claims and vindications (Isidore Niépce's in 1841, Victor Fouque's in 1867, Adolphe Mentienne's in 1891, etc.) that led to sometimes significant historical disclosures. In 1949, the publication by Russian historian Torinan Kravets of a large body of Niepce-Daguerre correspondence preserved (since 1840) in the Russian Academy of Sciences still echoed that ancient feud, which has, repeatedly since then and

even as recently as 2004, been rekindled by various publications of such documents.

More generally, the keen interest that scientists initially took in the invention and its scientific applications explains the leading role that chemists and physicists played among early photo-historians. Beyond Arago, who authored, in addition to his famous 1839 speech to the French Parliament, several memoirs on the subsequent development of photography, a number of the leading academic scientists of the time contributed historical remarks and some essays on photography, its origins, and its significance, especially for the theory of light. These include the Englishmen John F. W. Herschel, David Brewster, and, more specifically for photographic methodology, Robert Hunt (whose *Treatise on Photography* (1841) and *Researches on Light* (1844) are, arguably, the most significant early publications on the subject), the Frenchmen Joseph-Louis Gay-Lussac, Jean-Baptiste Biot, the Germans Johann Madler, Alexander von Humboldt (and, later, Hermann Vogel, perhaps the single most influential scientific writer on photography in the nineteenth century), and the American expert on photochemistry John W. Draper.

These early accounts, more scientific than technical, paved the way for at least two subsequent kinds of "scientific" histories of photography. One was embedded in the larger genre of popular science, represented by encyclopaedias, magazines such as *The Scientific American* (founded in 1845), and illustrated surveys of the "wonders of modern science" of the kind that the French polymath Louis Figuier became famous for; these perpetuated a number of legends about the beginnings of photography but maintained its link to popular and general culture. The other was the later, far more specialized, and ever-widening investigation of what would come to be known as the "prehistory" of photography, which would often be associated with more strictly technical, or methodological, surveys of its development. In the last years of the nineteenth century, this trend, which may perhaps more properly be called technical, was represented by the British expert John Werge (*The Evolution of Photography*, 1891) and, above all, by the Viennese chemist Josef-Maria Eder, arguably the first major historian of photographic and imaging technologies, with his monumental *Ausführliches Handbuch der Fotografie* in four volumes (1891–96), followed by his groundbreaking *Geschichte der Fotografie* (four editions were published between 1895 and 1932). In the twentieth century, this brand of technological history was primarily pursued by German-language historians, from Erich Stenger to Helmut Gernsheim, though it had echoes in France (with Georges Potonniée) or in the United States (with Edward Epstean, originally a photo-engraver, who was also Eder's English translator); but its influence can be felt, until the end of the twentieth century, over much photo-history.

Although practitioners or advanced amateurs often had a hand in this scientific-technical brand of photohistory, as shown by the examples of Vogel, Werge, or Eder, another, more specifically professional, brand of photohistorians emerged very early on with the appearance of the first specialized treatises, or handbooks. Daguerre himself had entitled his 1839 manual *Historique et description des procédés du daguerréotype et du Diorama.* While most of the handbooks published in the 1840s contained few historical remarks, the formation after 1850 of more self-conscious professional organizations and the appearance of the first specialized magazines (in France, the U.K., and the U.S.) was accompanied by the publication of more ambitious treatises that more and more often included several historical chapters. One of the very first such compendia was the American Henry Hunt Snelling's *The History and Practice of the Art of Photography*, published in 1849, but it was soon followed by a host of competitors (such as, in the U.S., John F. Towler's *The Silver Sunbeam* and Marcus A. Root's *The Camera and the Pencil*, both published in 1864). The Société héliographique (founded in 1851, replaced in 1854 by the Société française de photographie), the Royal Photographic Society, formed in 1853, or the American "daguerrean" associations, each of which started publishing a magazine between 1850 and 1855, all busied themselves, and increasingly with time, with historical investigations. Writers such as Ernest Lacan in France or H.H. Snelling in the United States came to be regarded as authorities on the subject by their peers. Indeed, this burgeoning historical, technical and critical curiosity cannot be separated from the campaigns waged by leading professionals (and some devoted amateurs) to establish their art, or their commerce, on a firmer cultural basis—in short, to legitimize photography, and to rally, towards this goal, the support of unified and coherent professional constituencies. Lacan, Snelling, and their likes were neither great scientists nor careful historians; their writings were eclectic, often second-hand, sometimes full of errors; they were prone to nationalist claims and parochial arguments on the universal usefulness of their activity; but in the second half of the nineteenth century, they probably best embodied the emerging self-consciousness of a "photographic field" that sought both recognition by the academies and a certain measure of autonomy and self-reliance. Moreover, this trend is important in that it set a model for later campaigns for the recognition and institutionalization of photography, photographic art, or photographic education, which, as in the example of Alfred Stieglitz's Photo-secession, most often included a strong interest in the history of photography and an equally strong doctrine about how it should be written. Even the typical eclecticism of much

20th-century writing on photo-history may, arguably, be ascribed to this professional model.

To complete this survey of nineteenth -century photo-historians, it must be noted that aside from the scientific and professional writers, there were a few attempts —though not many— at more cultural, or philosophical, interpretations of the invention of photography. Some important accounts of photography's beginnings were thus penned by a few artists and art critics —such as the Frenchman Francis Wey—, or essayists and writers such as the Frenchman Charles Baudelaire, the Englishwoman Elizabeth Eastlake, or the American Oliver Wendell Holmes. It is surprising to see how much these early, often bold, commentators foreshadowed the later, more celebrated theses of twentieth-century critics such as Walter Benjamin or Roland Barthes. Until the end of the century, however, photo-history, like photography itself, remained very much the province of aficionados and professionals, while the general public had to be content with brief overviews placing it among the wonders of the century.

Though this entry cannot concern itself with the many succeeding generations of photo-historians after 1900, some remarks are in order as to how these later writers participated in the changing perceptions of nineteenth-century photography. To be sure, the major shift was from the perception of photography as invention to its recognition as art, and that paradigm change was deeply influenced by the crusades of virtually every avant-garde from Modernism to Conceptual art, as well as the strategies of influential collectors and then museums. Photo historians participated, often actively, in this shift, a major example being Beaumont Newhall, art historian turned curator of photography at New York's Museum of Modern Art (MOMA) and then the single most influential photo-historian of the twentieth century, who increasingly regarded the history of nineteenth-century photography as a history of pictorial expression, rather than one of technology. At the end of the twentieth century, the training of art historians routinely encompassed photography, and especially its "primitives," by now firmly established on the art market and in the artistic canon; ever-more expansive exhibitions and monographs were devoted, largely by historians with a training in art history, to a growing number of early masters. But this inclusion of photo-history into art history, the subject of much passionate debate after 1980, must not be overestimated, and neither should the work of twentieth -century photo-historians be reduced to it. At least three other separate trends must be noted here. First, many collectors of early photographs were also experts on "photographica" (materials, objects, practices, etc.), and, from Gabriel Cromer to Helmut and Alison Gernsheim, Floyd and Marion Rinhart, or Michel Auer, they have not only kept alive an interest in the history of photographic technology but expanded it in many ways. Second, it must be stressed that, exactly at the same time as Modernist-inspired exhibitions of the photographic art pioneered its recognition in the 1930s, in Germany, France, and the United States, other perspectives on the early history of photography emerged, in the very same countries, from the inspiration of folklore studies, social history, and sociology. Examples include, in the United States, Robert Taft's *Photography and the American Scene* (1938), but, more decisively, the important German works of Helmut Bossert and Heinrich Guttman, Heinrich Schwarz, Siegried Kracauer, and even Gisèle Freund, all of which left their imprint on the shorter and better-known essays by Walter Benjamin. This sociological trend, which, among other things, paid close attention to the reception, spread, and social uses of photography in the nineteenth century, has arguably exerted, if indirectly, just as strong an influence as the art-historical model did on later more cultural histories of photography, of the kind exemplified, in the 1980s and 1990s, by Naomi Rosenblum and especially Michel Frizot. Lastly, one cannot but observe, since 1990, that photography and photo-history have been increasingly understood as the matrix of a broader cultural history of images or visual culture, and that their appeal largely outreaches the realm of any specialized branch of cultural history.

PHOTOLITHOGRAPHY

Photolithography is a photomechanical printing process that combines lithography with photography. Throughout its history, photolithography has included a variety of forms and printed image effects. Today, it is used in the printing of everything from magazines to soup can labels.

Lithography Lithography was invented in 1798 by a German author, Aloys Senefelder, who was looking for a practical way to publish his plays. Lithography is based on the principle that water and grease do not mix. The traditional lithographic process is as follows: On a flat printing surface marks are made in a greasy medium. The surface is dampened with water, which settles only on the unmarked areas, as it is repelled by the greasy drawing medium. Next, a roller covered with greasy printing ink is rolled over the surface. The ink adheres only to the drawn marks, the water repelling it from the rest of the surface. Finally, the ink is transferred to a sheet of paper by running the paper and the printing surface together through a special press.

From the beginning artists were intrigued with lithography, as they could draw and paint directly onto the printing plate. Many famous artists, including Pablo Picasso, Marc Chagall and Andy Warhol, have used this process. In the early 19th century lithography was usually monotone and not favored for commercial purposes. Stones were used as the printing surface, which was a cumbersome and expensive method. By the 1850s stones were replaced with metal plates— first zinc, then copper in the 1890s. After the American Civil War mass production of lithographs was possible. However, it wasn't until after the 1876 Centennial Exhibition in Philadelphia, where it received great exposure, that lithography flourished.

The first photolithographs As early as the 1850s, attempts were made to create lithographic printing surfaces by means of photography. While the ultimate goal was to create photographically realistic images, the first photolithographs could only create lines. These prints are often called *line photolithographs*. In this process, a document, such as a pen and ink sketch or hand written document, was photographed. The negative that was produced was used to expose a photographically sensitive sheet. The lines of the image would harden and the image was transferred to the printing stone or metal plate for printing. Transferring the image this way from a paper sheet, as opposed to drawing the image directly onto printing stone or plate, is called *transfer lithography*. From the 1860s, line photolithography was used to reproduce engravings, maps, architectural drawings and similar documents. In many early examples, it is difficult to near impossible to determine if such a lithograph was a photolithograph or a manual (by hand) lithograph.

While line photolithography was useful, there was strong desire to add tone and similar detail to the print. The earliest commercially viable technique that could create tone was the *ink-photo*, developed by a London firm, Sprague and Co., in the early 1880s. This was a transfer lithograph using the reticulation of gelatin to break up the photographic image into dots and squiggles. Once the image was photographically transferred on the gelatin surface, it was transferred to the printing stone or zinc plate and printed. This process is closely related to the collotype. The ink-photo was easier and cheaper to mass produce than the collotype, but the image was inferior. "Inc-Photo" and the company name is often printed is often printed on these prints. The ink-photo processes was used to illustrated many books.

Halftone photolithography With the introduction of the half-tone process, commercial printers could first make photolithographic prints with near photographic detail. Halftone is a photomechanical process that is applied to numerous printing processes, including relief (the common method of printing for 19th century publications), intaglio and lithography. It is often referred to as the *screen process* or *dot process*. With the use of special screens or glass with cross-hatched lines that break up the image, the halftone process translates the tones and detail of a photographic image into a printed pattern of tiny dots. Under magnification these dots are obvious, but from normal view they meld into what appears to be photographic tone. Typically, in the darker areas of the print, the dots are larger and closer together. In the lighter areas, the dots will be smaller and further apart. Examination of the photographically realistic image in a modern newspaper or magazine will reveal the halftone dots.

The halftone process was quickly applied to commercial relief printing, with half-tone prints commonly

appearing in newspaper and similar publications in the 1880s–1890s. The practical commercial application of halftone to photolithography was not so swift. Today, halftone photolithography is a dominant form of commercial printing.

PHOTOMECHANICAL: MINOR PROCESSES

The nineteenth century produced a great many photomechanical inventions that never became very successful. There were many reasons for this. The processes had to be practicable and they had to offer advantages over competing technologies, such as speed of operation and reduced cost. New processes could takes years of development at great expense and working conditions did not allow any significant control on important variables such as air temperature, humidity and levels of sunlight. The period literature is filled with comments to the effect that certain processes that made use of gelatin coatings "worked better on the Continent than in England," on account of the dryer weather. Technical manuals often described changes in chemical formulas based on the season, e.g., "during the winter months, a five percent solution of bichromate is recommended while two percent will suffice in the summer months."

There were also human factors such as a tendency for employees to resist changes that would have threatened their job security.

Etched Daguerreotype

Within weeks of Daguerre's announcement (1839) experimenters were trying to convert the daguerreotype image into a printing plate suitable for intaglio printing. The daguerreotype picture is produced by the deposit of mercurial vapor which combines with the silver and the polished surface of the silver surface itself. As the electro-chemical relations of these two metals are dissimilar, it was thought that the daguerreotype plate could be etched by the agency of the voltaic battery. Dr. Berres of Vienna, Fizeau in France, and Grove in England, succeeded either by direct chemical action, or by electro-chemical processes in engraving these plates, and in many examples the details were preserved "in a very charming manner." Claudet was very successful in engraving the daguerreotype picture by a modification of the process by Fizeau. The latter gilded the daguerreotype image, and then etched the parts not covered by the gold, which acted as a resist. The difficulty of biting the daguerreotype plate image to a sufficient depth to obtain the requisite ink-holding grain soon led to abandonment of the method.

Nevertheless, a number of publications were produced by this form of *etched daguerreotype.* The first one was by Joseph Berres of Vienna, *Phototyp nach der Erfindung des Prof. Berres in Wien,* (Vienna, 1840), illustrated with 5 plates from daguerreotypes, etched with nitric acid. Also of note are the *Excursions Daguerriennes, représentant les vues et les monuments anciens et modernes les plus remarquables du Globe,* (Paris, 1840–1843) in which three of the 111 plates were printed directly from daguerreotype plates by the Fizeau process.

Dallastype

This was a process for making relief blocks for typographic printing. It was probably the most successful invention of Duncan Campbell Dallas, who made half-tone blocks, and used a ruled screen instead of, or sometimes in combination with, his dallastint reticulated grain. The blocks were made of type metal, evidently cast in plaster molds taken from the gelatin relief. Dallas presented an example of his work to the *Photographic News* in 1864, calling it "dallastype." Dallas, however, appears to have changed the names of his processes as time went on.

Dallas advertised dallastype, dallastint and chromodallastint in W.T. Wilkinson's *Photoengraving* (ca. 1888–1890), but the only one that seems to have been used in books to any extent was dallastype. Some of the illustrations in Robert *Dickson's Introduction of Printing into Scotland,* 1885, were dallastypes. They were also used in Dickson & Edmond's *Annals of Scottish Printing,* published by Macmillan & Bowes in 1890. Pulls from some of the blocks in the latter book were given to William Blades by Dallas and are now in a scrapbook in St. Bride's printing library, London.

Expresstypie

A process for making grained half-tone blocks, invented by Cronenberg, ca. 1895. It used a grained screen, placed in contact with a gelatin dry plate, to make a grained negative. This was printed onto zinc or copper in the usual way. The grain had a reticulated character resembling that of collotype.

Goupil Gravure

Invented by Rousselon in France (ca. 1874) who de-

scribed his process as follow: "The value of our process of photogravure consists in the possibility of obtaining, by means of light, an etched copper-plate exactly like the ordinary copper-plate, and giving all the gradations of tone and half-tone, as drawn by nature in the ordinary photograph. Our process is founded on the discovery of a chemical substance which crystallizes under the influence of light, the crystals becoming larger the longer they are exposed to it. After exposure it only remains to make a deposit of copper, by means of the electric battery, on the crystalline surface, and thus a plate is obtained yielding proofs in which every detail and gradation of tone is faithfully reproduced."

Walter B. Woodbury, the inventor of the woodburytype, asserted that the Goupil process was based on a suggestion made by him to Goupil around 1870. According to Donald Cameron Swan, the process was based on his father's (Swan's) photo-mezzotint process.

Goupil and its successor, Boussod, Valadon, & Cie, used the process extensively for art reproduction, less frequently for printing original photographs. The overall excellence of a Goupil gravure –the density of black, the separation of tones, and the clear, crisp quality of the image– was not surpassed until the introduction of the Rembrandt photogravure process in 1894. Goupil gravures appeared in Seeley and Co.'s monthly art periodical *The Portfolio*.

Luxotype

A half-tone process patented in 1883 by Brown, Barnes and Bell, a Liverpool firm of photographers. A photographic print was pressed against a metal plate engraved with a stipple in relief, and thus became embossed with a stipple. It was then strongly lighted from one side so that the stipple could be photographed, and a negative suitable for making a half-tone block was thus obtained. A modification of the process was to rub a pigment into the depressed parts of the embossed surface of the print, so that it could be copied by direct lighting. Specimens can be seen in *Photographic News,* vol. 27, 1883.

Photoxylography

Name given to early photoengraving processes (from the early1850s on) that used the production of a photographic image on boxwood blocks as a guide for the engraver's knife, instead of using an image drawn by hand on the wood block. According to Stannard (*Art Exemplar,* 1859) the number of the *Microscopic Journal* for June, 1853, was the first and a thoroughly successful operation on an extended scale of this beautiful invention. Photoxylography was used by the *Illustrated London News* from 29 Dec. 1860. Pannemaker and his students are mentioned as the best practitioners of this art.

These techniques, in capable hands, gave beautiful results, but were inferior to true continuous-tone processes like collotype and aquatint photogravure, and the introduction of the half-tone process of the early 1880s made their practice largely obsolete.

Photozincography

A photolithographic process worked out by Col. Sir Henry James at the Ordnance Survey Office in Southampton, England, and at first, starting in 1859, simply a method of preparing a photo-lithographic transfer and applying it to a zinc plate, afterwards printed from. Direct prints from negatives were then made on the zinc plates. Photozincography may refer to a line or half-tone process.

Sir H. James read a paper to the British Association "On photozincography," in Sept. 1861. His first successful photozincograph was a reproduction of an etching, in 1859. A facsimile of the *Domesday* book, or ancient record of the Survey of English lands, ordered in 1086 by William the Conqueror, followed later in 1859.

PHOTOMICROGRAPHY

Photomicrography is a hybrid innovation that grew out of the convergence of the novel nineteenth-century technologies of photography and microscopy. Although Victorians occasionally used the terms photomicrography and microphotography interchangeably, the photographic process was different for each. Microphotography involved taking a photograph of a large object (a portrait, page of text, or anything easily observed with the unaided eye) and reducing it to microscopic dimensions for viewing with the aid of a microscope. Photomicrography used the microscope to photograph a magnified image of microscopic-sized specimens (e.g., algae and other minute organisms, insects or their parts, animal and plant tissues); from these photographs enlarged prints and magic lantern slides could be prepared for both the advancement of knowledge and entertainment. Owing to its usefulness as a scientific laboratory tool, photomicrography endured through the Victorian era and after.

In England in 1802, Thomas Wedgwood and Humphry Davy first captured images of objects using a microscope with sunlight as the light source and pieces of white leather sensitized with silver nitrate. By the mid- to late-1830s, William Henry Fox Talbot had experimented with photomicrography using his "photogenic drawing" salt print process (Talobotypes/calotypes) producing images depicting the microscopic structure of plant sections; other English workers also used this technique, but Talbot's process did not adequately convey the fine detail of the original microscopic image. This technique did permit relatively easy duplication of images, however. Also in England around 1840, London surgeon and microscopist Jabez Hogg produced photomicrographs of biological specimens as did Manchester optician and inventor John B. Dancer, although the latter is better known for his microphotographs of famous people and scenes.

Continental Europeans were more prominent in the pursuit of photomicrography as a laboratory tool than their English contemporaries owing to their adoption of the daguerreotype. In 1840, the Viennese physical scientist Andreas Ritter von Ettingshausen produced wonderfully sharp daguerreotype images of microscopic cross-sections of botanical specimens, as did his contemporary the Viennese anatomist Josef Berres.

The Paris physician Alfred Donné and colleague, Léon Foucault, produced in 1844–45 the first biomedical textbooks to be illustrated with engravings made from his daguerreotype photomicrographs (*Cours de Microscopie Complémentaire des études Médicale, Anatomie Microscopique et Physiologie des fluids de l'économie* and *Atlas du cours de microscopie exécuté d'après nature au microscope daguerreotype avec M. Léon Foucault).* Included were images of salamander blood, pollen grains, and starch granules.

Daguerreotypes had the advantage of showing fine detail, unlike calotypes, but they were not readily reproducible in large numbers. The development of the wet collodion process overcame this obstacle, for it allowed prints of photomicrographic subjects to be produced in quantity permitting mass distribution in scientific publications, such as the pioneering illustrations contained in the English *Quarterly Journal of Microscopical Science* during the early 1850s. The dry-plate, or gelatino-bromide process, formulated by Dr. Robert L. Maddox, one of the Victorian era's great English photomicrographers, did much to popularize photomicrography and to make it more convenient. Other scientists advanced photomicrography through their publications and research. Most notable among them were Joseph von Gerlach of Erlangen, who wrote a treatise on *Photography as an Aid to Microscopic Research* (Leipzig, 1863), and Berlin bacteriologist and physician, Robert Koch. In 1877, Koch took the first photographs of bacteria; four years later, at the International Medical Congress in London, he displayed a series of photomicrographs of bacterial cells and tissue sections that aided in the dissemination of his sophisticated ideas on the germ theory of disease and helped silence skeptical colleagues. At the close of the century, almost all that was known about medical photography and photomicrography in Europe was contained in Albert Londe's *La photographie médicale. Application aux sciences médicales et physiologiques* (1893).

In America proponents of scientific photomicrography were supported not by universities or research institutes, as their counterparts in Europe, but by museums, which were then the intellectual equivalent. The Smithsonian Institution in Washington, D.C., published Dr. John Dean's research concerning the gray substance of the medulla oblongata and trapezium; this 1864 work was illustrated with photomicrographs of neuroanatomical sections. The recognized doyen of American biomedical photomicrography, however, was Dr. Joseph J. Woodward of the Army Medical Museum (AMM) also in Washington. Woodward, a Philadelphia-trained physician who became a military surgeon at the beginning of the Civil War, assumed museum duties under the auspices of the Office of the Surgeon General in 1862 and remained in the museum for the next 20 years. The AMM would develop a reputation for its extensive use of medical photography along with applied art techniques to create permanent visual records of soldiers' injuries, ailments, and pathological specimens. Military personnel prepared microscopic slides and undertook all photographic work within the museum. He and the AMM fast became recognized internationally as the center for photomicrography in America at this time. These medical photomicrographs were in demand and exchanged for images produced by other photomicrographers such as Maddox in England and Gerlach in Germany.

Woodward's pursuit of photomicrography was grounded in two intellectual traditions. One was the published work of Donné, Hogg, Dean, and other European and American photomicrographic pioneers. The other arose from his unwavering commitment to the usefulness of the microscope as an aid to understanding the causes of disease. Woodward's knowledge and position aided the efforts of two assistant army surgeons, William Thomson and William Norris, who, using the wet collodion process, first took photomicrographs of pathological preparations in spring 1864. The specimens were prepared by Woodward and photographed through a Zentmayer microscope (the official U.S. Army instrument stipulated by Woodward). During the next two decades, Woodward himself produced thousands of photomicrographs depicting a dazzling array of pathological conditions and other biological specimens.

For Woodward, photomicrography was first and foremost a scientific tool. Although like many amateur microscopists and photographers he did capture in his photomicrographs the beauty of diatoms (phytoplankton that exhibited many beautiful shapes, appearances and arrangements) better than any one else, this aim did not fully interest him. Rather, he used these microscopic creatures as test subjects to determine the resolving power of his lenses; owing to his skills both as a microscopist and photographer, he was able to work at the absolute technical limits of the best equipment available. Woodward's Toner Lecture series presented in 1873 at the Smithsonian Institution is also exemplary of his scientific approach. Concerned by the structure of cancerous tumors and how adjacent tissue was affected, Woodward prepared a series of 70 lantern slides from the museum's collection of photomicrographs for his lectures. Not only did he wish to educate his medical audience through these novel visual media, but he also desired to show how his illustrations corresponded with the latest scientific findings of European histologists. In so doing, Woodward ably demonstrated how photomicrography was becoming a necessity in the laboratory setting.

Woodward's legacy to scientific photomicrography went beyond his own contributions, for the AMM spawned successors through the nineteenth century and beyond: Dr. George M. Sternberg used this technique in bacteriological studies of the blood of yellow fever sufferers in Cuba; army surgeon William M. Gray, museum microscopist and photographer, became known for his series of histological photomicrographs. By the close of the nineteenth century, photomicrography had advanced enough to record such intricate processes as the reproduction of cells and their nuclei by division (mitosis and meiosis), with chromosomes clearly visible.

Overlapping the activities of laboratory-based investigative scientists who used the microscope-camera combination as a powerful scientific tool were the activities of other Victorians who pursued photomicrography as an uplifting recreation or who, as avocational scientists, studied natural history (i.e., descriptive and inventory-based science). Microscopy, then, like photography, became a feature of polite Victorian culture, especially in England. The study of the microscopic world became genteel recreation for both men and women, as they peered at the teeming life in samples of pond water or at the beauty of a butterfly's scales. The natural revelations of the microscope bolstered religious viewpoints of God's infinite creativity and wisdom. Photomicrography fit nicely with this worldview as it could make tangible to many what only amateur microscopists previously could see. Numerous books existed which included plates of photomicrographs of minutely detailed examples of the plant and animal kingdoms, while extolling the virtues of photomicrography. In *Nature through Microscope & Camera,* for example, published by the Religious Tract Society of London, Richard Kerr bemoaned the fact that amusement had become the order of the day in later Victorian England at the expense of education. However, the evils of trashy novels, bridge parties, and football and cricket talk could be counteracted somewhat, he maintained, through the entertaining and civilizing power of the microscope, especially when it was equipped with a camera. Photomicrography was instructive, useful and an intellectual pastime that would be good for the nation. Commercial vendors also sold slide sets of preserved biological specimens for "amateurs" to photograph through their microscopes. Especially enchanting for photographers were diatoms owing to the distinct markings of these microorganisms, consisting of striations and concentric rings of dots. Equally intriguing was photographing snowflakes. In 1885, the American amateur photomicrographer, Wilson A. "Snowflake" Bentley, first photographed an ice crystal through a microscope; he would continue this work in sub- freezing weather for the next 40 years, producing about 4,500 photomicrographs, and helping to prove that no two snowflakes were the same.

The apparatus available for photomicrography ranged from the relatively simple and cheap to the most complex and expensive. Regardless of sophistication or cost, the hobbyist, serious amateur, and scientist alike used a similar combination of equipment for photographing through the microscope. Critical was the light source, which had to be intense and constant to compensate for the lack of sensitivity of photographic plates. Bright sunlight was effective. At the AMM Woodward was able to take full advantage of natural daylight because of Washington, D.C.'s, southern latitude and his use of a heliostat, which constantly tracked the sun. But those

who worked at night, or who did not live in sunny climes, could not avail themselves of this form of light. In such circumstances, electric light, kerosene and oil lamps, or the combustion of magnesium ribbon were used. The preferred artificial illumination was a combination of oxygen and coal gas or hydrogen ignited under pressure to heat a block of lime white-hot to produce limelight. Of course, a major disadvantage of this method was the likelihood of setting wooden photographic equipment and furnishings on fire.

As important was the work area, which would probably incorporate a darkroom, where photomicrography was undertaken. The location had to be free from vibration to avoid obtaining blurred images (exposures could take upwards of several minutes); precautions were observed such as suspending equipment from beams, or equipping table legs with rubber shock absorbers. Similarly, it was recommended not to undertake photomicrography at times of the day when heavy traffic was moving in nearby streets. Initially, the choice of compound microscope was not itself crucial, although later in the century the better the fine focusing mechanism and lenses on the instrument, the sharper the image to be photographed. Instruments manufactured in England were often bulky, with body tubes up to nine inches long, compared with more compact continental European microscopes that typically had shorter body tubes of approximately six inches. Perhaps because of this difference in construction, English photomicrographers usually aligned the microscope, bellows, and camera/plate assembly horizontally; the convention of most Europeans was to align their equipment vertically. The later Victorian period saw the adoption of European techniques owing to the domination of German laboratory science and the attendant rise of optical manufacturing companies such as Carl Zeiss and E. Leitz, which produced superior quality, standardized photomicrographic apparatus.

Following the Victorian era, improved optics for both cameras and microscopes, newer photographic techniques and equipment such as faster speed black and white roll film, 35 mm color slide processes, motion picture and digital technologies, led to higher quality, more detailed and more revealing photomicrographs. Yet these later improvements should not overshadow the revelations and achievements of this original nineteenth-century convergent technology. Just as important was the lasting philosophical impact that photomicrography had on the scientific mind. While art (sketching and painting) as applied to medicine and science would endure, laboratory scientists believed that photography through the microscope was more accurate than artistic drawings of specimens done laboriously by hand and from memory. In brief, photomicrography (and biomedical photography in general), like science itself, was perceived to be objective, free of human bias, and more truthful; such rhetoric did much to propel all three pursuits during the nineteenth century and later.

PHOTOMONTAGE AND COLLAGE

Photomontage is created when an original composite image is photographed to produce a seamless unified effect in order to turn out duplicate photographic copies. Montage is from the French "monter," meaning to mount. It is a hand process used to alter camera-derived images and introduce subjectiveness into a photograph. Generally, existing photographs are cut apart and selected portions are glued onto a flat surface and rephotographed. The widespread use of photocollage had its start in early photo albums before the days of mass production. In these personal albums, photographs and flowers were pasted onto pages and later hand painted or sketched on by the album's creator. Photomontage on the other hand, was a thing people in mourning created to ease their grieving. The photomontages usually consisted of cartes-de-visite and montaged portraits on to elaborate photographic backgrounds and typically included a photograph of a picture frame on cabinet. From these creations came the development of montaged multi-view panels which were then re-photographed and sold as cartes-de-visite, thus creating the market.

In 1863 André Disdéri applied for a French patent for his "carte mosaïque" (mosaic carte). The precedent was the composite images of celebrities and eminent personalities that were commonly circulated by means of the printing press. Disdéri's mosaic cartes, featuring thematic portrait composites of actors, dancers, generals, the French royal family, and social groups received enthusiastic public support. Each mosaic carte could be comprised of twenty to one thousand faces. They served as advertising (studio address appearing on either the front or back of the carte) and people could come to his "Palace of Photography" and also buy a carte of their favorite personality or have one of their own made by the man who photographed everyone from Napoleon III to the Pope. The introduction of the cabinet style photograph starting in the 1860s offered the mass-market a larger image area that the carte-de-visite and encouraged more photographers to experiment with combining images.

As in combination printing, montage was devised to overcome aesthetic and technical limitations. The concept of removing a photograph from its original context and placing it into a new one has had profound effects on the viewer's willingness to accept as "real" visual information supplied by the photograph. The mosaic broke the rules about representing perspective, point of view, space, and time, and yet the public willingly accepted these radical changes as long as they remained photographically anchored. The term, photomontage, was not introduced until after World War I by the German Dadaists.

Collage (from the French *coller*, to glue or paste) is the practice of cutting and pasting together of two- and/or three-dimensional materials, including lace and dried flowers and plants, to form a new visual composition. In creating a collage no effort is made to conceal that the result has been assembled and is not a seamless image. Collage can be seem in Victorian family albums that incorporated the hobbies of appliqué print and watercolor that allowed people, almost exclusively women, to privately alter and interpret photographic images.

Another form of collage involves bringing together disparate images to form a new meaning. During the American Civil War, the United States Post Office Dead Letter Office assembled groups of photographs in a grid fashion and displayed them in hopes that someone would recognize a face and claim the photograph. This practical strategy of disseminating would eventually be adopted into artistic and scientific photographic practice.

Lady Filmer (1840–1903) was an aristocratic amateur who made early collages that combined carte-de-visite portraits with watercolor designs of butterflies and floral arrangements. These pieces, with their occasional sexual allusions, disclose a pre-Freudian spirit of unconscious association, a component of mental life not subject to recall at will, which required a new form of expression because the language for such a discussion had yet to be invented. Since such work was done for personal reasons and was not publicly exhibited or written about, it appears that there was no nomenclature to discuss what was being done. This sort of individual interaction with photographs did allow people with some artistic skill to reorient images in time, space, and meaning. Collage positioned photography to investigate free association, to use cut and paste methods to examine dreams and enable the unconscious, repressed residue of socially unacceptable desires and experiences to be consciously presented. The technique is the forerunner of surrealistic practices and images developed in the twentieth century.

Hand-coloring was widely practiced from photography's earliest days of to overcome its initial inability to record color. For an extra fee, the operator made notes about the color of the sitter's clothes, eyes, and hair. Color was hand-applied, based on these notations, directly on the finished image, which covered every process including daguerreotypes, paper prints, and tintypes. By 1843 John Plumb, Jr. was offering "color" portraits in his chain of studios by electroplating portions of the finished daguerreotype.

Alfred H. Wall promoted the practice in his *Manual of Artistic Colouring as Applied to Photographs* (1861). Wall, a former miniature and portrait painter, said that painting over a photograph was no more unacceptable than painters such as Leonardo and Titian painting over the *abbozzo*. Wall complained that artists repudiated hand-colored photographs because they were not paintings and that photographers rejected them because

they altered the camera's image. Wall saw no reason for censuring work that combined "the truth of the one with the loveliness of the other."

Composite and hand-colored images required time and deft handwork. This addition of time was seen as a way to make photography less mechanical and more artistic. This in turn increased a photograph's value and encouraged photographers to portray subjects previously reserved for painters. As photographs were not precious objects, some people took the liberty to interact with this supposedly fixed form of representation and interjected their own personal feeling about the subject. This began an ongoing exploration of fabricating illusion that expanded the photographic syntax to include subjective reality and how the tension between the two could produce new meaning. Hand-coloring and mixed media methods began to extend and transform the photograph into areas that conventional photography could not go. Conceptually, it acknowledges a photograph is not a fixed entity, but one that is open to continuos process that can accommodate change, expansion, and innovation.

PIAZZI SMYTH, CHARLES (1819–1900)

British astronomer

Piazzi Smyth (who used his middle name together with his surname) was born in 1819 in Naples, Italy. He seemed destined for fame in the field of astronomy. Named after the Italian theologian and astronomer Giuseppe Piazzi (1746–1826), he was the second son of Rear-Admiral William Henry Smyth, F.R.S., who had once been president of the Royal Astronomical Society, and Annarella Warington. Piazzi Smyth received his scientific education early, first in his father's observatory at Bedford and then at the Royal Observatory at the Cape of Good Hope, South Africa, where he assisted Sir Thomas Maclear from 1835 to 1845. His first calotypes date from around 1843; it is likely that he learned the technique from Sir John Herschel, a close family friend who was also in Cape Town at this time. His interest in photography would also have been nurtured in the circle around his father's close friend Dr. John Lee, which included William Henry Fox Talbot, James Glaisher, and Sir David Brewster; and at the salons of astronomer and amateur photographer Lord Rosse.

In 1845 Piazzi Smyth was named Astronomer Royal for Scotland, and the following year became Regius Professor of Practical Astronomy at the University of Edinburgh. Though hampered throughout much of his career by the chronic underfunding of the Calton Hill Observatory (recently placed under treasury control), Piazzi Smyth devised brilliant projects relating to the observation, measurement, and documentation of astronomical phenomena. One of the earliest of these initiatives was an expedition to Tenerife, the largest of the Canary Islands. In June 1856—accompanied by his new bride, Jessica Duncan—Piazzi Smyth went to the volcanic island to test his theory that the stars would be better observed from high points above ground-level pollution, to observe the solar spectrum, and to measure the thermal radiation of the moon, thus establishing the modern practice of high-altitude observation and pioneering spectroscopy and infrared astronomy. He also undertook a significant photographic documentation project, resulting in the first stereoscopically illustrated book: *Teneriffe, an Astronomer's Experiment; or, Specialities of a Residence above the Clouds* (1858), which contains 20 plates (from wet-collodion negatives on albumen paper) and sold for 21 shillings. Piazzi Smyth chose the stereoscopic format because the equipment was comparatively portable and because he felt it provided maximum accuracy and objectivity while minimizing the risk of accidental flaws and tampering. Far more effectively than the drawings and paintings he also executed on site, Piazzi Smyth's photographs demonstrated the clarity of the atmosphere at high altitude. Upon his return from Tenerife, he turned over the printing to Glaisher, a fellow astronomer and accomplished photographer, and A. J. Melhuish, photographer and optician. Publisher Lovell Augustus Reeve then supervised the production of an edition of 2,000, which entailed the mounting of 40,000 stereo pairs onto pre-printed pages. Jessica Piazzi Smyth printed additional photographs for subsequent official reports of the expedition (1859), and Piazzi Smyth employed another method of photographic reproduction—a photoglyphic engraving etched by Talbot—in an account published the *Edinburgh Astronomical Observations* (1863).

Piazzi Smyth's work in Tenerife earned him a Fellowship in the Royal Society, but his next major project—an excursion to Egypt to measure the Great Pyramid of Gizeh—was not as well received, largely owing to his expressed intent to prove the divine basis of the pyramids' construction. Piazzi Smyth had first encountered this theory in the writings of one of its most vocal proponents, John Taylor, whom he met through either Herschel or Lee. Piazzi Smyth was intrigued, and eventually obsessed, with the idea that the seeming coincidence of its measurements (the "sacred cubit") with the earth's polar axis reflected God's intervention—and that he could demonstrate this with modern instruments of quantification.

Photography was one of these tools, and despite severe financial limitations Piazzi Smyth made several extremely important advances in Egypt, where he applied new techniques that had not yet been tested in the field. The gear that he and his wife packed for their journey in November 1864 included a dry-plate apparatus, a pair of small-format cameras wet plates, magnesium wire, chemicals, a dark tent, a microscope, and various measuring implements. Piazzi Smyth specially designed the small cameras to produce miniature (1 inch square) negatives on 1 x 3-inch glass microscope slides, and to keep out the dust that caused problems for wet collodion. (He had experimented with the miniature format in Russia in 1859, achieving instantaneous effects in urban scenes and englarging them later.) To document his measurements of the pyramid's exterior, he took photographs that include rods and figures for scale. But to photograph the dark interior chambers, he generated bright light by employing magnesium wire, which had been discussed in the photographic journals and presented by Brewster at the March 1864 meeting of the Photographic Society of Scotland in Edinburgh.

Returning to the U.K. with 166 images (about half on dry plates and half on miniature wet collodion plates), he set about making enlargements, breaking with current precedent by cropping selectively. Prints were exhibited at the September 1865 meeting of the British Association for the Advancement of Science, held in Birmingham, and the images reached a much wider audience through lantern-slide lectures. Piazzi Smyth's ideas about the pyramids attracted a following of religious fanatics but were viewed with suspicion in scientific circles. The Royal Society's dismissive attitude prompted Piazzi Smyth to resign his fellowship in 1874, but he continued to make valuable contributions in various fields, spectroscopy in particular. In 1876 he designed another special small-plate camera, this time to produce systematic photographs of cloud formations—the first application of photography as a serious tool for meteorological research. Piazzi Smyth retired from his professorship and his post of Royal Astronomer on 18 August 1888, and he and his wife settled near Ripon, in Yorkshire. There Piazzi Smyth adapted his solar spectrograph for photographic work and recorded the entire range of the solar spectrum. He also resumed cloud photography, making 500 photographs in three years and presenting examples to the Royal Society and to the Royal Society of Edinburgh. He died on 21 February 1900.

BRITT SALVESEN

Biography

Charles Piazzi Smyth was born in 1819 in Naples, Italy, the son of amateur astronomer Vice-Admiral William Henry Smyth. He received his scientific education in his father's observatory at Bedford and then at the Royal Observatory at the Cape of Good Hope, South Africa (1835–45). In 1845 Piazzi Smyth was named Astronomer Royal for Scotland, and in 1846 became Professor of Practical Astronomy at the University of Edinburgh. He published the first stereoscopically illustrated book, *Teneriffe, an Astronomer's Experiment*, in 1858, and in subsequent trips to Russia (1859) and to Egypt (1864) continued to employ photography for documentary purposes, putting into practice theoretical improvements such as dry plates, miniature negatives, and magnesium flares. In his final decades, Piazzi Smyth was somewhat alienated from the British scientific community, largely owing to his eccentric views on pyramidology. He resigned from the Royal Society in 1874, retired from his professorship in 1888, and settled in the Lake District, where he designed cameras suitable for spectroscopy and cloud photography. He died at Clova, his Yorkshire home, on 21 February 1900.

PICTORIALISM

Pictorialism was the vanguard movement in art photography from about 1891 to 1910. It was especially strong among photographers in the United States and Europe who established their reputations in an organized international movement. They banded together to establish photographic processes as art. The work of camera, composition and printing served related artistic ideals: the ascendancy of the individual over the mass, the emergence of the artist from the crowd and the value of scarcity.

Apart from the broad aim to make pictures by photography, almost nothing else about pictorialism is straightforward, certainly not its beginning or its end. The years 1891–1910 may signal the start and finish of the art movement, but not the limits of the everyday word "pictorial." This is partly a problem of terms: pictorialism was an end-of-century organized movement, whereas the word "pictorial" had been in general use in the 1860s and simply meant looking like a picture. In the 1890s art photographers who wanted to demonstrate their modernity turned "pictorial" into a contemporary artistic "ism." However, the arguments that tore the art movement apart stemmed from the general meaning of the word "pictorial"—looking like a picture. Increasingly, no one could agree what a picture should look like. The nature of pictures suddenly became uncertain, and so did pictorialism.

Henry Peach Robinson described the nature of the pictorial in photography in the 1860s. He wrote eleven books on art photography and the most popular, *Pictorial Effect in Photography*, was printed four times from 1869–1893. Pictorial effect was achieved by making photographs look picturesque, overlaid with the early 19th century individualism of Romanticism and combined with the mid-century fashion for storytelling pictures. Pictorial effect depended on adapting the forms and styles of academic painting, including the architecture or structure of the image. Robinson used combination printing to build his pictures in the darkroom, but his interest in Pre-Raphaelite painting and its patchwork of parts meant that the space in his finished photographs often looks strange and unrealistic, though produced by purely photographic means.

In the 1880s Robinson's piecemeal style was condemned by Peter Henry Emerson. Both men believed that photographic techniques could be used to make art, though they emphasized different procedures. Emerson believed that a photograph must be made in the camera rather than in the darkroom. Ideally, this meant creating the picture in a single composed shot with no faking and dodging. Emerson replaced the word "pictorialism" with "naturalism" which claims to represent the actual world as it appears before the camera. But Emerson was just as obsessed as Robinson with art and personal expression, though the ways of achieving both were changing. During the 1880s, there was a shift away from anecdotal pictures, and this is evident in Emerson's work. Some of the earliest images published in *Life and Landscape on the Norfolk Broads* (1887), such as "The Dame School," tell stories, but most of them do not. Emerson gradually dispensed with content. The late images, published in *Marsh Leaves* (1895), are dominated not by subject matter but how photographs represent light and shade.

By the late 1880s, art photographs were not tied to storytelling paintings. They could be meaningful on their own, especially if they were atmospheric, impressionistic or symbolic. Moreover, what caused so much experimentation and excitement in the 1890s was the sheer number of techniques available to turn photographs into art.

Although the pictorialists needed mass-produced photographic materials, they pretended to stand apart from automation, and celebrated hand-work or other skills. Pictorialists used the best materials available in the High Street, but disdained the ordinary commercial or industrial nature of photography. They intended their photographs to be completely different from the objectivity sought by scientists and social recorders. The emphasis was not on utility but on expression. As artists, they also set out to be utterly different from snapshooters.

Antony Guest, in his book *Art and the Camera* (1907), claimed that the highest aim of every amateur was to glimpse the "Dream City of Art." This was the distant, magic home of the artist, that "gifted being for whom there is more richness in life than for ordinary mortals." To signal that they placed feeling and imagination over the authority of fact, the pictorialists embraced soft focus and the evocation of mood. Though engaged in dreaming, they also knew they had to express this in new photographic techniques. They became experts in combining different graphic devices. When art photographers pictured themselves at work on a print, which was rarely, it was to demonstrate their skill in precise and difficult processes. Alvin Langdon Coburn photographed himself working at an etching press, and John Cimon Warburg pictured himself working on the oil pigment of a gum print.

The pictorialists' program was romantic-expressive. It was concerned with identifying and staying close to the supposedly eternal standards of nature, beauty and truth. It was optimistic about the world it surveyed and wished to conserve. However, by 1908 the pictorialists were in open conflict about the nature of their art. The movement began to break up, signalled by the collapse of the Brotherhood of the Linked Ring in London in 1910. That year, more divisions surfaced in the United States. Alfred Stieglitz organized The International Exhibition of Pictorial Photography in Buffalo, New

Delton, Louis-Jean. Mr. Brower's American Trotters.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum,

York, to display work from 1894–1910. However, he included only the work of his own circle known as the Photo-Secessionists. The offense taken by the counter-Secessionist organization, called the Photo-Pictorialists of America, was so great that Stieglitz decided to take no further part in advancing pictorialism. The rows among other pictorialists carried on, with further splits evident in exhibitions designed to keep pictorialism alive to the present day. Despite its popularity, or because of it, pictorialism's contribution to art photography was largely ignored until the late 1970s. Recognizing its historical importance also meant acknowledging its ignominious end. In 1978 historian Weston Naef described pictorialism's late phases as "the most despised art movement of the twentieth century."

Since the late 1970s, there has been an increasing interest in pictorialism, with more books, exhibitions and auction-house sales of the work. Stieglitz and other Photo-Secessionists remain the best-known art photographers of the period. The orthodox history centers on Stieglitz and his circle and has altered little other than to recover a few neglected artists—significantly men whose careers were discernibly thwarted by Stieglitz, such as Fred Holland Day and Rudolf Eickemeyer Jr. That history repeats the aims of pictorialism laid down by its first advocates. It tends to repeat the self-assessments and earliest reviews of the movement as based in personal vision, with emphasis on the spiritual superiority of the artist in a materialistic world.

Of course, this history continues to separate photography as art from its increasing ease, cheapness and popularity. From the early 1890s, some photographers saw the mass production of easy-to-use cameras as a threat to art. Whereas once it had been possible to make art photographs only with whole- or half-plate cameras on a tripod, now people tried to achieve similar effects with hand-held cameras and negatives no bigger than a quarter-plate. In theory, if these newcomers had the correct disposition they also had the potential to make art. In theory and in practice, as George Davison showed with "The Onion Field" (1889), an art photograph could be produced with a pinhole camera, with no lens or plate at all. Davison demonstrated that technology was irrelevant, since the basis for art was the romantic-expressive temperament.

Yet, despite the importance of character, technology was still a crucial factor in differentiating the artistic amateur from the snapshooter. Art photographers bought their own expensive equipment, furnished their own darkrooms (or used those of exclusive clubs), and produced individual and exquisite prints. In the 1890s, an enthusiast for hand cameras warned buyers against trying to "take" a landscape with a cheap camera without a shutter. The ownership of the landscape, even at the level of ideas, remained with those who were not only cultivated but also rich enough to afford elaborate plate cameras. It was important to stay up-market with equipment, or (like Davison) temper low-level technology with a superior understanding of composition and darkroom skill.

The mass production of photographic goods led inevitably to the popularity of photography as a pastime among the lower middle classes, and an increasing number of clubs and societies. The *British Journal*

Photographic Almanac for 1881 listed 20 societies, all in large cities in England. By 1891, this number had risen to 172 and, by 1901, had risen again to 229. Societies were also founded in towns and suburbs. The spread of clubs and societies throughout Europe and the United States meant a proliferation of art interest among amateurs, so the serious art photographers had to become much more exclusive.

Exclusivity could be achieved by being knowledgeable about art. Many ideas in art, such as aestheticism and naturalism, already had long histories in the 19th century, but the pictorialists tried to see their relevance to contemporary art. They studied recent versions of the arts of "ism": aestheticism, naturalism, impressionism, Japonisme, and symbolism. Pictorialists rummaged in these varied art styles for prescriptions and justifications to create for themselves an art movement that was primarily aesthetic.

Though satirized in the 1820s, aestheticism survived into the 1890s as the affected and extravagant cult of the beautiful that characterized the "Aesthetic Movement." In his conclusion to *The Renaissance* (1873), Walter Pater claimed that those with "sensibility" would find the most precious moments of life in "the desire of beauty, the love of art for art's sake." In Britain, aestheticism in art was first ridiculed because of its dandyism and then tainted by its association with the perceived decadence of Aubrey Beardsley and Oscar Wilde. Nonetheless, an enthusiasm for "art for art's sake" was important in dislodging Victorian moralizing and anecdote from art and photography.

Naturalism was chiefly concerned with representing an idealized country life, as if it actually existed and could be shown directly, seemingly without mediation or manipulation. The countryside and country folk appeared to be both natural and heroic. The art movement developed in Europe and the United States from the 1820s. Towards the end of the century naturalism was continued in Britain in the paintings of George Clausen, who was a friend of Peter Henry Emerson. During the same period in the United States naturalism flourished in the paintings of Albert Bierstadt, and in the photographs of Rudolf Eickemeyer Jr., and in Arthur Scott's photographs for John Coleman Adams's *Nature Studies in Berkshire* (1899).

Even as it developed, Impressionism was the most famous of all French art movements. Although controversial in the 1870s, "impression" was quickly (and loosely) adopted as a way of viewing the world. The term was not confined to one style of depiction, but described an attitude to art that had already been made famous by Emile Zola in 1866, when he remarked that a work of art was "a corner of creation seen through a temperament." Photographers latched onto that idea even more than the methods of Claude Monet or Edgar Degas. The word "impression," as long as it was associated with artistic temperament, became the most widely used term—sometimes of abuse—in *fin de siècle* art photography. Part of the problem in Britain, at least, was that the word was linked with James Abbot McNeill Whistler, whose impressionistic "Nocturnes" had been so controversial in the 1870s, but who was feted by the time he died in 1903. A particularly rich example of his influence can be seen in Edward J. Steichen's "Flatiron" (1907). Steichen achieved his effect by making a print from a complex mix of blue pigment gum bichromate and platinum salts, which required considerable technical mastery.

Pictorialists liked the decorative pattern and order of Japonisme. It is characterized by a pronounced flatness of the picture, high skyline, or the abstract nature of the overall image. It was made popular in the United States (among others) Arthur W. Dow's *Composition* (1899). Japanese woodcut design is common in pictorial photography, as in James Craig Annan's "The White House" (1905) and Alvin Langdon Coburn's "Wapping" (plate 10 from *London*, 1909).

Symbolism was a highly charged, eroticized art form in Europe. The pictorialists translated it into something gentler. It had a pronounced mystical air, as in George H. Seeley's "Glowworm" (1903/08), Clarence Hudson White's "The Bubble" (1898/1905), and Anne W. Brigman's "Spirit of the Glacier" (1906). In Britain, Alvin Langdon Coburn was captivated by the mystery religion of Rosicrucianism and illustrated the mystical poet and playwright Maurice Maeterlinck's *The Intelligence of Flowers* (1907).

Though fraught with ambiguity and conflict in their practice, art photographers nevertheless modeled themselves on the art establishment. They held annual "salons," put their prints up for sale, judged each others' work, and awarded medals. They kept up a continuous flow of critical opinion and confirmatory acts. They took portraits of each other, wrote reviews, and formed alliances. An accumulation of opinion and reputation flowed within and across continents. Their activities created a "hothouse" atmosphere, designed to keep out what they felt to be the enemies of art. The density of material flowing in the system appealed to the Romantic standards of truth and beauty, which was opposed to the banal and manufactured.

This clamour for prestige among art photography has been harshly judged by historian Ulrich Keller. However, what is important about his work, and perhaps suggests why it has been somewhat overlooked in the standard books on the pictorialists, is that he moves away from taking them entirely on their own terms as artists. He insists not only on examining their contradictions, but also on placing them in the contexts of art production and consumption and business.

Attacking their aesthetics, Keller writes that the pictorialists were "charmed" by the high status "reserved for the artist/genius in Victorian times" and set their sights "on producing high-art works à la Titian and Rembrandt." However, the claims for art were not always based on the "old masters." Other favored models included popular contemporary (or still fashionable) artists such as Jean Baptiste Camille Corot, George Frederic Watts, and, above all, Whistler. Further, the pictorialists could not have accepted that their place was to stay with what Keller calls the "merely decorative" arts of the Aesthetic Movement, since they were contending for a new space for art photographs as *pictures*.

Keller also argues that in constructing their own fame, the pictorialists built "a prestige-oriented pseudo art world" on a medium with no stable position or history as an art form, and with negligible support from curators and collectors. The pictorialists' self-promotion was indeed similar to that of the art world, no doubt because of prestige. It could not have been for financial reward, since none of the practitioners was making serious money from art photography, and yet they continued to pursue it in their spare time.

The position of the pictorialists is complex, because most were middle-class professionals. Pictorialism was only a hobby and full-time camera work was extremely rare. Yet the attraction of mimicking high art becomes clearer if it is considered in terms of social class. Artistic production and promotion had no direct business significance and was largely concerned with membership of the correct social set. In London, the elite art photographers formed the Brotherhood of the Linked Ring in 1892, breaking away from the already elite (but inartistic) Royal Photographic Society. But despite their secession, art photographers were not bohemians seeking a place outside the market. On the contrary, they were themselves a niche market. The big photographic firms recognized the special cachet of art, and financed the amateur magazines to encourage art aspirations. They continued the same appeal in organized amateur exhibitions with special sections for the elite art photographers. For instance, Kodak's large exhibition in London in 1897 featured well-known British pictorialists such as Henry Peach Robinson, James Craig Annan, George Davison and Alfred Horsley Hinton. Furthermore, many of these photographers were employed in the trade. Hinton was a dealer in photographic goods and editor of *The Amateur Photographer* from 1893–1908; Annan was employed in his father's firm of portrait, commercial and industrial photography; Davison was directly connected with Kodak from 1889–1913, and was Managing Director of the company in England from 1900–07. Robinson was a professional portrait photographer and successful author. Other exhibitors included such famous members of the Brotherhood of the Linked Ring as Malcolm Arbuthnot, who married a Kodak heiress and managed the company's Liverpool branch, and James Booker Blakemore Wellington, who founded the company of Wellington and Ward, manufacturers of photographic plates.

The tendency to retreat into metropolitan and otherwise exclusive societies was matched in Europe in the Cercle l'Effort (Brussels) and the Trifolium (Vienna), and in the USA by the Elect (Chicago) and the Photo-Secessionists (New York). Such elite clubs were directly comparable to the exclusive gentlemen's clubs of high society. In addition, many of the leading members of these societies were unusually wealthy and highly educated. The Wiener Camera Club enjoyed the patronage of the Royal Family and aristocrats, as well as photographers of international standing and high status, including lawyers (Joseph T. Keiley), bankers (Robert Demachy), merchants (Theodor and Oskar Hofmeister), and heirs (Heinrich Kühn). Not surprisingly in such company, the emphasis was on stylish clothes, on gatherings in fine restaurants, and luxurious club accommodation.

The pictorialists agreed on their exclusivity. However, they scarcely agreed on anything else. They constantly wrangled among themselves about methods and styles. The movement began promisingly in 1891 with an art photography exhibition organized by the Trifolium group in Vienna, but personal rivalries meant it ended badly in London in 1909–10 with the self-destruction of the Brotherhood of the Linked Ring. Pictorialism then rapidly disintegrated as a forceful movement.

The seeds of discord were already present from 1889. Despite the importance of the final pictorial effect, this was nevertheless related to technical choices, and art photographers engaged in bitter disputes over processes. The controversy over printing began in 1889, when Emerson caused a scandal by advocating differential focusing, and thereby broke with sharp imagery. The arguments were complicated by those who advocated print manipulation in the darkroom and those who believed the photograph should be printed "straight," insisting on the purity and integrity of the chemical process. The opposing factions never resolved the matter in arguments stretching over twenty years, and from this distance the differences between them are less striking than their similar aim—to make rare and unique prints that were remote from everyday snapshots, or illustrations printed in magazines and papers by off-set lithography.

Divided by technique, the two main camps held some ideas in common. For example, both camps declared that truth to nature was the most important ideal, and neither believed this should be mistaken for realism, or too much detail. However, one camp declared that it was the duty of the photographer to improve on reality by any means possible in order to approach the ideal of nature. These means included staging scenes, altering

actuality, and combining or altering negatives in the darkroom. The leader of this group was Henry Peach Robinson, but he died in 1901, and then the chief exponents of such practices included such different stylists as Lydall Sawyer, Alfred Horsley Hinton, and Francis James Mortimer. Nature could also be improved by using one of a number of oil pigment processes, such as the gum print, which were invented and improved upon in the first years of the 20th century. These enabled such different photographers as Robert Demachy, Dudley Johnston, Leonard Misonne, and Edward Steichen to use a brush to coat the paper with oil pigment. They applied as much pigment as they liked to make images that were varied in draughtmanship and rich in color, often looking like lithographs. Opponents of those "handwork" methods referred to such images disparagingly as "fuzzygraphs."

The opponents of "handwork" also believed that art resided in nature but thought that true artists should be able to see the composition before them in the groundglass screen of their camera. They advocated "straight" or "pure" photography, with the minimum of darkroom interference. Since the 1880s, the leading proponent of "pure" photography was Emerson, who never joined any of the secessionist art societies but was extremely influential. He claimed that the mass market was spoiling photography, declaring the order of rank for pictorial representation to be oil paintings first, followed by photogravures and finally "a good photograph, one which is a picture, and which is printed in platinotype." Emerson's ideas were carried forward by Stieglitz and many other pictorialists, including Frederick H. Evans, George Davison, and Alvin Langdon Coburn. These photographers liked to make platinum prints, which had a metallic sheen, or photogravures, which could look like engravings or etchings.

Arguments between the "pure" and "handwork" camps helped to destroy late pictorialism, but other factors were involved. In addition to the squabbles among its advocates, pictorialism was already in a weak position. With some justification, the death of pictorialism as a form of modern art stems from its politeness. Consistently, pictorialism is consigned to the margins because of its attachment to the drawing-room values seen in the art of the late Victorians and Edwardians. Its advocates wrote dull appreciations according to increasingly old-fashioned formula. However, pictorialism continued to flourish in camera clubs and international exhibitions because it was pleasant and not too modern. Its popularity increased in the clubs because it helped produce an idealized or improved view of a utilitarian or mechanized world. Of course, once pictorialism became popular, its appeal to the famous *fin de siècle* art photographers ended.

Pictorialism suffered even more when one of its methods, combination printing, was put to new use—but not in art. When it was dangerous or forbidden to use a camera outdoors during wartime, combination printing was widely used to fake war scenes that were useful propaganda; no doubt that contributed to pictorialism's sudden demise in depicting truth to nature after 1918.

The more pressing problem by 1910, however, was that pictorial aesthetics seemed outdated. The Victorian ideals, the comfortable drawing-room life, which is so evident in Edwardian pictorial photography, were no longer the appropriate style for art as modernism gained ground in Europe. *Fin de siècle* art movements were brushed aside by modernism; optimism based on eternal values was destroyed as mechanization took command. The conserving arts gave way to the explosive forward movement of the avant-garde. Pictorialism could not stand the blast of modernism in the guise of Cubism, Futurism, abstraction, Neo-classicism, New Realism, and Surrealism.

Despite its elitist claims as an art form, the pictorialists' grasp of contemporary art trends was always tenuous, even before 1910. Pictorialism was never avant-garde when compared with current movements in Fine Art. It was always behind the times. When it seemed to be getting abreast of the times, as in Alvin Langdon Coburn's Futurist-inspired "Vortographs," exhibited in London in 1917, or in Paul Strand's Cubist-inspired work published in the last issue of Stieglitz's *Camera Work* in 1917, it was vilified by most pictorialists. Coburn retired from photography and *Camera Work* folded—though Steiglitz and Strand went on to make enormous contributions to art photography *outside* pictorialism. The reputations of these men have remained high not so much for their contribution to pictorialism, considerable as that was (especially from Stieglitz and Coburn), but because of their dedication to the elitist, exclusive nature of art photography. As soon as pictorialism became common fare, a way of making pictures that any enthusiast could enjoy, it was of no interest to the elitists. Once it had failed to keep its distance from the mass of amateurs, pictorialism could no longer fulfill its ambition to be art, because art by definition was made by and for the few, and not by or for the multitude.

PIGOU, WILLIAM HENRY (1817–1858)

English photographer

Dr. William Henry Pigou took over the task of recording the ancient monuments of the Bombay Presidency from Colonel Thomas Biggs in early 1856 and spent over a year as Government Photographer on the project. Before taking on this assignment, Pigou had been a member of the Bombay Photographic Society (since 1854) and, according to Biggs, had several years experience of photography in India. Some fine landscape images by Pigou also survive.

Using large format paper negatives (up top 16" × 12"), post-waxed, Pigou's work was, with a few publicly criticised exceptions, precise, architecturally accurate, and usually photographed under oblique lighting conditions selected to reveal the intricate sculptured facades which decorated many of these monuments.

His work, together with that of his predecessor and his successor, was eventually published in India in 1866, subsidised by the Committee of Architectural Antiquities in Western India, in Taylor and Henderson's *Architecture in Dharwar and Mysore. Photographed by the late Dr. Pigou, Bombay Medical Service, A. C. B. Neill, Esq. and Colonel Biggs, Late of the Royal Artillery*. These large format portfolios—containing tipped-in albumen prints—were published in London by John Murray. Some of the photographs were later used as the basis for the engravings which illustrated James Fergusson's History of Indian and Eastern Architecture, also published by John Murray, in 1876.

JOHN HANNAVY

PIOT, EUGÈNE (1812–1890)

French photographer and publisher, collector, and art historian

A wealthy amateur, Eugène Piot started practicing daguerreotype in 1840, when he traveled to Spain with his friend Théophile Gautier (both were part of the Romantic community which colonized the Rue du Doyenné, in Paris in 1835). The poet mentioned this photographic venture in his travelogue, *Tras los Montes*, but none of Piot's plates survived. A remarkable art connoisseur and collector (he bequeathed his collections to the Institut de France, the Bibliothèque Nationale, and the Louvre), Piot traveled and photographed in Italy, Greece, and the Near East.

His subjects are chiefly architectural views related to his artistic and archeological interest. He is mostly known for publishing photographic albums a few months before Blanquart-Évrard, to the surprise of the photographic milieu. Familiar with publishing, Piot created, in 1842, an art journal, *Le Cabinet de l'amateur et de l'antiquaire*. In June 1851, he released

the first (and probably unique) installment of *L'Italie monumentale*. Emphasizing on the competition between photography and printmaking, Francis Wey considered that "thus begins the series of art travels books illustrated by photography: Mr. Piot created a new commercial field" (*La Lumière*, August 17, 1851, p. 111). His other publications—none of which he completed—include *L'Acropole d'Athènes* (1852), *Temples grecs* (1854), *Rome et ses environs*, and *L'élite des monuments français*.

Piot exhibited at the Royal Society of Arts in London (1852), at the 1855 Exposition universelle in Paris (First Class Medal), and at the Société française de photographie (1857, 1859).

PIZZIGHELLI, GIUSEPPE (1849–1912)

Giuseppe Pizzighelli (according to his friend and co-researcher Josef Maria Eder) was the son of an Austrian army surgeon of Italian origin, and was educated at the military academy in Vienna.

He is first recorded as a keen amateur photographer in the late 1860s, while a serving lieutenant in the Austrian army, working with his friend and fellow officer Victor Tóth, and wet collodion plates and 'Busch combination lenses for portraits and landscapes' (Eder 1945).

Despite training as a military engineer, in 1878 Pizzighelli was appointed as head of the photographic department of the Austrian army's Technical Military Committee in Vienna, with the rank of captain, and his important published contributions to the development of photography all date from after this appointment.

It was during this posting that Pizzighelli joined with Baron von Hübl in the preparation of platinum prints—following William Willis's instructions. Von Hübl was a fellow captain—later to achieve the rank of Field Marshall—and their work led to the introduction of a significant improvement to the process that Willis had patented in 1873. It was Pizzighelli and von Hübl's work in the later 1870s and early 1880s which improved the reliability and manufacturing consistency of the paper itself, and led to much more widespread use of platinum as the ideal 'permanent' printing medium.

He and von Hübl published their experimental results in early 1882, and their work was awarded a medal by the Vienna Photographic Society—an organization with which he would have a continuing relationship. An abridged version of their account was translated into English and published in the *Journal of the Photographic Society* in the same year.

Their much more comprehensive book *Die Platintype* was also published in 1882. It was also translated into French and published by Gauthier-Villars of Paris in 1883 and, translated into English by J. F. Iselin and edited by William de Wiviles lie Abney, it was published in London by Harrison & Sounds in 1886.

The platinotype enjoyed considerable popularity within the expanding community of art photographers in the closing years of the ninettenth and early years of the twentieth centuries—notable inclusions being Frederick H Evans, Paul Martin, Alfred Steiglitz, Paul Strand, and Clarence White.

While several published sources make much of the claim that Pizzighelli and von Hübl gave their process 'freely to the world,' an 1887 patent exists in Pizzighelli's name which suggests the contrary. By that time he had been posted to Bosnia as an engineering officer, and was working alone. That 1887 patent refers to a modified version of the platinotype—a printing-out paper using sodium ferric oxalate and potassium chloroplatinate which did not require further development. It was briefly marketed as the Pizzitype, but ironically—bearing in mind that he and von Hübl had improved the consistency of the developed platinum print—it was, allegedly, inconsistency in manufacture which led to the material being withdrawn from sale.

Pizzighelli and Eder are credited with the production of the first chemically developed gelatin silver chloride emulsions in 1881—both prints and glass diapositives—twelve years before Leo Hendrik Baekeland's introduction of Velox 'gaslight' paper. They had started their collaboration in 1880 and reported their work to the Vienna Academy of Sciences in January 1881, publishing their results in a lengthy-titled pamphlet in the same year—*Die Photographie mit Chlorsilbergelatine und chemischer Entwicklung nebst einer praktischen Anleitung zur raschen Herstellung von Diapositiven, Stereoskopbildern, Fensterbildern, Duplikat-Negativen, Vergrösserungen; Kopien auf Papier …* Eder went on to produce the first gelatin silver chloro-bromide emulsions himself. When later writers asserted that others had prior claim for the production of the first developed silver chloride emulsions, the 75-year old Eder asserted his

and Pizzighelli's claims to their invention in the *Journal of the Photographic Society* in 1930.

To demonstrate the fineness of the grain structure of their silver chloride plates, Eder and Pizzighelli made reduced size positives from existing collodion negatives by their friend Victor Angerer, the well-known Viennese portrait photographer. These were exhibited at the twentieth anniversary exhibition of the Vienna Photographic Society in 1881. What caused especial interest amongst those seeing these images for the first time was the hitherto unavailable range of print colours which the two pioneers had produced by using a range of different developers. In Edward Epstean's translation of Eder (1945) the colours are described:

> The warmest bright red shades were developed with hydroquinone and ammonium carbonate, the brownish tones with ammonium ferro-citrate, the greenish brown tones with alkaline gallic acid solution, and so forth… This diapositive exhibit was awarded the gold-enamel medal by the Vienna Photographic Society.

Pizzighellis and Eder's work was further developed by Dr. Ernst Just in 1882, and by Leon Warnerke in 1889.

In his role as head of the army photographic department, Pizzighelli was clearly an influential figure. It was to him that Adolphe Steinheil brought his newly computed aplanatic lens set for testing in 1881. The aplanat design had been something with which Steinheil had been working since the late 1860s, producing lenses which were virtually free of both chromatic and spherical aberrations, and which offered a very flat field—characteristics which were essential for much of the work in which Pizzighelli's unit was engaged.

Amongst many texts, Pizzighelli wrote two manuals on photography—*Anleitung zur Photographie für Anfänger* published in 1890, and *Handbuch der Photographie. Für Amateure und Touristen,* published in 1892.

After a lengthy military career—achieving the rank of colonel—he retired to Florence in 1895, where he began an enduring relationship with the Società Fotografica Italiana, eventually become a director and later president. He died in Florence in 1912, at the age of 63.

PLATEAU, JOSEPH ANTOINE FERDINAND (1801–1883)

Belgian physicist, inventor of the phenakistiscope

Joseph Plateau was born in Brussels, Belgium, in 1801. He became an orphan at fourteen. A pupil at the Atheneum, Brussels 1817–22, he was much influenced by his teacher Adolphe Quetelet. Quetelet would later found the periodical 'Correspondence mathematique et physique,' in which Plateau's technical papers were published. Plateau enroled in the Philosophy Faculty of the University of Liège in 1822. In 1823–24 he obtained diplomas in art and law. Fascinated by chemistry, Plateau carried out his own experiments and in 1824 obtained the Diploma in Physical and Mathematical Sciences. He became a mathematics teacher in 1827, and had soon published a paper on optical perception, and designed instruments for perception experiments. His 1829 doctoral thesis, 'Dissertation on Several Properties of Impressions Produced by Light on the Organ of Sight,' includes observations on colour theory, and also anorthoscopic (distorted) drawings which appear normal when viewed through a spinning, slotted disc. The anorthoscope was marketed in 1836.

In 1830 Plateau moved to Brussels, teaching physics 1833–34. By late 1832 he had invented the phenakistiscope, or phénakisticope [original spelling]—from *phenax* -"deceptive" and *skopeo*, "I look at." An almost identical device, the stroboscope, was invented simultaneously by Austrian physicist Prof. Simon Stampfer. Plateau's instrument comprised a disc with a small central hole, mounted on a handle so that it could spin freely. Each disc had small equidistant radial apertures around the circumference and pictures on one side. The disc was spun with the pictures facing a mirror, and the moving images viewed through the slots, by reflection. Other versions of the device comprised two discs on the same shaft, one with slots and the other containing a sequence of images. When the two discs rotated, an animated picture was seen by viewing the picture disc through the slots in the shutter disc. Most of the animation sequences were drawn in a cycle, a continuous flow with no beginning or end. Plateau's first subject was a line drawing of a pirouetting dancer, in sixteen positions.

Versions with a variety of names, including Phantasmascope and Fantascope, were sold commercially as a philosophical toy by various publishers in France and England, with discs featuring a wide range of imaginative animated drawings, including abstract designs of coloured balls. Plateau himself received no financial reward for his invention.

Within a few years Plateau had produced an improved version, with backlit pictures on translucent varnished paper, designed and geared in such a way that the optical

distortions apparent in the original model were reduced. The subjects were fantastic characters designed by the Belgian artist Jean-Baptiste Madou, extrapolated into motion sequences by Plateau himself. The result could now be viewed more comfortably with both eyes, and by more than one spectator.

Plateau moved to Ghent in 1835, and became a professor at the University. Plateau's experiments relating to visual perception were wide-ranging, and included the persistence of luminous impressions on the retina, accidental colours, the contrast of colours, and coloured shadows. He observed and commented on many aspects, including 'irradiation'—the phenomenon of a bright object seen against a dark background appearing larger than it actually is, related to the recurrent mystery of the apparent size of the moon being larger on the horizon than when it is high in the sky. He devised an instrument to study the effect, which is measurable, and his results were published in 1839. When he was around forty-two years old, Plateau gradually went blind as a result of an inflammation of the eyes. (This was probably not, as is often suggested, caused by experiments involving direct viewing of the sun). Undaunted, he continued to experiment assisted by his colleagues, friends and family, including his elder son Félix. For decades Plateau continued his studies of visual persistence, especially the varying persistence of different colours. He believed that this effect was a property of the retina, but it is now known to be linked to the brain.

As well as undertaking optical research, Plateau also studied the phenomena of capillarity and surface tension of liquids, and his important work in that field is still well known. Many experiments describe the structure of soap films, illustrating the mathematical problem of the existence of a minimal surface with a given boundary—now named Plateau's Rules. Stereoscopic photographs of Plateau-type laminar soap films formed on wire shapes, taken about 1880, are in the J. Plateau collection, Ghent.

Plateau's phenakistiscope viewer evolved into the zoetrope drum-form moving picture device, and was the spur for many later experiments. In 1843 the obscure English experimenter T.W. Naylor suggested a machine for projecting phenakistiscope-disc drawings, and a plan of the device was published.

Several of Plateau's correspondents and contemporaries soon suggested viewing devices for a more ambitious idea; the presentation of moving photographs. Inventor of the stereoscope Charles Wheatstone, daguerreotypist Antoine Claudet and others struggled with the problem over many years. In 1852 the French optician Jules Duboscq combined Plateau's phenakistiscope with Wheatstone's stereoscope to produce the Bioscope, a direct viewing instrument for producing a stereosopic photographic moving image. (The name would later be used for motion picture film machines). In 1879 Eadweard Muybridge devised his successful Zoogyroscope or Zoopraxiscope projector developed from Plateau's phenakistiscope principle, with glass discs bearing painted figures based on his famous American sequence photographs. Joseph Plateau died in 1883. His colour vision research was an important contribution to the subject, and his principle of producing moving images by rapid succession of a number of progressive poses would later be a key feature of the invention of motion pictures on film.

STEPHEN HERBERT

Biography

Born in Brussels on October 14, 1801. His father was Antoine Plateau (1759–1815), his mother Catherine Thirion (1771–1814). After his father's early death, an uncle supported and encouraged Plateau's early studies. Plateau married Fanny Clavareau, August 27, 1840. He was a member of the Royal Academy of Belgium, a correspondent of the Institute of France, and a member of many European academies and learned societies. Joseph Plateau died in Ghent on September 15, 1883, forty years after he lost his sight. No photographic portrait was known until the 1990s when an evocative daguerreotype, taken by photographer Pilizzaro in 1843 just before Plateau went blind, was discovered in France. It was acquired by the Museum of the History of Science, University of Ghent, and is now in their permanent collection.

PLATINOTYPE COMPANY

In 1879, William Willis junior founded the Platinotype Company in order chiefly to manufacture and market his platinum printing papers. Five years of research in his private laboratory at Bromley, Kent, had followed his initial patent of 1873—Improvements in Photochemical Printing—before Willis advanced sufficiently to offer his invention, described in his patent of 1878, to the public. A factory was established at 66 Beckenham Road, Penge, and the Company's sales office at 29 Southampton Row, High Holborn, London, which later

transferred to 22 Bloomsbury Street.

By 1880 the first commercial platinotype papers were on sale, with a choice of rough or smooth surface, on medium or thick paper, at a price of 1/- (one shilling = 12 'old' pence = 5 'decimal' pence) for a sheet 17.75 x 22.75 inches; other sizes could be supplied pro rata at a unit cost of ca. 4 d/sq.ft ('old' pence per square foot). By 1892, the Company was selling platinotype papers in nine sizes, pre-cut to match the negative formats then current, at a unit cost of ca. 8 d/sq.ft, which remained constant over the next 15 years, and may be compared with the cost of ca. 3 d/sq.ft for printing-out papers, and 6 d/sq.ft for the new bromide enlarging papers. For storage, perfect dryness was of paramount importance, otherwise the sensitizer became fogged by the action of moisture; accordingly, the Company supplied the paper sealed in soldered tins, and recommended storing it in special tubes containing a desiccant of anhydrous calcium chloride. Sensitized textiles could also be supplied for 1/- to 1/6 per square foot: nainsook—a very fine muslin; sateen—for d'oyleys, mats, and lampshades; and rough oatmeal cloth—for screens, antimacassars, cosies, and mantle-cloths.

Because the process was protected by Willis's later patents of 1878 and 1880, prospective users, both amateur and professional, were initially obliged to pay the Company 5/- for a licence to practise platinum printing. This requirement was suspended in 1888 when Willis launched his new cold bath process, described in two more patents, of 1887, in which the development bath contained all the platinum salt. It proved short-lived, however, owing to an uneconomic defect: platinum metal tended to precipitate from the stored developer. Willis withdrew this platinum in the bath process in 1892, upon introducing his final, most successful modification, cold development paper, which he protected by secrecy rather than patent.

In 1885 the Platinotype Company was awarded the gold medal of the International Inventions Exhibition. By the 1890s, Willis's range of papers offered every combination of texture, weight, more or less contrast, and black or sepia image—numbering about 20 varieties. These sensitized papers were of two main types: one could only be developed hot, the other was also suited to development at room temperature. The image colour varied slightly, from bluish-black in cold development (ca. 20 °C), especially using the Company's proprietary D Salts as developer, to brownish-black at high temperature (ca. 75 °C). Most workers preferred cold development to avoid scalding their fingers. Willis also devised Sepia platinotype papers, which incorporated a mercury(II) salt in the sensitizer. These called for hot development; but to obtain a sepia colour with the ordinary papers, some workers added mercuric chloride to their cold development baths.

The company's platinotype papers were coded by a single letter to designate hot bath papers, a doubled letter for cold development papers, and 'S' to indicate sepia papers. Willis later added a parchmentized paper having a semi-glossy surface—Japine paper. The surfaces, weights, and image colours available were as follows:

A, AA Smooth surface, medium weight
B, BB Smooth surface, heavy weight
C, CC Rough surface, very heavy weight,
K, KK, KS Smooth surface, heavy weight, higher contrast
S Smooth surface, medium weight, sepia colour, hot bath process
RS Rough surface, very heavy weight, sepia colour, hot bath process
T, TT, TS Rough surface, heavy weight, higher contrast
Y, YY, YS Smooth surface, very heavy weight
Z, ZZ, ZS Slightly rough surface, very heavy weight

Willis purchased the platinum salt, potassium chloroplatinite, from the leading precious-metal refiners, Johnson Matthey, whose company records for the sales of this salt make possible a rough calculation that the production of platinotype paper was usually in excess of one million square feet per year.

Other goods marketed by the Platinotype Company included chemicals, porcelain dishes, printing frames, and calcium chloride tubes. A director of the company, Herbert Bowyer Berkeley (1851–1891), was responsible for one of the most significant improvements to photographic processing by discovering that developers for silver emulsions could be stabilized by the inclusion of sulphite, which enabled the development of negatives to greater density ranges without fogging. The company marketed this important innovation in 1882 as the very first proprietary developer, "Sulpho-pyrogallol." The works manager of the company's factory in Penge, WH Smith, also collaborated with Willis to produce a hand-portable 'Key camera,' patented on 28 March 1889, which incorporated a novel method of changing the glass plates.

The chief competitor to Willis's platinotype was Pizzighelli's printing-out platinum paper, invented in 1887, which was manufactured by Hezekiel and Jacoby in Berlin, Dr Just in Vienna, and Unger and Hoffmann in Dresden. Such paper was also made in England by Berger and Company, and by Hardcastle; but the major photographic companies, Ilford and Kodak, did not enter the platinum paper market until the early 20th century. To retail the Platinotype Company's products in the United States, the sister-company of Willis and Clements was founded ca. 1885, with offices at 25 North Seventh Street, Philadelphia, later moving to 1624 Chestnut Street. Rival suppliers in the United

States included JC Millen of Denver, Colorado, E and HT Anthony of New York, and the American Aristotype Company of Jamestown.

As a consequence of the "platinum famine" brought on by the Russian Revolution and the Great War, the Platinotype Company had to diversify its products, introducing as substitutes "Satista" paper in 1913, and "Palladiotype" paper in 1917. On the death of William Willis in 1923, the Company passed to his younger brother, John, and was subsequently headed by a cousin, Alfred Willis Clemens, until 1937, when the Company was voluntarily dissolved.

PLATINUM PRINT

From the earliest days of photography, the noble metal platinum was recognised as a potential image substance. Both Sir John Herschel in 1839, and Robert Hunt in the 1840s, sought to employ platinic salts photochemically, but found no real success. Printing in platinum did not show any promise until 1873 when, in search of a greater permanence than silver afforded, William Willis junior, of Bromley, Kent, turned to experimenting with the little-known platinous—as opposed to platinic—salts. Progress did not prove easy, however: to achieve satisfactory quality, Willis had to include salts of silver, lead, and even gold in his sensitizers. Such uncertain mixtures won little attention for his processes at first. In the struggle to fulfil his original concept, Willis's endeavours spanned twenty years of research, producing five British patents. By 1878 he had succeeded in eliminating the silver from his sensitizer, which emboldened him to found the Platinotype Company to market his platinotype paper, but its processing called for a scaldingly-hot, poisonous, developing bath, which had little appeal.

By the mid-1880s Willis was facing competition from Giuseppe Pizzighelli and Baron Arthur von Hübl in Austria, who devised a printing-out platinum paper in 1887. The photographic press praised Willis's paper in 1888, but it was not until 1892 that he finally perfected the process with his "cold development" paper, which was instantly acclaimed, ensuring that his product enjoyed much wider use. By the close of the century, more platinotypes could be seen on the salon walls than any other print medium: the process had achieved pre-eminence.

Platinotype is a later addition to the group of iron-based photographic printing processes, whose principles were discovered by Sir John Herschel in 1842, using ammonium ferric citrate. Platinotype differs in requiring ferric oxalate, which is decomposed by light to insoluble ferrous oxalate, as first noted by Johann Wolfgang Döbereiner in 1831. At this stage, the image is faintly visible, partially printed-out in pale buff on a yellow ground. It further requires development in a bath of hot (80 ˚C), strong (30 per cent) potassium oxalate solution to solubilise the ferrous oxalate, which can then reduce the platinous salt, included as potassium chloroplatinite, to platinum metal in a finely-divided state known as "platinum black." These two reactions may be represented by the following chemical equations:

ILLUSTRATION

UV light + $Fe_2(C_2O_4)_3$ —> $2FeC_2O_4 + 2CO_2$

UV light + ferric oxalate —> ferrous oxalate + carbon dioxide

$2FeC_2O_4 + 4K_2C_2O_4 + K_2PtCl_4$ —> $2K_3Fe(C_2O_4)_3 + 4KCl + Pt$

ferrous + potassium + potassium —> potassium + potassium + platinum

oxalate oxalate chloroplatinite ferrioxalate chloride metal

To clear the print, all the residual chemicals are removed by three successive baths of very dilute hydrochloric

acid, followed by washing in water, to leave an image of pure platinum black embedded in the surface fibres of the paper sheet.

The problem with this elegant process is that the reduction of the platinous salt is slow, and may be further inhibited by additives in the paper, such as gelatin size. Unless the reaction is speeded up by using hot developer, the chemicals tend to wash out of the paper before the image is fully developed. How Willis's "cold development" paper overcame this problem was never disclosed, but it appears to employ an alum-rosin paper size in preference to gelatin. The maintenance of a dry storage environment for unexposed paper was vital to avoid degradation by moisture. In contrast, the presence of some moisture was essential to facilitate the chemistry of the printing-out platinotype process of Pizzighelli and Hübl; but this was hard to control, so attempts to market commercial papers of this type foundered rather quickly.

Platinotype claimed a threefold advantage over all other photographic printing processes: it was said to be "permanent, artistic, and simple." Acknowledged as the easiest process, it was three times faster than silver printing-out paper. Of its permanence there could be no doubt, because platinum is the most inert of metals, impervious to attack by any common substance. What was not recognised in the 19th century, is that platinum black is also a very efficient chemical catalyst and, when exposed to the—usually polluted—Victorian atmosphere, it promoted the formation of strong acids within the paper fibres. Thus the paper of a platinum print may be embrittled by acidic degradation over the years, albeit the image remains pristine: historic platinotypes should therefore be handled carefully, to avoid damage.

Concerning the aesthetics of the process there was at first some equivocation: the dominant photographic print medium from 1855–1895, was the albumen print, providing the familiar brown silver image in a glossy layer of hardened egg white. For photographers habituated to this medium, the neutral grey-black platinum print with its luminous tonal gradation and totally matte surface came as a shock. Some connoisseurs greatly preferred it, however, dismissing albumen as "sharp and slimy." To accommodate all tastes, Willis introduced both "Sepia" and "Japine" platinotype papers into his commercial range. Platinum printing was much used for portraiture, landscape, and important documentary work. Like albumen, it could only be contact-printed. Platinotype paper cost about twice as much as silver printing-out paper, but it was comparable in price with the new (1890s) bromide enlarging papers.

Platinotype was the favoured medium of the Brotherhood of the Linked Ring; notable users included Frederick H. Evans, whose great series of cathedral interior studies was begun in 1890, Henry Peach Robinson, whose most important exhibition work was printed entirely in platinum, as was the portraiture of Frederick Hollyer, the atmospheric landscapes of Alfred Horsley Hinton, and George Davison, the genre studies of Frank Meadow Sutcliffe, and, from outside the fraternity, Peter Henry Emerson with his handsome volume of 40 platinotypes, *Life and Landscape on the Norfolk Broads*, printed in limited edition by James Valentine of Dundee.

By 1900, the platinum print had reached its zenith, widely acknowledged as the finest printing medium in the photographic repertoire; but its glory would prove short-lived: the First World War would transmute platinum into a strategic material, requisitioned for making explosives, rather than pictures. Photography's most beautiful and permanent of all processes enjoyed a commercial lifespan of only 30 years, but happily the tradition of the hand-crafted platinum print continues even today.

PLUMBE JR., JOHN (1809–1857)

"After having devoted nearly all our time, for upwards of three years, upon the U.S. transcontinental railroad—exhausting all our pecuniary means—we at last, after being laughed at as a madman, were obliged to resort to taking

daguerreotype likenesses, in order to keep up the soul of our undertaking, by supporting our body." John Plumbe, Jr., *The Plumbeian*, January 6, 1847.

John Plumbe Jr., a man of extraordinary ability and vision, was the pre-eminent promoter of photography in America during the 19th century and the first effective advocate for a United States transcontinental railroad. Plumbe was born at Castle Caereinion, Welshpool, North Wales, on July 13, 1809. His family was English and when John was twelve they immigrated to the United States. Trained as a civil engineer, he was quick to comprehend the importance of railroads to national development and passionately presented his idea for a Pacific railroad to Congress in 1838, a decade before others seriously considered the matter.

Plumbe first became aware of the wondrous daguerreotype process while in Boston during the Spring of 1840 where he probably received instruction from Daguerre's agent, François Gouraud. Turning to photography to finance his railroad ambitions, Plumbe helped to shape a developing industry. With unbounded optimism and tireless vigor Plumbe immersed himself in the new art and science to become America's first nationally known photographer. He attained this distinction by winning the highest honors in photographic competitions at scientific and industrial fairs. Plumbe was the first to introduce a franchised photographic business, establishing within six years a chain of twenty-six galleries in the United States with outlets in Paris and Liverpool, most of which were accessible by railroads. He advertised his business extensively in the leading American newspapers and furthered his reputation through brand name recognition, requiring all photographs from his numerous galleries to prominently bear the Plumbe name.

Beginning in Boston in 1840, Plumbe established the United States Photographic Institute and opened branch galleries or "photographic depots" as the railroad advocate called them. In addition to taking photographic portraits, Plumbe manufactured and imported cameras and offered complete daguerreotype outfits. He taught the first generation of American photographers including Gabriel Harrison, William Shew, and Samuel Masury. Plumbe's 1841 daguerreotype manual is the earliest published American photographic work. Pursuing an interest in color photography, Plumbe purchased from Daniel Davis Jr. in 1842 the rights to a patented process to apply color to daguerreotypes by selective electroplating and he promoted this feature extensively.

By 1843 Plumbe relocated the center of his photographic operations to New York City where many noted celebrities of the day frequented his fashionable Broadway establishment. Plumbe's New York gallery was filled with the likenesses of famous authors, artists, musicians, and entertainers, among them Washington Irving, Edgar Allan Poe, John James Audubon, and Tom Thumb. Many of these fine daguerreotype portraits were reproduced as lithographs by print maker Nathaniel Currier.

Plumbe opened a daguerreian gallery in Washington, D.C., late in 1844 where he photographed the leading statesmen of the day. On several occasions Plumbe received invitations to the White House from President James K. Polk and secured the first photographs showing the interior of the Executive Mansion, including the earliest portrait of a United States President with his Cabinet. In the Spring of 1846, Plumbe produced a series of architectural daguerreotypes of Washington, D.C., depicting the United States Capitol, the White House, the Patent Office and Post Office. These images, the earliest photographic records of Washington, D.C., are now preserved at the Library of Congress.

Toward the end of 1846 Plumbe established the National Publishing Company in Philadelphia and issued a series of decorative sheet music, "The Plumbe Popular Magazine," and a portfolio of thirty-four lithographs entitled "The National Plumbeotype Gallery." All of these works were illustrated with "Plumbeotypes," namely lithographs made from zinc plates transferred from Plumbe daguerreotypes. "The National Plumbeotype Gallery" is of particular importance as it represents the first collective collaboration of photography and print making for portraiture. However, the public did not favor Plumbe's ambitious publishing efforts and by mid-1847 he was forced to suspend all production and refocus his attention to the photographic business and his transcontinental railroad advocacy. John Plumbe suffered severe financial reverses during 1847–1848 due in part to the mismanagement of his vast enterprise and the significant increase of competition in the photographic field. By 1849 all of his fine establishments had either been sold to meet the obligations to his creditors, or had been transferred into the hands of his operators.

During the Gold Rush of 1849, Plumbe journeyed to California to determine first hand the feasibility of a Pacific railroad. Encouraged by his survey Plumbe continued to write, lecture and memorialize Congress for the construction of the transcontinental railroad. He returned to his family's home in Dubuque, Iowa, in 1854 where he opened a U.S. patent agency and a steam milling operation.

Suffering from physical and mental illness John Plumbe Jr. ended his eventful life on May 28, 1857. In 1976 a group of historians erected a monument at Plumbe's grave site extolling his contributions to photography; his genius for promoting photography in America was second only to that of George Eastman.

Clifford Krainik

Biography

Born in Welshpool, Wales, July 13, 1809, he immigrated to America age twelve and studied civil engineering. He advocated construction of U.S. transcontinental railroad in 1838. Plumbe turned to photography in 1840 to finance railroad advocacy and established twenty-six galleries in major U.S. cities between 1840 and1846. He manufactured and imported daguerreotype supplies in Boston and New York City. Plumbe was awarded medals at institute competitions in Boston, Philadelphia, and New York. He purchased patent rights for color daguerreotypes in 1842. Plumbe promoted brand name recognition and advertised extensively. He secialized in celebrity portraits in Washington, D.C., and New York galleries and established the National Publishing Company in Philadelphia in 1846.

Inventor of the plumbeotype process (lithographs from daguerreotypes), he took the earliest photographs of the U.S. Capitol and the White House in 1846. He suspended his photographic business, 1847–1849, and moved to California (1849–1853) where he continued to advocate for the transcontinental railroad. Plumbe committed suicide at Dubuque, Iowa, May 28, 1857. A monument was erected to Plumbe at the Linwood Cemetery in Dubuque in May of 1976. The first retrospective exhibition of his work was held at the Historical Society of Washington, D.C., 1997.

PLÜSCHOW, PETER WEIERMAIR WILHELM (1852–1930)

Italian photographer

Born Mecklenburg, Germany 1852. By the 1870s Wilhelm Plüschow had a photographic studio in Naples trading in studio portraits and occasional journalism. First cousin to Baron Wilhelm von Gloeden whom he assisted in turning his interest in photography into a business in Taormina, Sicily in 1888. By now both were photographing the male nude. Influenced by Gloeden's style, by the time Plüschow moved to Rome as 'Guglielmo Plüschow,' he was producing male and female nudes which gained a reputation throughout Europe and America for overt homoerotica. Much praised by the author John Addington Symonds who lived in Rome, Plüschow, along with his Sicilian assistant, Vicenzo Galdi (1856–1931), often avoided the more romantic trappings of Gloeden's classical props, in favour of realism, with an emphasis on the sexual promise of male peasant youth. Forerunners of Pier Paolo Pasolini (1922–1975) and his love of *ragazzi*, Plüschow and Galdi's overt depictions of potent male sexuality, many said pornography, landed both of them in trouble and Plüschow was forced to return to Berlin and obscurity in 1910. Even now, while Gloeden can still be read as the poetic homeric dream. Plüschow, with his once only photographed models in highly suggestive poses, still challenges and he rarely enters the directories. However he can be regarded as a pioneer of contemporary gay culture, perhaps in time more relevant than Gloeden.

ALISTAIR CRAWFORD

POITEVIN, ALPHONSE LOUIS (1819–1882)

French chemist and printmaker

Poitevin was born in 1819 in France. He contributed to several fields of photography. He took up the study of photography while still a student in the Ecole Centrale, almost immediately after Daguerre's process was published in 1839. He recognized the one great defect of this method is that it gives but a single photograph. He tried to solve that problem by trying to make molds by electrically depositing copper upon the silver plate carrying the daguerrean image. During this work he discovered a method of photo-chemical engraving upon plates coated with silver or gold. This discovery turned out, however, to be of no practical importance. In 1847 when working at the Eastern Salt Works he continued his work on trying to make copies of daguerreotypes on silvered copper. The details of these methods were published in two papers in *Comptes Rendus Hebdomadaires*

des Séances de l'Académie des Sciences (vols. 25 and 27, 1848), as well as in his book. In this case copper was deposited on the lights, fixed and covered with a solution of gelatin, which was allowed to set and dry slowly. Then it was stripped, carrying the copper deposit with it. In this way he was able to transform daguerreotype images into negatives from which prints could be made on silvered papers. Experience from this early work led him to his most important discovery, the photographic engraving technique, which happened in 1854.

Poitevin is recognized for establishing the basic principles of *photo-lithography*, *carbon printing* and *collotype printing*. In August 1855 he patented a helioplastic process, by which films of dichromated gelatin were exposed to light under a negative and then soaked in water, which resulted in a relief image from which a mold could be made. Mungo Ponton in Scotland had discovered in 1839 the effect of light on dichromates and William Henry Fox Talbot had in 1853 discovered that dichromated gelatin which had been exposed to light would allow greasy ink to adhere to it, although it repelled water. Based upon these facts Poitevin invented his new photo-lithographic processes: carbon printing and collotype printing. A negative was printed onto a tissue of pigmented gelatin and potassium dichromate that, when washed and transferred to a second sheet, produced a durable, rich shiny print. Carbon prints are noted for their permanence and their rich and glossy dark tones. The carbon print process reached the height of its popularity between 1870 and 1910.

His work in heliochromy started in 1865 with some experiments on the possibility of recording colors on paper coated with silver chloride, similar to the earlier work by Herschel and Becquerel. First it was necessary to obtain violet sub-chloride of silver before recording the images. To sensitize the paper for exposure he dipped the paper in a solution of potassium dichromate and copper sulfate and let it dry. When such a paper was exposed to light beneath a transparent colored picture, such as a painting on glass, the colors of the picture reproduced on the paper. The main problem with heliochromy of this type was how to fix the images. As a fixing solution, Poitevin used water with sulfuric acid and after that glazed the pictures with albumen, but permanent images proved impossible to retain. Specimens of the process were exhibited at the 1867 Paris exhibition.

In 1879 he described an iron printing process which was his last publication in the field of printing processes based on photographic techniques.

HANS I. BJELKHAGEN

Biography

Alphonse Louis Poitevin was born at Conflans, Sarthe, France, in 1819, and educated at St. Calais. In 1839 he went to Paris and entered Ecole Centrale des Arts and Métiers, leaving it in 1843 with a Civil Engineer Diploma. After the publication of the daguerreotype process in 1839, Poitevin took up the study of photography while still a student at Ecole Centrale. After his Diploma he was appointed engineer at Eastern Salt Works which he resigned from in 1855 to move to Paris to work on his printing process and to start a printing company. However, he was not that successful in business and he sold his patent rights to Lemercier, a well-know French lithographer. At this time Poitevin became a manager at Pereire's Chemical Factory in Lyon. From Pereire's factory he went to the glassworks at Ahun-les-Mines and then to those of Falembray. Later he spent some time in Africa at the mines Kefun Thebul. In 1869 he returned to France where he started to work at an alum factory in St. Germain Lambron.

Poitevin was awarded several medals and prizes, e.g., a silver medal by the Société d'Encouragement des Arts for his photo-chemical engraving method. For the discovery of the permanent photographic printing process he was awarded the Duc de Luyne's Prize of 20,000 francs and the Marquis of Argentil's Prize of 12,000 francs as well as the order of Chevalier of the Légion d'Honneur. Poitevin died at Conflans on March 4, 1882.

POLAND

Poland of the 19th century was divided up amongst three neighbouring countries: Russia had the Kingdom of Poland and Warsaw (i.e., the central area), the Austrian-Hungarian Empire had Galicia, Lwów and Cracow (i.e., the southern and eastern area) and the Prussian Kingdom had the Poznan part (the western area). After 1945 up to the present time, the Schlesien, Pommern and Ost-Preussen territories became part of Poland, however they were an integral part of Prussia during the 19th century. As in western Europe, the development of photography there depended on the demands of a society that was not as affluent as that of western Europe. It also depended on new technological methods being used in France and Germany. Initially, photographers used to travel to

Paris, London or Berlin to learn the trade, nevertheless after 1851 they travelled in order to study the collodion process. Unfortunately, most towns do not have any documentary archives, nor information on the number of photographic concerns nor how long they lasted.

Warsaw. From January 1839, frequent articles appeared on the subject of daguerrotype photographs; by October of the same year daguerrotype photographs sent over from Paris and Berlin as well as the work of the physicist, A. Radwański, were being exhibited. In November, a French revue was sold that included an article by M. Strasz discussing the daguerrotype process and A. Giroux's camera that had been brought over from Paris was sold for 1000 roubles. The bibliophile, S. Mielżyński, translated the revue in Paris and then sent it on to Posen, where it appeared in the press prior to November 13. In January 1840, a new translation was sold in Warsaw. The following people used daguerrotype photographs to enhance their work: the artists: M. Zaleski (1839–42) and A. Wysocki (1841–42); the astronomer: A. Prażmowski (1839) and the lithographer: M. Scholtz (1840–41), who from 1842 earned money on his daguerrotype photographs From 1842, itinerant daguerrotypists from Berlin and Vienna came to Warsaw. The most famous establishments were as follows: K. Beyer (1845–77) who produced scenes of Polish towns, catalogues exhibiting ancient and historical monuments and thousands of portraits; K. Brandl (1857–98) the creator of nature photographs; J. Mieczkowski (1850–1915) who took part in 9 exhibitions and who was awarded a prize for his portraits.The first photographic firms that were set up in larger towns were in: Częstochowa (1864, M. Arbus); Kalisz (1857, S. Fingeruth); Kielce (approx. 1858, W. Krajewski); Lublin (1857, T.Boretti); Łódź (1862, D. Zoner), E. Stummann from 1874 and B. Wilkoszewski from 1888 took photographs of towns; Piotrków (1865, K. Suplik); Płock (1864, P. Pawłowski); Radom (1860, L. Makarski).

Lwów, the capital of Galicia, discovered daguerrotype photography due to the work of Professor J.Gloisner. People could pay to have their portraits taken at H. Chołoniewski's and J. Pohlman's establishment (1843) as well as at Szarmacki and J.Dobrowolski's photographic firm (1844). E.Trzemeski (1869–post 1914) left the greatest heritage. In 1883 he took 20 photos related to Jan III Sobieski and scenes of Galicia (a gift for the Photographic Society in Paris in 1886) and produced albums of the following towns: Podhorce and Zloczów. In 1890 together with J. Eder he published a zincography. T. Szajnok, active from 1863 until his death in 1894, produced phototype samples which he sent to Paris in 1870, he published albums of the towns of Krasiczyn and Żólkiew in 1868–69 and in March 1891 helped to set up the first association of amateur photographers—the Amateurs Club. After 1861, J. Eder, published a series of photographs of Cracow, Przemyśl, Rzeszów, Rabka and railway train stations. Those that most frequently exhibited their works in western Europe, were: T. E.Bahrynowicz, J. Eder, Z. Goldhammer, N. Lissa and D. Mazur.

Cracow, the ancient capital of Poland, that was just a small provincial town in the 19th century, discovered daguerrotype photography in 1840 via the work of the physicist S.L.Kuczyński, in 1844 via the work of A.Wysocki, and approximately in 1850 the work of J.Schindler. Itinerant photographers were as follows: H. Wilczek (1843), J.W. Weniger (1851) and A. Weidl from Vienna (1854), K. Szczepkowski (1844–47), D. Zoner (1844,1847), I. Marek (1849,1856/57), Birnstein (1856), F. Gantenbein (1858). Most probably, the first permanent establishment was that of S. Żabieński (1845–52), then W. Maliszewski (1848–80), S. Balicer (approx. 1848), I. Mażek (1860–63) and Ignacy Krieger with his son Natan (1860–1926), who after 1870 produced 113 photographs of historical monuments, peasant types and Stachowicz's drawings and sold them in four sizes. The most famous firm was that of W. Rzewuski (1859–96) who focused on wealthy people, town scenes and works of art. A. Szubert from 1867 took photos of the surrounding countryside of Cracow and also concentrated on various works of art; he was awarded many prizes at a number of exhibitions. Manuals began being published in Cracow: A. Karoli (1893), W. Kleinberg (1894) and A. Larisch (approx. 1902).

The Tatra mountains and its inhabitants, a 110 kilometers south of Cracow, were photographed by: A. Szubert (from 1871), W. E.Radzikowski (1891–99) and M. Karłowicz (after 1902). In the spring of 1871, the members of the Association in Berlin organized an excursion to the Tatra mountains, and in 1872 their chairman, H.W. Vogel, took a number of photos there. Photographers tended to limit themselves to portraits in the other towns of Galicia. After 1870 some firms opened up but there were very few of them. There were two famous photographers from Kamieniec Podolski namely J.Kordysz (approx. 1860–71) a member of the French Society of Photographers who exhibited town scenes and peasant types at their exhibition of 1863 and M.Greim, who subsequently bought his firm and continued with his activities. Polish people were a majority in the area where Poznan was the capital. From 1842 various photographers worked there namely: J.T. Willnow from Berlin and Tuch from Hamburg. The first permanent establishment was that of B. Filehne (1844–approx.1880). The family of A. Zeuscher produced the greatest number of photographs of Poznań inhabitants (1857–1915). After the revolution of 1863/64 many emigrant Poles earned a living from photography: C. Mietkiewicz and N. Straszak in Brussels, W.Ostroróg "Walery" in Paris, J. Kordysz in Kiev, J. Migurski in

Odessa, J. Berkowski in the Kingdom, W. Malinowski in Riga. Amateurs: L. Barszczewski in Central Asia, J. Kozłowski in Suez, J. Potocki in Africa, J. Stróżecki, R. Szwoynicki, L. Kraszewski and others in Siberia. There were about 35 in France and approximately 60 photographers in Berlin who had Polish surnames. A large percentage of photographers were of Jewish origin.

Schlesien. This was a very industrialized region with numerous wealthy towns and bourgeoisie that made the most of their photographers. I have a list of approximately 210 daguerrotypists and itinerant photographers prior to 1860 in Schlesien. 19 originated from Berlin and 38 were from Breslau (Wrocław), its capital. Here, amateur photographers, K. Langhans and T. Goldamer, exhibited daguerrotype photographs at the art exhibition of 1840. In 1844, the mechanic, Karl Staritz, took daguerrotype photographs, and from 1846, E.Wehnert earned his living from them. H. Krone was born here and taught the daguerrotype process, he was known for his activities in Dresden. The most prolific, with thousands of architectural photographs were made in the establishment of E.v. Delden (1877–97), a Berlin man. A.Leisner from 1876 covered the surfaces of porcelain dishes with photos from the surroundings of Waldenburg (Wałbrzych).

Pommeren. The area including the Baltic coast line, with two ancient and wealthy ports. Danzig, where monuments were first photographed by C. Damme (1850). In 1858, E. Flottwell sold a series of 8 photographs of the town and 23 photographs in connection with the 300th anniversary of the grammar-school. The following photographers printed their own photographs of monuments: R.Fischer (approx. 1870), A. Gottheil (approx. 1860), R.T. Kuhn (approx. 1894) and H. Ruckwardt (1889). The most famous ones in Stettin were the following: E. Kiewning, L. Klett, A. Pauly.

POLICE PHOTOGRAPHY

The emergence of photography in the nineteenth century coincided with the introduction and professionalization of the police. In 1800 the world's first professional police service was established by Act of Parliament in Glasgow, in response to the failure of the city's old system of employing unpaid constables and hired watchmen to keep law and order over the expanding population. Other industrialised British towns experiencing similar rises in criminality quickly followed suite. In 1829, just a decade before the public announcement of the daguerreotype, the Metropolitan Police Force (The Met) was founded in London. The Met, the first civil police force organized on modern lines, provided the model for other early municipal police forces around the world, including in Gibraltar (1830), Toronto (1834), Boston (1839), and New York City (1845).

Nascent law enforcement agencies soon recognised the value of photography for identifying criminals. From as early as 1841 in France, and over the next decade in other Western Europe countries and the United States, police forces paid professional daguerreotypists operating in the vicinity of their stations, to take portraits of suspects. Ambrotypes mounted in ornamental frames, dating from the late 1850s and 1860s in the collection of Birmingham's West Midlands Police Museum show how closely early police photographs resembled regular commercial studio portraiture. By the 1870s their format and conventions were gradually adapted to police requirements. Offenders were photographed against plain backgrounds, posed frontally—sometimes with a mirror to simultaneously show their profile—and often holding a board on which was written their name and detention number. Attention was directed towards their hands—placed on their chest—which were considered useful for identification purposes. The photograph illustrated a paper record documenting further details including name and aliases, date and place of birth; marital status, occupation and address; vital statistics and distinguishing features; reason for conviction and sentence.

From the mid-1850s, with the technical advances in the positive-negative system of photography and the diffusion of the carte de visite, the practice of creating and disseminating portraits of criminals became more widely used. Photographically-illustrated criminal records were sorted and classified according to offence committed in albums and card indexes. In America these 'rogues' galleries' were often displayed in a grid—on purpose-made boards or racks—in police stations. As the number of records grew, sorting, classifying and, particularly, retrieving an individual's details became increasingly impractical.

In 1856 the journalist and critic Ernest Lacan (1829–79) advocated the wider use of portrait photography by the French police for checking recidivists and escapees. However, his suggestion for the systematic use of the medium to apprehend criminals was not adopted until the 1870s. Following the violent repression of the Paris Commune of 1871, the Parisian police used photographs taken by the Communards of themselves posing proudly and defiantly on their barricades or triumphantly beside the destroyed Vendôme Column, to track down and punish the insurgents. In addition, Eugène Appert (active

1870s) took individual photographs of those incarcerated in Versailles for the police, prefiguring the format and practices adopted by the studio established in the Paris Police Department in 1872—the first official photographic service to be set up in a police station.

In 1888 Alphonse Bertillon (1853–1914), who had begun his career as a record clerk in the Paris Police Department, became Director of its Identification Bureau due to his invention of anthropometry—the first scientific system of criminal identification. The system, named *bertillonage* in his honor, consisted of recording eleven measurements of set parts of the head and body on a card which, accompanied by two photographs and additional physical details such as eye and hair color, established a unique, classifiable and, most importantly, retrievable criminal record. Replacing the unreliable system of eyewitness accounts, in 1882 *bertillonage* had led to a marked increase in the number of arrests of multiple offenders and was subsequently adopted by police departments outside of France, such as New York City (1888), Argentina (1891) and Chicago (1894). Since bertillonage used photographs in the process of identification, in 1888 Bertillon annexed the préfecture's photography studio to his own department and introduced a strictly uniform photographic technique to complement the system's precision. Bertillon stipulated the standardization of lighting conditions, exposure time, distance from the subject, pose and scale of reduction, ensuring that a clear full face and profile portrait—a mug shot—appeared on each identification card. He also created the *portrait parlé*, an identification chart of sectional photographs of facial features, such as ears and noses, mounted side by side to enable comparison and contrast.

Photography also played an important role in the solving of crimes, by identifying and documenting clues as well as people. Although not widely accepted as evidence in a court of law until the end of the nineteenth, forensic photography was used from the late 1850s to discredit forged documents (*Luco et al. v. USA*, 1859), record crime scenes (Lausanne, France, 1867), including traffic accidents (*Blair v. Inhabitants of Pelham, USA*, 1875) and provide evidence of injuries (*Redden v. Gates, USA*, 1879). Bertillon contributed greatly to this field by devising metric photography—the inclusion of a measuring scale in photographs to provide a permanent record of the scale and relationship between objects at a crime scene. He also developed contact methods of photography which he used for reproduction and enlargement of admitted or questioned documents, most famously *le bordereau* in the case of the Dreyfus Affair for which he submitted evidence for the prosecution in 1894. Soon after the turn of the century bertillonage was supplanted by the more reliable system of dactyloscopy or identification by fingerprints. Ironically, this change of method caused a growth in the number of specialized police photographers as it increased the need for records to be made of impressions of finger and handprints found at crime scenes. This practice, of which examples can be found in the Archives Historiques et Musée de la Préfecture de Police, Paris, was initiated by Alphonse Bertillon in the 1880s.

Photographs of criminals were also adopted outside the judicial system. In the 1860s c*artes de visite* of notorious villains were sold to the public, satiating popular fascination with deviancy and abnormality and prefiguring the celebrity status accorded to gangsters in 1930s America. In the 1870s police photographs were subjected to statistical analysis in order to identify a criminal 'type.' These investigations were underpinned by the pseudo-sciences of physiognomy and phrenology, a belief in the correlation between an individual's internal character traits and their facial features or shape of head. Italian criminologist Cesare Lombroso (1835–1909) assembled a collection of photographic portraits of murderers in the hope of discovering clinical signs of disposition to criminality. Meanwhile in Britain, influenced by the evolutionary theories of his cousin Charles Darwin, British biostatistician and eugenicist, Francis Galton (1822–1911) devised a new system of physiognomic record to show the features common to violent criminals, felons and sexual offenders. Galton created 'composite portraits' by re-photographing pictures of prisoners on the same plate by successive multiple exposures to create a photographic 'mean.' Although the notion of the 'born criminal,' who can be recognized by certain physical traits, such as a low forehead, 'jug ears' and large jaw, is now considered incorrect, it continues to influence representations of criminals in popular culture.

POLLOCK, ARTHUR JULIUS (1835–1890), HENRY ALEXANDER RADCLYFFE (1826–1889), AND SIR JONATHAN FREDERICK (1783–1870)

English

Baron Pollock was Lord Chief Baron of the Exchequer and succeeded Sir Charles Eastlake as second president of the Photographic Society from 1855 to 1869. Sir Frederick insisted that photography should be called a practical science rather than an art and we have him to thank for suggesting that the society should form a permanent collection. He married twice and had a very large family. Henry was the eleventh child from his first marriage, Julius was the thirteenth and the first son of his second marriage. Like their father, both sons were members of the Photographic Society of London.

Henry was educated at Trinity College, Cambridge and became Master of the Supreme Court of Judicature. He published 'Directions for Obtaining Positive Photographs upon Albuminized Paper' in the Society's Journal in1853 and a glycerine process for dry-collodion plates in 1856. As well as conventional half-plate prints he produced stereo images and there are thirteen examples in the Getty Collection.

Both brothers photographed at the family home Hatton, west of London and in North Devon. The half-brothers were obviously close and in 1860 Henry married Amelia Bailey from Lynton in North Devon and Julius married her sister Ellen a year later.

Julius was educated at Kings College, London, and trained as a physician. He made photographic studies of people with deformities and an album of his work is in the collection of the Royal College of Medicine.

IAN SUMNER

PONTI, CARLO (c. 1822–1893)

Optician and photographer

Carlo Ponti, optician and photographer, was born in Sagno in the Canton Ticino around 1822–1824. As an adult he moved to Paris, where he worked in the Cauchoix studio for about five years. He then moved to Venice for good in 1852 and opened a little optician's shop in piazza San Marco 52. His high quality products soon made him famous throughout the Veneto province, and for many years he had sole rights on some of them. He began to expand in many directions, working as an optician, or creating and built instruments for astronomy and physics and photographic lenses (especially for panoramic shots). He sold his own creations, as well as those of other companies; and was a photographer, editor and distributor of photographic prints, both his own and others. Thus he was a versatile personality, informed and attentive to scientific innovations, the demands of the market and progress in know-how in the field of photography. He enlarged his store, and his clientele and sales grew. He became famous, and obtained various forms of recognition: on 30 May 1854 he was awarded a silver medal for photographic equipment, lenses in particular, at the Esposizione Industriale Veneta (industrial exhibit for the Veneto province). In the same year he started to photograph Venice with a systematic thoroughness, and in 1855 he already had a catalogue of 160 photographic views of Venetian architecture (*Guida fotografica illustrata della città di Venezia*), each with a historical and aesthetical caption. An introductory text goes through the evolution of Venetian architecture. Ponti presented the work at the Universal Exhibition in Paris in 1855 as a photographic history of the various architectural styles typical of the city, and he won a prize for it. His multifarious career made it necessary for him to collaborate with different people, like Francesco Maria Zinelli and Giuseppe Beniamino Coen. He also worked with the most important photographers in Venice, like Carlo Naya (1816–1882), Domenico Bresolin (1813–1899), and Antonio Fortunato Perini (1830–1879). Domenico Bresolin, painter and photographer, studied at the Accademia di Belle Arti in Venice. Ever since the 1850s, he had concentrated his efforts in the calotype process, doing important views of the monuments of Venice. His photographic prints, which he also did as albumen prints, are among the best in the period in terms of their definition and the quality of the printing. In 1864 he obtained the chair in landscape at the Accademia (the position had formerly been held by Francesco Bagnara), and stopped taking photographs. In that year, Bresolin handed over his studio and archive to Carlo Ponti, who then distributed the other photographer's images with the "Ponti" stamp, thus creating quite a few attribution

problems. Ponti then handed Bresolin's studio over to Giovanni Brusa. Antonio Fortunato Perini collaborated with Carlo Ponti after 1854, and he probably did some of the photographs in the catalogue Ponti presented at the *Exposition Universelle* in Paris in 1855. Perini was among the first to open a photographic studio in Venice and to spread the albumen print technique. He was especially concerned with the photographic reproduction of the manuscripts and miniatures in the Biblioteca Marciana.

Carlo Naya opened his photographic establishment in Venice in 1857. He worked with Ponti from that time onwards, furnishing Ponti's shop with photographic prints which were often pubished by Ponti with his own trade mark, and, as in the case of Bresolin, considerable confusion occurred in this case, too. Together with Ponti, he also published several albums of views, among which were the *Vedute di Venezia*, which came out the day after the Veneto was annexed to Italy in 1866.

Ponti did his photographs between 1854 and 1875. He took shots not only of Venice, but also of other places in northern Italy, and, between 1860 and 1865, Rome. He published other catalogues of his works, the *Catalogo di fotografie delle principali vedute* in 1864 and, in 1872, the *Catalogo generale delle fotografie*.

In 1860, he created a special viewer for large format photographs, the *Aletoscopio* (from the Greek: "precise view"). In 1861 he presented it to the Société française de photographie and, on 14 April of the same year, to the Istituto di Scienze, Lettere ed Arti in Venice, where he earned honourable mention in May. On 11 January 1862 Carlo Ponti obtained sole rights for his invention and began to sell it. Later, he created different variants, like the Megaletoscopi*o*, a bigger version of the Aletoscopio, which he had finished in 1862. For the new invention, he was awarded the Grand Prix at the Great International Exhibition in London that year. He registered the trade mark on 10 July of the same year, entrusted the manufacture of the apparatus to the cabinet maker Demetrio Puppolin and then promoted sales. He also made a special version of the Megaletoscopio, the Megaletoscopio privilegiato, to see slightly curved photographs. Both the Aletoscopio and the Megaletoscopio—and their variants—made it possible to see the same images enlarged by lenses, and with two different effects: the "day effect," with reflected light, and the "night effect," in transparency. In this last case, the photograph was reinforced on the back by other sheets of paper painted in different colours and pierced with little holes. The whole, illuminated from the back, changed the colours and light of the positive image, creating a "night effect."

In 1866 Carlo Ponti became the official photographer of His Majesty Vittorio Emanuele II, when the Veneto became part of the Italian nation. His growing business enabled him to open branches in other cities: Paris, London, Liverpool, Berlin, Stuttgart, Lyons, New York, Chicago, Philadelphia, Boston, Montreal, and San Francisco. At this time Ponti lost sole rights on the sales of the Aletoscopio and its variants because of the administrative uncertainty in which the Veneto found itself in the years following the annexation. In fact, an apparatus now housed in the Musée Suisse de l'Appareil Photographique in Vevey bears the trademark of Carlo Naya, who, copying Ponti's models, had begun to manufacture and sell the Aletoscopio. This initiative got him involved in a long legal battle in 1868, and Ponti used every means he could to get Naya sentenced. From 1868 onwards, then, the collaboration between the two photographers stopped. Until 1876 Ponti tried to get back sole rights on his creation, but without any success. He made, however, countless variations on his first apparatus, and gave them highly original names: Amfoteroscopio, Dioramoscopio, Pontioscopio, Cosmorama Fotografico are only a few examples.

The invention of the Aletoscopio must be placed together with those inventions that, slowly and well before the 19th century, led from the static image to the image as something with movement, and, to cinema. Ponti played an active part in this story, from the moment that stereoscopic photography began to be widespread and the subsequent experiments that increasingly expanded the potential range of expression of photographic images.

Carlo Ponti died in Venice on 16 November 1893; he was blind by that time, but had spent many long years of his life in a profession he had taken up out of passion and honesty.

The Museé Suisse de l'Appareil Photographique in Vevey houses an exemplar of the Megaletoscopio, accompanied by twenty albumen prints attributed partly to him and partly to Carlo Naya. More of his photographs are in public and private collections (Fototeca della Soprintendenza per il Patrimonio Storico, Artistico e Demoetnoantropologico, Brera, Milan; Museo di Storia della Fotografia Fratelli Alinari, Florence; Dietmar Siegert Collection, Münich; Wilfried Wiegand Collection, Frankfurt am Main; Department of Photography, J. Paul Getty Museum, Malibu).

SILVIA PAOLI

Biography

Carlo Ponti was born in Sagno (Canton Ticino) sometime between 1822 and 1824, and died in Venice on 16 November 1893, by which time he was already totally blind. At present, research has not turned up very much about his life or training. We only know that he went to the Cauchoix studio in Paris for five years, studying as an optician and photographer. He set up residence in

Venice, where he worked as an optician, photographer and publisher of photographic prints, but he never gave up his Swiss citizenship. He soon became rich and famous, and this led him to open branches of his firm in Paris, London, Liverpool, Berlin, Stockard, Lyons, New York, Chicago, Philadelphia, Boston, Montreal, and San Francisco. He showed his photographs and the lenses and apparatuses he invented at the main exhibits of the time: Venice 1854, Paris 1855, London 1862. He became famous through his invention of a special instrument for viewing enlarged photographic images, the *Aletoscopio,* and he created various versions of it. He published several catalogues of his images in 1855, 1864, 1866, and 1872. Ponti was a well-read, multifaceted personality, and was always interested in the latest scientific and cultural developments of his time.

PONTON, MUNGO (1801–1880)
Inventor and polymath

The Scottish lawyer Mungo Ponton was the inventor of a photographic process that was to lead to developments that would have a huge impact on the visual culture of the nineteenth century and beyond through the mechanical reproduction of photographic images.

The announcements in January 1839 by Louis Jacques Mandé Daguerre and William Henry Fox Talbot of the discovery of photography created a ferment of interest in Edinburgh, Ponton's home-town. Edinburgh had just gone through a period of intellectual prominence, known as the Scottish Enlightenment, which had seen a flourishing in the arts and sciences and many gifted and able scientists were keen to experiment with the new discovery. The meetings of the Society of Arts for Scotland, which had been founded by Sir David Brewster in 1821, was the forum for discussion of the invention of photography in the months following the announcements of Daguerre and Talbot.

Ponton had began experimenting with Talbot's process and this was when he made his remarkable discovery, which he presented to a meeting of the Society of Arts for Scotland on 29 May 1839. His paper was titled "Notice of a cheap and simple method of preparing paper for Photographic Drawing, in which the use of any salt of silver is dispensed with." What Ponton had discovered was the light sensitive qualities of potassium dichromate. This was to be the basis of many mechanical means of the reproduction of photographs and of producing permanent images.

Ponton had found that a piece of paper soaked in potassium dichromate was sensitive to light and an object place on the surface would leave an outline with gradations of tone "according to the greater or less degree of transparency in the different parts of the object." Fixing was simply a matter of washing in water when those portions which had been acted on by the light readily dissolved and those exposed were completely fixed. Ponton did acknowledge that the process was not sensitive enough to be used in a camera.

It is not known if Ponton realised that the potassium dichromate solution he was using was combining with the gelatine used to size the paper to create the chemical reaction. However, of particular importance for the development of Ponton's process, and its use in future printing techniques, was that he did not try to patent his discovery but on the contrary made it available and it was published in the *Edinburgh New Philosophical Journal* in July 1839 and widely reproduced.

Those who experimented with Ponton's discovery included Talbot, Edmond Becquerel, Alphonse Louis Poitevin and John Pouncy, who all took out patents for the processes they developed. Talbot in particular appreciated the important part played by gelatine. Joseph Swan also patented his carbon process and later recalled that his first attempt at photography was after reading about Ponton's process in a weekly journal and that he was not slow to grasp the underlying principle. In 1840, at the age of seventeen, M Carey Lea, who was to become one of the leading American photographic scientist in the nineteenth century, used Ponton's process to produce a series of photogenic drawings. The album of these is in the Franklin Institute, Philadelphia.

Ponton deserves the accolade of a pioneer of photography although he left it to others to exploit the use of potassium dichromate and the processes that were a

direct consequence of Ponton's discovery include; gum bichromate, carbon printing, photogravure, Woodburytype, Autotype and collotype. The mechanical production of photographs made them widely available and easily accessible with a huge impact on visual culture up to the present time.

The potassium dichromate process was not Ponton's only involvement in photography. In March 1840 he reported to a meeting of the Society of Arts for Scotland that he achieved a daguerreotype image on lithographic stone. In 1845 he won the Society's silver medal for his process on how to register the hourly variation in temperature on photographic paper. (He had already received a silver medal in 1838 for his improvements to the electric telegraph.) Also in 1845 he described a variation of the calotype process for portraiture allowing shorter exposures.

No known photographic images by Ponton are known to exist although these must have been produced in the various processes he used. Various items belonging to him, comprising drawings and publications as well as a photograph of him, aptly a carbon print, and a portrait oil painting by Samuel Mackenzie, are in the Scottish National Photographic Collection at the Scottish National Portrait Gallery, Edinburgh.

The combination of a busy business life and his amateur scientific experimenting took a heavy toll and Ponton's health and he suffered a major breakdown in about 1845. He had to retire from his legal work and by 1846 had moved to the milder climate of Clifton, Bristol, England, where he was to remain until his death. He was more-or-less an invalid for the rest of his life and much of the time he was house-bound, describing himself in correspondence as a "close prisoner." However, his physical limitations did not effect the activity of his brain. He had become a Fellow of the Royal Society for Edinburgh on 20 June 1834 and presented papers on polarisation and micrometry. He subsequently devised a photometer and presented a paper about this to the Society in 1856. In 1859 and 1860 Ponton presented papers to the British Association for the Advancement of Science on the laws of chromatic dispersion and the wave-lengths of the solar spectrum. He contributed articles to various journals and was responsible for a number of publication on scientific and religious themes including a mingling of the two. The titles were: *The Sanctuary—Its Lessons and Worship (*1849), *The Material Universe: Its Vastness and Durability* (1863), *The Great Architect; as Manifested in the Material Universe* (1866), *Earthquakes and Volcanoes* (1868), *The Beginning: Its When and Its How* (1871), *Glimpses of Future Life* (1873), *Songs of the Soul: Philosophical, Moral and Devotional* (1875) and *The Freedom of the Truth* (1878). In *Songs of the Soul* there is hymn "Praise God who roused the quivering light" which is a celebration of photography.

RODDY SIMPSON

Biography

Mongo Ponton was born at Balgreen, Edinburgh, on 20 November 1801, the son of a farmer. After his schooling, most likely at the Royal High School of Edinburgh, he became a legal apprentice and on 8 December 1825 he was admitted to the Society of Writers to the Signet, an ancient legal fraternity dating back to the fifteen century. Ponton showed commercial acumen as well as scientific innovation and was a founder of the National Bank of Scotland and became its secretary. On 24 June 1830 Ponton married Helen Scott Campbell, the daughter of the brewer, Archibald Campbell. The couple had seven children: Elizabeth born on 8 April 1831, John on 20 March 1832, Archibald Campbell on 9 June 1833, Alexander Campbell on 30 September 1834, Mungo Stewart on 31 August 1836, Bethia Katherine on 28 July 1838 and Matthew Moncreiff on 19 March 1841. Ponton's first wife died on 7 August 1842 and on 7 November 1843 he married Margaret Ponton, to whom he may have been related, the daughter of Alexander Ponton who was a solicitor. A son, Thomas Graham, was born on 28 August 1844. Ponton married for a third time on 1 August 1871 when his bride was Jane McLean the daughter of an Edinburgh merchant.

Ponton died at his home 4 Paragon, Clifton, Bristol on 3 August 1880. Of his children, John became a newspaper editor in the United States while Archibald became a prominent architect in Bristol and inherited at least some of his father's interest in photographic experimentation. In 1908 Archibald won the silver medal at the Tunbridge Wells Arts and Crafts Technical Photographic Section for the discovery of Autochromatic Shadow-Graphs.

PORNOGRAPHY

Origin, production, and market

Pornography is the presentation of the nude body, or of sexual behaviour designed to arouse the viewer's excitement. The tradition of pornographic images can be traced back to the first-century fresco found in a Pompeii brothel. In the nineteenth century, the invention of photography provided an unprecedented realistic quality, and it was not long before this invention was adopted to represent nude figures, for the purpose of academic study or of erotic pleasure. Pornography as a genre shares many common features with two other categories, viz. erotic photography and photographs of the nude, and the attempt to clearly differentiate them has proved extremely difficult, for the realism and indexical quality of photography have broken down the division between the transcendental and the transparent, undermining the legitimate status of the naked body in visual presentation. In the endeavour to define these genres, the aesthetic quality presented in the pictures and the purposes behind their production can serve as important criteria: while nude photography displays the ideal beauty of the human body (whether successfully or not) and closely allies itself to academic art, erotic photography is intended to elicit sexual responses from the viewer, while avoiding an explicit presentation of the sexual act. In the genre of pornography, sexual scenes and the explicit display of bodily private parts become indispensable themes, and the aim is the gratification of the viewer's psychological and physical pleasures. Such pictures have proved to be disturbing to many viewers and, as Martin Myrone suggests, while erotic art is regarded as realistic, concerned with love, and of supreme technical excellence, pornography is considered to be crude (in its means of expression), unreal, brutal, and ugly (Myrone 2001, 31).

Even if pornography is assigned to a different category from nude and erotic photography, the three genres were initially difficult to separate, and they may actually come from the one original source—nude photography. In 1841 Lerebours opened a studio in Paris, advertising the first photographic nude under the name of 'academies' thus is considered as the first nude photographer. The period following1845 witnessed the blossoming of nude photography produced by professional studios. Owing to the controversial nature of this art-form, many nude pictures remain anonymous, and they are difficult to date precisely. Furthermore, only a small number of photographers are known for their erotic or pornographic production: Auguste Belloc, Bruno Braquehais, Felix Jacques-Antoine Moulin**,** Giacomo Caneva**,** Jean-Louis-Marie-Eugene Durieu**,** Julien Vallou de Villeneuve**,** and Louis Jules Duboscq, have produced commercially-oriented erotic and pornographic photography.

Continental countries such as France, Italy, and Holland, being more tolerant of obscene images than Victorian Britain, have been the major suppliers of these images, and Paris became the unchallenged centre of the erotic photography industry, exporting its product throughout Europe. For wealthy tourists, Paris provided easy access to browsing obscene, bawdy, and pornographic works. Certain studios in Paris would accept commission from customers to make nude photographs according to their special requirements. Daguerreotype nudes could be bought in opticians or from street vendors around a certain area (e.g., the Palais Royale in Paris). As for the more explicit, pornographic images, the luxury brothels in both Paris and London were the venues where these could be acquired. The prosperous pornography industry was, however, by no means given the seal of official approval. Distributors of pornography had to perform their activity discretely to avoid police interference. Regulations against, and censorship of, pornography were suggested and implemented from time to time. In Britain, Lord Campbell, recognising that pornography was a cause of social disorder, proposed the Obscene Publication Act in 1857, in the hope that the production and distribution of pictorial and literary pornography would be brought under control. In France, the authorities tried to draw a line between academic study of the nude and pornography. Nude photography could be sold, under the title of academic study, but only within the walls of the Ecole des Beaux Arts. The so-called soft-core erotica could be openly sold, but its legality was based on ambiguous guidelines, and the vagaries of the government censors decided whether it was pornography or not (Godeau 1986, 94).

It is difficult to say exactly how many erotic and pornographic pictures were made during the nineteenth century, since this production was underground and not officially recorded. Nonetheless, the mass production and wide market can be gauged from reports of several police raids of 'dirty photos.' One of the most famous cases is the raid made on Henry Hayler at his Pimlico studio in London. As the *Times* court report of April 20, 1874, pronounced, the police seized

> no less than 130,248 obscene photographs. Mr. Collette said the defendant had been for years engaged in this traffic. Hayler and his wife and family were themselves represented in the photographs. The man went round to dealers with miniatures photographs numbered, and they were ordered of him in large and small quantities.

Across the Atlantic, around 194,000 obscene photographs, together with 5,500 indecent playing cards, were seized by Anthony Comstock, a special agent of the US Post Office, in 1873–74 alone.

Although the market of pornographic pictures proved to be large, in the early years the audience was limited to the upper-middle class, owing to its rather high price.

For example, a tinted erotic stereograph plate cost some 20 francs, and explicit scenes would cost more, while the average daily wage of a worker in the 1850s was around 3 francs (Richter 1989, 88). Daguerreotype pornography was often exquisitely hand-coloured, exhibiting careful arrangement of lighting and the model's pose. Together with the singularity of each plate, such a daguerreotype was designed as a personal deluxe item to be enjoyed by the privileged.

In order to meet the growing demand and to expand the market further, the photographers of the period were inspired to produce less expensive stereoscopic cards on salted paper, which is more commercially attractive than daguerreotype nudes. Notwithstanding, it was not until the 1880s and the appearance of a new, cheaper format of pornography—the postcard—that the working class generally gained access to pornography. Unlike stereoscopes, postcards require no special viewing apparatus. They are financially affordable, even to the poor, and have the ability to communicate through their images and the written messages they carry simultaneously. For the first time, the working class became consumers rather than merely objects of pornography (Sigel 2000, 860).

Style and Model

Nineteenth-century pornographic pictures share great similarities in terms of their composition and style. This may be due in part to the rather narrow subject-matter, which is mostly of a secret, sexually allusive nature. A female model is often placed in the setting of a private bedroom or toilet, photographed as if she were caught in the process of undressing or, in some more explicit pictures, displaying her private parts and caressing herself in a sexually arousing way. A large dressing mirror is commonly used in the setting; not only is it a necessary furnishing in such a room, it also performs the function of reflecting more of the model's body to the viewer. Feminine items such as jewellery, flowers, drapery, and lace also serve as indispensable decorations on the model, enriching the picture with details and also providing a vivid contrast of texture from the naked flesh.

Pornography that shows explicit sexual activities largely follows the mode already present in graphic art. Images of coitus, oral sex, and masturbation appearing in pornographic photography could all be found in earlier and contemporary prints. Nevertheless, the technique of photography does influence the mode of representing sexual scenes and requires certain necessary modifications, therefore resulting in a repertory of pose, which becomes in a sense more limited (Godeau 1986, 96). For example, while the traditional pornographic print had displayed sexual activity, photographic pornography would show a fragmental part of the woman's body or the detailed, focused presentation of intercourse of man and woman. Such depiction of a fragmental body rather than of full-scaled sex in action is the result of the long exposure-time required by early photography. In some cases, photographers adopted a serial format to present sexual activity in progress and provide it with a storyline: for example, a French pornographic 'Wedding Series,' presently held in the Kinsey Institute's archive, shows the newly-wed couple undressing, caressing each other, and having sex, in three continual pictures. The viewer would therefore observe these pictures with the anticipation of watching a drama. As Linda Williams argues, such continuum pornography attempts to render the "truth" of sex not as an exhibitionistic pose but as an act (Williams 1995, 27). Later in the century, with the development of more instantaneous forms of photography and shorter exposure lengths, the models would appear to be literally 'caught in the act' (Williams 1995, 31), and such sexual acts gradually became a staple of photographic pornography.

Beside the sexual act between man and woman, gay or lesbian sex constitutes a smaller, but undeniably significant aspect of the pornographic repertoire. To the heterosexual viewer, such gay porn not only provides a deviant sexual spectacle, but also violates the patriarchal order by blurring the boundary between the active/passive, male/female divide which is often presented in heterosexual porn. To modern researchers, gay pornography of the nineteenth-century suggests a new way to understand contemporary sexuality, as will be discussed below.

Pornography and Its Spectatorship

Although the proliferation of mass-produced pornography in the nineteenth century has been acknowledged, it was not until the 1960s, when there emerged some alternative views about Victorian values, many of them of feminist origin, that these 'dirty photos' begin to receive serious attention. To researchers, pornography seemed to open a new path to understanding nineteenth century histories, especially those of society, gender, sexuality, class, and even colonialism. Among these, the long-held impression of prudent Victorians in sexual denial was questioned from time to time, through the study of pornography and other unearthed literature. It is suggested by Steven Marcus in his *The Other Victorians* that these materials evince the dark Freudian underside of Victorian values, or as Michel Foucault proposes in his *History of Sexuality*, paradoxically constitutes a part of the vast apparatus of production of sexuality.

On the other hand, when the history of pornography itself is concerned, the indexical, excessively realistic quality of photography has made these pornographic pictures quite distinct from pornography in traditional formats such as print or painting. In Abigail Solomon-

Godeau' s view, such images do not represent an extension of an existing tradition of erotic and pornographic images, but rather constitute a whole new genre, one made possible only with the invention of photography and the new status of the photograph as trace of the real (Godeau 1991, 229). As such, previous ways of reading images are no longer sufficient, and the demand arises for novel approaches to supply interpretation for this new genre. Some have tried to study these images in the light of feminist film theory, focusing on the key role of the spectator in the whole operation and production of pornography. This is not only because much of pornography's arousing effect is achieved in the eyes of the viewer—which explains in part why the separation of erotic pictures from dirty ones is often a controversial issue—but also because the spectator is regarded as directly exercising his active power over the female object as the result of photographic technology, which seemingly provides the real presence of the woman's flesh. When it comes to stereoscopic porn, the secretive voyeurism and the sensational tactile illusion offered by the apparatus enhance the visual pleasure even further, and the objectification of the woman's body becomes inevitable.

There are yet other ways of viewing nineteenth-century pornography where the spectatorship is concerned. Some theorists are not satisfied with the fact that the viewer is homogenised as an active and masculine master in male-gaze theory, recognising that there are impasses in the theory which would handicap the study of other important audiences of pornography, such as the female viewer. Although women were unlikely to be the targeted audience of pornography, wide dissemination made it impossible for them to avoid the sight of pornographic images. Upper-middle-class women seem to have had ready access to pornography, and with the emergence of pornographic postcards from the 1880s, even working-class women could afford a sexual spectacle if they so wished. Such an 'unnatural,' outrageous scene of woman looking at pornography, and even sharing the male attraction to pornography, has proved especially disturbing. According to Walter Kendrick, this historically new phenomenon of woman as porn observer may well have been the real cause of the alarm felt by moral defenders, which triggered a series of trials and regulations on obscene materials, both in France and Britain. In the contemporary study of nineteenth-century pornography, however, the significance of the female spectator and her relationship to these images is surprisingly ignored. Williams suggests that the omission may be ascribable to the dominance of the "male gaze" model, which fails to consider "a plurality of differently disciplined spectator-observers seduced in different ways by a range of erotic-pornographic images" (Williams 1995, 22). Such an omission is observed to have also happened in the case of gay porn and gay viewers. The male gaze model of interpreting pornography, however, does provide a way of seeing how these marginalised images might have helped to consolidate the social order, be it of gender or class, by showing the stereotypical relationship between man and woman. On the other hand, the challenge to such an approach not only proposes to interpret these images from multiple viewpoints, but also suggests how pornography might actually be the focus of a subversive spectatorship. No matter what kind of approaches are taken to understand these images, nineteenth-century pornography has claimed an important role in the study of contemporary history, reminding researchers, through its controversial nature, of the possibility of a more fluctuating social relationship.

PORTER, WILLIAM SOUTHGATE (1822–1889)

American photographer

At the Great Exhibition of 1851 at London's Crystal Palace, a panorama of the Cincinnati waterfront was exhibited. Comprising eight separate whole plate daguerreotypes, the panorama measured over five and a half feet in length, and was of a quality so high that historians have been able to identify every vessel moored along the banks. The panorama was photographed across the river from the rooftop of a building in Newport, Kentucky, by Charles H Fontayne and William Southgate Porter in September 1848.

Porter had first worked with Fontayne in his Baltimore studio in 1844, and after Fontayne moved to Cincinnati in 1846, appears to have operated the studio alone until, in the spring of 1847, he opened another studio—Porter's City Daguerreian Gallery—in Pittsburgh. By late 1847 he had employed S. Hoge as an assistant, but by the spring of 1848, he had sold the Baltimore studio to Hoge and worked in Pittsburgh, where on May 22 he produced another remarkable panorama— comprising seven whole plate daguerreotypes—of Fair Mount Waterworks. This time the images were vertical and presented in a mount measuring 367mm x 998mm.

He rejoined Fontayne in Cincinnati later that year, and their partnership lasted until 1852, when Fontayne once again left the business. After a succession of other partners, he operated alone after 1863 from several addresses.

JOHN HANNAVY

PORTUGAL

The first news of the discovery of the technique of fixing images obtained with a camera obscura arrived in Portugal in 1839 through periodicals imported from France and the United Kingdom. In the same year Portuguese periodicals published notices presenting the calotype (*Revista Literária*, Porto, March 1839) and the daguerreotype (*O Panorama*, Lisbon, May 1839) processes The earliest recorded photograph taken in Portugal dates from 1841, a daguerreotype portrait taken by the English painter, William Barclay. In the early years, all equipment was imported, and experiments with the daguerreotype process were conducted in several institutions from ca.1842, including the physics department of the University of Coimbra.

During the 1840s and 1850s some European daguerreotipists, mainly French, travelled through Spain and Portugal, to make a business in portrait photography. Amongst the first in itinerant photography of the two first decades were Blackwood (Porto, 1843–44), the French Giles (Lisbon, 1843–44), Madame Fritz (Lisbon, ca.1843–45), E. Thiesson (Lisbon, 1844–45), who did a lot of commercial portrait photography in Lisbon and took some photographs of Africans with an anthropological approach, Adolpho and Anatole (Lisbon and Porto, 1845), Chambard & Poirier (1846), Dubois & C.ª (Lisbon; Porto, 1849; Coimbra, 1855, 1856), Juliette de Humnichi (1851), P. K. Corentin (Porto, 1851, 1853, 1856; Lisbon, 1851–52; Coimbra, 1852; Minho province, 1853), who taught photography and wrote the *Resumo historico da photographia desde a sua origem até hoje* (1852), the first photographic book published in Portugal. Some found here conditions for a more permanent business like the French Pedro Cochat (1849–57), J. Rodrigues Marten (ca.1849–53) or Martin (1857–63), Louis Monnet (Porto, 1856–62; Braga 1856–57, 1861; Coimbra, 1859), probably the first to do stereoscopic work and instantaneous photography in these towns, Alfred Fillon, established in Porto (1857–59), and then in Lisbon (1859–ca.69, ca.71–81). Wenceslau Cifka was probably the first to open a permanent photographic studio in Lisbon (1848–ca.80). To improve their incomes, some of these early foreign photographers made digressions to take portraits in the province where there weren't any established photographers. Many gave photographic lessons and sold photographic apparatuses, performing a major role in the formation and establishment of the first Portuguese photographers. These also established their businesses in the main cities: Francisco Augusto Metrass (Lisbon, 1847–ca.1848), Lucas de Almeida Marrão (Lisbon, 1851–97), Miguel Novaes (Porto, 1854–68), also painters, Francisco Augusto Gomes (Lisbon, 1852–71), Vicente Gomes da Silva (Funchal, Madeira island, ca.1848–1906), and António da Conceição Matos (Coimbra, 1856–69), also a painter. While most of these photographers offered only daguerreotypes, some also offered prints from paper and glass negatives—albumen on glass and wet collodion—and ambrotype positives In this early period there were already a few amateurs like the Count of Farrobo (1849), the painter João Baptista Ribeiro (1852–54) and Carlos Alexandre Munró (1857–66). Calotype practicionners were rare in Portugal. We should mention the British amateurs Frederick William Flower (ca.1853–58), and Joseph James Forrester (ca.1854–59), both in Porto. Forrester was also the author and editor of the earlier known Portuguese publication illustrated with a tipped-in photographic print (1855).

In the 1860s, with the popularity of the carte de visite format, a reduction in costs, and the popularity of the

family album, there was an exponential increase in the number of photographic studios in the main cities. Some former portrait-painters became part or full time photographers. Between the most significant photographers of this decade, for their quality and production, were Lisbon's studios of the Club Photographico Lisbonense (1860–62), Santa Bárbara (ca.1865–70s), Joaquim Coelho da Rocha (1865–91), José dos Santos Loureiro (1863–80), Francesco Rocchini (1865–93), a former cabinetmaker who also built photographic cameras and other apparatuses on demand, the Swedish M. J. Schenk (1850s–80), also a painter, who introduced here the diamond cameo portraits in 1867, and José Nunes da Silveira (ca.1860–67), who introduced the wothlytype process in Portugal and Spain in 1864, António da Fonseca (1862–92), Photographia Universal (ca.1866–1900), and Augusto S. Fonseca (1868), Porto's studios of the German Martin Fritz (1859–ca.1874), Henrique Nunes (1861–66), José da Rocha Figueiredo (1863–69), Photographia Nacional (1865–74), Photographia Talbot (1865–79), Sala & Irmão (1863–ca.94), Pinto & Ferreira (1863–67), Manuel José de Sousa Ferreira (1868–1906), and José Joaquim da Silva Pereira (1870–81), Coimbra's studios of Arsène Hayes (1863–74), and José Maria dos Santos (1869–1900), Braga's studio of Matias António de Magalhães (1864–69), Guimarães's studio of António Augusto S. Cardozo (ca.1860–78), also a painter. Madeira island's João Francisco Camacho (1863–92), Luanda (Angola)'s Abílio Moraes (ca.1863–ca.72), followed after his death by his widow and their sons. As in other countries Portuguese photographic studios were essentially supported by the studio portraits.

Eduardo Knopfli and Jacques Wunderli kept doing itinerant work throughout the country since the early 60s and throughout the 70s, although in the 80s we find the second established in Viseu and Braga. Secondary towns register the passage of occasional itinerant photographrs from early dates, but only had their first permanent studios in the sixties. We should also mention the amateur photographers Carlos Relvas (ca.1862–ca.93), Filipe Mesquita who made a large series of stereoscopic views of Lisbon (Lisbon, early 1860s), Russell Gordon (1861) and Amélia de Azevedo (ca.1863), both in Madeira Island. Worth of remark was also José António Bentes, a military officer who wrote a manual (1864) and a treatise of photography (1866). This decade foreign photographers made significant views work in Portuguese territory like the stereoscopic series taken by R. A. Miller/Miller & Brown in Açores archipelago, or J. Laurent, large format views and stereoviews (ca.1868–69).

In the late 1850s, and throughout the 1860s, several important series of architectural and topographical photographs were produced. Eugène Lefèvre took views of the main cities and monuments and made an *Album de Portugal* (1857). Some individuals belonging to the cultural elites of the time, inspired in foreign photographic inventories of patrimonial works, were personnally commited in the register and inventory of Portuguese monuments, like Antero de Seabra, an amateur photographer, who took photographs of monuments, urban landscapes, as part of a personal project (ca.1858–64), and public works for the Ministério das Obras Públicas (ca.1861–64). He printed a series of photographs under the title *Portugal*. Joaquim Possidónio Narciso da Silva, architect of the royal house and archeologist, also photographed Portuguese monuments, archeological sites and objects and edited them in the *Revista Pittoresca e Descriptiva de Portugal* (1861–63). The British Charles Thurston Thompson photographed monuments in Porto, Coimbra, Batalha Alcobaça, Tomar and Lisbon, for the South Kensington Museum of London (1866). In 1866–67, 1877 and 1879 Carlos Relvas photographed Portuguese monuments and landscapes by his own iniciative. Both published some of this work in the photographically illustrated periodical *Panorama Photographico de Portuga*l (1869–74). Diogo (or Jacques) Francem photographed monuments for the Portuguese section of the Paris 1867 international exhibition (1865–67). Henrique Nunes photographed monuments and archeological pieces published in the book *Monumentos Nacionaes* (1868) and latter in the *Boletim da Real Associação dos Architectos Civis e Archeologos Portuguezes* (1874–82), Francisco Martins Sarmento documented his pioneer archeological works (1868–76), and Augusto Xavier Moreira took a series of views of the monuments of Lisbon (1865–68), sold both individually and in albums. The Lisbon photographers Augusto César Pardal and his son published reproductions of art objects and engravings reproducing famous paintings (1869–79).

The early 1860s saw the first publications illustrated with tipped-in photographs, predominantly carte-de-visite size albumen prints, depicting authors and other celebrities—continuing a publishing tradition which had previously depended on engravings. The publication of such editions reached its peak in late 1870s and early 1880s, the tipped-in photographs being replaced by collotype illustrations in the 1880s, and eventually photogravure.

Amongst the most significant photographers who opened their studios in the 1870s were Lisbon's studios of Photographia Popular (ca.1870–99) who worked in several processes, including carbon and photo-mechanical prints, Alfred Fillon (2nd studio, ca.1871–81), Ricardo Pereira de Melo Bastos (1872–85), António Maria Serra (1872–1900), Photographia Central (1872–1900), Damião da Graça (ca.1872–1900), Martin Fritz (ca.1874–ca.1888), Henrique Nunes (ca.1869–83), João Francisco Camacho (1879–98), Porto's Photographia Universal

(1870–1900), Photographia da Casa Real of Emílio Biel (ca.1874–1900), União (1872–1900), and Célestin Bénard (1869–90), Coimbra's studios of J. Sartoris (1876–1900-) and Adriano da Silva e Sousa (1876–1900), Braga's António Pereira da Silva Braga (1870–79), Viana do Castelo's José Joaquim Ferreira (1870s–80s), Póvoa de Varzim's António José de Barros (1874–94), Tomar's António da Silva Magalhães (ca.1871–97), Ponta Delgada (Açores)'s António José Raposo (ca.1870s–91), Luanda (Angola)'s José Nunes da Silveira (ca. 1869–78), and José Augusto da Cunha Moraes (ca.1877–97), José R. Gambôa in Moçambique and S. Tomé (1875–95), and Maria Eugénia Reya Campos, self-entitled the first Portuguese woman photographer, who's activity goes back at least 1872, established in Évora (1881–82), and in Lisbon (1885–1900-). In this decade the French photographers and editors J. Lévy & C.ª published extensive series of images of Portugal in several formats, including glass and paper stereoviews and magic lantern slides (ca.1875). Lachenal & Favre (1871– ca.82) and Adolphe Block also edited stereoviews of Portugal. Amongst the relatively small number of amateurs we should mention José Gil (ca.1876–1905) and Maria Collecta d'Assumpção Pacheco, (Elvas, ca.1876, 1892).

With the consolidation of photographic business in the main cities, from the seventies to the end of the century, we assist to the progressive establishment of photographic studios in small towns, seaside resorts, and spas. Some of them formerly had studios in the main cities and many worked as collaborators of the main photographers. Seasonal activity became common among some city photographers who every year opened temporary photographic studios in these places, accompanying the public affluence in the respective seasons. The regional spreading of photographic studios continued progressively towards the end of the century, and some small province towns only had their first permanent studios in the following century.

In the 1870s José Júlio Rodrigues, professor of chemistry at the Polytechnical Academy and responsible for the photographic section of the *Direcção Geral dos Trabalhos, Geodésicos, Topographicos, Higrographicos e Geológicos do Reino*, had a major role in the experimentation and introduction of several photomechanical processes. He organized the first national photographic exhibition in these installations (1875), published the book *Procédés photographiques et méthodes diverses d'impressions aux encres grasses* (Paris, 1879) and started making experiments with the collotype process in 1874. Carlos Relvas introduced in Portugal the Carl Heinrich Jacoby's collotype variant in 1875. Emílio Biel & C.ª Porto's important photographic studio learned the technique and used it to illustrate many books and several albums (1880s–1900s). Biel's house investment in this technique has attainned unrivaled mastering in Portugal.

Amongst the most significant photographers of the 1880s were Lisbon's studios of Augusto Bobone (1885–1910), also a painter, Muñiz & Martinez (1888–1900s) and Joaquim Fritz (ca.1888–91), Porto's studios of the Photographia Moderna of Leopoldo Cyrne & C.ª and latter of Ildefonso Correia & C.ª (1884–1900s), who edited the internationally upraised photographic magazine *A Arte Photographica* (1884–85), Peixoto & Irmão (1881–1900s) who practised a lot of processes, including carbon and photo-mechanical printing, introducing the woodburytype technique, Fulgêncio da Costa Guimarães (ca. 1883–94), Henrique António Guedes de Oliveira (1886–1900s), Coimbra's Adriano Gomes Tinoco (ca.1884–1910), Braga's Photographia Universal of A. Solas (1883–88), Viseu's Francisco Paino Perez (1884–87), a Spanish formerly established in Coimbra (1787–80) who also did itinerant work in the Beira and Alentejo provinces, Funchal's (Madeira island) Augusto Maria Camacho (1882–1900s), Manoel d'Olim Perestrello (1879 or 1888–1910s), Goa's (India) Souza & Paul (ca.1890s–1910). The amateur Adolpho Moniz photographed in Portuguese India (ca.1890). Qualified amateurs like Paulo Plantier (Lisbon, 1887), Joaquim Augusto de Sousa (Funchal, 1870–1905), Eduardo Alves (Porto, ca.1884–86), Antero Araújo (Porto, 1885–86), Margarida Relvas (1884–85), and Camilo dos Santos (1886–87, 1898–99) revealed technical maturity and aesthetical formation. Many of these, along with professionals and foreign photographers participated in the *Exposição Internacional de Photographia*, organized by Photographia Moderna and realized in 1886 in Porto's Crystal palace. Two years before, Álvaro Joaquim de Meirelles claimed the invention of a movement stereoscope, adapting two praxinoscopes to a stereoscope viewer. During this decade Emílio Biel & C.ª documented the newly built railroad lines of Beira Alta (1882), Douro (1883–84), Minho, and the construction of Porto's bridges of D. Maria Pia and D. Luís.

Between the most significant photographers in the 1890s were Lisbon's studios of Arnaldo da Fonseca (1891–ca.96) who published a photography treatise (1891), Vidal & Fonseca (1895–1914), and the reporters António Novaes (1896–1900-) and Joshua Benoliel (1898–1900-), Porto's José de Carvalho (1890–96), Braga's Francisco G. Marques (1893–1925), Póvoa de Varzim's Avelino Barros (1895–1900-), Viseu's Perez & Filhos (1880s–90s), Santarém's Manoel A. Silva Nogueira also established in Faro worked in Caldas da Rainha during thermal season and Nazaré during bath season, Évora's Ricardo dos Santos (1887–1900), Lourenço Marques (Moçambique)'s Louis Hily (ca.1894–1905) and the brothers J. and M. Lazarus (1899–1908). Manuel Goulart, originary from the Açores archipelago and established in New Bedford (U.S.A.), took a large stereoviews series entitled Azores, Madeira and Portugal (1897).

Some amateurs also emerged in this decade, like Aurélio da Paz dos Reis, who introduced cinema in Portugal (Porto, 1896), and did extensive stereoscopic work.

In the last decade of the century, and the early years of the 20th century, there was a significant growth in the number of photographic studios away from the major population centres, driven by population movement, and by a reduction in prices which brought photographic portraiture within the reach of all levels of society. At the same time, many more people became involved in amateur photography in Portugal, as was happening in other countries.

The first photoengravings made and published in Portugal appear for the first time in 1890s periodicals, made by Lisbon's studios of José Pires Marinho (1894), Castello Branco & Alabern (1895), and Porto's Marques de Abreu (1898).

From the 1840s until the end of the century, French and British photographic publications were available in bookshops in Lisbon, Porto, and Coimbra. 'The majority of photographic plates, cases, cards, albums, cameras, and other apparatus was imported and sold by specialist dealers in the major cities. Only two short-lived attempts to develop a Portugese manufacturing industry met with any success—in Lisbon, the factory of *A Portugueza* (1899) and the Porto factory of Pinheiro d'Aragäo & C.a.

POSITIVES: MINOR PROCESSES

During the first sixty years of photographic experimentation, a host of processes were devised for printing positives from camera negatives. Their proud inventors tended to confer idiosyncratic names on these innovations, adding to a bewildering list that obscures the commonalities of these nineteenth-century processes: many are just minor variations on well-established photochemical themes. To confer some structure on what would otherwise be a miscellany, the processes for making positive photographs are gathered here into five basic categories, according to the nature of the light-sensitive chemical: whether it is a salt of silver, iron, uranium, or chromium, or an entirely organic compound. The accompanying Table is intended as an alphabetical finding-aid by name, giving the inventor, date, category, and essential nature of each process.

Silver Halide Processes

The transformation of a silver halide (chloride, bromide, or iodide) into silver metal by the action of light has always provided the mainstream of photographic practice. The major 19th-century processes for making silver positives are described under the entries for Albumen, Bromide print, Daguerreotype, Gelatin silver print, Photogenic Drawing, Salted paper print, Tintype and Wet Collodion positives. This section outlines the other named silver processes, which found less widespread recognition. It may be assumed that the light-sensitive component was silver chloride and the image consisted of silver, except when stated otherwise, and that all the processes (with one exception) were therefore "negative-working," i.e., they inverted the tonal scale, making a positive from a negative, and vice versa. Many of these processes differ only in the organic binding agent which acted as the vehicle for the silver halide, or in the substrate upon which it was coated. Included here as photographic "positives" are those silver processes that actually furnished a negative image, which was then treated or mounted so that it appeared positive when viewed under reflected light, i.e., minor variations of the Ambrotype, Daguerreotype and Tintype processes. In the Table, this category of process is designated as "silver negative."

Aristotype was just an elegant proprietary name for a silver chloride printing-out paper, using either collodion (Johann Obernetter 1868), or gelatin (Paul Liesegang 1884) as the binder, rather than albumen. *Aristo-Platino* was a silver halide paper marketed by the American Aristotype Company (1894), which required toning–with gold, platinum, or both. *Platino-Matt* and *Platino-Bromide* papers also belied their names, being silver halide papers, with starched matt surfaces to mimic platinotype.The *Alabastrine* process was a variant of the Ambrotype invented by Frederick Scott Archer in 1851: an underexposed wet collodion negative on glass, presented as a cased object, was backed in the mount with black paper so that a positive image was seen by reflected light. Alabastrine had the added

feature that the silver image was bleached by mercuric chloride, converting it to silver chloride and mercurous chloride, so whitening the deposit in the highlights. The *Pannotype* of Wulff and Company (1853) is another variation on Ambrotype, backed by black waxed linen, or leather, rather than paper.

The *Hillotype* enjoys a notorious history: it was claimed in 1850 to be a natural colour version of the Daguerreotype, and the life of its inventor, Levi Hill, reads no less colourfully. Although denounced as fakes by jealous daguerreotypists of the day, there are specimens of original Hillotypes in the Smithsonian Institution. Hill's chemically bizarre procedure is complicated and dangerous, but was carefully replicated in 1985 by Joseph Boudreau, who succeeded in obtaining Hillotypes showing some vestiges of "natural colour."

The first *Direct positive* silver photographs were created in 1839 by Hippolyte Bayard, who used his unnamed positive-working process directly in the camera with considerable success. In 1840, Henry Talbot devised a similar "positive photogenic drawing paper" which he called *Leucotype*: an ordinary salted silver paper was heavily exposed and fixed, to provide a uniform, black ground of silver; treatment with strong potassium iodide solution rendered this layer susceptible to bleaching by light, which formed pale yellow silver iodide. Such photographs tend to fade in the light, and are very rare.

With their *Hyalotype* of 1849 the brothers Friedrich and Wilhelm Langenheim provided the earliest lantern slides as silver-albumen positive transparencies (diapositives) on glass, using the Niépceotype process of 1847 due to Claude Felix Abel Niépce de Saint Victor. Other variations bearing names suggestive of a glass substrate were: John Whipple**'s** *Crystalotype* of 1854, and the *Opalotype* publicised by P.C. Duchochois in 1865 using translucent opal glass. The *Crystoleum* process of 1880 involved glueing an albumen positive face down onto a concave glass surface, removing much of the backing, and colouring by hand in oils. Such manual embellishment featured in other named processes: Wilson**'**s *Sennotype* of 1864 was a hand-coloured albumen positive on glass; Urie's *Relievotype* of 1854 was a collodion positive on glass with the background scraped away, and re-backed with a painted card; it was introduced by Thomas Lawrence in 1857.

A wider range of substrates was made possible in 1888 by the Kodak Company's *Transferotype*, which was a "stripping emulsion" whereby the silver-gelatin image could be transferred onto glass or canvas, for example. Prints on genuine ivory are rare; *Ivorytype* (John Mayall 1855) and *Eburneum* prints (John Burgess 1865) were imitations on specially-whitened substitutes. To make satisfactory photographic images on enamels and ceramics which had to be fired at high temperatures under a glaze, the *Photoceramic process* due to Pierre Michel Lafon de Camarsac in 1855 used chemical toning to replace the silver by a more refractory noble metal, such as gold, platinum, or iridium. Other photoceramic techniques employed refractory pigments applied by the carbon process (see below).

Some silver sensitizers incorporated novel chemical constituents. Robert Hunt added succinic acid in his *Energiatype* process of 1844: a paper that could either be printed-out, or developed (with ferrous sulphate, causing Hunt to re-name this process "*Ferrotype*"—not to be confused with the alternative name for Tintype.) Jacob Wothly included uranium salts in a silver emulsion in his eponymous *Wothlytype* of 1864. Extravagant claims for this print-out process (sometimes misleadingly called Uranotype) attracted attention initially, but its virtues were soon discounted; it did however represent the first use of collodion as a binding agent.

Iron Carboxylate Processes

The "ferric" processes—collectively called 'siderotypes' by Sir John Herschel—are based upon light-sensitive salts of iron(III) with "vegetable acids" such as citric, tartaric and oxalic, which are polycarboxylic acids. The photochemistry is described under light-sensitive chemicals, and under Cyanotype and Platinum Print—the two major nineteenth-century iron-based printing processes. Besides these two, there were more than a dozen minor siderotype processes, both positive- and negative-working, which furnished images in a variety of substances.

Henri *Pellet's process* of 1877, called *Cyanofer* in France, produced Prussian blue prints, but differed from the simple cyanotype in being positive-working. A version of the sensitizer due to Giuseppe Pizzighelli and Ludwig von Itterheim contained a mixture of iron(III) chloride, tartaric acid, and gum Arabic: the gum was hardened by the iron(III) salt, but where light fell this was reduced to iron(II), allowing the gum to re-soften. A developer of potassium ferrocyanide formed Prussian blue in the insoluble, unexposed regions and, to fix the image, the Prussian white formed in the soluble, exposed regions was washed away. The Pellet process was reputed to be difficult to work satisfactorily—highlights were often blued—but it found some application for copying purposes, for instance reproducing maps for the Survey of India Office. Alphonse *Poitevin's process* of 1860 had a commonality with Pellet's: it was also positive-working, and relied on the ability of iron(III) chloride to harden a colloid, in this case gelatin carrying a pigment. In regions where the light caused reduction of iron(III) to iron(II), the gelatin re-softened, and was washed away in the development bath with its attendant pigment. Also based on cyanotype were John Mercer's

Chromatic photographs on textiles of the 1850s, but the Prussian blue images were alkali-bleached to iron(III) hydroxide, which then served as a mordant to bind vegetable dyestuffs.

The *Palladium print* is a close analogue of the platinum printing process, and came to be much-used from 1916, when its invention was credited to William Willis, whose Platinotype Company marketed a commercial *Palladiotype* paper. There is, however, evidence that prints in palladium were made and exhibited as early as 1856 by Charles Burnett of Edinburgh, as described below under uranium processes.

Several siderotype processes yielded an image of silver, by the iron(II) photoproduct reducing silver nitrate. This theme originated in 1842 with Sir John Herschel's *Argentotype*. His sensitized paper was coated with ammonium iron(III) citrate, and the development bath contained silver nitrate. In 1843 Herschel also devised his curious *Breath print* process, using a mixture of ferrotartaric acid and silver nitrate. No image was visible after exposure, but it sprang into existence as soon as the paper was breathed upon, because exhaled moisture promoted the development reaction. Towards the close of the nineteenth century, several derivatives of Herschel's argentotype appeared: variously dubbed *Brownprint* (patented by H. Shawcross in 1889), *Sepiatype* (Sharp and Hitchmough Company 1891), and *Vandyke* (Arndt and Troost 1895), they mixed ammonium iron(III) citrate with silver nitrate, adding tartaric acid to inhibit precipitation of silver citrate; images printed-out in shades of brown, were washed in water, and fixed in dilute sodium thiosulphate. A closely-related process, but employing iron(III) oxalate, was the *Kallitype*, so-named and patented by W.W.J. Nicol in 1889, 1890, and 1891, although this well-explored formulation had been anticipated as early as 1844 by Robert Hunt in an unnamed process. Kallitype needs an alkaline-buffered developer to avoid re-dissolving the silver image. Owing to difficulties in fixing and clearing, iron-based silver prints were generally prone to deterioration, and acquired a poor reputation for permanence. Despite wide publicity of these processes in the nineteenth-century photographic literature, surprisingly few historic specimens have been positively identified in present-day collections.

The most striking of Herschel's 1842 discoveries was *Chrysotype*, which provided deep purple images in nanoparticle gold (a pigment known to ceramicists as the Purple of Cassius). For chemical reasons, Herschel's procedure required the gold salt to be in a developing bath or wash; such profligacy inhibited his pursuit of the process, but a number (ca. 20) of his specimens have survived perfectly to the present. Later attempts to re-invent the gold process (Robert Hunt 1844, Alfred Jarman 1897) re-named it *Aurotype*. By the end of the nineteenth century, the employment of gold as a printing medium had been completely discounted, although it continued to be much used for toning silver images.

Between 1842 an 1844, Herschel was also striving to perfect an iron-based process providing an image in metallic mercury; he found indications that both negative- and positive-working versions might be possible. This may account for Talbot's suggestion of the name *Amphitype* for this process (not to be confused with the 1849 silver *Amphitype* of Blanquart-Evrard), replacing Herschel's original name of *Celanotype* (also spelt *Kelaenotype*). According to Herschel, his mercury photographs were the most exquisite imaginable. The process was doomed to failure, however, because mercury metal is volatile, and in the space of a few days or weeks such images simply evaporate. Specimens authenticated by Herschel's own annotations exist today as stained scraps of paper, without any discernable images.

It has long been known that iron(III) salts react with gallic or tannic acid to produce intense black pigments; iron-gall ink has been the chief writing medium since medieval times. Procedures for making photographic images in this substance devised by *Colas* (1883), Alphonse Poitevin (*Ferrogallic process* 1859), and *R. Nakahara* (1894), were all positive-working and chiefly used for copying line drawings and text, rather than continuous-tone pictorial purposes.

The *Dusting-on* or *Powder* process of Henri Garnier and Alphonse Salmon (1858) made use of the hygroscopic property of iron(III) citrate to remain tacky, especially in sensitizers containing sugar or honey; it only dries and hardens where exposed to light. A positive-working image could therefore be obtained by dusting over the exposed paper with a powdered pigment, which adhered selectively to the shadow areas.

Johann *Obernetter's ferrocupric* process of 1864 involved a roundabout chemical procedure to yield an image in the stable pigment, Hatchett's brown, copper(II) ferrocyanide. In Thomas *Phipson's* little-known process of 1861, ammonium iron(III) oxalate was the sensitizer; it was reduced by light to an iron(II) salt, which reduced potassium permanganate solution to the insoluble, brownish-black manganese dioxide.

Uranium processes

In this minor category, the oxidation-reduction chemistry is analogous to the previous iron case. Invented by Charles Burnett over 1855 to 1857, the uranium printing processes were capable of yielding images in stable substances, just like the siderotype processes. Under the action of light, and in the presence of organic matter, a uranium(VI) salt was reduced to uranium(IV), which in turn reduced a noble metal salt to the metal. By this means, Burnett made the first *palladium prints* in

1856, and obtained fine images in gold and silver. The uranium salts were washed out in the wet processing, so the finished *Uranium prints*, as they were inaccurately called, should contain no uranium, only the precious metal, and are therefore not radioactive. However, this is not true of Burnett's other uranium printing process of 1855, sometimes called *Uranotype*, as a close analogue of the Cyanotype: the uranium(IV) photoproduct reacted with potassium ferricyanide to yield uranyl ferrocyanide, a Bartolozzi-red pigment (also formed in the "uranium toning" of silver or platinum prints). Such photographs will be radioactive. In 1858, Niépce de Saint Victor also published, and sought patent rights for uranium printing processes essentially identical to those published by Burnett a year earlier. Unsurprisingly, this gave rise to some highly acrimonious exchanges in the photographic periodicals of the day.

Dichromate Processes

The orange-coloured, water-soluble dichromates of sodium, potassium, and ammonium were called "bichromates" in the nineteenth century—a nomenclature now disapproved as chemically misleading, but which persists in photohistorical usages. Under the action of light, dichromates are reduced by organic matter to chromium(III) salts, which have the ability to harden organic colloids, such as gum or gelatin, as explained under light-sensitive chemicals. If a pigment is incorporated in the sensitized layer, it will be retained where light has fallen and rendered the colloid layer insoluble, but may be washed off the paper where the colloid remains soluble—in the unexposed regions—thus providing a negative-working photographic process.

The major nineteenth century dichromate processes may be distinguished by the colloid: Carbon printing uses gelatin, Gum Bichromate employs gum Arabic (gum Acacia), but in the Fresson process the identity of the colloid still remains a proprietary secret. Dichromate processes are also of great importance in the preparation of plates for photomechanical printing processes.

Mungo Ponton was the discoverer of light-sensitivity in dichromated paper in 1839; he noted that exposure caused a colour change from yellow to brown, and the former could be washed out, leaving a negative-working image in white on greenish-brown. Henry Talbot experimented with dichromated gelatin in 1852 with a view to using it for photomechanical printing, but Alphonse Poitevin is generally acknowledged as the major promoter of the photographic pigment printing processes in 1855. *John Pouncy* obtained a patent for the gum process in 1858. Some named minor variations on the major dichromate processes will now be outlined.

The direct carbon process of 1878 due to Frédéric *Artigue*, also known as *Charbon-Velours*, was improved by his son, Victor in 1893, and was the forerunner of the Fresson process; the image was developed by a mildly abrasive suspension of sawdust in water. *Autotype* was the name adopted by the Autotype Fine Art Company, set up in the 1870s, for its carbon transfer tissues, marketed in a variety of pigment colours. *Lambert-type* (1875) was a carbon transfer from the surface of collodionised glass, so produced a print surface of notable brilliance. The *Photo-aquatint* was a re-naming of the gum bichromate process in 1894, when it was popularised by the skilled exponents, Alfred Maskell, Robert Demachy, and Alain Rouillé-Ladevèse.

Dusting-on or *Powder processes* are also possible with dichromated colloids. In preference to iron salts, Garnier and Salmon turned to dichromated gum and sugar in 1859, relying on this hygroscopic colloid to remain 'tacky' in the absence of light. Pigment was dusted onto the exposed surface, as described before, to yield a positive-working image. It is alleged that the funerary ashes of cremated loved-ones could thus be used to constitute their own portraits! Alessandro Sobacchi's *Anthracotype* of 1879 was also a dust-on process, using graphite powder as the pigment. There is also an *Ink* processes in hardened dichromated colloids due to G.W. Perry in 1856 or V.J. *Sella's process* of 1857. Thomas Manly's *Ozotype* of 1898 included manganese(II) salts in the dichromate sensitizer, and essentially produced hardening of a separate gelatin layer by diffusion transfer. Manly's *Gum ozotype* of 1899 was the analogue using gum Arabic.

A few dichromate processes differ from those above in not entailing colloid-hardening. The *Aniline process* of William Willis senior (1864) relied on the residual dichromate, after exposure, to exert a powerful oxidising action on aniline vapour, producing in the unexposed areas intensely coloured "aniline dyes" of the mauveine type. It enjoyed some importance as an early positive-working reprographic process for plans.

The *Chromatype* process of Robert Hunt (1843) had several manifestations: he added copper(II) sulphate to the potassium dichromate to improve its sensitivity; the image substance formed by development was an insoluble chromate of a heavy metal such as silver, mercury or lead, which are all highly coloured—orange and red. This process is positive-working, commonly producing a yellow image on an intense red ground of silver chromate, and, because dichromate solutions tend to penetrate paper, the image is usually clearly visible on the verso. Hunt also employed gold chloride to develop a *Gold chromatype* in which the final image was deep violet nanoparticle gold. Burnett's little-known dichromate-based *Cuprotype* of 1857 resembles Hunt's chromatype in its sensitizer, but the image substance formed was Hatchett's brown, copper(II) ferrocyanide, as in *Obernetter's process*.

Alphabetical List of 19th Century Photographic Processes for Making Positives

Process	Inventor	Year	Category	Image	Binder & substrate
Alabastrine	Scott-Archer	1851	Silver negative	Silver chloride	Collodion on glass with black backing
Albumen	Blanquart-Evrard	1850	Silver	Silver	Albumen on paper
Ambrotype	Scott-Archer and Fry	1851	Silver negative	Silver	Collodion on glass with black backing

Organic Processes

This category is rather diverse in the materials it embraces, but all are purely organic, some macromolecular or colloidal, and do not involve inorganic salts. The photochemistry is not well-understood in all cases, but entails colloid-hardening and dye-bleaching processes.

The oldest organic process was also the first to provide a camera image that has survived to the present day: the *Heliographic* process invented by Joseph Nicéphore Niépce around 1822, also known as the *Asphalt* or *Bitumen* process. Bitumen of Judaea dissolved in oil of lavender was thinly coated onto a metal plate or stone; the layer hardened selectively in the light, and was developed by the same solvent. Niépce employed it mostly as a photoresist to make lithographic plates for the photomechanical copying of engravings. But upon a shiny metal plate (tin, pewter, or silver-plated copper) a degree of tonal reversal gave an apparently positive image, which could be enhanced by iodination. Such a camera photograph by Niépce, dating from 1827, is in the Gernsheim Collection of the University of Texas. A point of terminology deserves clarifying here: although the very first photographic process was named "héliographie" by Niépce, later in the 19th century the word "heliography" came to be widely used for all "sun-printing," moreover "heliographic processes" included those intended specifically for reprographic copying purposes, that is for line, rather than continuous tone, images.

The *Physautotype* process due to Nicéphore Niépce and Louis Daguerre (ca. 1830) was rediscovered only recently (ca. 1995) by Jean-Louis Marignier: exposure to light of colophony resin (abietic acid) can cause its insolubilization, even without the presence of metallic salts. The image on glass or shiny metal is developed by washing, and has a subtle character when viewed by transmitted light: its visibility depends on selective optical scattering, rather than absorption, of the light.

The *Anthotype* or *Phytotype* process, first devised by Herschel in 1839, simply entailed the bleaching by sunlight of fugitive flower colorants (now known to chemistry as anthocyanins). Herschel found most success with yellow japonica, red poppy, common heartsease, double ten week stock, harlequin flowers, and purple groundsel; he crushed the flower petals to pulp, extracted the expressed juices with alcohol, and filtered the solutions for dyeing the paper. To bleach the dye under an engraving, giving a positive image, required exposures to bright sun ranging from an hour or two for the most sensitive dyes, to several weeks for the least. By dispersing sunlight with a prism, Herschel performed spectrographic analyses of the responses, which showed that a given dye was most effectively destroyed by light of its complementary colour. Herschel believed this positive-working process had potential for a system of direct full-colour photography, but could find no method of fixation, as the pictures inevitably faded in the light.

Monochrome images were later obtained by the more sensitive *Diazotype* or *Feertype* (Adolf Feer 1889), and *Primuline* (A.G. Green, C.F. Cross, and E.J. Bevan 1890) processes, which depended on the decomposition of diazonium salts by light. The remaining unchanged salt—which is highly reactive—was then allowed to couple with an organic compound included in the developer to yield an azo dye, so providing a positive-working reprographic process in a variety of colours, determined by the choice of the coupling agent.

POSTCARD

A postcard is a 3½ × 5½" stiff card with a printed image on its face (recto) and room for an address, message, and postage on its back (verso).

The postcard, however ubiquitous in the twenty-first century, is a quintessential product of the nineteenth century, embodying many of the characteristics of the age in which it was born and developed. On one hand, the postcard was a means of rapid, brief communications in an increasing busy age. Gladstone, for example, wrote much of his voluminous daily correspondence on plain halfpenny postcards. On the other hand, the craze for sending and collecting picture postcards epitomized the Victorian mania for acquiring, classifying, and arranging specimens.

The postcard's visual antecedents include eighteenth-century pictorial visiting cards and trade cards, nineteenth-century pictorial writing paper and envelopes, and cartes-de-viste, the collecting craze of the 1860s. The development of the postcard's physical format is directly linked to nineteenth-century postal regulations imposed by both individual countries and the International Postal Union. In the early nineteenth century, mail rates were based on the number of sheets in a letter (including the envelope), and the distance it was to travel. In 1840 the British Post Office instituted the penny post, establishing a flat rate of one penny per half ounce. Letter writing became affordable for a greater part of the population. As people became dependent on corresponding by post for both personal and commercial use, they sought ways to exchange messages more rapidly and economically.

In 1865 Dr. Heinrich von Stephan, a German post office official, proposed an "offenes Postblatt" or open post sheet, at the Austro-German postal Conference. He described a printed, postage-paid card with one side for the address and the other for the message, which could provide the user with a certain ease and convenience not associated with paper-and-envelope letters. Although von Stephan's idea was not adopted by the Germanic postal service, the idea of open-sheet letters, sent at printed material or penny post rates was adopted by some people throughout Britain, Europe, and North America, especially for business matters. In fact, the earliest postcard is generally acknowledged to be Lipman's Postal Card, a plain card published in Philadelphia in 1861 (patent applied for by John P. Charlton).

The idea of a postcard continued to gain currency throughout the 1860s, culminating with a suggestion by Dr. Emanuel Herrmann, an Austrian professor of economics, for a "Correspondenz-Karte" to be printed by the post office on a "thin buff-colored slice of cardboard." Similar to von Stephan's idea, Herrmann saw his card as a solution for sending a brief message by post. Later that year the Austrian post office produced what is considered to be the first official postcard. On its face of was printed the Austrian emblem with "Correspondenz-Karte" above it, a two kreuzer stamp in the top right-hand corner, and three ruled lines in the center for the address. It was immediately popular—2, 936,102 cards were sold in first three months.

The first official German, English, and Swiss postcards debuted the following year, and the first U.S. postcards were printed in 1873. The standard postcard size was 4 ¾ × 3 1/3 or 4 ¾ ×3 inches (4 ½ × 3 ½" for the British size). In the first year of their use 75 million halfpenny cards were posted in Britain alone. By 1903

the number of postcards sent in Britain was almost ten times that amount.

Although entrepreneurs quickly recognized the possibility of producing cards embellished with borders, advertisements, and pictures, governments continued to regulate and monopolize postcards. Privately printed postcards could be sent through the post, but at the standard, rather than reduced, rate. In general, there were fewer postal regulations on the continent than in Britain and the United States, so countries such as Germany, Switzerland, and Austria led the way in the evolution from the plain postcard to the picture postcard. Various people are claimed to have produced the first picture postcards. The two most often agreed upon are Leon Bésnardeau and A. Schwartz, both of whose cards appeared in 1870, inspired by the Franco-Prussian war. An Austrian postcard printed by A. Schwartz of Oldenburg, showing a soldier and cannon in upper left-hand corner, is considered to be the earliest government-issued pictorial postcard. In France Leon Bésnardeau, a stationer in Sillé-le-Guillaume, printed a card for the Breton troops showing stacked weapons and an empty battlefield surrounding the address area.

In 1870 English firms began to print pictorial advertisements on post office halfpenny cards, but these were not considered to be official cards, nor were they picture cards in the purest sense. In 1872 private printers in many countries won the right to print cards provided they had official postage printed on them. German, Swiss, and Italian publishers all printed early view cards; in Nuremberg J.H. Locher of Zurich printed a series of views of his city which may have been the earliest view cards issued. Although the printers had won a victory for cards with pictures, the use of such cards was still strongly tied to commerce. Single-color small views of cities and attractions such as spas and restaurants were printed on cards more to attract business to these venues than for the sake of producing an attractive card that would be purchased and sent for its intrinsic value.

In 1875 the First Congress and International Postal Treaty established a fixed rate for letters sent to all member countries of the union. Postcards could now be sent abroad between member countries at half the letter rate. However, at this time the address and postage were still placed on the front of the cards, which constrained the size of the image. It gradually it became the practice to reserve one side for the address, with no other writing allowed on it, and the other side for the picture and stamp. The choice was between having a front with smaller pictures and space for writing, or a picture covering the entire face, so that if the sender wished to include a message it could only be written over the image. The divided-back postcard, which solved the problem of providing space for the message, address, and postage all on one side of the card, leaving the other side completely free for the image, did not come into being until 1902, when it was adopted by Great Britian, with other countries quick to follow suit.

Although instantaneous photography was readily available by the time the first postcards appeared, real photographs were not used as postcards until almost the turn of the twentieth century. Instead, photographs formed the basis from which the image was reproduced. By the 1890s single-color picture postcards had given way to full-color cards reproduced from photographs by means of collotype, chromolithography, photogravure, or half-tone photo engraving. The photograph was seen only as the basis for the card. Even when it recorded an event, the photograph was thought of solely as the intermediary from which half-tone blocks could be made and printed. Thematic cards such as those made popular by Bamforth and others were carefully posed and arranged and views were carefully framed. Such cards were advertised as being based on "real life photos."

The potential of the real-photo postcard was realized late in the century when established photographers began to capitalize on their existing stock of images and expertise. While some well-known photographers scoffed at the picture postcard medium, others such as William Jackson in the United States, and Francis Frith and Valentine and Sons in England, recognized the potential for both making and publishing photographic postcards. Soon other photographers began selling negatives to picture postcard companies.

The real–photo postcard was given a boost just before the turn of the century when George Eastman introduced lightweight, hand-held cameras pre-loaded with 100-exposure rolls of film. Advertised by the slogan "You press the button, we do the rest," the entire camera was returned to Kodak for developing. One could receive either small prints or sepia-colored real photo postcards.

Starting in 1902 Kodak offered a pre-printed card back for printing negatives as postcards. Many itinerate photographers used postcard stock, and they and other professional photographers could have their name or logo printed on it. Glass plates and sheet film were also available in postcard size. The following year the #3A Folding Pocket Kodak was introduced which took postcard-sized photographs on roll film. It included a waist-level viewfinder that could be rotated 90 degrees, allowing the user to take horizontal as well as vertical pictures. Postcard format cameras were soon produced by other manufacturers. Made by amateurs and "professionals" alike, the age of the gelatin silver snapshot photograph had begun, lasting well into the first half of the twentieth century.

POSTMORTEM PHOTOGRAPHY

Postmortem photography has its roots in a long tradition of posthumous memorial and funerary portraiture. These costly portraits were mainly of wealthy persons or well-known figures who were usually depicted as if still living. Visual clues within the painting signaled that it was a post mortem portrait. These portraits were intended to create the illusion of life in death. Although usually for the private consumption of the family of the deceased, they sometimes had a more public, commemorative purpose.

The first postmortem daguerreotypes were made in 1841, only two years after the daguerreotype was introduced. For the first time, photography made postmortem portraits relatively accessible for all who wanted them. At the apex of the Victorian obsession with death, postmortem photographs became a popular accoutrement of the rituals of death and mourning. The realm of posthumous portraiture shifted from a strictly upper class practice to a middle and lower class one. By 1850 almost any family that desired an image of their dearly departed could afford the cost of approximately 25 cents for a daguerreotype.

This phenomenon is another instance of how early photography was quickly put into the service of an existing or perceived daily need. By the mid-nineteenth century the preoccupation with death had taken a firm hold on both sides of the Atlantic. Death was seen as the ultimate act of nature, in both romantic and realistic terms. Due to the high mortality rates of the nineteenth century, especially among infants and children, death was perceived as God's will, beyond all human control. Ever-present and inevitable, death was an accepted familiar. Because death usually occurred at home, the experience of death was shared by all family members, as a event to be recorded and remembered. The death of a loved one signaled the completion of relationships, the closing of the circles of family and life. In some sense, the visual manifestations of mourning, and perhaps postmortem photographs most of all, were the links that served as both the aperture and closure of the circle.

Postmortem photography served several purposes. It was a way to console the bereaved, to share the image and details of the death of a loved one with those who had not been there, and to memorialize the deceased. A photograph created a tangible object that represented the deceased. This became especially important when the posthumous image was the only existing likeness of the individual. Postmortem photographs were kept on parlor tables and mantels and in family albums. They were also sent to far away relatives along with written accounts of the death. In all aspects postmortem photographs were literally "memento mori." Elizabeth Barrett wrote of a postmortem daguerreotype in her possession, "It is not merely the likeness which is precious—but the association and the sense of nearness involved in the thing…the fact of the very shadow of the person lying there forever!…I would rather have such a memorial of one I dearly loved, than the noblest artist's work ever produced" (Gernsheim and Gernshiem, *History of Photography*, 64).

Early on some miniaturists and other artists turned to photography, recognizing it as both a faster way to record the deceased and as a way to increase their business. Conventions from the posthumous painting tradition such as the inclusion of watches and clocks or bottles of medicine are often found in early photographs. Photographers did not hesitate to advertise their services. "Secure the shadow 'ere the substance fade" was a popular early advertising slogan for daguerreotypists. In an era when photographic portraiture was still not considered a matter of course and many of the living had never had a photographic portrait taken, it called out to the increased importance being placed on portraiture, whether living or posthumous, as a method of remembrance. Nathan Burgess concluded his 1855 article "Taking portraits after death" with these words: "How true it is, that it is too late to catch the living form and face of our dear friends and will illustrate the necessity of procuring those more than life-like remembrances of our friends, ere it is too late—ere the hand of death has snatched away those we prize so dearly on earth" (*The Photographic and Fine Art Journal,* 8:80). This practicality of this statement lies in the fact that before

Aubert, Francois. Corpse of Emperor Maximillian.

embalming became prevalent photographs had to be taken quickly while the body was on ice. The deceased were often buried on the same day they died. Thus the deceased was often rushed to the photographer's studio or the photographer often came to the home on short notice.

The intimacy of early postmortem images is striking. They often show in death that which would not have been shown in life. Images that we would consider very private—a wife mourning a husband at his death bed; women and girls in white burial gowns, meant to represent confirmation or wedding dresses, yet bearing a close resemblance to nightgowns; the overt portrayal of grief rather than stoic acceptance; even the canonized poses of grief which seem so staged and histrionic to contemporary viewers—were readily viewed and widely. The admittance of the photographer to a very private space shows the status of the photographer, along with the doctor and clergyman, as an important character in the final act of death. It bears repeating that throughout the 19th century grief was an acceptable public emotion, widowhood was seen as a lifelong female role, and the discussion of death and the deceased was considered a polite topic of conversation.

Unlike conventional portrait photography, in postmortem photography long exposure times were possible without discomfiting the sitter. The problems often encountered with blurring were not an issue, resulting in images that were crisper and of an often higher quality, than those of live subjects. The need to remain still during long exposures often created a lack of facial expression in images of the living, grieving relatives. Their grief was most often expressed through the conventional symbolism of their poses. This creates the dichotomy wherein portraits of the deceased seem to have a more expressive, relaxed demeanor than those of the living. Articles in photographic trade journals described techniques for photographing the dead including lighting and positioning the body, practical advise such as having relatives leave the room "should they witness some little mishap likely to befall the occasion" and how to open the eyes of the deceased with a spoon.

The earliest postmortem photographs were the simplest. In the daguerreotypes, ambrotypes, and other plate images of the 1840s and 50s the deceased was portrayed close-up and alone, with few, if any, accoutrements. Little attempt was made to soften the effects of death. With the exception of the "sleeping" child, the fact of death was quite obvious. Many images were taken exactly where the deceased had expired, without arranging the body. Often parents are shown holding a child in their laps, as if it is still alive, or holding it up for. Frequently the subject, usually a child, is placed across a studio chair or couch in a pose representing "the last sleep." Some images of this type depict the child in its bed, often in a christening outfit. "The last sleep" was the dominant theme of postmortem photography from 1840–1880. The close-up, "sleeping" image conveyed the ancient symbolism of death as sleep or a rest from one's labors. This convention can also be seen as the denial of death. It is often difficult to tell, especially in images of the very young, if the subject is living or deceased.

Sometimes the subject is seated upright on a chair or couch with its hands crossed in its lap and the eyes closed. The seated pose seems also to be an attempt to portray the subject as alive, although death is more evident than in the 'last sleep" convention. This pose was especially favored when no living portrait had been taken or when the family was considering having a posthumous portrait.

The inclusion of favorite items of the deceased in the image is concept taken from the posthumous portraiture tradition. Children were often depicted holding a small doll or favorite toy. Scattered toys (often studio props), abandoned in the moment of play symbolized the deceased's departure. Another subject favored for infants was the "from carriage to coffin" convention depicting the infant laid in a baby carriage with its small coffin present in the background shadows.

Sometimes multiple images were taken of the deceased: alone, with a parent or spouse, at the gravesite, and so on. Since daguerreotypes were unique images, this was one way of creating more than one image. Such images also recorded the different aspects death and mourning and the specific events and feelings associated with them.

Special black mourning cases embossed with funerary designs were made for postmortem daguerreotypes. If no postmortem photograph had been taken a photograph of the person while alive was sometimes put in a mourning case. Funeral notices, poems, letters, and other small remembrances were often kept in the case. As the century progressed photographs were included in mourning lockets and rings and all sorts of other memorial photographic paraphernalia was invented. In 1851 a U.S. patent for a special case to imbed daguerreotypes in tombstones was granted.

In the 1860s with the advent of albumen prints and the invention of the popular carte-de-visite, multiple prints of the postmortem photograph became possible. This facilitated the dissemination of images to relatives in distant locations, often accompanied by a letter describing the death, funeral, and mourning practices being observed. At this time images start to depict simple surroundings and tend to show the subject "at peace" with the hands crossed over the body.

In the mid-19th century the illustrated press such as the Illustrated London News and Harper's Weekly routinely published images of death, particularly images from war or gruesome accidents. In 1863 Matthew Brady began to produce images of the civil war dead that were sold to a popular audience in the form of stereographic cards. Images of death became a type of collectible news item. While this topic deserves further exploration elsewhere, for the purposes of this article it is worth noting that such wide acceptance of death as news image probably would not have been as easily accepted by the public were it not for the already widespread production of postmortem photographs for private use.

By the 1870s stereographs become a popular format for postmortem images. The stereograph's popularity was soon eclipsed by the larger format cabinet card, which afforded greater freedom in the posing, lighting and background of the postmortem portrait. The cabinet card remained popular through the turn of the century. In the larger format images of the dead became more staged and an interest in the beautification of the deceased surfaced for the first time. Rather than recording the raw facts of death, or denying death, flattering poses and the increased inclusion of symbolic accoutrements pointed out the transience of life. A stopped clock signaled the moment a life had ended; a rose held downward held indicated that the child depicted was indeed dead; the head and body resting on pillows stood for eternal sleep and a closed book symbolized a closed life. Flowers were also placed around the body. Flower arrangements in symbolic shapes such as crosses became popular. Personal effects, especially for children, were increasingly included and elements of the photograph were often hand-tinted.

In the 1880s the practice of embalming the deceased became more common, allowing more time to beautify the corpse and to set up elaborate poses and scenes. Casket photographs become more popular as the more luxurious and comfortable looking cloth-lined casket replaced the narrow wooden coffin heretofore in common use. Sometimes the image of the deceased was superimposed into the center of a stock background of flowers and wreathes, creating a lush, abundant setting foretelling the deceased's final destination in paradise. From 1885–1910 this increased emphasis on placing the deceased in the coffin within a larger funeral "scene" became more popular, especially for adults.

Beginning in the early 1880s black mourning cards were frequently distributed to mourners. The simplest contained only the name of the deceased. The most elaborate contained a poem from the vast stock of funeral literature that had been written over the course of the century, as well as a photograph of the deceased. This sideline to the practice of postmortem photography continued through the early decades of the 20th century. It is but one example of the numerous businesses that grew up around the high Victorian preoccupation with death and contributed to the outcry by numerous late Victorian social critics against the commercialization of death.

In the late 19th century death and the responsibilities associated with it increasingly moved from the home and family to institutions. The death of the sick occurred more often at the hospital, the body was prepared by professionals at the funeral parlor rather than by the family, and the wake was held there instead of at the home. The formal room in the family home known as the parlor where important visitors were received and viewings and wakes were held began its transformation into the modern living room as the funeral parlor replaced many of its previous functions. Postmortem photography taken at the funeral home emphasized the social aspect of the funeral, both as a family gathering and as the last record of the deceased as a tangible member of the family circle. The funeral director often took on the role of postmortem photographer, a service that he could discreetly offer the family.

As funeral rites and practices changed, some aspects of death became more private and many of the visible trappings of mourning began to disappear. The practice of photographing the deceased became more private, as evidenced by the fact that photographers no longer openly advertised their postmortem services.

The postmortem image seems have been made more for the private consumption of the family or even the individual within the family who requested it. By the turn of the century, the popularity of amateur photography brought about by the Kodak brownie camera had already made the need for a professional postmortem photographer even less necessary, particularly for those who wanted their desire to record the deceased to be more private. The photographic postcard format was popular among amateur postmortem photographers, but unlike other subjects, it was rarely sent through the mail as a postcard. When postcard images were sent, they were enclosed in a letter. Since the format was inexpensive and supplies were widely available it was often simply the format of choice for private consumption. By the end of the century, postmortem images in general were more frequently kept and put away rather than openly displayed or sent to relatives.

The practice of postmortem photography continued throughout the 20th century and is still alive in the 21st century. However, by the 1930s and 40s new funerary rites and customs had supplanted the high Victorian funerary practices. Death was no longer a socially acceptable topic of conversation; grief and mourning became very private, with view visible manifestations. In a manner of speaking, postmortem photography, once openly discussed and displayed, went underground.

Note: This article of necessity focuses on the 19th century Anglo-American practices of postmortem photography. A survey of practices around the world, focusing on places like Mexico, which have a rich and distinct tradition of postmortem photography, requires a separate series of articles.

POTTEAU, JACQUES-PHILIPPE (1807–1876)

J.-P. Potteau first practiced photography in 1861 when he was an assistant in the laboratory of malacology, at the Natural History Museum in Paris. His photographic work, at its beginning, is difficult to distinguish from that of Louis Rousseau, whose activity he takes over as the official photographer, in a field as vast as the museum's collections. Today he is better remembered as a portraitist, an important work undertaken as early as 1862 in his studio next to the botanical garden—Jardin des Plantes. Many foreigners visiting Paris where taken there and Potteau was able to portrait tens of people, members of Oriental embassies—China, Cochinchina, Japan, or Siam. He also started taking anthropological portraits of Algerians, Annameses, Bohemians, Indians, Italians, Kabyles and French. His photos are highly restrained: the models are posed either full face or side view, frontal, from a fixed distance, somewhat gravely. This approach to portraiture will be more frequently used, in the nineteenth century and later, for ethnography or even anthropometry. J.-P. Potteau's works, rich of more than a thousand photos, are yet to be fully explored. Most of his works is preserved at the Quai Branly museum in Paris.

JÉRÔME GHESQUIÈRE

POU Y CAMPS, JUAN MARIA (1801–1852)

Spanish photographer

One of the first daguerreian manuals to appear in Spain—*Exposicion Historica y Descripcion de los Procedimientos del Daguerreotipo y del Diorama* was translated from the inventor's original text by Joaquin Hysern y Molleras. It contained extensive notes on experiments carried out by Dr. Juan Maria Pou y Camps—one of the first to make daguerreotypes in Madrid—who also published the volume.

He had attended public demonstrations of the process in Paris, and recognised that the process could be improved significantly. By the end of October 1839 Pou and colleagues in Madrid had produced their first images, and before the end of 1839, their improvements and observations on the process had been incorporated into the manual.

One suggestion was the adaptation of the camera to act as a photometer. Thus he was probably the first

person to recognise that photographers needed some means of accurate exposure determination.

His interest in photography, however, seems to have been relatively short-lived, and there is scant evidence of further engagement with the medium after 1840.

Dr. Juan Maria Pou y Camps was born in Girona in northern Spain and studied pharmacy in Barcelona, becoming Professor of Pharmacy in Pamploma by the age of 28. By 1849 he was listed as Professor of Pharmacy at the University of Madrid. He died in Madrid in 1852.

JOHN HANNAVY

POUNCY, JOHN (C. 1808–1894)

Active from the daguerreotype period John Pouncy remained firmly a Dorset photographer based for his whole life in the county town of Dorchester—yet his reputation was international. His long career, his patents in 1858 (No.780), 1863 (No.267) and 1868 (No. 3849) for his carbon process and his venture into colour fine art reproduction should all be seen in the context of his obituary: he "displayed a strong will and firm determination, and when one he had convinced himself that he was right it was difficult to move him" (*Dorchester Chronicle*, 29 March 1894).This determination provides the context for the fraught reception of his claims since his reluctance to reveal the exact details of his discoveries clearly fostered popular disbelief and pedantic professional jealousies.

Pouncy was copying prints and drawings as early as 1855 but the un-gentlemanly grilling which this provincial entrepreneur received from the Photographic Society came to a head 1858 (with Roger Fenton in the chair) and was first unravelled by Arthur T. Gill in a series of two articles in 1965. The complex story of how a pioneer determined not be overwhelmed if not bullied by the combined scientific might of London prompted Gill to ask whether this surprisingly dramatic meeting "did not nearly come to blows" (*Photographic Journal*, February 1965, 57). To several authoritative audiences Pouncy demonstrated his ability to produce prints but he would not divulge the exact process—individual prints were, and still are, very convincing, but they did not lend themselves to mass production so Pouncy's discovery was soon superseded by more robust processes which could be applied on a commercial and industrial scale. The Victoria and Albert Museum holds at least one print which proves just how tonally rich Pouncy's images could be in comparison with the rather less satisfactory views reproduced in his famous publication *Dorsetshire Photographically Illustrated* (1857) which can claim to be the first to transfer photographic images into published illustrations—though these look much more like lithographs than photographs.

Pouncy, whose own confidence can hardly have been aided by the consistent misspelling of his name (Pouncey) over three consecutive meetings by the otherwise punctilious Photographic Society, was not going to be forced to reveal every detail of his revolutionary carbon process which promised to make permanent images often still infamous for their evanescence: he was well aware that he would "have the credit of one of the greatest discoveries photography has ever known" (*Photographic Journal*, 11 December 1858, 91). Despite this lack of commercial success it would still be true to say about him that "there need be no more lamentation over fading photographs" (*The Builder*, 31 October 1868, 800). It is clear that on many occasions that he could show examples of his process so it is with some justification that he claims "I can produce in printing ink of any colour direct from the negative photographic positives, negatives, transparencies, transfers for lithographic or press printing, and photographs in ceramic colours, which can be transferred to and burnt on china, earthenware, &c" (*British Journal of Photography,* January 13 1865, 18).

His process turned out in the end to be far less successful than that of Pretsch and Poitevin and their successors like Swan. Poitevin won the prestigious Duc de Luynes competition in France: Pouncy was awarded the silver medal and complained of French perfidy. Pouncy never conceded his claims and for a period of at least ten years in several countries continued such a concerted campaign that it has successfully baffled photographic bibliographers ever since. He certainly applied his skills in an apparently successful colour reproduction process for paintings in conjunction with his son Walter (the 1868 patent) which is still in need of a modern study by historians of art and printing quite apart from photography. The quite conventional Pouncy studios in Dorchester are the locus of several photographic puzzles needing further scrutiny. Even before taking up photography John Pouncy was a painter, glazier, carver, gilder and dealer in oil paintings so it is clear that he continued mix and apply these skills using photographic techniques to the point where the *Art Journal* gave a favourable endorsement in an undated article (presumably of the late 1860s) in relation to the colour copying of paintings by John Faed. This later manifestation of a permanent colour process was read to Photographic Society of Scotland in 1864 (described in *The British journal of Photography*, 1865). The extent of colour printing or application to ceramics associated with Pouncy remains uncertain.

Though Pouncy was championed by Thomas Sutton and was much feted, by the 1870s he would have known about the more viable variants of his process being brought to industrial success by photographers like Adolphe Braun and companies like the London Stereoscopic

Company but he continued to operate for another thirty years keeping secrets which are still only partially understood. He remained an independent pioneer: a sign outside his shop in Dorchester reinforces the proprietary nature of his claims "John Pouncy Inventor of Photographs in Carbon and Oil Colours on Canvas Panels. Inspection invited. To be only obtained from John Pouncy"

IAN LEITH

Biography

Pouncy lived his entire life in the market town of Dorchester maintaining his business in decorative materials as well as photography. Born in 1808 or 1809 he owned a succession of shops and studios in the town at least one of which proudly advertised his quite justifiable claims to photographic fame. His son Walter (1844–1918) collaborated with him and later operated in Swanage, Dorset. Elsewhere, he exhibited in Edinburgh)[1858, 1863, 1864) and London ([1862) receiving medals in Berlin (1865), Edinburgh (1863), and Paris. He died in Dorchester in March 1894.

PRESTWICH, WILLIAM HENRY (1831–1912)

English photographer

William Prestwich was the head of a talented family most of whose members were engaged in some form of the photographic business. From 1870– 892, Prestwich ran a string of photographic studios in the London area, and at the same time took out a series of patents for improvements in lenses, emulsions, stereoscopes and lantern slides. This in turn led to the formation of the Prestwich Manufacturing Co., in T ottenham in 1895 with his son John, destined to become one of the pioneer firms in the field of cinematograph equipment.

The firm started as the Moto Photo Supply Co., in the City of London, and sold their products through the established firm of W C Hughes. Prestwich illustrated his first camera in the *Magic Lantern Journal Annual* (1897– 1898), following this with a demonstration at the Hackney Photographic Society. Several early motion pictures used it, notably by Prestwich's son Edward, including Queen Victoria's Diamond Jubilee, and W.G. Grace at Lord's. A fiction film, *The Artist's Model*, was made in 1898.

Prestwich retired at the end of the century, and the firm, later known as J A Prestwich Industries Ltd continued under John Prestwich's direction until his death in 1952. The firm was taken over by Villiers Engineering in 1964. William Prestwich died in Laughton, Essex November 1, 1912.

DAVID WEBB

PRETSCH, PAUL (1808–1873)

Austrian photographer

The publication in 1856 and 1857 by Paul Pretsch's Patent Photo-galvanographic Company of the first part of *Photographic Art Treasures or Nature and Art Illustrated by Art and Nature* was heralded as a new era of photo-mechanical reproduction, and as a practical means of bringing lower costs to the publication of photographically illustrated works.

However, the limitations of the process, the need for extensive retouching, and the lack of subtlety in the important mid-tones of the image, brought criticism and acclaim in equal measure from the photographic press. Five parts were published, each containing four images. Photographers included Roger Fenton, appointed

photographic manager of the company in 1856, William Lake Price, Lebbeus Colls, and William Howlett. Contributions by Oscar Rejlander and others were planned but never published.

Before the company went into production, Pretsch received a letter from Talbot requiring him to purchase a licence, as he asserted that Pretsch's process infringed his 1852 patent. There were fundamental similarities.
