Paul Pretsch was born in Vienna and trained as an engraver. He moved to London in 1854 for the express purpose of exploiting his new process. Two British patents were granted in 1854 and 1855, and premises established in London's Holloway Road.

By 1858 the company had ceased trading, and Pretsch later worked for de la Rue as an engraver.

JOHN HANNAVY

PREVOST, CHARLES HENRY VICTOR (1820–1881)

French and American photographer

Victor Prevost was born in 1820 in La Rochelle, France. As a young man, he studied art in Paris with Paul Delaroche. He went on to work as a lithographer, and exhibited several lithographs at the Paris Salons of 1845 and 1846.

Soon after this, however, Prevost decided to go to New York City, where he began earning his living as a lithographer. In 1848 and 1849, Prevost worked for the lithographic forms of Goupil, Vibert & Co. and Sarony & Major.

From 1850 until 1852, Prevost worked in a studio with five other artists. One of the other tenants was a daguerrotypist, which may have piqued Prevost's interest in photography. Prevost's workplace was also only a few blocks from the Broadway studios and galleries of the major daguerrian portraitists of the city.

During the early 1850s, the daguerreotype was the primary photograph format in the United States. Although in 1840 William Henry Fox Talbot had introduced the calotype, a paper-based photographic process, he took out a patent on the process and required anyone interested in using it to license the technique. Only a few American photographers cared to do so, none of them in New York.

Meanwhile, the paper negative process was further developed by several Frenchmen. Gustave Le Gray, a French artist, developed a method of waxing the paper negatives before they were placed into the sensitizing bath, which allowed the negatives to be kept for two weeks before exposure, and then to be kept for up to a week before developing and printing. Le Gray published his findings in France in July 1851; they were translated and printed in America in 1852. One of the few American photographers interested in the new paper process was Victor Prevost.

In 1853, Prevost traveled to France to learn this new method of photography from Le Gray. While there, Prevost made a series of photographs of the French countryside, which were subsequently published in an illustrated edition of *Twenty Years After*, a historical novel by Alexandre Dumas. In these early examples of his photographic work, Prevost manages an exquisite feel for composition, and shows a mastery of the new technique.

Upon returning to New York in the latter part of 1853, Prevost set up a photographic studio at 43 John Street. Later that year, he entered into a partnership with Peter Comfort (P.C.) Duchochois, whom he had met in France. Duchochois became known for his prolific contribution to the photographic scientific literature.

In a New York City business directory for 1853, Prevost listed himself as a photographer. Other major photographers in the city continued to list themselves as daguerrians. The next four years were Prevost's most productive as a photographer, and resulted in the first paper-based photographs of New York City.

While some of Prevost's images echo standard scenes that were being engraved and lithographed for public consumption at the time, his photos display a more artistic sensibility, in keeping with his training. In New York City, Prevost mainly photographed outdoor scenes—commercial buildings, churches, backyards of urban residences, larger country estates and residences, and ships in dock on the Hudson. Similarly, the rural estates and scenes he photographed in upper Manhattan, West Point, New York, and several towns in New Jersey display a sense of scale more in line with the Hudson River School artists than with daguerrian portraiture.

Prevost entered some of his photographs in the photographic competition at the New York Exhibition of the Industry of All Nations at the Crystal Palace in 1853–1854. He was awarded several honorable mentions but his photograph made from a waxed paper negative lost the prize to one taken with the wet-collodion, glass-plate negative process. Nevertheless, Prevost was intrigued by the exhibition and took many photographs of the interior of the building, including several views of neo-classical statues, as well as the large machines exhibited.

In 1854, Prevost traveled to West Point to photograph the solar eclipse on May 26. Many daguerrotypists photographed this astrological event, but Prevost appears to have been the most prolific photographer, making nineteen exposures onto waxed paper negatives in quick succession. A subsequent album was made, showing the consecutive prints, as well as a smaller composite image printed from all the negatives.

That same year, photographs by Prevost and Ducho-

chois were published in the *Photographic and Fine Art Journal,* along with a note celebrating their work. Despite this praise, it was difficult for the two to compete with the successful daguerrian studios that dominated New York's photographic market. Prevost's partnership with Duchochois only lasted until 1855, after which he went to work for Charles Fredericks, another photographer who was expanding from daguereotypes to include paper photographs made from wet collodion glass plate negatives. While working for Fredericks, Prevost listed himself in city directories as a chemist, suggesting that he mixed chemicals or printed photographs for Fredericks.

In 1857, Prevost gave up on earning his living through photography. His wife Louise had been assisting her aunt at her school near Madison Square, Madame Chegaray's Institute for Young Ladies. Victor Prevost joined the faculty as a teacher of drawing, painting, and physics. He continued to work as an educator until his death.

Despite having abandoned photography as a career, Prevost continued to photograph the continually changing face of New York City. In the fall of 1862, he photographed and compiled an album of 35 views in Central Park, which was still undergoing construction. These albumen prints were made from glass negatives. In the late 1870s, he completed an album of eighteen photographs of the American Museum of Natural History. The photographs show the exterior of the building, completed in 1877, and several of its collections.

Prevost died in New York in April 1881. He was buried in Calvary Cemetery in Brooklyn. He was largely forgotten after his death, until a cache of his negatives was discovered in 1901, and he was thereafter celebrated as the creator of the first paper photographs of New York City.

Collections of Prevost's waxed paper negatives and/or surviving salt and albumen prints are held by the following institutions in the United States: George Eastman House, Metropolitan Museum of Art, Museum of the City of New York, New-York Historical Society, New York Public Library, and Smithsonian Institution.

JENNY GOTWALS

Biography

Charles Henry Victor Prevost was born in 1820 in La Rochelle, France. As a young man he studied art in Paris under Paul Delaroche. Prevost worked as a lithographer, and exhibited his work in the Paris Salons of 1845 and 1846. In 1849, Prevost was living in New York and was married to Louise Berault. Their son Emmanuel Emile was born in 1850. In 1853, Prevost went to France, where he learned Gustave Le Gray's new method for creating calotypes. From 1853–1855 Prevost had a partnership with P.C. Duchochois, and began taking paper photographs of New York City urban sights, and rural areas in upper Manhattan and New Jersey. Prevost exhibited his calotypes at the New York Exhibition of the Industry of All Nations at the Crystal Palace in 1854. From 1855–1856, Prevost worked for photographer Charles D. Fredericks. In 1857 Prevost began working as a teacher, and continued to work as an educator and principal until his death. Prevost died in New York in April 1881.

PRICE, WILLIAM LAKE (1810–1896)

English photographer

Like many early photographers, William Lake Price originally trained as a painter, turning to photography c. 1854. Before that date, his landscape and architectural watercolours had been exhibited widely, including several exhibitions at the Royal Academy in London, and the Old Water Colour Society.

He joined the Photographic Society of London shortly after its formation, and exhibited his work at the Society's Annual Exhibitions from 1855 until 1860. His work was predominantly both genre and portraiture, and his study 'Don Quixote in his Study' was widely exhibited, and also chosen as one of the photogalvanographic plates for the first series of Paul Pretsch's *Photographic Art Treasures* published in 1857. His portraiture subjects included Prince Albert, Owen Jones, and many of the leading Royal Academicians of his day, including William Powell Frith, Clarkson Stanfield and David Roberts.

Lake Price was a popular lecturer on many subjects relating to photography, and his lectures were widely published in photographic journals in both Britain and

the United States. His book, *A Manual of Photographic Manipulation* was first published in 1858 by John Churchill in London, with a second edition published a decade later. He announced his retirement from photography in 1862, but returned to both practice and write about photography six years later, continuing to lecture and write intermittently until 1889.

JOHN HANNAVY

PRINGLE, ANDREW (b. 1850)
English photographer

To his contemporaries, Andrew Pringle was "a gentleman" and "usually polite and obliging." One of three brothers, Pringle was educated at Harrow School, then Trinity College, Cambridge, before serving in the 8th Hussars.

Pringle took up photography in 1874 and travelled in France, Germany, Switzerland, Italy, Spain, and Africa. He investigated all processes and, with Professor W K Burton, published *Processes of Pure Photography*. By 1886, he specialised in photomicrography and at a dermatological congress, Pringle created a sensation by illustrating a rare bacillus. He wrote textbooks on the optical lantern, and on photomicrography, and contributed illustrations to *Kleine's Histology*.

When he was President of West Kent Amateur Society, *The Photographic News* of 1889 asserted that Pringle never took offence "until his good nature was rudely strained by the incautious." His procedures were methodical and by noting every factor affecting development, as well as "anything else that occurred to me," he identified "the secure exposures, the doubtfuls and the 'instantaneously'-exposed plates, which were sure to require more or less care."

Pringle was a Fellow of the Royal Meteorological Society and a former president of the Photographic Convention.

RON CALLENDER

PRINTING AND CONTACT PRINTING

Shortly after William Henry Fox Talbot produced his first successful images with his Photogenic Drawing process in 1834, the concept of printing was introduced into the practice and language of photography. This

marked the most radical difference between the daguerreotype and the paper negative. The unique direct positive of the daguerreotype may, initially, have offered finer detail and higher quality, but the ease of duplication via the negative marked the real birth of photography as we know it today.

It was inspired thinking on Talbot's part to recognise that the lights and shades, reversed in his photogenic drawing, could be restored by exposing another sheet of salted paper in contact with the negative. Just as the original photogenic drawing paper was exposed in the camera until a visible negative image of the required strength was achieved by the action of light alone, so the first positive prints were exposed in contact until the positive achieved the required density. No development was originally involved, with the exposed and printed-out image then simply fixed and washed.

As Robert Hunt wrote, in 1857, in his *Manual of Photography,*

> The copying frame is an indispensable requisite to the photographer: it is used for copying all objects by transmission, and for multiplying the original pictures, obtained by means of the camera obscura from nature: it is, indeed, the printing-press of the artist.

The 'copying frame' remained the essential tool of the photographic printer for several decades, with racks of frames arranged outdoors and directed towards the sun—as seen in the celebrated panorama of Talbot and Henneman's printing establishment at Reading. Because of the low sensitivity of the material, and the inherent density of the negative, printing on a commercial scale only became viable once the negative was waxed or oiled to increase its translucency—and thus reduce exposure times. Only then could multiple copies be made within an acceptable time frame—the approach adopted by Talbot for *The Pencil of Nature* (1844) and *Sun Pictures in Scotland* (1845).

Commercially available printing frames used two sprung bars across the back to hold the negative in close contact with the positive paper. A hinged back allowed for one spring to be released, and the printing paper gently folded back to assess progress.

The 'salt print' as it became known, remained, essentially, the same material which had been used in the camera, the only difference, as it evolved, being the introduction of a 'developer' to reduce exposure times. That 'developer' was not dissimilar to the sensitizing bath used to activate the light sensitive chemistry before exposure—namely silver nitrate, acetic acid and gallic acid.

The idea of developing prints was originally proposed as an expedient for printing on dull winter days—where light levels might double or even treble exposure times. Sparling's *Theory and Practice of the Photographic Art* (1856) advised that 'positive printing by the negative method,' as the production of developed prints was known, should only be undertaken by the most skilful. Quoting another eminent teacher on photography, he reported that

> Mr Hardwich advises the amateur to master the manipulation of the ordinary positive process before trying that by development… … The exposure to light is conducted in the ordinary printing frame: it extends from a few seconds upwards. On removing the negative a very faint image is seen, which develops rapidly when the gallic acid is applied. The development being completed, the prints are well washed and fixed in hyposulphite of soda, one part to four of water. The tint is improved by adding a little nitrate of silver (a few drops of the exciting bath) to the gallic acid towards the end of the process, but a better plan is to tone the prints in the gold bath

The quality of the salt print, correctly exposed and processed, was high, and despite the introduction of the albumen print in 1850, salt prints remained popular with many users well into that decade. Thus, many of the prints published in 1856 after Roger Fenton's trip to the Crimea were developed salted paper prints—and despite problems of fading experienced by many users, many of Fenton's Crimean images retain their original richness.

Albumen printing paper, introduced in 1850 by Blanquart-Evrard of Lille, offered a higher concentration of silver halide, contained within a thin layer of egg-white on the surface of the paper, significantly enhancing the sharpness of the print, and extending the tonal range. Like salt prints, albumen paper could be used either as a printing-out paper or as a developed paper with a significantly shorter exposure. As Blanquart-Evrard's intention in introducing the paper was to introduce commercial production methods, the developed print was the norm, and with it, he claimed to be able to produce in excess of two hundred prints per day from a single negative. That represented a remarkable progression from the original printed-out salt print, where the daily output from a single negative was counted in single figures.

Guidance on the progress of the printed-out image, assessed by inspection, was offered in many manuals. Sparling (1856) advised that

> if the general aspect of the print is a rich chocolate-brown in the case of albumen, a dark slate-blue with gelatine or ammonio-nitrate paper, or a reddish-purple with paper prepared on serum of milk, probably the subsequent colouration will proceed well.

Again, the printing frame was the only piece of equipment necessary—that is until the introduction of the Solar Enlarger in 1857. David Acheson Woodward designed and patented the idea of the solar enlarging camera, able to make enlarged life size prints from

quarter plate and half plate negatives with an exposure of about forty-five minutes. The camera used a mirror and condenser lens to focus sunlight on to the negative, the image being projected on to the paper via a copy lens. Patented improvements to the solar enlarger, in the 1860s and 1870s saw it equipped with a heliostat—a clockwork motor to rotate the mirror—thus ensuring that the light beam remained concentrated on the condenser lens throughout the exposure.

A modification of Woodward's design, introduced in 1864 by Desiré Charles Emanuel van Monckhoven, was the first instrument to really look like an enlarger. Fitted into the wall of the darkroom, it gathered light in the same way as Woodward's apparatus, but used a more complex lens assembly to correct for spherical aberration and thus produce a sharper more evenly illuminated print.

The enlarger, faster printing emulsions, improved processing chemistry and brighter light sources revolutionised the production of prints by the 1890s.

By that time, though, the higher and higher quality and sharpness of the print had prompted some image-makers to revisit the impressionistic quality of the paper negative and salt print, and also to invent, explore and develop alternative readings of the positive image through ink, gum, platinum, carbon and other printing processes. Together, they offered photographers a huge diversity of means of expression by the century's end.

PRINTING-OUT PAPER

While the idea of printing-out paper is as old as photography itself, such products remain available today, meeting the needs of a small specialist market where the unique characteristics of such papers are still sought after. Today's papers, based on gelatine-silver chloride technology, can trace their lineage back to the 1880s, but the first printing-out papers were used by Fox Talbot in the 1830s.

The term, 'Printing-Out Paper,' and its abbreviated form P.O.P. date only from the early 1890s, when Ilford Ltd in England coined the phrase and introduced it as a trade name for their silver chloride paper, but it has since been applied retrospectively to a large group of printing materials.

The essential and defining characteristic of a printing-out paper is that the image is produced by the action of light alone. There is no chemical amplification of that image by development, the printing going through the simple stages of exposure, fixing and washing, or exposure, toning, fixing and washing, the latter sequence resulting in a richer print colour and greater permanence.

Generally speaking, the earliest printing papers were of very limited sensitivity, requiring long exposures in contact with a paper or glass negative. They could be toned, fixed and washed in relative well-lit spaces, and certainly by candlelight. Thus, such prints were not dependent upon a safe-lit darkroom. Their modern counterparts, however, require to be treated with a greater deference if optimum print quality is to be maintained.

Printing-out papers fall into three categories, two of which are based on silver halide chemistry. The third group comprises processes such as cyanotype (qv), using non-silver-based light sensitive chemistry, where the exposed print is washed to remove soluble salts after exposure.

The two major silver-based groups are salted papers and those papers where the light sensitive chemistry is held in an emulsion or carrier coated on to the surface of the paper itself.

Fox Talbot's salted paper—effectively the same material used to make a negative in the photogenic drawing process—was the first printing process, achieving widespread popularity and almost-universal dominance for more than a dozen years. Although it could be used as a developed paper—with exposure times reduced from hours to seconds—many amateurs and professionals alike continued to use it without development. There

were advantages—the developed image rarely exhibited the extended tonal range of the printed-out version.

The same was true of albumen paper, the first paper to carry the image on the paper surface, and introduced in 1850s by Blanqart-Evrard. Although conceived as a developed printing material—to facilitate printing on an industrial scale—albumen was used by a large percentage of photographers, again amateur and professional, as a printing-out material. It was easier to manipulate, more predictable, and less susceptible to the vagaries of changing chemical strengths and conditions.

Granted, developed papers were faster to use, but only when large production runs of prints from single negatives were being made, were such considerations important. In the home darkroom, or small professional studio, printing was a lengthy process in any case. Salted paper had to be made by hand by the photographer, and while albumen paper could be bought already coated with the albumen layer and some of the chemistry, it had to be sensitised and dried before it could be used.

In 1866, the Frenchman Juan Laurent in collaboration with Spaniard José Martínez-Sánchez perfected 'Leptographic' paper ('Leptofotografía'), a collodio-silver chloride printing paper which was sold ready to use. The light-sensitive silver chloride was held in a binding layer of cellulose nitrate, separated from the paper by a layer of barium sulphate (later known as baryta), giving a much whiter base colour to prints than had been previously possible with albumen paper. The baryta layer acted as a barrier, eliminating the spotting from rusting metal particles in the paper which sometimes happened with albumen papers, and at a stroke, the introduction of this paper removed from the photographer all the paraphernalia of having to sensitize the paper before use, as had been needed with albumen. As the manufacturers claimed it had three times the sensitivity of albumen, exposure times for contact printing could also be reduced significantly. Despite such promise, the paper was not a commercial success, and it would be the 1880s before ready-made silver chloride papers achieved significant popularity.

In 1882, William de Wiveleslie Abney published the procedure for making a gelatine-silver chloride paper, but it did not immediately go into production.

One of the first collodio-chloride papers to achieve success—and very similar in chemistry to Laurent's—was introduced in 1884 by Paul Eduard Liesegang of Dusseldorf, who called his paper 'Aristotype.' In the following year, fellow Germans Ashmann and Offord added gold to their emulsion, and in so doing created a paper which self-toned in the fixing bath, eliminating one of the processing stages.

It has been argued that, after the introduction of commercially manufactured gelatine dry plates, the commercial manufacture of ready-to-use printing papers was driven not by an increase in printing efficiency, but the continuation of the subtle print quality which had been possible with albumen. Collodion and gelatine-based printing papers, when developed, produced a neutral image, whereas when used as printing-out papers, the rich warm brown tones of the gold-toned albumen paper could be imitated.

The year after Liesegang's success, in 1885, the Britannia Works Company in England—forerunner of Ilford Ltd—introduced the first of their gelatine-based silver chloride papers, a product which was replicated throughout the world by several companies. It is the successor of that gelatine-based silver chloride emulsion which persist as a specialist product today.

PRITCHARD, HENRY BADEN (1841–1884)

Henry Baden Pritchard was born on 30 November 1841 the son of Andrew Pritchard the well-known optician, spectacle and optical instrument maker. He was educated in Eisenach and Lausanne and entered the War Department at Woolwich Arsenal in 1861 at the age of twenty and remained there until his death, superintending the photographic branch. He married Mary Evans in 1873 after meeting her at the house of his friend H.Pp Robinson in Tunbridge Wells.

Pritchard joined the Photographic Society in 1868 and was elected to Council in 1870, he became Honorary Secretary in 1872, returned to Council in 1874 and

was Vice President at the time of his death. Between 1868 and 1877 he published twelve communications in the Society's journal. He was treasurer of the Photographers' Benevolent Association.

In 1880 Pritchard took over as editor of the *Photographic News* after the death of G. Wharton Simpson and extended the journal's reporting of news and scientific coverage. His *The Photographic Studios of Europe* (1882, second edition 1883) was based on his original reports carried in the *Photographic News* between 1880 and 1883. He also edited the *Year Book of Photography* from 1881–1884. Pritchard wrote or edited other photographic technical books and contributed numerous papers to photographic, scientific and other journals. He was elected a Fellow of the Chemical Society in March 1872.

Although his photographic activities were prolific Pritchard also published several novels and a play. He died suddenly of pneumonia at Blackheath, Greenwich, on 11 May 1884 at age forty-three.

MICHAEL PRITCHARD

PROCESS PHOTOGRAM

The precursor to *The Process Photogram* was an ad hoc series of articles and reports in *The Photogram* from its launch in January 1894. Subsequently *The Process Photogram* would claim its launch date as January 1894. *The Photogram* was edited by Henry Snowden Ward who had a particular interest in photo-mechanical processes and he justified its inclusion in what was primarily a photography journal by stating: 'we believe that photo-processes are on the eve of great advancement.' That statement was not misplaced as the 1890s saw a significant increase in interest in all methods of transferring photographic images on to the printed page through a mechanical press using inks. Three-colour work and the reproduction of photographs in periodicals and catalogues were particular concerns of the magazine.

In January 1895 *The Process Photogram* was launched as a separate supplement. Snowden Ward stated: 'The Process Photogram is the outcome of a double wish. Photographic readers wished for less process matter while photo-mechanical readers expressed a wish for more. To meet both we start a new edition at first, with only eight extra pages, devoted to purely process matter.' The initial print run of 1000 was increased to approximately 2000 after A W Penrose & Co offered to send it free of charge to their customers. *The Process Photogram* was strongly practical in its articles and focused on trade news and apparatus, descriptive visits to companies, theoretical articles on, for example, printing screens and reviews of patents, new techniques, processes and equipment. In 1896 the supplement added '*and Illustrator*' to its masthead which it retained until volume XII number 144 of December 1905. Number 145 of January 1906 number 145 saw the journal being renamed *The Process Engraver's Monthly. The Process Photogram.*

From January 1907 it appeared as a totally separate publication from *The Photographic Monthly* (the successor to *The Photogram*). Its stated aim was to be the representative organ of all who used photo-mechanical and photo-chemical methods of illustration: workers in zincography (line and half-tone), collotype, photolithography, photogravure, Woodburytype and other photo-reproduction processes and to provide an epitome of technical progress and discovery and a means for the discussion of commercial subjects. It's size and pagination was increased and it promised new pictorial, confidential (trade) and special supplements.

The Process Engraver's Monthly, with the subtitle *Process Photogram* until 1947, continued until volume 56 (1956) when it became *Process: the photomechanics of printed illustration*, and from 1961 *Graphic Technology*.

PROJECTORS

The projection of glass-based images was already commonplace when photography was introduced. The slide projector, or magic lantern, had been invented in the seventeenth century, perhaps by the Dutch scientist Christiaan Huygens, and was in widespread use in Europe by the end of the century. The popular Phantasmagoria was a ghost-show using lantern projections. Few projectors dating from before 1800 have survived. A typical magic lantern of that date comprised a rectangular or cylindrical metal body containing the illuminant (an oil lamp) capped with a chimney or cowl, hooded to reduce lightspill. The arrangement of the internal components was: concave metal reflector, lamp, then a large glass condenser lens to concentrate the light. The slide stage, an external construction of grooved supports into which long glass painted slides could be moved along, was fixed in alignment with the condenser. In front of the slide stage was the objective, or focusing, lens; a sliding tube containing one or more glass elements.

Soon after the introduction of photography, photographic images were being made on glass. To show

photographic slides at their best, magic lantern lenses needed improvement. Spherical aberration, which blurred the edges of the projected image—more evident with the fine detail of a photograph than with earlier painted scenes—could be reduced when the Petzval lens, designed for cameras in 1841, was adopted for slide projection. Chromatic aberration, causing color fringing—which became more apparent with monochrome photographic images—was corrected with the introduction of achromatic lenses.

In Britain in particular, from the 1850s, many magic lanterns had wooden bodies, usually with a sheet metal lining to protect the wood from the internal flame, with a metal dome top and cowl. These wood-bodied projectors, being cooler externally, were safer to operate. The external metal parts were usually made from brass and lacquered, the device taking on a prestigious appearance, conferring status to the user.

From mid-century, professional users of the lantern—lecturers and showmen—started to employ limelight as an illuminant. Hydrogen and oxygen gases from leather bags (later, metal cylinders), were mixed in the limelight burner to produce a strong flame. This flame played on a small cylinder of quicklime, which glowed white hot. Much brighter than an oil lamp, limelight could produce very large screen images.

Other illuminants introduced included, from the 1850s, the electric arc lamp—though providing the necessary current was difficult and limited its use—and from the 1890s, acetylene.

One important magic lantern, the Sciopticon, developed in the United States in 1869, had a larger condenser than usual to avoid cropping the corners of a projected image and an improved lamphouse for cooler running.

From the 1830s, it became the practise for advanced presentations to use two magic lanterns mounted side-by-side, with a manually-operated rocking double-shutter arrangement in front of the lenses. Each shutter had a serrated edge, and as the shutter unit was operated the image from one projector gradually faded out as the image from its twin projector faded in, producing a dissolve effect. These pairs were difficult for one operator to manage, and in the late 1850s the vertical double or biunial lantern was introduced and eventually became popular. With one lantern above the other, manipulation of the slides was easier. From the 1870s the triple lantern (some versions known as triunials) started to appear from English, German, and later American manufacturers. Some biunial and triunial lanterns had slots in which glass filters could be placed, useful for giving instant color tints to photographic slides.

A different method of construction became popular in the United States. The base of the lantern comprised two parallel metal rods, on which the components—reflector, illuminant, condenser unit, slide stage and focusing lens—were mounted. Each component could slide to and fro, enabling very easy adjustment of their relative positions. Vertically stacked double and triple versions were also manufactured. In America slide projectors—especially biunials—became known as stereopticons, even though the image was not stereoscopic. (Today, the term can lead to confusion as it is also used to mean a hand-held or cabinet 3-D viewing device).

Most early slides were set in wooden frames, but from the 1870s mechanical slide holders made the changing of unframed glass slides easier.

Special lanterns for the projection of opaque pictures and objects, including (from the 1840s) photographic images, were known as episcopes, megascopes, or wunderkameras. Epidiascopes could also show transparent slides.

The first color photographs, made using the additive process by James Clerk Maxwell in Britain in 1861, were projected by means of superimposed slides from three magic lanterns, each with a color filter: red, green, and blue.

From the late eighteenth century, lanterns for domestic use were made in Germany, which continued to be a major producer throughout the nineteenth century, during which production became widespread in England, France, and the United States. Most lanterns for use in the home had simple pressed steel bodies, and used paraffin (kerosene) lamps. The finish was sometimes bare metal in the early days, and later a black 'lacquer' (paint), or a chemically-produced blue metallic effect. From the 1840s to the 1920s, the miniature magic lantern was a popular children's toy. Slides were mostly painted or lithographed, but some later German and English toy lanterns showed photographic slides made in small sizes.

Photographic societies frequently projected slide images made by their members, and this use of the lantern for amateur photography extended its sphere of operation. A specialist use was the projection of microphotographs, by means of a high-power magnifying attachment. Some lantern users, especially those with church and scientific connections, were uncomfortable with the term 'magic,' referring instead to the 'optical lantern.'

Photographic motion pictures came to the lantern screen from 1895–96, and would eventually become a special branch of optical projection. Many early film machines could also show conventional lantern slides, usually by the operator simply pushing the lamphouse from the cinematograph mechanism to the slide stage.

During the twentieth century, the magic lantern evolved into the 35mm slide projector.

PROUT, VICTOR ALBERT (active 1850s–1860s)

English photographer

Prout was an early professional photographer largely recognised today for his three distinct early 1860s publications: *The Interior of the Abbey of Westminster: The Thames, from London to Oxford, in Forty Photographs,* and *Mar Lodge, August 1863. A series of photographs illustrating the visit of their Royal Highnesses the Prince and Princess of Wales to Mar Lodge, the seat of the Rigfht Hon.the Earl and Countess of Fife, during the Braemar Gathering of 1863.* The Westminster Abbey folio, published by P.&D. Colnaghi & Co.Ltd. in 1860, contained 23 albumen prints showing the abbey's ancient monuments. Prout made good use of the dramatic natural light for these early interior views. Later, photographs from this series were published as stereos by the publisher James Elliott. The most distinctive of his works is undoubtably the unique series of 40 panoramic views of the Thames, England's greatest river. The publication is not dated but was produced around 1862 in two parts and published by Virtue & Co. The tranquil wide-angle views were made with a special panoramic camera built for Prout by London opticians Ross & Co.When first published the Thames river photographs were not credited to Prout but have been attributed to him since. The Mar Lodge publication contained 70 studies, ranging in size from carte-de-visite to whole-plate, were published by Prout in 1864. The tableaux-style photographs were staged for the camera by the actor and artist the Hon. Lewis Wingfield (1842–1891). All of Prout's known images are well-executed, exhibiting good technique and careful use of daylight to produce his collodion negatives. He exhibited his architectural studies along with copies of paintings at London photographic exhibitions between 1856 and 1862 and operated a portrait studio at 15 Baker Street, Portman Square, London from 1862–1865. Prout was able to produce a wide range of high-quality work, all of it artistic in style and content. However, he seems to have had little commercial success and in the mid 1860's moved to Australia and worked as a studio photographer with Freeman Brothers in Sydney from around 1866. He is known to have made the only photographic portrait of the colonial artist Conrad Martens.

IAN SUMNER

PULITI, TITO (1809–1870)

Italian

Tito Puliti (1809–1870) trained as a pharmacologist before becoming an assistant in the Royal Museum of Physics and Natural History in Florence. There, on 2 September 1839, in the presence of Giovanni Battista Amici, he made the first daguerreotypes in Tuscany—and probably the first in Italy—by following instructions received the day before. On 7 October, in the third session of the first meeting of the Society of Italian Scientists, which was held at Pisa under the patronage of Archduke Leopoldo II, Puliti exhibited his daguerreotypes to the delegates, having already shown them at the Accademia delle Belle Arti in Florence. At the end of the session he was invited to demonstrate the process on 10 October by taking a daguerreotype of the Cathedral buildings from the hospital of Santa Chiara.

GRAHAM SMITH

PULMAN, GEORGE (d. 1871)

English-born photographer

George Pulman was originally from Manchester, UK, and travelled to New Zealand after the Land Wars of the 1860s. In 1867 he commenced business with his wife, Elizabeth Pulman, as the proprietor of a photographic studio in Shortland Street, Auckland, specialising in topological and portrait photography. Upon George's death on 17th April 1871, Elizabeth took over the photographic business, which went on to become one of New Zealand's most influential studios. In later years Elizabeth was aided by her son Frederick Pulman. Although there is a large archive of surviving photographs held in museums, particularly of their

Maori portraits, as the photographs were identified under the studio name it is difficult to assign whether the photographer was George, Elizabeth, or Frederick Pulman. However due to their flattering and sympathetic style of portraiture that allowed the personality and individuality of the sitter to come through, it appears that they were commissioned by a large number of Maori clients. To emphasise the Maori identity of individuals the studio owned and used cloaks, hei tikis (pendants), meres (clubs), taiahas (spears), and huia feathers so that they could enhance the 'Maoriness' of those portrayed. The Pulman Studio was sold shortly before Elizabeth Pulman's death in 1900, including a selection of landscape negatives that were purchased and subsequently reprinted by the New Zealand Government Tourism Department.

JOCELYNE DUDDING

PUMPHREY, WILLIAM (1817–1905)

English photographer

Born on February 4, 1817 in Worcester, the son of a Quaker glove-maker, William Pumphrey held the daguerreotype licence for York from 1849—only the second photographer to operate in the city—having acquired the photographic interests of Samuel Walker the licensee since 1844.

Before taking up the new profession of photography, Pumphrey had trained as a science teacher, and taken up a teaching position in York in 1845. When William Henry Fox Talbot relaxed his calotype licensing terms in 1852, Pumphrey started to exploit the process producing and publishing portfolios of views of the architectural heritage of York and its environs. The earliest dated examples of this aspect of his work date from October of that year.

Throughout 1853, he published a sixty-image part work of these views, but by the following year he is believed to have sold his studio and taken up a position as superintendent of an asylum.

Thereafter his enduring interest in photography appears to have been as an amateur. In 1866 he organised an exhibition of art and industry in York, including a number of his own stereoscopic views. A second exhibition in 1879 was also successful.

He retired to Bath in 1881, and moved to Bristol in 1895 where he died ten years later on 28th March.

JOHN HANNAVY

PUYO, ÉMILE JOACHIM CONSTANT (1857–1931)

French photographer

Émile Joachim Constant Puyo was born in Morlaix in 1857 and died in 1931. He was a French Army officer, serving first in artillery, being after promoted to commander (Commandant was sometimes used as his nickname). He served in Algeria them returned to Paris to the commanding office. He practiced photography from 1887 and ended leaving the army in 1902 to pursuit a photographic career.

Entered the *Photo-Club de Paris* in the mid 1890's. This association published the *Revue Française de Photographie* were he published many photographs as well as technical articles. In these texts he promoted pictorialism, as an aesthetic, was well as a *technically* based movement. In 1896 Puyo wrote *Notes sur la Photographie Artistique*, the first of many articles and books on equipment and processes that he would publish throughout his career.

Along with Robert Demachy he was one of the best known French pictorialist photographers photographing folk types, landscapes and mostly the female figure. He was a pioneer of several painterly processes, mostly bromoil, used by their ability to create an unrealistic rendering, closer to painting than to photography. He used soft-focus lens in order to achieve the same goal. His work was widely successful and he was published in many countries outside of France including Alfred Stieglitz's *Camera Work*. He participated in many exhibitions, including a group show promoted by Stieglitz in 1906 and a 1931 Paris retrospective with Demachy.

He continued to practice pictorialist photography after World War I, after his friend Demachy abandoned photography and the Photo-Secession in New York ended.

His work is now present in many collections, including 160 images in the French *Médiathèque de l'architecture et du patrimoine.*

NUNO PINHEIRO

Q

QUINET, ACHILLE LÉON (1831–1900)

French photographer and studio owner

Born in 1831, Achille Quinet was a successful photographer who operated a studio at 320 rue St Honoré, Paris from about 1869 to 1879. Although Quinet made photographs of the moments and architecture of Paris as well as a series of views of Italy, he is best known for his landscape, animals and figure studies, many of which were made in or around the town of Barbizon and the forest of Fontainebleau. These photographs, which were likely intended as aids to painters, are generally albumen prints mounted on blue card stock, with the stamp "Étude d'Après Nature' as well as a red rubber stamp of his name. Some images are mounted on white stock with the blind stamp "*A le. Quinet fils.*"

A member of the Sociéte Française de Photographie from 1876 to 1894, Quinet exhibited his work at the universal exhibition of 1878. Most of Quinet's work is housed at the Bibliothèque Nationale, Paris, where he deposited his *Etudes* at the Depôt Légal in 1868, 1875, and 1877. Quinet's work is occasionally confused with that of his contemporary, Constant-Alexandre Famin. While the pair made photographs with similar subject matter, general stylistic differences distinguish the two. It is possible that Quinet, acting as a publisher or distributor, placed his own stamp on works made by Famin. After 1879, Quinet moved to Cély, near the Forest of Fontainebleau, where he died in 1900.

SARAH KENNEL

R

RAMON Y CAJAL, SANTIAGO (1852–1934)

Santiago Ramon y Cajal (1852–1934) is famous in Spain as its sole Nobel Prize winner. He shared the prize in Medicine in 1906 with Golgi. His professional practice was a principal but not sole driver of his interest in photography.

His passion for photography dated back to his childhood, with his introduction to the amazing detail of daguerreotypes. He practiced many of the various process advances as they came along, including 'inhaling the delicious aroma of collodion' and then the beautiful gelatine-bromide emulsions.

He was important for photography in Spain and internationally as he experimented with and published papers and books on numerous processes in the late 1800s and early 1900s, especially in stereo and in the new color technologies as they emerged, and in his pursuit of color images of microscopic subjects. He promoted photography in Spain, and when the Photographic Society of Madrid was founded in 1899 (later the Royal Photographic Society) he was named honorary President.

He experimented with many processes, especially the Autochrome process, and contributed to getting consistent results with the Lippmann process. With his skills as a microscopist it was easy for him to section his Lippmann images and directly show their internal layered structure (others who published such sections included Edgar Senior, Richard Neuhauss, Herbert Ives and Hermann Krone). Some of his conventional images, including a beautiful autochrome self-portrait, are in the collections of the Instituto Cajal in Madrid. His draft for his book on color photography (1912), held at the National Library, is hand illustrated in color. A view of it is reproduced in Sougez's *Historia de la Fotografia* (1991).

Besides the book, which received wide use in Spain, and his articles in technical journals all over Europe, he published a number of articles on photography, stereo photography and color photography in popular Spanish journals.

His Nobel was for his pioneering efforts in the development of contrast-enhancing stains for microscope slides and for his drawings of the microscopy of the human nervous system, including the delineation of neurons and their connections. These drawings still set a standard for accuracy in current medicine, and his stains are still in use. He and Golgi were at odds over the nature of the neuronal system. Cajal's viewpoint is more in line with the modern one.

RAOULT, JEAN (IVAN PETROVICH) (active 1860s–1880s)

Professional photographer

French by birth, Jean Raoul was owned a photographic studio in Odessa in 1860-1880s. He created ethnographic photographic studies in many areas of Russia. In late 1870s Raoul published the album "Collection de

types des Peuples de Russie, Roumanie et Bulgarie," a collection of "folk types," shots of everyday life and surroundings, mostly from Russia's south, which consisted of more than 200 photographs. Raoul's photographs of 1880s depicting landscapes, the people and the antiques of the Caucasus, the Crimea and the Volga river were also assembled into albums. In 1877–1878, during the Russian-Turkish War, Raoul travelled to Romania and Bulgaria where he photographed the military actions of the Russian forces. In 1879–1882 during the expedition to the Northern Caucasus, Georgia and Armenia and later to Athos and Palestina devoted to the searching for the Christian antiques Raoul was a photographer accompanying Prof. N. P. Kondakov. In 1884 staying in Constantinople after one of Kondakov's expeditions, Raoul decided to returne to France. In 1890s he owned a photographic studio in the south of France. He won prices at the Paris Geographic Exhibition (1875) and at the World Exhibition in Paris (1878) for photographs of people of Moldavia, Bessarabia and Odessa.

ALEXEI LOGINOV

RAU, WILLIAM HERMAN (1855–1920)

American photographer

William Herman Rau, a successful commercial photographer, was born in Philadelphia, Pennsylvania on January 19, 1855 to German and Swiss immigrant parents Peter and Mary Elizabeth Witschi Rau. He began his photographic career at thirteen as an assistant to Philadelphia photographer William Bell, and in 1874 served as a photographer with the United States government's Transit of Venus expedition in the South Pacific, the first of many photographic journeys. In 1881 he and Philadelphia photographer Edward L. Wilson embarked on a photographic trip through the Middle East, and Rau made subsequent photographic journeys to many other countries including Belgium, Germany, France, the Netherlands, Italy, England, and Mexico. In 1891 and in 1893 he received the important commission of photographically documenting the Pennsylvania Railroad's lines for promotional purposes, and in 1895 received a similar commission from the Lehigh Valley Railroad. Rau also served as the official photographer for the 1904 St. Louis World's Fair and the 1905 Louis and Clark Exposition. From 1886 until his death he operated a busy commercial studio in Philadelphia with an extensive stock of lantern slides. Rau was active in photographic associations including the American Lantern Slide Interchange and the Photographic Society of Philadelphia. William Rau died in Philadelphia on November 19, 1920.

SARAH J. WEATHERWAX

READE, JOSEPH BANCROFT (1801–1870)

English chemist

The Reverend Joseph Bancroft Reade was born in Leeds, Yorkshire, and was ordained as a deacon in the Church of England at the age of twenty-four.

His interests in chemistry date from an early age, and interests in science and microscopy endured for most of his life. He served as President of the Royal Microscopical Society in 1869 and 1870.

Of particular interest in considering his engagement with photography is a letter he wrote in 1839, quoted by Sir David Brewster in 1847, describing a photographic process involving the use of silver nitrate and gallic acid, and which was fixed with 'hypo.' Brewster asserted that Reade's successful experiments may have predated Talbot's calotype patent by up to two years. It was later claimed that, having lectured on his process in 1839, Reade had 'published' his process before Talbot's patent was granted.

Research has demonstrated, however, that the reports of Reade's lecture and letter were partial and the dates incorrect. His process was a modification of Talbot's *photogenic drawing* process, and his reference to hypo post-dated Herschel's publication of his researches on the chemical.

Notwithstanding that, Reade's 'priority' was quoted by lawyers for Martin Laroche in the court case *Talbot v Laroche* in 1854, in an attempt to undermine Talbot's legal position.

JOHN HANNAVY

REEVE, LOVELL AUGUSTUS (1814–1865)

English publisher of photography

Through his many publications Lovell Reeve advanced public expectation of the photographically illustrated book.

Born in London, Reeve was apprenticed to a grocer, but his interests quickly focused on natural history and his first book, *Conchologia Systematica,* was published in 1842 or 1843. His interest in shells and natural history in turn led to an engagement with stereoscopic photography.

His first book as publisher, in 1858, was Charles Piazzi Smyth's *Tenneriffe: An Astronomer's Experiment*, the first book to be photographically illustrated with stereographs. It presented twenty pairs of prints mounted on the octavo pages of the book, and Reeve initially commissioned Negretti & Zambra to design and manufacture a stereo viewer especially for viewing book-mounted images.

The Stereoscopic Magazine first appeared in July 1858, and continued until early 1863, publishing three stereo images per month, by Fenton, Howlett and others, with accompanying texts 'by Writers of Eminence.' Reeve also published periodic sets of stereo cards under the umbrella title *The Stereoscopic Cabinet*.

The Conway in the Stereoscope with text by James Davidson and twenty stereographs by Roger Fenton, was published in 1860, and additionally contained advertisements for other proposed publications and sets of images, several of which are presumed never to have been published. Many of the images from the book were re-published in *The Stereoscopic Magazine.*

JOHN HANNAVY

RÉGNAULT, HENRI-VICTOR (1810–1878)

French photographer and scientist

Henri-Victor Régnault was born on 31 July 1810 in Aix-la-Chapelle (now Aachen, Germany). Régnault, who used the given name "Victor," was the only son of André Privat Régnault, a military geographic engineer in Napoleon's Imperial Corps, and Marie Thérèse Massardo. His father died on the Russian campaign in 1812 and his mother died six years later, leaving the eight-year-old Victor and a younger sister without family or means. In 1830, Régnault won entrance to the prestigious École polytechnique. Graduating third in his class, he continued his training as an engineer at the École des Mines, where he studied with the celebrated chemist L.-J. Gay-Lussac. After his election to the Chemistry section of the Académie des sciences in 1840, Régnault turned his interest to the emerging field of experimental physics. His major research topics were patently useful to the state's plans for industrial development, and brought him lucrative government research commissions. Régnault also received multiple academic appointments, including Gay-Lussac's coveted chair in chemistry at the École polytechnique (1840), and the chair in physics at the Collège de France (1841).

Like many of his academic colleagues, Régnault was captivated by the promise of photography as a tool of empirical science. Known as a master of precise scientific method and measurement, Régnault would apply this talent to refining the inexact practices of early photography. In 1841, when William Henry Fox Talbot sent Jean-Baptiste Biot samples of his photographic paper, Biot passed them on to Régnault, who was already experimenting with daguerreotypy. Régnault soon adopted Talbot's paper negative process and in 1843, Richard Calvert Jones wrote to Talbot from Paris, telling him he had been making calotypes with Régnault and Hippolyte Bayard. Little else is known of Régnault's photographic activities prior to 1847, when Louis-Désiré Blanquart-Evrard devised improvements to the English process that circumvented Talbot's patent restriction in France. Régnault was charged with examining Blanquart-Evrard's process for the Académie in April of 1847. He subsequently became one of the most avid practitioners of paper negative photography and contributed at least fourteen images to Blanquart-Evrard's Imprimerie Photographique editions in the early 1850s.

In January of 1851, Régnault joined a diverse group of artistic, literary, and scientific figures in founding the Société héliographique, which precipitated a sudden increase in his photographic activities. Always worried that he was not devoting his full energy to his scientific career, Régnault claimed that did not take up photography for pleasure, but because he intended to illustrate a physics textbook with photographically derived illustrations, for which he invented a method of chemically reducing photographs to line drawings. This project, while never realized, may be connected with ten photographs of staged acoustic experiments Régnault made in 1851. Two substantial portrait series also date from this time: portraits of his colleagues in science and academe, and a large group of intimate portraits of his family. He also contributed two methods to the technical discouse: the use of pyrogallic acid (which quickly superceded gallic acid as the premier developing agent) and the use of a vacuum pump in uniformly sensitizing photographic paper.

In 1852, Régnault's photographic and scientific careers came together with his role as a government arts administrator when he was appointed to the prominent directorship of the state-owned Manufacture Impériale de porcelaine de Sèvres. At Sèvres, he found another devoted calotypist in Louis Robert, the head of the painting atelier, who had begun working in photography around 1850. Both men frequently photographed the factory environs in the early 1850s. Régnault also took advantage of the pastoral scenery around Sèvres to create his most artistically ambitious images: large format (approximately 35 × 44 cm), atmospheric landscapes of the Seine and woodlands around Sèvres. Several of these lush landscapes were exhibited in London in 1852 and 1853, courtesy of Régnault's friend John Stewart. These appear to have been the only public exhibitions of Régnault's work in his lifetime. His photographic practice was essentially private, notwithstanding his role as a central figure and technical expert in photographic circles of the 1850s.

Régnault accepted the presidency of the newly formed Société française de photographie (S.F.P.) in 1855. With their unanimous vote, the new society's members recognized Régnault's ability to bridge the concerns of science, art, and industry, a goal that would

be precisely served by Régnault's involvement in the highest circles of power in the Académie des sciences, Académie des beaux-arts, and the Second Empire government. With his ties to British photographers such as Sir John Herschel and Sir David Brewster, Régnault would also serve as a link between the British and French photographic worlds. His scientific expertise and faith in empirical method, moreover, made him a superior technical expert, and he duly focused his efforts for the S.F.P. on extracting rational methods and practices from the informational disorder surrounding the nascent medium. In this way, he presided over the field of European photography for nearly fifteen years, guiding discussions of technical, professional, and occasionally aesthetic concerns and serving as arbiter of all debates presented to this most influential photographic organization on the Continent.

Although he is known to have practiced wet plate photography and other process variants as they appeared in the late 1850s and 1860s, Régnault's principal photographic work was confined to his paper negative photography of the early 1850s. Increasing professional obligations and poor health curtailed his leisure photography after 1855, but he continued to serve actively as president of the S.F.P. until his resignation in 1868. Crushed by the death of his son, the celebrated painter Henri Régnault, in the Franco-Prussian War, he withdrew from public life and died in 1878, on the seventh anniversary of Henri's death.

Without exhibition reviews or other discussions of his work in the photographic press of his day, Régnault's photography was overlooked by historians until the late 1970s.

LAURIE DAHLBERG

Biography

Victor Régnault was born on 31 July 1810, in Aix-la-Chapelle, France (present-day Aachen, Germany). A devoted experimental chemist and physicist in the Académie des sciences, Régnault first experimented with daguerreotypy around 1840. Introduced to paper photography in 1841 by J.-B. Biot, who gave him samples of Talbot's sensitized paper, Régnault eventually became a serious practitioner of calotypy, which he applied to multiple purposes in the early 1850s, including scientific use, portraiture, still life, and landscape. He was a founding member of the Société héliographique in 1851, and the first president of the Société française de photographie (1855-1868). Appointed director of the state porcelain factory at Sèvres in 1852, Régnault also experimented with vitrifiable photography and convinced the state to allow photographic documentation of the Sèvres wares. A technical expert and authority, Régnault experimented with all photographic processes, but only his paper photography survives. He died in 1878.

REID, CHARLES (1837–1929)
Scottish

Charles Reid was born at Turriff, Aberdeenshire in 1837 and operated a photographic studio in Wishaw, North Lanarkshire.

Reid specialised in animal studies and it is for these small albumen and large carbon prints that he is known today, producing a large quantity of high-quality studies of sheep, cattle, birds, horses etc. The resulting prints are usually monogrammed C.R. and numbered in the negative. Many were printed and published by G.W. Wilson and Company.

Reid's pictures are always well composed and show good technique and many examples of his small studies were purchased by artists as reference for their paintings and sculptures. His large carbon studies of Highland cattle and sheep graced many late Victorian parlours.

Reid travelled extensively around Scotland and the North of England finding suitable animal subject matter and he showed considerable patience in working with a wide range of creatures and producing such good quality work ,which rarely shows a hint of blur. He exhibited his photographs in the 1880/90's and also gave lectures to the Edinburgh Photographic Society during this period. He published an article 'Some Notes on Animal Photography' in The Practical Photographer in 1895.

His sons continued his business well into the 20th Century.

IAN SUMNER

REJLANDER, OSCAR GUSTAV (c. 1813–1875)

Oscar Gustav Rejlander was born in Sweden. Little is known about his early years, but as a young man he studied painting on the continent, where he became familiar with the work of the old Masters, whose influence is apparent in some of his best known photographs. His career as a photographer began when he was thirty-nine, and was centered in Wolverhampton and London. Rejlander was an ingenious photographer who produced a highly diverse body of work that included portraits, genre scenes, figure studies, allegories and literary illustrations. His versatility is a reflection in part of the difficulties he and other photographers of the period encountered as they tried to earn a living from this fledgling medium.

Rejlander is most often remembered for inventing combination printing, a process in which different plates are painstakingly combined into a single, integrated image. Beyond making good exposures and prints, issues of scale and consistent lighting (and shadows) were essential in creating convincing final prints. Rejlander's successful combination prints are remarkable considering the complexity of the wet plate process, long exposure times, and fleeting lighting conditions. Combination printing required careful conceptual work of the final image, along with a good deal of skill and patience in its execution, and Rejlander's background as a painter no doubt were helpful in both regards.

Rejlander's best-known photograph, *The Two Ways of Life* (1857), was a combination print painstakingly

Rejlander, Oscar Gustave. The Madonna and Child with St. John the Baptist.
The J. Paul Getty Museum, Los Angeles

assembled from over thirty separate plates. The final print evokes after Rafael's *School of Athens,* but Rejlander's allegory had an expressly Victorian flavor, with one side representing virtuous activities like reading and tending to the sick, while the other side depicts several deadly sins. The inclusion of languorous, bare-breasted nudes provoked a fair amount of controversy when it was first shown, even though Queen Victoria found sufficient merit in *The Two Ways of Life* to purchase a copy for Prince Albert, who reportedly kept it on his wall for the rest of his life.

Many of Rejlander's other photographs are equally innovative. Rejlander grasped in prescient ways the potential of the photographic medium to capture an unfolding scene or even stop action long before such images were technically possible. In many of his genre studies he conveys a sense of spontaneity in a scene, despite the cumbersome wet collodion process and slow exposure times. In a picture like *The Juggler* (c. 1855) he constructed an effective illusion of a man juggling several decades before such images were technically possible. Rejlander's accomplishment lay in his ability to *conceive* of such images as natural extensions of photographic seeing.

Many of Rejlander's genre pictures and portraits involve children, a photographic subject that was very popular with the masses as well as photographers like Hill and Adamson, Charles Dodgson, and Julia Margaret Cameron. Here again, he experimented with various moods, ranging from depictions of angelic children (again evoking Rafael) to poor waifs who could easily populate the novels of Charles Dickens. He photographed children at play, at rest, in the nude, and at their mother's breast. His most commercially successful photography, *Jinx's Baby*, depicted a small child in the midst of a howling cry. This photograph was one of roughly eighteen pictures which Rejlander produced as illustrations for Charles Darwin's *The Expression of the Emotions in Man and Animals* (1872).

Rejlander brought a sense of humor to photography, a rarity among 19th century photographers, who were a rather somber and serious lot. Only Nadar, among Rejlander's contemporaries, expresses a comparable *joi de vivre* in his photographs. In one combination print, *O. G. Rejlander Presents O.G. Rejlander* (c. 1871), he theatrically presented himself as an alter-ego militia man. In *Happy Times*, he and his wife, both well into middle age, smiled jauntily at the camera with unmasked good humor. Rejlander depicted scampish children being chastised by cranky, outraged elders. Rejlander also enjoyed satire: in *Did She? (c. 1862)*, two men gossip and snicker about some unsuspecting young lady, while *The Empress Nicotena (c. 1857)* depicted an old and weathered crone holding a mask of youth in front of her face with one hand as she reached for tobacco with the other.

Some of Rejlander's studies convey a sense of sexuality that defy the typical Victorian stereotypes. Rejlander's approach was at times light-hearted, as in *Washing Day* (c. 1855), where a two older women washed clothes in the foreground while a younger woman hung hosiery on a line to dry while openly flirting with a young man. Some of his studies of paired, unclad women suggest lesbianism, and one light-hearted photograph featured two soldiers who flank a third man who is dressed as a woman. Masturbation was clearly implied in *The Bachelor's Dream* (c. 1860), where a sleeping man reclined beside a dress hoop populated toy female figures, his hand resting on his groin. Paintings or photographs that address issues such as these are extremely rare in Victorian England, or even on the Continent, where the underground traffic in photographic pornography was more developed.

Despite a lengthy and prolific career, which included several published essays on photography, Rejlander died impoverished and largely forgotten. The press complained about what they perceived to be shoddy technique, and others questioned some of his subject matter. Rejlander's positions on the artistic potential of photography were controversial in some quarters, and his adventuresome efforts to expand the range of photographic expression no doubt confounded some of his peers. Peter Henry Emerson's scathing review in 1890 of Rejlander's posthumous, four hundred print retrospective sealed his fate for several generations of Modernist photographers and historians.

In his published writings, Rejlander was a consistent champion of photography's legitimate role in the production of art by painters and, increasingly, photographers themselves. Like Arago and Talbot, he grasped reflexively some of the possibilities of photography, both in the ambitions of combination printing and naturalistic, "stop-action" scenes, and in his ability to achieve psychological insight in a broad variety of photographic genres.

RELVAS, CARLOS (1838–1894)

Carlos Augusto de Mascarenhas Relvas e Campos (1838–1894), was the best know 19th Century Portuguese amateur photographer. He was a very rich farmer and a nobleman from Ribatejo in central Portugal. His enormous wealth allowed him the time and resources for an important photography practice, including the building of the exotic and magnificent House of Photography, entirely dedicated to his photography. He was initiated in photography, using wet collodium, most likely by W. CifKa in the early 1860's. During his life he experimented with most new photographic processes: Collotype, Gum, Carbon, and Gelatin.

As an amateur he was not constrained by the limitations of a daily portrait business and embraced most of the acceptable genres of 19th Century photography: Portraits of family and friends, including the royal family, landscapes and folk types. These were many times performed by his servants and employees, he photographed in the studio, many times with painted backdrops. One of the most important parts of his work consists in art reproductions, being the photographs he made of the tomb of the King Pedro I and his mistress Inês, he made in 1868, some of the first of that genre. He also made the 52 photographs of the decorative arts exhibition in Lisbon. His photographs where part of the Fine Arts Academy in Lisbon report on northern Portugal monuments. Carlos Relvas participated in many exhibitions in Portugal and abroad, including the Paris Universal Exhibition in 1876, and the Vienna Universal Exhibition were he won prizes.

In 1884 organizers of the Portuguese first national photography exhibition invited him has an honorary president and only after his refusal turned to the king Ferdinand. He died in 1894, after a horse accident.

Due to family quarrels most of his negatives were sold after his dead and many were lost. Even so a large amount of then are in Portuguese national institutions and a major exhibition was held in 2003 in Lisbon's Ancient Art Museum.

RETOUCHING

The retouching of photographs was a habitual and extensive practice. The aesthetics and practices of retouching can be separated into two broad periods. The first is from the early 1850s to the early 1860s. The second is from the 1870s onwards to the end of the century. Separating the two phases are differences in the practical process of retouching, and its impact upon perceptions of photography.

The reworking of photographs was a prominent concern as early as the 1857 Art Treasures exhibition. During the 1850s, retouching was a term covering various forms of manipulation, including colouring. Of the 240 portraits exhibited in Manchester, a large number had been altered. A review in the *Liverpool and Manchester Photographic Journal* drew attention to both the number of touched photographs and the extent of their alteration. It noted that, in some cases, "no trace of the original picture is visible, its only use apparently being to secure identity and truth, the visible picture being laid over the other in oil and water-colour" ("Exhibition of Art Treasures at Manchester," 126). At this stage, most manipulation would have been carried out on the positive print rather than on the glass-plate negative.

Coloured photographs were intended to alleviate the unflattering and mechanical harshness of the monochrome picture. The practice thereby made the resultant pictures more akin in appearance and status to miniature portraits. As such, colouring reflects photography's initial subservience to the dominance of fine art aesthetics. In 1862, the *London Review* claimed that coloured photographs approached more closely to oil paintings because they were the result of study and generalisation, which were qualities lacking in an ordinary photograph. On a more pragmatic level, miniature painters put out of business by photography found themselves employed by photographic studios. In 1857, Elizabeth Eastlake claimed that there was no photographic establishment that did not employ artists for finishing pictures, at salaries of up to £1 a day.

In order to counter the hybridity of coloured pictures, there were numerous claims that the realism of photography was its unique element. Manipulation of photographs was felt to undermine the most valuable quality of the medium. Efforts were consequently made by the Photographic Society of London to prevent any retouched photographs being shown at their annual exhibition. The rules of entrance for the 1857 exhibition at South Kensington, for example, included precise instructions regarding retouched photographs. They would be admitted only if accompanied by untouched copies of the same picture. Positive pictures from touched or painted negatives also had to be described accordingly. These instructions continued to be repeated but judging by the complaints of some reviewers they were far from being universally followed. In 1864, the Photographic Society of London debarred from their annual exhibition any coloured or touched pictures. Although the effect was a much reduced exhibition, the rules did enforce

Southworth, Albert Sands and Josiah Johnson Hawes. Lemuel Shaw. *The Metropolitan Museum of Art, Gift of Edward S. Hawes, Alice Mary Hawes, and Marion Augusta Hawes, 1938 (38.34) Image © The Metropolitan Museum of Art.*

a pure photographic aesthetic where there was a clear demarcation between "real" and fabricated pictures.

Despite the efforts of some members of the photographic community, retouching, and debates upon its efficacy and honesty, were commonplace during the 1850s and 1860s. In the *carte-de-visite* era, methods could be as crude as the retouching of eyes by putting pinpricks in the negative. During the 1870s and 1880s, retouching continued to be prevalent. This second phase of retouching differed from the early years of photography though in that the dominant means of manipulation was through working upon the negative rather than painting upon the positive print. Photographic manipulation became particularly common after the introduction of the dry-plate negative in the early 1870s because these were easier to rework than the existing wet-plate negatives.

In addition the technical ease with which retouching could now be carried out, the introduction of a larger format of cabinet photograph presented a greater threat to a sitter's vanity. Any blemishes or wrinkles were more likely to be evident. The value of producing of flattering pictures certainly encouraged the widespread use of retouching. As the *Photographic News* put it in 1872, photographers knew that "those portraitists who retouch most effectively secure the largest share of public patronage" ("Retouching and Photographic Truth" 25). An equally important reason for the practice, however, was the removal of technical imperfections

and the desire for greater realism. The amount of light used by photographic studios, for example, considerably deepened any wrinkles and accentuated the signs of age: retouching was argued to be a means of making a photograph into a better likeness.

The specialist photographic journals often contained advice on how to manipulate negatives, and there were numerous instruction manuals published. These suggest that, at its best, retouching was a complex practice that required a high degree of artistic skill and an intimate knowledge of facial physiognomy. All too easily, however, zealous retouching could give sitters' faces a waxdoll or billiard ball appearance. Many articles on retouching, although not against the practise *per se*, were concerned that too much unskilled work would destroy popular belief in photographic realism. As one manual put it, "The clever pupil of the celebrated Professor Scratchpaw took in other pupils until the scratchpaw aborigines flooded the market with *re* or *misre*-presentations of somebody or other, and the result was that the real retoucher has always been at a premium" (Hubert, 7–8).

Retouching was carried out using a variety of soft lead pencils upon a glass negative coated with a solution that allowed the pencil to bite. Elaborate professional equipment, including desks with inbuilt lights and reflectors, aided the task. Most manuals recommended the use of lines to accomplish any desired alterations, much in the way a steel or wood engraver would work. Retouching varied from the carefully precise work to the brutally extensive. As *The Art of Retouching* put it:

> Do not on any account forget to touch ladies' waists in a specially hearty matter, if you want to keep on good terms with them. You are always safe in cutting off an inch on each side, and in some cases, where corpulence is rather conspicuous, two or more inches will never be missed. (Hubert 49)

Instruction manuals contained far more information, however, than simply the removal of waistlines and double chins. They included details of how to soften the lines around the temples; how to remodel the furrows around and under the eyes where the studio light would cause dark shadows; and how to thicken and darken hair through careful manipulation. Necks, cheeks, jowls, all were subject to the retoucher's pencil. Carried out with skill and subtlety, retouching could add *gravitas* to a sitter's appearance as well as remove years.

REUTLINGER, CHARLES (1816–1881)

French photographer

Charles Reutlinger was founder of the highly successful eponymous Paris photographic establishment, in business from 1850 to 1937, which was known for its portraits, theatrical cartes de visite and cabinet cards, as well as erotica and, later, fashion and proto-surrealist photographs.

By the time Reutlinger was 18, he was already known to be practicing the art of silhouette portraiture, which his aunt, Madame la Conseiller Weiss, had been doing professionally since around 1820 in Karslrhue. He moved to Stuttgart around 1835, where he met Georg Friedrich Brandseph, an established silhouette artist, who was among the early adapters to the burgeoning field of daguerreotype portraiture. It may have been Brandseph who interested Reutlinger in the new art, but it is undoubtedly during that time that Reutlinger came to know about the work of Daguerre and Niepce, and he established his own photographic studio in Stuttgart at 8 Fürtbachstrasse by 1849.

Reutlinger certainly arrived in Paris with some amount of portrait photography business and technical acumen already, since, by 1851, his photographic advertisement was running in the publication *La Lumière*, offering, as well, to instruct others in the art of "daguerreotype on paper."

From the early 1850s, Reutlinger was a prolific producer of carte de visite portraits of the notable figures in cosmopolitan Paris, including politicians and royalty, musical celebrities, and theatrical stars. Among the portraits in the collection of the Bibliothèque Nationale are the Le Prince Napoléon-Bonaparte (ca. 1853) and Édouard Manet (1875). His atelier was decorated

elaborately, with the furnishings and decor serving as settings and props in the portraits. The cartes were stamped "Ch. Reutlinger" on the back, with a coat of arms and address, and sometimes "garantie d'après nature."

Portrait photography was an ideal symbiotic partner with the emerging cult of celebrity, especially the fascination with theatrical stars. Both were dependent on artifice and capitalized on fantasy, and photographers and performers were glad to cooperate to increase their profits.

Reutlinger's early style was somewhat distinctively archaic, in that it drew upon the formal conventions of the silhouette portraits by preferring to vignette bust portraits, rather than the full length portraits preferred by Disderi and other contemporaries.

The medium for Reutlinger's commercial production, the carte de visite, was a photographic process patented in Paris by André Disderi in 1854. They were albumen prints printed onto cards of standard sizes (4½ × 2½ in.), which had engraved labels on the back with the company's name, address and coat of arms. In the 1860s, a larger format (6¾ × 4½ in.) was introduced, the cabinet card, which replaced the bulk of Reutlinger's production for the remainder of the century, until supplanted by less expensive postcards.

Reutlinger became a member of the Société française de photographie in 1862, and his more beaux arts photographic works were included in their exhibitions throughout the 1860s and 1870s. The works shown were predominantly artistic portraits and studies "after nature," in keeping with the academic aspirations of that organization. In the 1874 exhibition Reutlinger exhibited six examples of what were labeled "aristotypes (silver gelatin prints)," and in 1876, a series of carbon prints.

Meanwhile, the increasing commercial demand for celebrity portraits was a boon to Reutlinger, who had, by 1873, a catalog of over 1,300 personalities available for sale. Their names, listed alphabetically and by genre or profession, were predominantly those of public figures and theatre stars, but also included members of the clergy (Catholic, Jewish and Protestant), visiting dignitaries, and great artists.

Reutlinger was by no means alone in capitalizing on the demand for theatrical stars, as his colleagues Nadar, Etienne Carjat, and others were highly successful in that regard. The great democratization of these images, available for a small price, allowed the public to select and repeatedly examine the likenesses of the famous. These, they mounted into albums, becoming, in effect, curators of their gallery of favorite portraits. Émile Zola's novel *La Curée* gives an indication of the entertainment value these provided, provoking passionate discussions by the collectors about the various merits and depictions of the personalities in their personal albums.

Ten albumen prints of his theatrical portraits were included in a 1875 publication by the Palais Royal-based firm Tresse titled *Foyers et Coulisses: Histoire Anecdotique des Théatres de Paris*. Many magazines also patronized Reutlinger and the other Paris firms for iconic images of everyone from statesmen to *demi-mondaines*, with a decided preference for the latter.

The costumed actresses, by far the most popular of the images produced in that era, naturally evolved into more and more erotic imagery, with an emphasis on actresses in the body stockings that were the theatrical facsimiles for nudity. This, in turn, gave way to Reutlinger photographing nudes and beauties in their underclothes, and making them available as a series called "des petites femmes de Paris." The fact that this was a thriving industry initially particular to Paris during the period is evident by the fact that erotic pictures continued to be referred to as "French postcards" well into the 20th century.

It is not clear how many of these nudes were made by Charles and how many were by his younger brother, Émile, who succeeded him as director of the business in 1880. It is certainly known that the catalog of existing images continued to be marketed and added to in Émile's era, and that Charles Reutlinger passed away in Paris in 1881.

The Reutlinger firm continued well into the twentieth century under a succession of family members, but the cartes continued to be stamped "Ch. Reutlinger" until 1895, when the stylized signature of Léopold, the son of Émile, became the label. Today, the bulk of the Reutlinger archives are housed in the Bibliothèque Nationale de France in Paris.

Reutlinger's legacy was as a pioneer in the commercial business of photography and creating a niche business in the great photographic metropolis that was Paris in the 30 years he was active there, recognizing and cultivating the uncharted territory of celebrity mania, then in its formative years.

DEIRDRE DONOHUE

Biography

Reutlinger was born 26 February 1816 in Karlsruhe as Carl Reutlinger, the eldest of four siblings. His brother Émile, who would succeed him as head of the firm, was born in 1825. Their father Léopold was a wine wholesaler and former military officer.

In 1850, upon moving to Paris, he changed his first name to Charles, and began to work in his home at 33 boulevard Saint-Martin (in a building which no longer exists). Charles Reutlinger, photographic artist, appears in the Bottin Paris business directory of 1853 at 112 rue de Richlieu on the corner of boulevard Montmarte. That is the address of the firm until 1864, when the

street number for the entrance around the corner, on the boulevard, is given.

Reutlinger's first award, a medal of London, was not noted on the backs of his photos, but he won a succession of honors during the next two decades, including first prize medals in the *Exposition internationale de Berlin*, 1865; the *Exposition universelle de Paris*, 1867; the *Exposition photographique de Hambourg*, 1868; and medals from the *Société Photographique à Paris*, 1870; the *Exposition universelle de Lyon*, 1872 and the *Exposition universelle de Vienne*, 1876. These medals were reproduced on the backs of the firm's cartes.

REY, GUIDO (1861–1935)
Italian photographer

Guido Rey was born in Torino in 1861, to Giacomo Rey and Lydia Mongenet de Resencourt. In 1879 he attended the Academy of Fine Arts in Torino. He worked in the family textile business for which he traveled quite often. He took his first photographs during mountain climbs in 1883–85 with the Sella family and started his pictorialist works only in 1892–93. He was active in organizing the Universal Exposition of Visual Arts in 1902 where Stieglitz, Demachy, C. White and Annan presented their works. He died in 1935.

Rey participated in the cultural life of his city but more importantly in the debate—at the European level—about photography as an art. He had a great passion for painting and he was the only European pictorialist to create sets with minute historical attention in Nipponic, Roman, Flemish and Neoclassic style, without manipulating the photographs. His intent was to describe the past in the every day scenes by having his models wear costumes that he designed. His book on alpinism was published in 1904 (*Il monte Cervino*). More appreciated abroad, his work was published on "The Studio" review and he was the only Italian to be published on "Camera Work" (1908).

REYNAUD, CHARLES-EMILE (1844–1918)
French inventor, artist, showman

Charles-Emile Reynaud was born at Montreuil-sous-Bois on December 8, 1844. An experienced creator of educational images for the magic lantern, in 1877 Emile Reynaud invented the Praxinoscope. This ingenious moving image toy featured a central circle of mirrors set in a shallow cylinder, opposite colour-lithographed sequence drawings on paper strips. The Praxinoscope Theatre followed; the cylinder set in a box with glass-covered viewing aperture, which reflected a card with a colored background. The animated subjects appeared superimposed on the scenery. A further development for projection, the domestic Projection Praxinoscope, used figures on glass. This led to the Théâtre Optique, a large-screen version. Long perforated bands, bearing characters painted onto squares of transparent material, were wound horizontally back and forth from reel to reel in the mirror-drum projector. The background was projected from a separate lantern. Shows commenced at the Musée Grevin, Paris, in 1892. By 1896 Reynaud was shooting photographic motion picture

films; subjects included clowns Footit and Chocolat. The individual film frames were mounted as perforated bands in the same manner as the painted strips. These presentations were eventually superseded by competing cinematograph shows; the last performance was in 1900. Between 1903 and 1907 Reynaud worked on a motion picture viewer for brief stereoscopic sequences. Emile Reynaud died at Ivry-sur-Seine, January 9, 1918.

STEPHEN HERBERT

RICHEBOURG, PIERRE AMBROISE (1810–1872)

Pierre Ambroise Richebourg was born in Paris in November 1810. Of his childhood and his formation few elements are known, except that he was trained in optics with Vincent Chevalier, father of Charles Chevalier, supplier of instruments of Daguerre. He seemed to have followed the lessons of the latter, of whom he created a portrait with daguerreotype in about 1844.

He was one of the first to exhibit daguerreotype portraits in Paris in late 1839. He was also, according to his own statements, the first to have carried out a series of daguerreotype images taken under the solar microscope for the course of Alfred Donné at the College of France, in 1840, from which he presented examples in front of the Academy of Science in Paris. The following year, following the death of Vincent Knight, he again took up Knight's trade and installed his shop and workshop not far from the Town hall, at 69 quai de l'Horloge (which will become, following a change of classification in 1851, number 29) where he made photographic portraits, sold photographic material, and gave lessons. In 1843, he published an instruction manual, *Nouveau manuel complémentaire pour l'usage pratique du daguerréotype* [the New Complementary Handbook for the Practical Use of the Daguerreotype]. The following year, his name appeared under the heading "daguerreotypist" and he presented in the "optical" section of the images at the exposure of the l'exposition des Produits de l'Industrie, where he received a favorable acknowledgement of the panel.

From the very beginning of the 1850s, he was one of the first French photographers to be interested in the new technique of the collodion, for which he developed, about 1851–52, a protective varnish for the negative plates. From this date he used this technique, to which he devoted a booklet in 1853, *New Handbook of Photography on Collodion*, in which he carried out the essence of his production. During the years 1850-1860, he entered many exhibitions, Paris (1855 (medal), 57 (medal), 59, 62 (medal), 64, 65, 67), Brussels (56, 57), London (58, 63), and Oporto (66). In 1855, he became a member of the Société française de photographie. Ten years afterwards, indicative of his fame, he appeared in the *Dictionnaire des Contemporains* of Vapereau.

His abundant production, often of excellent technical quality with some exceptions, is worthy primarily due to the diversity of the addressed subjects, characteristic of the multitude of the fields of applications of photography under the second Empire. The various mentions of the photographer one finds on the seals and publications are indicative of this eclecticism. In the years 1860, his name in organizations was frequently followed by the description " Photographe des Palais Nationaux " then, from 1864 as "Photographe de la Couronne." In 1858, he was described as a "photographer of the contests, the official albums, and the artists" and since 1864, as a "the photographer of Town hall" and "photographer of the Ministry for the Art schools."

One of his fields of interest was the reproduction of works and objets d'art, which he explicitly mentioned as one of his specialties since 1847–48. It is known that he made reproductions for various artists, painters (Billhook, Leroux), sculptors (Préault), and goldsmiths (Wheat-Meurice). He also made photographic copies of the paintings in the Salon, in particular those of 1857, 1861, and 1865. The work of Theophilus Gautier appeared at Gide and Baudry in 1859, *Trésors d'Art de la Russie ancienne et moderne*, decorated with sixty photographs chosen from more than two hundred created by Richebourg in Russia since 1857.

On this occasion he developed a system that enabled him to reproduce images of a whole cupola with a high geometrical degree of accuracy. With this production a certain number of remarkable series devoted to the interiors of various palaces and imperial residences were added: the castle of Fontainebleau (about 1860), the palace of Luxembourg (about 1859), that of the Elysium (1864), the Pompéienne Villa of Prince Napoleon (about 1865).

Parallel to this activity Richebourg expressed a taste for what one can describe as topical photography. Introduced in the mid-1850s, in the imperial milieu, he successively photographed the reception of Queen Victoria at the Town hall of Paris (1855), which he reproduced, for the people of Paris. He then documented the ceremonies of the birth and baptism of the Prince Impérial (1856), and the festivals of Cherbourg (1858). During this period Richebourg announced that on request he would travel around France. It is likely that a number of engravings made from his photographs and used in *L'Illustration*, emanate from such commissions. This continued until the beginning of the 1870s, through the series made by Richebourg containing images of various inaugurations (le palais du Luxembourg (1858), the chantier de l'église saint (1861), Arc de Triomphe de l'actuelle place de la Nation. In 1871, he created some

pictures during and after the events of the Commune, some of which were again interpreted in engravings.

A commercial portraitist, he was also interested from the early 1850s in passport photos and identity cards, and in January 1853 establsihed a program for passports with photographs in front of the ministry for Justice. Thereafter he seemed to have worked sporadically for the Prefecture of Police force: in 1869, in particular, he made and marketed negatives of the victims of the Troppmann assassin. In addition, as a photographer on behalf of the Ministry for Agriculture and the Trade, he regularly created images of the animals of the annual agricultural shows of Poissy, Paris, and Chartres. Several of these images were presented at the time of the various expositions in which it took part. He also left stereoscopic images, in particular some daguerreotypes of nude females. The last mention that one finds of Richebourg dates to 1872, in *Moniteur de la Photographie*. One does not know with certainty his date of death. His abundant body of work is found in public collections in France and abroad.

RIGBY, LADY ELIZABETH EASTLAKE (1809–1893)

English artist, writer, and critic

Elizabeth Rigby, Lady Eastlake was born in Norwich on November 17th 1809, daughter of the obstetrician and gentleman farmer, Dr. Edward Rigby. After spending extended periods of time abroad in Germany and Estonia she settled in Edinburgh between 1842 and 1849, where her tenancy of the city coincided almost exactly with the photographic partnership of Hill and Adamson. In Edinburgh, she became one of Hill and Adamson's early and most frequent sitters, sitting for about twenty portraits. She married Charles Lock Eastlake in 1849 and moved to London where she continued to publish reviews for the periodical press, mainly in the area of the visual arts and to translate and edit art-historical texts. She died at her London home in 1893.

Elizabeth Rigby sat for her first calotype portraits in Hill and Adamson's studio in the summer of 1843 and formed opinions of the process to which she remained faithful throughout her life. She expressed her thoughts on photography to her friend John Murray, publisher of the *Quarterly Review*, soon after this first sitting: '… I venture to send you a few specimens, being assured that you will appreciate their truth and beauty, though few do. It appears to me that this is the only line of photographic drawing which can at all assist an artist—it was absurd to think that any would supersede him. I send you various specimens of the subjects to which it has been turned here … I have enclosed three of myself, not the best impressions … I *admire* myself very much, but cannot get the world to agree with me. The downcast eyes were a necessary consequence of the most brilliant sun which prevented their being raised the least higher. With old faces it is most successful—producing the most exquisite Rembrandt effect. …'

Fourteen years later, in April 1857, Eastlake wrote one of the earliest critiques on photography, an article in the *Quarterly Review* reviewing seven related publications. In large part the piece is a history of photography distilling the information from the listed texts into a reliable, chronologically arranged account of the development of the processes collectively contributing to a history of photography. Eastlake gives a lucid account of the various chemical experiments in photography up to 1857, 'when the scientific processes on which the practice depends are brought to such perfection that, short of the coveted attainment of colour, no great improvement can be further expected.' (459) The more discursive portions of Eastlake's essay articulates mid nineteenth-century debates about the status and rôle of photography. Granting 'Photography' the upper case and making it a feminine noun, like Art and Nature, Eastlake proceeds to measure the artistic successes and shortcomings of the photographic process in conveying nature. She first draws and then preserves a distinction between photography as an art and photography as a popular past time, the latter owing more to 'the hunger for facts.' She is thus untroubled by claims that photography will supersede art or supplant the work of artists, convinced that 'Photography is intended to supersede much that art has hitherto done, but only that which it was both a misappropriation and a deterioration of Art to do' (466). She therefore views photography as a means of relieving the artist of a 'burden' of 'literal, unreasoning imitation' (466), arguing that 'what she [photography] does best is beneath the doing of a real artist at all' (467).

Eastlake was herself an amateur artist, skilled in drawing portraits of friends and family and adept at producing topographical views of cities and landscape [4]. Eastlake sees photography as another form of drawing, 'the solar pencil' (445), capable of communicating

an objective account of appearances although, in her opinion, somewhat limited in its formal properties. She is most critical of photography in respect of its deadening effect on form and failure to represent the full tonal range of its subject, what she refers to as 'the falling off of artistic effect' (462). She observes: 'If the cheek be very brilliant in colour, it is as often as not represented by a dark stain. If the eye be blue, it turns out as colourless as water; if the hair be golden or red, it looks as if it had been dyed, if very glossy it is cut up into lines of light as big as ropes' (461) In landscape too, she finds that photography fails to properly convey the 'breadth and gradations of nature': 'The finest lawn turns out but a gloomy funeral-pall … trees, if done with the slower paper process, are black, and from the movement, uncertain webs against the white sky.' (463).

Eastlake's essay appeared in the wake of the wet-collodion process and she is ambivalent about the fine detailing that the process afforded. Eastlake acknowledges the 'pictorial feats' achieved by wet-collodion, for example in its precise rendition of 'Alpine masses' but she retains an aesthetic preference for the soft papers and gentler outlines of the calotype, setting up an opposition between the former's assertion of 'facts' and the latter's facility for the picturesque. The picturesque is an important and recurring motif in Eastlake's essay, used specifically to mean the opposite of descriptive. She presents picturesque conventions such as imprecise outline, broad suggestion and pleasing irregularity in the representation of nature as a benchmark of artistic practice, stating: 'If the photograph in its early and imperfect scientific state was more consonant to our feelings for art, it is because, as far as it went, it was more true to our experience of Nature. Mere broad light and shade, with the correctness of general forms and absence of all convention, will, when nothing further is attempted, give artistic pleasure of a very high kind; it is only when greater precision and detail are superadded that the eye misses the further truths which should accompany the further finish.'(p. 460) It is not only the fine detailing that Eastlake finds objectionable in the improved 'scientific state.' She also laments the lack of 'mystery' in the wet collodion print and she sees portraiture as its chief casualty: 'Every button is seen—piles of stratified flounces in most accurate drawing are there,—what was at first only suggestion is now all careful making out,—but the likeness to Rembrandt and Reynolds is gone! (p.461) Her repeated references to Rembrandt in the essay reiterate her preferences for the picturesque, where character studies are suggested rather than the descriptive where physiognomy is minutely told.

In reading Lady Eastlake's *Quarterly* review her connection to both the Royal Academy (her husband was its President) and to the Photographic Society (her husband had been its chair) should be borne in mind. It is quite plausible that Eastlake's essay was as much an iteration of Victorian academicism as it was a critique of photography. In her comparison of the 'free-will of the intelligent being' to the 'obedience of the machine' she is ostensibly distinguishing between the artist and the camera but she may equally well be referring to the very contemporary fashion for Pre-Raphaelitism. Knowing that Eastlake frequently used the *Quarterly Review* to settle old scores it is quite possible to read her reference to the artist's '… power of selection and rejection, the living application of that language which lies dead in his paint-box' (466) as a further public rejection of the strictures of John Ruskin.

RIIS, JACOB AUGUST (1848–1914)
Dannish photographer

There are not many examples of photography changing societies perception so as to render significant social and political change, indeed some would argue that photojournalism simply sells newspapers. One exception would be Jacob Riis, (born Ribe, Denmark, emigrated to USA 1870) who used photography to provide evidence of the appalling conditions of the slums of New York City which he photographed in the 1880s for 10 years, often at night, and with an early use of magnesium powder, culminating in the most famous of his books, the first of its kind: *How the Other Half Lives* (1890). Packed 522 to the acre of mainly immigrants, New York had the worst disease ridden slums in the world. In 1877 Riis became a police reporter for the *New York Tribune* but found that his words, and indeed the printed woodblock illustrations made from his photographs, had little impact. But as a result of publishing his night photographs, the flop houses and police '5 cents a spot' lodgings were abolished and a new era of treating the poor and homeless began in the USA with Riis at the forefront of the campaign. Known as the 'Emancipa-

tor of the Slums,' esteemed by Theodore Roosevelt, Riis proved that photography could be an active agent of change. "I had a use for it, and beyond that I never went" became the touch stone for many a campaigning documentary photographer thereafter.

ALISTAIR CRAWFORD

RIVE, ROBERTO (active 1860s–1880s)
Italian photographer and studio owner

Roberto Rive worked as a photographer in Naples from the beginning of the 1860s, with a studio in Palazzo Serracapriola, Vico Carminello, 38, Riviera di Chiaja. In 1865 he moved to Palazzo Lieti, Via Toledo, 317 and, from 1886 until 1889, he had a studio in Salita San Filippo, Riviera di Chiaja, 15. In 1867 Rive took part at the Exposition Universelle Paris. He became very well-known for his portraits and views, some of which were in stereoscopic size. He took photographs of all the famous monuments in the South of Italy, in Naples, Pompeii, Paestum, Sorrento, Capri, Amalfi, and of the most important towns and archaeological sites in Sicily, as well as other historical towns such as Florence, Pisa, Siena, Rome, Genoa and Venice. He was also an inventor and he patented a special photosensitive paper which was used above all in Southern Italy. Outstanding photographers, such as Luigi Borlinetto (1827–1904), who was a very well—known scientist in Padua, used the paper invented by Rive (Borlinetto used it in a variant form, with the addition of potato flour, water and alcohol). Roberto Rive continued to practise as a photographer until the end of the 1880s.

SILVIA PAOLI

RIVIÈRE, HENRI (1864–1951)
French

Benjamin Jean Pierre Henri Rivière is primarily known as a printmaker. He was also an engraver, theatre director, collector, painter, and writer, and in the late twentieth century his skill in photography was acknowledged. Rivière did not sign or mark his photographs. Yet despite the obscurity surrounding his photographic work, photography was integral to Rivière's oeuvre. The main collection in the public realm at the Musée d'Orsay, Paris reveals that Rivière was one of the most original amateur photographers in France at the end of the nineteenth century.

Born in Montmartre, Paris in 1864, Henri Rivière grew up in this artistic milieu, spending summers with in Aix-les-Bains in the Pyrenees where he experimented with watercolour and studied nature. These trips, along with early travels to St Briac in Brittany where he would return again and again, shaped his art. Rivière was taken on by an academic and art teacher, Emile 'Père' Bin, a period of formal training lasting only a year due to Bin's unforeseen death.

Rivière was inspired by the pull of modernity, engrossed in the journal *La Vie Moderne*, and the work of Puvis de Chavannes and the Symbolists, the Impressionists, the Nabis and other contemporary artists. He was to be self-taught for the rest of his life, and generally progressed through solid periods of time using a particular medium. He produced etchings from 1881 to 1885 and then again in 1906; photographs largely from 1887 to 1912; large format wood engravings from 1890 to 1894 and watercolours from 1910 to 1950. He was to be both respected and criticised for making large format prints in large editions, which were controversially destined as much for the wall as for the collector's portfolio.

Rivière leapt adeptly into the Paris art scene of the 1880s, strengthening friendships with his childhood friend Paul Signac and other artists, including the painter and entertainer Rudolphe Salis, who ran a cabaret, the Chat Noir. The cabaret was a hotbed of political mockery, creative fervour and fun, and as a result was very popular with avant-garde artists. In 1882, Rivière became the assistant secretary of the associated journal, *Chat Noir*. At this time he began to make etchings of the countryside from the sketches he had made in Brittany.

The Chat Noir produced spontaneous plays using shadow puppets. Rivière, realising how popular it was, formalised the production. By 1886 until the end in 1896 when Salis died, Rivière was stage director of these unique performances, 43 in all, that pre-empted cinema in their screen-like movement and light effects. Rivière cut characters and images out of zinc, and created a sense of perspective in the design. In 1890 he introduced coloured lights to simulate day and night in his production of *La Marche à l'Etoile.* He documented his work at the Chat Noir with photographs, encouraged by his friend there, Charles Clos. Many of these images are of his colleagues at work, taken close-up from a range of perspectives, and often obscured by flash or the surreal floating effect of electric lights. The photographs never accompanied articles about the Shadow Theatre—George Redon's illustrations were commissioned for magazines. Rivière used his images to help him when designing new sets and to record the complicated machinery involved. His photographs sometimes preceded/inspired a theatrical story, such as his 1887 show, "La Tentation de St Antoine."

Rivière began to teach himself photography from 1887 and practised it for about twenty-five years, by which time photography was over popular in his eyes. He used a wooden camera with bellows and a (printing) frame, identical to the one Degas was to use a few years later. His glass plates were far larger than the film

negatives used by Bonnard and other artists. He was a skilled technician, mastering the cyanotype for images with shadows requiring contrast and the gelatin-silver print on matt paper to achieve luminous greys.

The Chat Noir photographs reveal Rivière's fin-de-siècle fascination with light, shade and silhouettes. Rivière described the lantern of the theatre as "the soul of the retreat," in an article in *Le Temps*, 1894, underlining the importance of light in his work and explaining in part his attraction to photography. These images fit a time when photographers such as his acquaintance Edgar Degas was experimenting with the effects of artificial light, reversing shades of light and dark. The abstract compositions and unusual perspectives pre-empt the later works of the Bauhaus photographer Laszlo Moholy-Nagy and modernists Ilse Bing and Man Ray.

Alongside the Chat Noir photographs, Rivière photographed other motifs that he used in his engravings. He focused on modern scenes of Paris around 1889, echoing Impressionist paintings of street life, with peoples' heads or feet cropped and shadows protruding into the frame from all corners. He concentrated on intimate scenes of family life in the 1890s, and his photographic portraits reveal silhouettes reminiscent of his shadow theatre days, and a fluid style recalling Degas' pastel outlines. Rivière focused on Breton ports and countryside from 1885 to 1900 and then miscellaneous subjects for the next twelve years. He covered topics beyond the pictorialist visions of outdoor nature in his prints, and used photography to record personal portraits and interior views of his home, restricted, or inspired, by the space and light in the apartment. By 1886 he and his wife Eugenie had a summer house in Loguivy, Brittany, and a large Parisian apartment on the Boulevard de Clichy.

Rivière combined classical, modern and decorative styles to produce elegant compositions, heavily influenced by the Japonaism popular at the time. Although Rivière was opposed to overt stylisation in art and examined nature fervently, his wood block prints reveal stylistic techniques from Japanese artworks—high perspective, unusual crops and large flat expanses of colour. Amassing one of the largest collections of oriental objects in nineteenth-century Paris, Rivière became close friends with a dealer, Florine Epstein-Langweil, and worked with his patron Tadamasa Hayashi, who imported Japanese woodblock prints to France.

His photographs of Paris reveal the modernist steep perspectives and sharp angles, stemming from Japanese influences. From 1899 Rivière used photographs and sketches to document the building of the Eiffel tower. He used these preliminary studies for a set of woodblock prints, after Hokusai, *Les Trente-Six Vues de la Tour Eiffel,* published as lithographs in 1902. He was the first person to image the Eiffel Tower and both his photographs and his resulting prints present radical abstract views. The prints were well received, Roger Marx writing in the *Revue Encyclopedique* ten years later that since producing them, Rivere 'has a cult of admiration long overdue' (Toudouze, 135).

Although Rivière did not intend his photographs to be "art," today they have been lifted from obscurity. Technically competent and aesthetically daring, Rivière's photographs bare witness to the nineteenth-century fascination with the effects of light and shade, steep perspectives and modern scenes and are both documentary and artistic. They pre-empt the modernist movement that gripped Paris in the 1920s and '30s and despite the self-effacing nature of the artist, are important proof of the fast pace of nineteenth-century Paris and the changing role of photography.

SOPHIE LEIGHTON

Biography

Benjamin Jean Pierre Henri Rivière was born in Montmartre, Paris, in 1864. He spent much time in Brittany and Aix-les-Thermes, in the Pyrennes. His father died in 1873 and his mother remarried in 1875. A friend of his step-father, Emile "Père" Bin, academic painter and teacher, accepts Henri Rivière into his studio in. Rivière met Rudolpe Salis in 1882 and discovered the Chat Noir, an artistic cabaret. From 1886 to 1896 Rivière ran the Shadow Theatre at the Chat Noir. He participated in his first exhibition in 1886, of works by Chat Noir artists. He met Eugenie Estelle Ley in 1888 and they married in 1895. In 1888 Rivière taught himself to make woodblock prints. From 1888–1902 Rivière worked on a series of lithographs of the Eiffel tower. Andre Antoine, friend of Rivière, formed the Theatre Libre and in 1888 commissioned Rivière to produce a program, co-produced with Eugene Verneau, a commercial lithographic printer who collaborated with Rivière on prints. In 1896 the Rivières bought a summer house in Loguivy, Brittany. Rivière produced his first major lithograph edition *L'Hiver* in 1896 and continued with engraving, photography and watercolour painting. His wife died in 1943. Rivière died in 1951, aged 87.

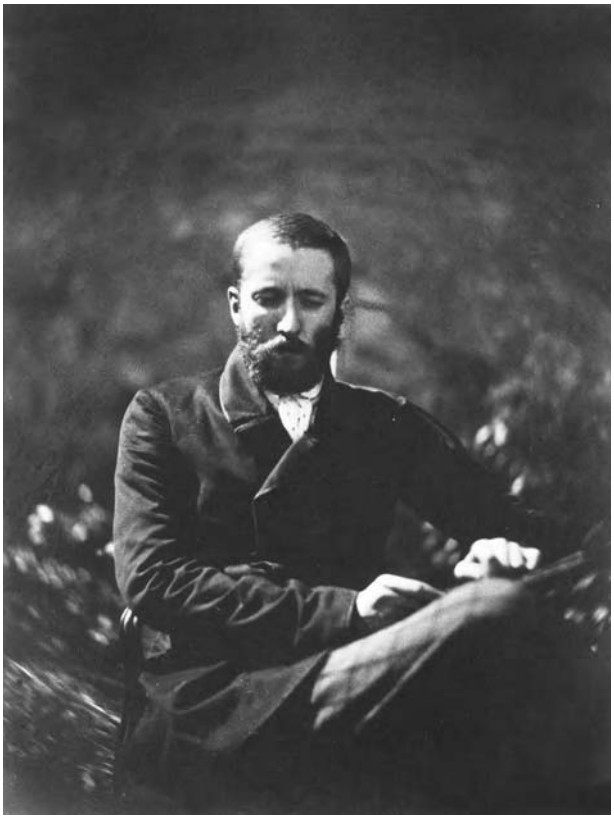
ROBERT, LOUIS RÉMY (1810-1882)
French photographer

Louis Rémy Robert was born in Paris on 3 October 1810, the eldest child of two artists, Pierre Rémy Robert and Anne Caroline Demarne. In 1813, Pierre Robert moved his young family to Sèvres, where his father-in-law, Jean-Louis de Marnette Demarne, a Belgian landscape painter, had secured him a job at the Manufacture Nationale de porcelaine de Sèvres. As a boy, Louis Robert assisted in his father in the *atelier de peinture sur verre* (glass painting studio) and was groomed to take a permanent place at Sèvres, but the Robert family intended that Louis would be more than an artist or artisan. Following his secondary studies, Robert studied chemistry with the illustrious chemist Jean-Baptiste Dumas, probably at the École centrale des arts et manufactures, a new school of industrial engineering in Paris. When his father died suddenly in 1832, Robert returned to Sèvres to assume the role of family breadwinner, and he ultimately spent the rest of his life at the manufacture in a series of increasingly important positions. With commissions for stained glass windows waning in the 1840s, the glass painting studio was phased out, and Robert ascended to the post of *chef de peinture* in 1847. In 1871, Robert became the first employee from the factory ranks to attain the position of Director of the Manufacture de Sèvres.

Robert began experimenting with photography around 1850. Material conditions made the Sèvres factory a natural place for photography to appear, where there were laboratories, chemical stocks, and the camera obscura already in use. Technical advice would have been available from Robert's former professor J.-B. Dumas, who also happened to be an early photographic expert living in Sèvres. In some early trials, Robert utilized outdated stationery bearing the old "Manufacture Royale" letterhead for making paper negatives, probably following Louis-Désiré Blanquart-Evrard's modifications to William Henry Fox Talbot's calotype process. Robert was soon experimenting freely with both wet and dry paper processes. He eventually became a recognized expert in all the period's methods, and from 1858 to 1872 he enjoyed a state appointment teaching photography to engineers at the École des ponts et chausées and the École du génie maritime.



Robert, Louis-Remy. Alfred Thompson Gobert.
The Metropolitan Museum of Art, Purchase, Joyce and Robert Menschel, Mrs. Harrison D. Horblit and Paul F. Walter Gifts, and Rogers Fund, 1991 (1991.1044) Image © The Metropolitan Museum of Art.

Raised in an environment filled with art and artists, Robert was already an accomplished portraitist who had exhibited pastels in the Salon (1848, 1849, 1850) when he took up the camera, and he may have initially approached photography with a view to creating *aides memoire*. By 1851 he was frequently posing his family members and colleagues at the Manufacture for portraits, many of which are remarkable for their animation and warmth, notwithstanding their lengthy exposures. A few images made of his colleagues in the laboratory are among photography's earliest images of workers in the workplace.

Robert's photographic activity increased steadily in the early 1850s. This was encouraged in part by the arrival in 1852 of the new factory director, Victor Regnault, who was an avid amateur photographer. Although the two men surely shared their interest, experience,

and expertise in calotypy, they practiced independently and cannot be called collaborators. Thus, while Robert and Regnault's relationship was never close—unlike Robert's friendship Count Olympe Aguado, with whom he made photographic outings—it did strengthen the place of photography at the manufacture. He may also have taught photography to others at the factory. Moreover, Robert's quasi professional photographic activities in the fifties leave no doubt that photography virtually became his second career. He was particularly active as a landscape and architectural photographer, beginning first by photographing in the nearby Parc de Saint-Cloud with his small portrait camera (approximately 27 × 22 cm), and later acquiring a larger camera (approximately 33 × 38 cm) for views. His invention of a negative holder that could be loaded with up to fifteen dry paper negatives allowed greater ease photographing in the field. In 1853 he published a portfolio of thirteen architectural views in Blanquart-Evrard's edition *Souvenirs de Versailles*, and his photographs of medieval architecture in Brittany were copied in lithography for publication in the first volume of *Anciens évêhés de Bretagne* (atlas and first volume, 1855). Traveling in Normandy in the early 1850s, he also made a series of large views on the grounds of the Chateau d'Eu. These muted pictures, which feature rustic, timbered sheds, barns, hay wagons, ancient, massive beech trees, and the architecture of the 18th-century glassworks on site, are indebted to the model of the Barbizon painters, who were in turn indebted to Robert's grandfather Demarne, who had been instrumental in introducing French painters to naturalistic Flemish landscape painting. Robert in fact maintained close friendships with two of the principal painters associated with Barbizon: Camille Corot, a family friend who lived adjacent to Sèvres, and Constant Troyon, an intimate friend since boyhood.

Robert's most well known photographic work, however, was in still life, and from the beginning of his photographic career he had envisioned using photography to document the extensive Sèvres output and historical collections. He photographed a few arrangements of ceramic vases, statuettes, glassware, and artist's props using paper negatives, but expanded and refined the project for the 1855 Exposition Universelle. The Manufacture de Sèvres was to be France's showcase institution for this international exhibition, and Robert thought to make photographic reproductions the factory's showpieces. Seeking a more subtly detailed image, he learned the albumen-on-glass process from Hippolyte Bayard, and produced a group of salted paper prints from glass negatives of Sèvres wares that was offered for sale at the exhibition. Robert won critical notice with these pictures in several photographic salons and exhibitions in the early 1850s and 1860s. In 1863, Robert proposed the funding of a photography studio at Sèvres for the purpose of cataloging the factory output, which was approved in 1865 after much ministerial resistance.

A member of the Société française de photographie from 1855 on, Robert was involved in the society's activities until the end of his life in 1882. His personal photographic production is estimated at some 600 paper negatives, but most of his later work on glass (outside of the factory catalog) has not survived.

LAURIE DAHLBERG

See also: Calotype and Talbotype; and Régnault, Henri-Victor.

Biography

Louis Robert was born on 3 October 1810, and was raised beyond the western edge of Paris in Sèvres, where his parents were employed by the Manufacture de porcelaine de Sèvres. Raised to take his place as a factory artist but trained also in chemistry, he directed the atelier of painting on glass from 1832 until 1847, when he was promoted to *chef de peinture*. He began working in paper negative photography around 1850 and turned the camera to portraiture, landscapes, architectural studies, and still life arrangements. His photographic activity at Sèvres was encouraged by factory director Victor Regnault, a fellow amateur photographer who assisted Robert in establishing a photography studio in the factory to record Sèvres' output and museum collection. Some of Robert's architectural work was published in the early 1850s, including thirteen views that comprised Blanquart-Evrard's 1853 edition, *Souvenirs de Versailles*. A technical expert in all the period's processes, he taught photography from 1858 to 1872 at the École des ponts et chausées and the École du génie maritime. He was active in the Société française de photographie from 1855 until his death in 1882.

ROBERTSON, JAMES (c. 1813–1888)

James Robertson was trained in London under William Wyon, the Chief Engraver at the Royal Mint. In 1841,

Robertson, James. A Turkish Lady. From the "Hickes Album" 1855–1860.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

he himself accepted an appointment as Chief Engraver at the Imperial Mint in Constantinople (present-day Istanbul), and held that position for forty years, until his retirement on October 29th 1881. Within days he sailed with his family to Yokohama, to join his brother-in-law and business partner, Felice Beato. He died in Japan on April 18th 1888.

The move to Constantinople, which may have begun for Robertson as a young man's light-hearted adventure, proved to be a step which changed the course of his life. Highly respected for his work, a senior officer of the Mint, and honoured several times for exemplary service, he still found time to open another avenue of artistic achievement. At some stage in 1852, possibly inspired by the example of another expatriate, the French engineer Ernest de Caranza, he took up photography, and for the next fifteen years devoted considerable time and effort to mastering the new art, and establishing a new business.

Conditions conspired to favour his ambitions. Constantinople itself was a prize for any photographer, exotic, picturesque, still little known but much dreamed of by westerners as the epitome of oriental mystery and romance. The recent, ever-expanding network of regular rail and steamship services throughout Europe and the Mediterranean basin had also put within easy reach of the city regions held in special honour: Greece, the cradle of Western civilization, and also Egypt and the Holy Land, the settings for hallowed events in the Old Testament and the New. Besides these places of timeless significance, there was one other which achieved great topical importance for a short time. The Crimean Peninsula, site of the war fought between Russia and the Allied Forces of Britain, France and Turkey in 1854–1856, lay just one full day's voyage from Constantinople.

Each of these territories was tapped for treasure by Robertson during his photographic period. Permanent residency in Constantinople made it possible for him to record at leisure the city's splendid buildings and characteristic street life. Images from other places were gathered in short, concentrated camera forays. His first album of Constantinople views was published in London in December 1853; his first sample of Grecian antiquities followed in 1854. As a pioneer war reporter, Robertson paid several brief visits to the Crimea between June 1855 and late spring 1856. On his way from the Crimea to England that summer, he stopped for a while in Malta, to take and sell photographs there as well, before continuing on his journey. With his two Beato brothers-in-law he made an excursion to Egypt and the Holy Land in the spring of 1857, and re-visited Greece later that year. After this flurry of activity the pace slowed, but a number of albums filled with assorted views of Constantinople, Athens and Jerusalem were issued at intervals until the autumn of 1867, when the end of his photographic adventure was announced by the sale of his business premises and all their contents.

Robertson's career had developed along logical and harmonious lines. In his days he was not only an engraver by profession, but also an amateur enthusiast who made charming, lively watercolours and sketches of the daily life around him. For such a young man, with an artist's training and an artist's eye, who was also making a home for himself in a strange, exciting world, it was natural to pick up a new toy, the camera, and play with it. Very soon he realized that he was ideally placed to derive profit as well as pleasure from the hobby. He tried many ways to bring his pictures to the attention of the public, and his enterprise provides an insight into the workings of the early photographic market.

By the end of 1854 he had established a studio in Constantinople, from which he sold prints to Western residents of the city, and to travellers passing through. From 1856 he expanded his business by working for a few years with Felice Beato, a photographer who went on later to an adventurous career in the Far East.

Robertson's pictures could be bought in London and Paris, and viewed there in photographic exhibitions. They were to be found in ports of call, like Malta, on the Mediterranean route, or purchased at a military camp in the Crimea. Engravings based on his work appeared in

books and on the pages of the illustrated press. Professional organizations like the Architectural Photography Association marketed his images, and so did commercial ones like the steamship companies, which offered engraved versions of his photographs as souvenirs.

Robertson's eye was caught by buildings, monuments, structures, the play of light on carved and modelled surfaces. His photographs of Grecian antiquities and scriptural sites in the Holy Land presented objects which may not have been seen before by his viewers, but which were already steeped for them in a thousand associations. As far as possible he tried to isolate the venerated subject matter from the distractions of contemporary life, with just a few small human figures to give a sense of scale. Even before he set foot in Athens or Jerusalem, he knew well what his camera must do. Its task was not to startle or surprise but to pay homage.

In the Crimea, Robertson was constrained by no such expectations. One of the first war reporters, he had to establish tradition, not to follow it. The pictures for which he is famous are silent witnesses to the cost of conflict. No dead bodies are shown, but the devastation of military fortifications and civilian buildings tells its sobering story. In Constantinople also, Robertson was free to tell a new tale, not to illustrate an old one. The city was fascinating to Westerners but occupied no special place in the collective consciousness. His camera could show both the architectural marvels of the place and the mundane life swirling around them. His record of the city earned him the title by which he is best known, "Robertson of Constantinople."

Bridget A. Henisch
Heinz K. Henisch

Biography

James Robertson, born in 1813–1814, in Middlesex. was the son of Thomas James Robertson, and he was christened in the Church of England. In 1855 he married Matilda Beato, and they had three daughters. Trained in London as a coin engraver, he spent forty years in Constantinople at the Imperial Mint. On his retirement there in 1881, he and his family went to Japan, where he died in 1888. Active as a photographer from 1853 to 1867, he exhibited examples of his work in Britain throughout that period, at the Royal Society of Arts (1854), the Photographic Society of London (1855–1858), the Manchester Art Treasures Exhibition (1857), etc. His Crimean photographs were on display in London and some provincial cities from December 1855 to December 1856. His first published album of views appeared in 1853, his last in 1864. Engraved versions of his pictures were shown from 1853 onward in several illustrated journals, in Britain and continental Europe.

ROBINSON, HENRY PEACH (1830–1901)
British photographer

Robinson was born in Ludlow, Shropshire, on 9 July 1830. He was the first child of John, a Master of the National School of the Church of England, and Eliza Robinson. Young Robinson had artistic ambitions, but as there was no formal art education available in Ludlow, he taught himself to draw and paint. Robinson's father, however, was unconvinced of his ability to make a living as an artist, so Robinson went to work for various printers and booksellers in Ludlow, London and Leamington for the years 1844–1856. Nevertheless, Robinson continued to draw and paint during these years, and he produced hundreds of watercolors, pen and ink drawings, and etchings. The acme of his artistic achievement came in 1852 when the Royal Academy accepted his painting *View of the Teme near Ludlow* for their annual exhibition.

In 1851 Robinson learned the daguerreotype process from a visiting photographer, and he experimented with photogenic drawings and calotypes, and then later with the collodion process. Dr Hugh Diamond visited Robinson in 1854 and enthusiastically encouraged Robinson's photography. Robinson continued to refine his photographic techniques, and in 1856 he decided to pursue commercial photography as a profession. With a loan of £100, Robinson opened a photography studio in Leamington on 12 January 1857.

Robinson is most well known for his attempt to create artistic compositions through photography. Basing his photographic art technique and compositional style upon principals of academic painting, Robinson produced large prints for the annual exhibitions of the Photographic Society. In 1858 Robinson exhibited *Fading Away*, which was controversial for two reasons: its subject matter and its compositional technique. Some critics felt that its subject, a young middle-class lady

dying of consumption, was too painful to depict with the realistic medium of photography. To compose the narrative image, Robinson used combination printing, a technique in which a photographer created a picture by printing parts of several negatives together. Robinson used this technique to make up for the technical shortcomings of the collodion process and because it allowed him to carefully compose an aesthetic picture. Whereas Robinson felt that photographers should be able to use any technique that furthered the aesthetic appearance of the image, Alfred H. Wall and other critics felt that combination printing was dishonest. Undeterred, Robinson continued to use combination printing for the remainder of his photographic career. In 1861 Robinson exhibited another controversial combination print of a young woman doomed to die—*The Lady of Shalott*. This photograph was based on the title character from Alfred, Lord Tennyson's allegory of artistic creation. In effect, Robinson's *Shalott* staked a claim that photography could illustrate and even interpret poetry, or in other words, it could depict the imaginary. Some critics had harsh opinions, saying that the subject went beyond the appropriate boundaries for photography.

After the two controversial subjects of *Fading Away* and the Pre-Raphaelite *Lady of Shalott*, Robinson vowed to stick to themes of "the life of our day," but he still wanted to create a type of photography that would be accepted as art. For the next fifty years, Robinson produced photographs that almost exclusively imitated British genre painting, depicting rustic maidens and old cottagers. This subject matter allowed him to explore the creative principles of photography while still permitting him to picture a conservative and familiar type of reality.

Robinson was an active member of the Photographic Society of London, to which he was elected in 1857. He was elected to the Society's Council in 1862, and he was elected Vice-President in 1870. In 1891, however, he withdrew from the Society after he was censured for allowing the late entry of George Davison's photographs into the annual exhibition. The following year he helped to form the Linked Ring, an association of photographers dedicated to developing their medium as an art.

Throughout his career, Robinson was a prolific writer, publishing nine books and over 150 articles in various photographic journals. His most popular book, *Pictorial Effect in Photography: Being Hints on Composition and Chiaroscuro for Photographers* (1869), went through four English and American editions and was also published in French and German. These books were mostly aimed at other commercial photographers, and Robinson encouraged these photographers to create pleasing images by following compositional and lighting principals of Fine Art.

Robinson operated commercial photography studios for the majority of his artistic career. His initial studio in Leamington fared well, and he offered portraits on paper, glass or ivory, plain or colored, as well as hand-colored art reproductions, landscapes, documentation of public buildings and residences, and printing of amateurs' negatives. Robinson suffered from ill-health, largely due to the hazards of photographic chemistry, and he halted commercial practice in late 1864. After more than three years of rest, Robinson opened up a commercial studio in 1868 with a partner, Nelson K. Cherrill, in Tunbridge Wells, Kent. Robinson and Cherrill collaborated on many artistic combination prints during their partnership, which lasted until 1875. Their lavish studio featured prominent displays of studio portraiture and also many examples of Robinson's artistic exhibition photographs. It also exhibited nearly fifty medals Robinson had won at various exhibitions throughout Europe and America. Robinson retired from commercial practice in 1888.

Although he had retired from commercial photography, Robinson was still very as an artist and writer. In 1889 began a brief, but very heated, public debate with the British photographer Peter Henry Emerson, who had implicitly criticized Robinson's oeuvre in his book *Naturalistic Photography for Students of the Art*. (Emerson disdained combination printing, for example, saying that it was "the art of the opera bouffe" and that Oscar Rejlander was the only artist he knew who had used it.) Robinson negatively reviewed Emerson's book, concluding that Emerson's theories were symptomatic of a recurrent "disease," for which Robinson's views were the "disinfectant." This prompted a heated and insulting reply from Emerson that concluded, "I have yet to learn that any one statement or photograph of Mr. H.P. Robinson's has ever had the slightest influence upon me, except as a warning what not to do." Their public debate effectively ended with Robinson's assessment of Emerson's retraction of his theories as "a petulant jeremiad."

Robinson died in 1901, survived by his wife, Selina, and their five children: Edith, Ralph Winwood, Maud, Ethel May, and Leonard Lionel.

ROBINSON, RALPH WINWOOD (1862–1942)
English photographer

Ralph Winwood Robinson, son of the eminent pictorialist Henry Peach Robinson (qv), took over the family portrait studio in Tunbridge Wells, Kent, in 1885 when his father's failing health forced his retirement. The business became known subsequently as H. P. Robinson & Son, and had a considerable reputation for child portraiture. He later took over the Rembrandt Studio in Redhill, and another in Croydon. He was a highly respected pictorialist in his own right, and his enthusiasm for exploring the unique aesthetics of the photograph led him to become a founder member of the Linked Ring Brotherhood in 1892.

Ralph W. Robinson also developed a ground-breaking approach to location portraiture, producing a highly acclaimed series published as Royal Academicians and Associates. These studies showed the artists at work in their studios, and sitters included Alfred Waterhouse, George Frederick Watts and others.

Like many professional photographers in the closing years of the 19th century, Robinson found his livelihood being eroded by offers of cheap portrait photography in return for coupons being offered by soap manufacturers and tobacco companies. As a direct result of this, Robinson and others banded together and established the Professional Photographers' Association in London in 1901.

JOHN HANNAVY

ROCHE, RICHARD (1831–1888)
Canadian photographer

Richard Roche was born on June 16, 1831 in England. He joined the Royal Navy in 1851, setting sail in October 1856 as a third lieutenant on HMS *Satellite* for British Columbia, which was reached via Cape Horn on June 7, 1857. He likely carried a camera with him, as a scrapbook at Yale University Library (call number WA MSS S-1817) contains photographs documenting portions of the vessel's voyage and the joint military occupation of San Juan Island in which Roche took part. Roche served on the ground as a member of the Northwest Boundary Commission in 1858 and 1859, who included among its members Royal Engineers trained as photographers, until he was recalled to assist in the joint occupation of San Juan Island by British and American troops. Early in 1860 just prior to the *Satellite*'s departure, he struck up a friendship with Francis George Claudet who lived aboard the vessel for a time. After Roche's retirement, he settled on the Isle of Wight where he died in 1888. Roche's name is commemorated by place names in BC and Washington. Less than three dozen prints identified or attributed as his work survive in Canadian and American public collections.

DAVID MATTISON

RODGER, THOMAS (1833–1883)
English photographer

As a 'boy assistant' in Dr. John Adamson's St. Andrews lecture room, Thomas Rodger could truly claim to have been in at the birth of photography in Scotland. He became interested in photography at an early age, being taught by Adamson and eventually assisting him.

Thomas Rodger was born in St Andrews. His father, also named Thomas, was a painter, but Thomas Jr. chose to study chemistry and later medicine rather than art. Nonetheless, by 1849, at the age of sixteen, he had opened a photographic studio in the city. He lived and worked at his studio, in St. Mary's Place, for his entire professional life.

Amongst his early calotype subjects—exhibited at the Aberdeen Mechanics Institute exhibition of 1853, were portraits of Dr. John Adamson himself, views of the ruins of St. Andrews Cathedral, and several of the city's colleges.

Rodger exhibited his pictures in London, Edinburgh and Glasgow over a period of several years, but all the images exhibited from 1854 were by the wet collodion process rather than the calotype.

Rodger's friendship with John Adamson endured for many years, and accounts of the 1857 Exhibition of the Photographic Society of Scotland report a series of posed studies of the game of golf—then enjoying a considerable resurgence of interest—credited jointly to the two men.

JOHN HANNAVY

RODRÍGUEZ, MELITÓN (1875–1942)
Colombian photogrpaher and studio owner

Melitón Rodríguez was born in Medellín, Colombia and worked at his craft between 1892 and c.1939. He may

have received some training from artist Francisco Cano but was primarily self-taught. He worked in partnership with his brother Horacio until 1897, after which he continued on his own. Although the Colombian coffee industry grew significantly during his lifetime and brought prosperity to the Medellín area, in general Rodríguez struggled to support his wife and nine children, three of whom later worked with him in the studio.

His images recorded a variety of subjects in both studio portraits of individuals and groups and in outside views. He photographed modern developments such as railroads, trolleys and automobiles; urban monuments, buildings and events; rural scenes, locations and people, and ethnographic "tipos." He is remembered for recording the opening of the Amaga Railroad line in 1914.

Rodríguez was passionate about his craft, painted his own backdrops and for several years kept a diary in which he recorded his attempts to develop his skills and abilities as a photographer. He received a number of local awards for his work and in 1895 received a silver medal at a New York show sponsored by the photography journal, *Light and Shadow*. The image was that of "Los Zapateros" ("The Cobblers"). His archive of over two hundred thousand negatives is considered the official record of the Province of Antioquia during the first half of the twentieth century. The archive is preserved in Medellín at the Biblioteca Pública Piloto.

Yolanda Retter Vargas

ROENTGEN, WILHELM (1845–1923)

Wilhelm Roentgen wrote or co-wrote fifty-eight scientific papers, but only the three he published on X-rays, which he discovered and named, are now well known. Among other subjects he investigated were the ratio of the specific heat of gases, the polarisation of light in gases, pyroelectricity and piezoelectricity, refractive indices of fluids, and the compression of liquids and solids. At the time of his discovery of X-rays in 1895, he was looking at electrical discharges through gases at low pressure.

Roentgen began studying cathode rays generated in a Crookes tube in the autumn of 1895. To detect them, he used paper coated with barium platinocyanide, which fluoresces when struck by cathode rays. On 8 November 1895 he noticed that one of the sheets, lying some distance away from the covered tube, was glowing. Photographic plates fogged in similar circumstances had been observed previously, but Roentgen was the first to investigate further. Since the range of cathode rays in air had been shown to be only a few centimetres, he deduced that the glow must be caused by some other form of ray. Placing his hand in the path of the rays caused the outline of his bones to appear on the coated paper.

X-rays are produced when cathode rays strike the wall of the tube and Roentgen experimented with a range of materials to determine their properties. He found that interposing materials varying in density affected the brightness of the rays by different amounts. A magnetic field did not deflect them as it did cathode rays but neither did they exhibit reflection, refraction or polarisation. It was because of these unusual characteristics that Roentgen characterised them as "X-rays," X standing for unknown as he could not determine their nature, although they were soon also known as Roentgen rays in his honour. The theory behind the phenomenon was unclear to him—he thought that they might be longitudinal vibrations in the ether. Later research showed that they were electromagnetic waves with a very short wavelength.

On 22 December 1895 he took the emblematic image of his wife's hand wearing a ring. He sent a paper entitled *On a New Kind of Ray* to the Würzburg Physical-Medical Society six days later and on New Year's Day 1896 sent copies, with samples of X-ray images, to a number of European colleagues. The story was published in Vienna on 5 January and was soon widely disseminated, bringing Roentgen instant fame. He followed his first paper with two more, in March 1896 and May 1897, which mapped the properties of the new ray.

The phenomenon was easily replicated, with unambiguous results; and unlike the increasingly abstruse details of laboratory science, the results were obvious to the layperson. Popular international interest too was immediate and paralleled scientific dissemination through the academic press. Awareness was stimulated by reproductions in illustrated magazines of X-ray images of a wide range of objects. They became the subject of an enormous quantity of commentaries as well as fiction, poetry and cartoons, though the satirical edge of many betrayed fears over loss of privacy and possible immorality.

The nature of X-rays raised the difficulty of fitting them into a conceptual framework, hence the alignment with photography which, despite the efforts of a number of early commentators to point out the obvious differences, glossed over the method by which each was achieved. As the images created by X-rays could be recorded on photographic plates, it was a natural assumption that they shared other characteristics. X-rays were seen as analogous to photography except that they captured information not visible to the naked eye.

Despite these differences the label "New Photography" caught on quickly, and had a certain validity. Photography had already extended the capabilities of perception, with its ability to freeze motion, take images of stars invisible to the naked eye and record microscopic organisms. At the same time Roentgen was announcing his discovery, moving images, which could reproduce motion, were being projected for the

first time, though at first X-rays received by far the greater coverage. X-rays appeared to be another method by which reality could be analysed with a permanent image as the result. The association was reinforced as photographers, realising the commercial possibilities, took up X-ray portraits as a side line. It was not long, however, before the negative side effects of uncontrolled use were appreciated.

Wild claims were made initially, for example one in March 1896 that X-rays were being used to transmit anatomical diagrams directly into the brains of medical students. Two months later a young farmer was reported to have used X-rays as an updated Philosopher's Stone to transmute cheap metal into gold. More reasonably, they were touted as an alternative to vivisection, their non-invasive character contrasting positively with the scalpel. The temperance movement too felt that they would have an educative effect by demonstrating the deleterious physiological effects of alcohol and tobacco.

X-rays also slotted into the discourse around spirit photography, with their shared emphasis on photographing the invisible, phenomena that could not be seen with the naked eye. The early terminology used to describe X-rays (notably ether and vibrations) was similar to that used by spiritualists, and the figure of Sir William Crookes, both inventor of the 'Crookes tube' that was an essential component in producing X-rays, and a figure strongly associated with Spiritualism, reinforced the link. Darget and Baraduc's thoughtographic experiments were conducted using a device called a 'radiographer,' showing a clear debt to Roentgen. The ability to see what was otherwise hidden was used to legitimate the claims of clairvoyants, who maintained that they did the same.

The medical and metallurgical applications of X-rays were quickly appreciated, assisted by Roentgen's refusal to patent the discovery so that humanity would benefit from it. Familiarity with the new technology, and appreciation of its limitations, soon caused a loss of interest among the general public. There was also an increased appreciation of the differences with photography during the second half of the decade, and "New Photography" faded away.

TOM RUFFLES

Biography

Wilhelm Conrad Roentgen was born 27 March 1845 in Lennep, Rhine Province but grew up in the Netherlands. He obtained his PhD on the properties of gases from the University of Zurich in 1869. In 1870 he moved to the University of Würzburg, the first of a number of academic posts in the next decade. After spells at Strasbourg, Württemberg and back at Strasbourg, he took the Chair of physics at Giessen University in 1879. Würzburg offered him the Directorship of its Physical Institute in 1888 and he became its rector in 1894. After a demonstration of X-rays to the Kaiser he was awarded the Prussian Order of the Crown, Second Class, and was made an honorary citizen of Lennep. He was appointed professor of physics at Munich in 1900 and accepted the first Nobel Prize for physics in 1901. He died of cancer on 10 February 1923 and was buried with his wife Anna at Giessen.

ROLL FILM

From the early 1850s, experimenters had been looking for an alternative to glass as a support for light-sensitive emulsions. The weight and bulk of glass plates added greatly to the photographer's burden, added to which, of course, was the constant danger of breakages. Talbot's caloytpe process had shown that paper could be used satisfactorily as a negative support. Paper could be used either in sheet form or as a long band. The first practical proposal to use a band, rather than a sheet, of sensitised paper came in a British patent of 1854 by Joseph Blakey

Spencer and Athur James Melhuish. They described a camera attachment called a roller slide or rollholder containing a band made by gumming together sheets of sensitized paper. The paper was attached at each end to a pair of rollers and could be wound from one roller to another in order to take several exposures in succession. Several similar devices were patented during the 1850s and 1860s, including one designed by the famous portrait photographer Camille Silvy, in 1867. None of these early devices, however, were widely used. The first rollholder to enjoy a modest degree of commercial success was designed in 1875 by Leon Warneke, a Russian living in England. Warneke's rollholder contained a one hundred exposure roll of tissue coated with a film of gelatine or dry collodion emulsion that could be stripped from the paper for processing. Warneke's design was the inspiration for the first commercially successful rollholder, designed by George Eastman and William H Walker in 1884. The Eastman-Walker rollholder used strips of sensitised paper or stripping film, sold under the name "Eastman's American Film." Such was Eastman's faith in the future of film photography that he changed the name of his company from The Eastman Dry Plate Company to The Eastman Dry Plate *and Film* Company. At this time, 'film' effectively meant "paper," used either as a negative material in its own right or as a support from which a negative-bearing emulsion layer could be stripped during processing. Eastman was not alone in realising the disadvantages associated with paper and the need to develop an alternative support for film photography. However, any substitute would have to fulfil a number of criteria—it would have to be light, tough, flexible and transparent. Many flexible film supports were tried in the 1880s, including the idea of using several layers of collodion emulsion, but the answer was eventually found in one of the most important synthetic materials developed during the nineteenth century—celluloid.

Celluloid has its origins in the work of an Englishman, Alexander Parkes. In 1855, Parkes was granted a patent for a substance which he called *Parkesine* produced using a mixture of oils and gums as a solvent for nitrocellulose. In America, brothers John and Isiah Hyatt discovered that camphor under heat and pressure acts as a nitrocellulose solvent. They called their new material *celluloid* and in 1872 they founded the Celluloid Manufacturing Company which made a range of products from celluloid, such as dominoes and billiard balls. As celluloid became better known, its qualities recognised and its use as a substitute for other materials widened, photographic experimenters became increasingly interested in its possibilities. A number of people attempted, unsuccessfully, to promote the use of sheets of celluloid as a substitute for glass plates, including David and Fortier in France and Waterhouse in England. The breakthrough came in 1888 when John Carbutt, an Englishman born in Sheffield who had emigrated to America as a young man, put on the market the very first commercially produced gelatin emulsion-coated celluloid sheet film. Although marketed as "flexible negative film," Carbutt's celluloid sheets were, in fact, relatively stiff and unsuitable for production in long strips for use in rollholders.

In 1887 Hannibal Goodwin, a relatively unknown clergyman and amateur photographer in Newark, New Jersey, filed an application in the U.S. Patent Office for a 'transparent sensitive pellicle better adapted for photographic purposes, especially in connection with roller-cameras.' Goodwin was a self-taught chemist and his patent application was broad and somewhat ambiguous in its wording. For two years, the application remained unissued, undergoing several amendments, but by this time other inventors, most notably George Eastman and his chemist Henry Reichenbach had entered the field. In 1888, the year that he introduced the Kodak camera, George Eastman began to seriously explore the possibility of manufacturing flexible rolls of sensitised celluloid. He set his young research chemist, Henry Reichenbach on the task and the following year both Eastman and Reichenbach filed patent applications for flexible celluloid film. These interfered with Goodwin's application, filed two years earlier, setting in motion a legal battle that would drag on for over twenty years. Eastman's celluloid film went on sale in the autumn of 1889 and was available in a range of sizes to fit the various rollholders and the growing range of Kodak cameras (four different models by this time). The commercial potential for rollfilm was enormous, as Eastman quickly realised. In March 1889 he had written to his business partner William Walker: "The field for it is immense… If we can fully control it, I would not trade it for the telephone."

Eastman did not enjoy a monopoly of film manufacture but his company did come to dominate the market. Throughout the 1890s, boosted by the rapid growth of amateur photography and its use in cinematography, transparent celluloid rollfilm was produced in ever increasing quantities. All this time, Goodwin's patent application remained under consideration. It was not until 1898, eleven years after his original application had been filed, that Goodwin was finally granted a patent. After his death in 1900, Goodwin's patent was sold to the American firm of Anthony and Scovill, who took out a suit against Kodak for patent infringement in 1902. The case dragged on for over ten years and, finally, in August 1913 it was ruled that Goodwin's patent had indeed been infringed, "not on the ground that Eastman had copied the process, but that Eastman's process, though an improvement, came within the Goodwin patent claims." The following year, Eastman paid

his competitor five million dollars as compensation. A huge amount, but tiny when compared to the profits that Eastman had earned from sales of celluloid film in the intervening years.

ROOT, MARCUS AURELIUS (1808–1888)

American photographer

At the height of his career in the 1850s, Marcus Aurelius Root was one of America's preeminent daguerreotypists, renowned for the elegance of his portraits, the eminence of many of his sitters, the flawless finish of his plates, and the size and opulence of his studios. Root was also one of the most prolific and influential writers on photography of his era, contributing numerous articles on both the art and profession of photography to the journals of the period. He supposedly coined the term "ambrotype." Root's book, *The Camera and the Pencil or The Heliographic Art* (1864), remains a major source on the theory and practice of photography in America in the 19th century. Finally, Root was a pioneering photographic historian and collector: *The Camera and the Pencil* includes the first the history of American photography ever written, and Root assembled a collection photographic original works spanning 1839–1876 for display in the Philadelphia Photographic Society's pavilion at the 1876 Centennial Exposition in Philadelphia, which resents the first exhibition surveying the history of photography. (This collection remained largely intact and forms the core of the collection of early Philadelphia photography held by the Library of Congress.)

Marcus Aurelius Root was born and grew up in Ohio, where he took art lessons and worked briefly as a portrait artist while studying penmanship (ornamental copperplate writing). Root moved to Philadelphia in 1832 to study portrait painting with Thomas Sully, but finding he lacked talent as a painter, began teaching penmanship, then a very lucrative profession. He opened a writing academy in Philadelphia in 1835, and devoted most of the next decade to running his school, teaching penmanship, and authoring manuals on its philosophy and practice.

In 1839 and into the early 1840s, Philadelphia—then the home of American science—was the major center of daguerreian activity and experimentation in the United States. Root naturally became interested in the process and by 1843 had learned it. His teacher was Robert Cornelius, one the first Americans truly to master the daguerreotype. (Cornelius, who introduced using bromine to increase the sensitivity of daguerreotype plates in 1839, opened the first portrait studio in Philadelphia 1840. He also invented the superior plate polishing compound used by many of the top American daguerreotype studios, including South and Hawes—and Marcus Root.) Deciding to practice daguerreotypy professionally, Root learned the business by becoming a partner in galleries in Mobile, Alabama, New Orleans, Louisiana, and St. Louis, Missouri, 1844–1845. In 1846, he returned to Philadelphia, bought out John Jabez Edwin Mayall, whose studio at 120 Chestnut Street was one of the city's leading daguerreian establishments, and within a short time had established a reputation for the superior artistic and technical quality of his portraits. In 1849, Root opened a studio in New York in partnership with his brother Samuel, but sold his share to his bother in 1851. In the meantime, Root consolidated his reputation by exhibiting his work at the annual fairs sponsored by Franklin Institute in Philadelphia (1844, 1846–1849), the American Institute in New York (1846–51), and at the international expositions at Crystal Palace in London (1851) and the Crystal Palace in New York (1853), where he won a bronze medal. In 1851, when the first American professional photographic journals were founded, Root became a frequent contributor, and by the time a serious injury suffered in a railroad accident caused his premature retirement from gallery work in 1856, he was recognized as one of the major figures in the profession in the United States.

Marcus Root wrote the *Camera and the Pencil* during his recovery. Conceived as a comprehensive two-volume theoretical and practical manual for practitioners, Root's magnum opus promotes photography as a legitimate aesthetic medium and as a significant form of American cultural expression. The first volume (1864), is one the major documents of 19th century photographic literature: it includes the first history of photography, chapters on aesthetics and art appreciation, and offers an extended discourse promoting the high standards of artistic and technical proficiency in the practice of the photographic profession of which Root was an ardent advocate. When the second volume, a handbook of processes and practical photographic technique, was destroyed in the presses when the printers burned to the ground, Root retired from the field.

Root's final contribution was the exhibition surveying the history of photography, 1839–1876, which he

organized for the Philadelphia Centennial Exposition in 1876. Granted only a small panel at the end of a dividing panel instead of the 12-foot wall he requested, Root was able to display only a fraction of the collection of original early material he had assembled, much of it obtained directly from Philadelphia's pioneer daguerrians. This collection—which included some of the earliest and most important examples of American daguerreotypes—remained largely intact after the Centennial and afterwards, and was eventually acquired by the Library of Congress, where it represents one of the great treasures in the Library's collection of photography.

When Marcus Root died in 1888 as a consequence of injuries received in a streetcar accident three years earlier, he was remembered as "one of the first daguerreotypists in America"—meaning one of the best and most successful. Indeed, portrait plates by Marcus Root typify and epitomize American studio daguerreotypy at its best, and good examples of his work are prized by collectors. In the end, however, Root's real importance lies not in his art, but in his writing and in his prescient understanding of the importance of preserving the story and the artifacts of photography's history.

ROSLING, ALFRED (1802–1882)

English

Alfred Rosling was a London timber merchant from a Quaker family who, as early as 1846, made large-scale stereo still-life calotype studies for use in a Wheatstone viewer. He was a founder member of The Photographic Society, becoming its treasurer in 1859, and The Photographic Exchange Club. He exhibited 20 landscapes from paper negatives plus four microphotographs from collodion negatives, in the first photographic exhibition, at the Society of Arts in 1852. Like George Shadbolt, who was also a timber merchant, Rosling was an early experimenter with microscopic photography.

He used calotype, waxed-paper ,as well as collodion negatives, favoring the French chemist Dr .J.M. Taupenot's dry collodion process.

In 1859 Rosling and his family moved to Reigate where they became neighbors of the famous photographer Francis Frith and in 1860 Rosling's 22 year-old daughter, Mary Ann, married fellow Quaker Frith, 38, who had recently returned from his travels to the Middle East. Rosling's landscape and tree studies were later published by Frith and many of his views taken throughout Britain were used in early photographically illustrated books.

Rosling's work, which is mainly known through his Exchange Club studies, as well as the views published in the 1860's by Frith, is always technically accomplished and carefully composed.

IAN SUMNER

ROSS, ANDREW & THOMAS (1798–1859)

Of all the British photographic lens manufacturers the firm of Ross was the most significant and long-lasting with an involvement in photography's British origins, innovations in optical design throughout the nineteenth and twentieth centuries and a history which only ended in the third-quarter of the twentieth century.

Andrew Ross was apprenticed to John Corless an optician and instrument maker in 1813, and worked with the optician Gilbert until 1829. By 1830 he had established his own business as an optician, mathematical and philosophical instrument maker and by 1839 was trading under the name of Andrew Ross & Co. Ross remained involved in the business until his death in 1859 training his son, Thomas (1818–1870), who was to succeed to the business and John Henry Dallmeyer (1830–1885). Dallmeyer married Andrew Ross's second daughter Hannah, and was left one-third of Ross's fortune of over £20,000.

Thomas Ross and Dallmeyer separated and Dallmeyer established his own optical business in 1860. The

Ross business became Thomas Ross & Co, then from 1871 Ross & Co and finally from 1898 Ross Ltd. During the second half of the twentieth century the firm became associated with the Houghton-Butcher photographic business. It was last recorded as a manufacturer c. 1970 making binoculars before it was dissolved in c. 1975.

From 1830 Andrew Ross quickly established a high reputation for his microscopes and he was responsible for a number of significant improvements in microscopy design some in conjunction with Joseph Jackson Lister (1786–1869). Both were founder members of the Microscopical Society of London. Ross was a supplier of lenses and optical apparatus to William Henry Fox Talbot from at least 1838 and Talbot also visited his Regent Street shop. During one such visit on 30 March 1839 it is likely that Ross mentioned the work of the Reverend J. B. Reade and his use of gallic acid when preparing sensitized paper. Reade had previously spoken to Ross about this, a fact which emerged in the 1854 *Talbot v Laroche* lawsuit.

Ross acted as an intermediary between Talbot and the Parisian optician of Alphonse Giroux, the maker of Daguerre's camera, ordering two daguerreotype cameras with lenses for 320 francs on 7 October 1839 following two months of experimenting with the daguerreotype and communication on the matter with Talbot. Talbot was later to recommend Ross's services in securing such apparatus to Walter Trevelyan in 1842.

The Petzval lens was one of the first lenses designed specifically for photography being announced in 1841. The lens worked at f/6 and Ross was immediately able to improve it to work at f/4. Ross's son, Thomas, working in his father's factory made a novel lens for Henry Collen on 2 June 1841 being a double made of two cemented achromatic lenses. It was not a commercial success being unable to compete with the superior definition of the Petzval. Ross made other lenses for Talbot.

Henry Collen, a professional calotypist in London, ordered a camera from Ross but by March 1842 was complaining to Talbot that Ross had not delivered it and probably never would as he was having difficulties with the curved paper holder made to correct the focus of the lens. In August Collen was complaining to Talbot that Ross had not delivered a large lens of wide aperture he had ordered. This was never made. In 1848 Talbot was recommending Ross's enlarging camera to Thomas Malone, another professional photographer.

This involvement with the British early photographers gave way to more commercial activities including in c1860 a mammoth lens with a focal length of 6 feet (*sic*) producing an image of 44 × 30 inches for John Kibble of Glasgow. The camera to which it was attached was mounted on wheels and drawn by a horse.

Aside from optics the firm also sold and made a range of cameras and photographic equipment. An extant catalogue from 1855 records Ross's success at the 1851 Exhibition for lenses and 'the best camera in the Exhibition' and it details a range of portrait and landscape lenses, cameras, stands and accessories, together with chemicals and equipment required to operate the Calotype, Daguerreotype and collodion processes. From 1861, Ross was also responsible for making Thomas Sutton's camera for panoramic photography and continued making it's distinctive water-filled lens. Ross's Universal Binocular camera of 1862 was a particular success.

From 1864 Thomas Ross developed a range of lenses called Doublets and based on his father's Collen lens. After Ross's death in 1870 the firm brought in a series of managers and lens designers including some from Germany who continued to produce new photographic lenses alongside the firms other optical products. In 1874 the firm brought out their portable and rapid symmetrical lens calculated by F. H. Wenham. Ross was the first firm to employ a scientist as a lens mathematician and Wenham was with the company from 1870 until 1888. He was followed by Hugo Schroeder.

Ross was awarded various medals and diplomas for their optics and claimed a list of the leading photographers of the period as users of the their lenses including: Henry Barraud, Francis Bedford, Henry Dixon & Son, Elliott & Fry, Thomas Fall, Robert Faulkner, Francis Frith, Frank Good, Hills and Saunders, Payne Jennings, Lock and Whitfield, J. E. Mayall, George Washington Wilson and Frederick York.

In 1890 the firm became Zeiss's London agents and made many Zeiss lenses, including the Protar (from 1 April 1892), the Planar, Unar and the Rudolph-designed Tessar, all under licence. Ross also made a version of a Meyer lens under it's own name as the Homocentric from 1902 which was a popular and long-lived design.

When Schroeder left Ross he was succeeded by J. W. Hasselkus whose first lens design was issued in 1898. The firm established a large factory at Clapham Common in 1899.

During the last years of the nineteenth century Ross issued several new designs of camera to supplement their traditional wooden field and studio cameras. The first of their twin lens reflex cameras the Portable (Divided) camera was launched in 1890 and a single lens reflex camera launched in 1905 which was made by Kershaw of Leeds. Other photographic optical equipment such as optical lanterns was also sold.

Throughout the nineteenth century photographic optics was just one part of the Ross company's wider optical manufacturing activities. While its involvement in photographic optics was maintained well in to the twentieth century cameras and associated photographic equipment was increasingly being bought in from other manufacturers and sold under the Ross name. Unlike

Dallmeyer which did develop some truly original lens designs the Ross company after Andrew Ross's death relied more on refining optical designs from Germany and selling its own version as well as manufacturing well-known German designs under licence. It introduced few original optical designs of it's own.

ROSS, HORATIO (1801–1886)

A talented marksman and athlete, Horatio Ross was also an important figure in the history of early photography in Scotland. He was born at Rossie Castle, Forfarshire Scotland on 5 September, 1801, the son of Hercules and Henrietta (Parish) Ross. He joined the 14th light dragoons in 1819 and retired as a Captain in 1826. Ross then embarked on a political career as a member of parliament for the Aberdeen and Montrose boroughs but did not seek re-election after 1834. An avid hunter, Ross wrote the introduction to a book titled *Deer Stalking and Forests*, in 1880. He lived at his family home, Rossie Castle until 1853, when he purchased the estate of Netherley in Kincardineshire. In 1834 he married Justine Henriette Macrae. Their marriage lasted over fifty years and produced five sons, Horatio, Edward, Hercules, Colin and Robert.

One of Ross's earliest photographs is thought to be a quarter plate daguerreotype, made in 1847, that depicts his eldest son and a friend, fishing. Although it is unusual for a amateur photographer to tackle the complexities of the daguerreotype process, eight plates at the Victoria and Albert Museum attest to Ross's perseverance and skill with this technique. Two years later, in 1849, Ross learned the rudiments of the paper negative process from a professional photographer from Edinburgh, James Ross (no relation). Several of his albumen prints (often measuring 11 × 14 inches) were made from waxed paper negatives but even by about 1856 Ross was also using the wet-plate collodion process. A photograph from about 1858, made by his wife Justine, shows him preparing a plate in his home studio.

Ross's primary subjects were his family and other deer stalking enthusiasts. He also made "trophy" photographs the spoils of his activities as a deer-stalker as we can seen in photographs such as *Stag in Cart*, c. 1858 (Gilman Paper Company Collection). Set against the rugged landscape of the Scottish Highlands, the fallen stags are often arranged in a manner meant to produce the best pictorial effect. The branch-like antlers of the deer are silhouetted against a blank sky or massive boulder in order to highlight their spiky form. He worked within the English Picturesque tradition, photographing views of shepherds' huts, winding streams, waterfalls and rocky outcrops. Some writers have even suggested that the frequent use of a screen of trees or rocky crevices is the result of Ross's expertise as a consummate hunter. He is also known for his views of Edinburgh and various estates (and private hospitals) from around the Scottish countryside.

One of the founders of the Photographic Society of Scotland in 1856, Ross was the vice-president at the time of the society's first exhibition and held that position until 1863. Ross was a forceful advocate for the place of the amateur photographer within the society. He even went as far as delineating which fields of photography were suited to amateurs and which should be left to the professionals in a paper he read to the February 10th 1857 meeting of the PSS, where he argued that the "proper field for the Amateur's labor is in the open air. Portraiture he should leave in the hands of the professional gentlemen." He later defended the position of the amateurs at a special meeting of the society in 1858, when the professional members sought to establish a greater presence on the on the hanging committee. His motion to reject a proposal that would limit the number of amateurs in the society was supported by the majority of members.

Although Ross's work was exhibited frequently during his lifetime it is not as well known today. There are several known albums of his work and his picturesque views are often compared to the work of his contemporaries Roger Fenton and Benjamin Brecknell Turner. As a gentleman-amateur photographer Ross was typical of many of photography's early inventors and experimenters. While his hunting scenes can be seen as the product of the particular class and generation, they, along with his landscapes and architectural views, and portraits of friends and family, form a unique picture of life in Scotland in the mid-19th century.

Horatio Ross died at Rossie Lodge, Invernesshire, on the 6th of December, 1886. The *Dictionary of National*

Ross, Horatio. Tree. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Harriette and Noel Levine Gift, 2005 (2005.100.17) Image © The Metropolitan Museum of Art.*

Biography emphasizes Ross's accomplishments as a politician, athlete and marksman. His versatility with various photographic processes and his enthusiasm for recording the life and landscape the surrounded him, have also left an indelible mark on the early history of photography in Britain.

ROSSE, LADY (1813–1885)

English photographer

Lady Rosse was born Mary Field in Yorkshire in 1813 to Anne Field and John Wilmer, a wealthy landowner. Her mother died shortly after her birth and she was raised by a governess. In 1836, she married William Parsons, Lord Oxmantown, and they took up residence at his family's seat at Birr Castle in Ireland. He became the 3rd Earl of Rosse after the death of his father in 1841. Lady Rosse took up photography in 1854 following the lead of her husband, who began experimenting with the daguerreotype process in 1842. Among her photographs that survive are group portraits, single portraits and landscapes, as well as many pictures of telescopes built by her husband. Lady Rosse was closely involved in the Earl's construction projects, and some of her first photographs portray his telescopes. The Photographic Society of Ireland awarded Lady Rosse their first Silver Medal in 1859. She was an elected member of the Dublin Photographic Society and the Amateur Photographic Association. Lady Rosse moved to London in 1870 following the death of her husband in 1867. She died in London in 1885 and was buried in the family vault at Birr Castle in Ireland.

ROSSETTI, DANTE GABRIEL (1828–1882)

English painter and photographer

Pre-Raphaelite painter and poet Dante Gabriel Rossetti was born in 1828 in London. Son of an Italian intellectual, Rossetti was the second of four children, including the art critic William Michael Rossetti (1829–1919) and poet Christina Rossetti (1830–94). Rossetti briefly trained as a painter at the Royal Academy schools and with Ford Madox Brown. He formed the Pre-Raphaelite Brotherhood in 1848 with other key members John Everett Millais and William Holman Hunt. Rossetti's relationship to photography was limited. He loosely used a group of photographs as the basis for many of his later portraits and studies of Jane Morris, the wife of designer, poet, and socialist William Morris. These albumen prints were taken in 1865 in the garden of Rossetti's home in Chelsea, London, by the photographer John Robert Parsons, but it is assumed that Rossetti posed Jane Morris himself. In the series of portraits, Jane Morris is posed against a cloth tent or a fabric-covered, patterned screen, wearing the loose-fitting clothes she adopted. She appears in several of the languid and flowing poses that Rossetti would make characteristic of her in his paintings. These photographs are housed in an album now in the collection of the Victoria & Albert Museum. Rossetti also posed with his siblings for a notable group of photographs taken in 1863 by Charles Lutwidge Dodgson (Lewis Carroll). Rossetti died in 1882 in Birchington-on-Sea after several years of illness.

Diane Waggoner

ROSSIER, PIERRE (1829–c. 1898)

Swiss photographer

Pierre Joseph Rossier was born on July 16, 1829, into a farming family in Grandsivaz, Switzerland. A passport issued to Rossier in October, 1855 listed his profession as photographer and indicated that he was to travel to France and England in order to practice his trade. Sometime between 1855 and 1858, Rossier was hired by the London photographic firm Negretti and Zambra. They sent him to Asia from 1859 to 1861, where he was among some of the first to produce commercial photographs (primarily stereographic views) of Japan and China. While in Japan, he trained Ueno Hikoma and other first-generation Japanese photographs in the collodion wet-plate procedure. His employment with Negretti and Zambra seems to have ended sometime in 1861. Rossier then traveled to Thailand, where he assisted the French zoologist Firmin Bocourt by taking ethnographic portraits of local people. He returned to Switzerland in 1864, operating a photography studio in Freiburg until at least 1876 that produced stereograph and cartes-de-visite views of local scenes as well as portraits. Captions on the mounts indicate that Rossier also had a studio in the Swiss city of Einsiedeln, although no dates of operation are known. He died in Paris sometime before 1898.

Karen Fraser

ROUCH, WILLIAM WHITE (1833–1871)

The business of William White Rouch & Co began in 1854 as a partnership trading under the name of Burfield & Rouch as operative chemists, philosophical and photographic instrument makers, at 180 Strand, London. By 1864 it was trading as W. W. Rouch & Co under which name it remained until it ceased actively trading in photographic equipment around 1914.

William White Rouch was a chemist and appears to have been the driving force behind the business. The firm was the wholesale agent for T. Frederick Hardwich's negative and positive collodion from the late 1850s and commenced dry plate manufacture from an early date. It was also active in the manufacture of photographic equipment advertising various forms of camera for amateur and professional photographers. Rouch also manufactured lenses and was an agent for the principal British and European lens makers and it offered a range of accessories for photography, chemicals and prepared collodions and papers. W. W. Rouch registered a design of portable camera with separate processing chamber in 1858 and the following year registered a portable dark tent which was still being advertised in the 1880s. An improved dark tent design was registered in 1861 and a photographic shutter in 1862. W. W. Rouch died at Mentone on 18 February 1871 aged 39.

A relation, Samuel White Rouch (died 1898) continued with the business. The Patent Portable camera of 1878 was based on S. W. Rouch's patent and proved very popular. It was improved in 1885 and in 1891 and the firm announced that it was being widely used by travellers and explorers including Henry Morton Stanley.

Rouch also introduced a hand camera to meet the demand for smaller, more portable cameras. The Eureka was one of the most popular magazine plate cameras of the later nineteenth century. It was based on Rouch's patents of 1887 and 1888 and the model was sold until at least 1910. The rear section of the camera held a number of plates (one model also made this interchangeable) allowing multiple exposures to be made before reloading.

Hand cameras aside, Rouch continued to offer older designs of cameras and photographic equipment and, increasingly, cameras from other makers. Its importance consequently decreased and the firm traded mainly as a retailer. After Samuel's death in 1898 his son William Albert Rouch continued to manage the business but his interests lay more as a photographer and he built up a successful career as a horse photographer illustrating several books during the 1930s.

By 1914 the manufacturing and retailing business had largely ceased and after the first world war the W W Rouch name continued as W. A. Rouch's photographic studio and remained in existence until at least the mid-1980s.

ROUSSEAU, LOUIS (1811–1874)

French photographer

Born on February 23rd, 1811 in Paris (France), Louis Pierre Rousseau pursued a lifetime career in the Museum of Natural History, mainly as assistant naturalist in the department of Malacology. He also took part in three scientific journeys.

His talent for preparing and drawing specimens contributed in the development of his interest in the publication of scientific illustrations. After the project of publishing a large number of engravings failed, he eventually turned to photography in 1853.

With Achille Devéria, assistant curator in the French national library, he undertook the publication by installments of *Photographie zoologique*, sixty photographs showing rare specimens from the Museum collections (salted paper prints- negatives by Louis-Auguste and Auguste-Rosalie Bisson and prints by Lemercier, and later plates made by the photomechanical process of Niépce de Saint-Victor). Despite constant praise for its accuracy and beauty the project was never completed. In 1854, Louis Rousseau took a series of portraits and photographs of skulls for the anthropological gallery.

A founding member of the *Société française de photographie* (November 15th, 1854), he received its instructions for his journey to the North Seas in 1856, where he made portraits of Inuit and Icelanders (collodion). He is not known to have taken photographs thereafter.

He died of an illness caught during one of his journeys on October 14th, 1874 in Paris, after a long career as a naturalist and a brief one as a photographer.

CAROLINE FIESCHI

ROYAL COLLECTION, WINDSOR

Members of the British Royal Family have collected photographs since the 1840s. By 2005 these amounted to hundreds of thousands of images, but it had not been until the late 1960s that certain of them were classed as a photograph collection, which was subsequently kept in the Round Tower at Windsor Castle in England. By 2005 it numbered at least 350,000 images, of which about a tenth had been acquired in the nineteenth century.

The first members of the Royal Family known to have been aware of photography were Queen Victoria, and more particularly her husband, Prince Albert, who took a keen interest in the new medium. Both had artistic skills and tastes, and were intrigued by new inventions. In March 1842, while the Court was at Brighton, the Prince had himself photographed by William Constable. The Queen and the Prince soon recognised photography's potential uses, whether for recording people and places,

for instruction and inventory purposes, or as an art form in its own right.

By the early 1850s, the Royal couple had commissioned photographers such as William Kilburn and Brunell to take pictures of their family. These were at first intended solely for private use, but within a few years the Queen and her husband had begun to realise how photography could be used to make the Royal Family better known to the public; this was to lead to the expansion of Royal photographic portraiture throughout the nineteenth century and beyond. By 1900, such images were as much an appanage of Royalty as painted State portraits had ever been.

In 1853 Queen Victoria and Prince Albert became patrons of the Photographic Society (later the Royal Photographic Society). When they visited its first exhibition in January 1854, the Honorary Secretary, Roger Fenton, showed them the latest developments in the art through his own work and that of other photographers. As a result he was given the first of his royal commissions, which included photographing the Royal children taking part in a series of tableaux to celebrate their parents' fourteenth wedding anniversary in February 1854.

Work by other photographers, including William Lake Price, Alfred Rosling, and Oscar Rejlander was also purchased by the Queen and the Prince. George Washington Wilson, Adolfe Disderi, and J.J,E. Mayall were commissioned for specific purposes: Mayall's *Royal Album*, produced in 1860, made photographs of the Royal Family available to the general public for the first time.

By the time of the Prince Consort's death in December 1861, he and the Queen had collected several thousand images. These included British and foreign Royalty, Royal Household officials and staff, friends, acquaintances, politicians, actors, artists and musicians and the armed forces. In addition there were views of Royal residences, scenes at Coburg and Gotha (made in 1857 and 1858 by Francis Bedford as birthday presents from the Queen to her husband); military, topographical, art and genre photographs, and reproductions of works of art.

Queen Victoria continued to collect photographs in memory of the interest which she and her husband had shared, but her preference was less for art and genre photography and more for portraiture; one series of 44 albums, *Portraits of Royal Children*, showed her descendants from 1848–1899. Many photographers, including Dr. Ernst Becker (Prince Albert's German librarian), T.R. Williams, William Bambridge, Leonida Caldesi, Camille Silvy, Hughes & Mullins, Hills & Saunders, Mendelssohn, Alexander Bassano, Charles Bergamasco, George Piner Cartland, Professor E. Uhlenhuth, Backofen, W. & D. Downey and others were employed to produce this record. Many were granted the Royal Warrant.

The Queen also collected photographs of her relatives, staff, and people she had met, or was unable to meet except through the medium of photography. Among the portrait photographers whose work she purchased was Julia Margaret Cameron. Other material showed military campaigns, ceremonial occasions, such as the Queen's Jubilees in 1887 and 1897, or historic buildings, such as J. Benjamin Stone's photographs of the Tower of London in 1898. Views taken in Europe, Australia, India, the Andaman Islands, Africa and elsewhere enabled the Queen to see foreign countries and parts of the British Empire which she herself was never able to visit.

Queen Victoria and Prince Albert had encouraged their children's interest in photography and several of them, including the Prince of Wales (later King Edward VII) and Prince Alfred (later Duke of Edinburgh and of Saxe-Coburg-Gotha) learnt how to use a camera in their youth. During the nineteenth century all nine Royal children, by this time adults with their own families, collected photographs and many of these, formerly kept in their separate residences, had by the late twentieth century become part of the Royal Photograph Collection. They included property belonging to Prince Alfred, Princess Helena (Princess Christian of Schleswig-Holstein) and Prince Arthur (Duke of Connaught) and his wife, as well as Queen Victoria's grandchildren, such as the future King George V and Queen Mary.

The most significant collection belonged to Albert Edward, Prince of Wales, who by the time of his marriage in 1863 had assembled at least 1,000 images, mostly documentary or topographical, such as Roger Fenton's Crimean War series, or the views taken by Francis Bedford during the Prince's Tour of the Near East in 1862. From an early age the Prince also collected photographs of works of art. During the1860s he assembled a number of volumes of views of foreign cities, important buildings and other material which interested him, including some genre photographs by R.P. Napper. The Prince and his wife, (later Queen Alexandra), kept photographs of themselves, their family and their residences, and by the 1880s had lent their support to a new development. Simplified cameras, for amateurs, were newly available, and George Eastman presented one to the Prince and Princess in 1885. Within a few years the Princess had become a skilled and enthusiastic practitioner.

The last decade of the nineteenth century saw the various collections expanding as the Princess of Wales, her daughter, Princess Victoria, the Duchess of York, the Duchess of Connaught and others began compiling albums which contained not only work by professional photographers but also their own snapshots. When members of the Royal Family openly supported photography by exhibiting some of their own work at

a Kodak exhibition in 1897, they gave considerable encouragement to the general public to take up the medium as a popular hobby.

ROYAL ENGINEERS

The British Army's Corps of Royal Engineers was probably the first military unit to receive formal instruction in photography. Between 1854 and 1855 a small number of Sappers were trained on an ad hoc basis by civilian photographers in order to capture scenes of the Crimean War and to reduce maps and plans for the Ordinance Survey. In 1856 the War Department appointed Charles Thurston Thompson (1816–1868), Superintendent of Photography at the South Kensington (later Victoria and Albert) Museum, to train the Corp's non-commissioned officers in the wet-plate process. On receiving their certificate of competency, they were despatched to companies stationed overseas, from Greece to India and China, to document work in progress and make topographical and ethnographical pictures. Often working under inhospitable conditions they produced the earliest significant bodies of photographs of many little known places and cultures. They painstakingly recorded from the crest of the Rocky Mountains westwards along the 49th Parallel to the Pacific coast for the US/Canada Border Survey from 1858–62, and the 400 mile journey inland from Zula, Eritrea to Magdala during the Abyssinian expedition of 1868. By the1860s photography was offered as an optional course at the School of Telegraphy at the Royal Engineers Establishment at Chatham. Captain (later Sir) William de Wiveleslie Abney (1843–1920) established a separate Chemical and Photographic School there in 1874 which was absorbed into the Survey School in 1904.

ROYAL GEOGRAPHICAL SOCIETY

The world through a lens

> No expedition … can be considered complete without photography to place on record the geographical and ethnological features of the Journey.
>
> John Thomson RGS Official Instructor in Photography 1885.

Photographs of Exploration

Today the Royal Geographical Society is today home to a remarkable collection of over 500,000 19th and early 20th century photographs. This collection was built up through the donation of photographs taken by many travellers, geographers and explorers. In addition, the growing importance the Society attached to photography during the Victorian period is in part due to John Thomson who in 1886 became the RGS's Instructor of Photography. He has recently undertaken photographic travels in China and Cambodia (alongside his celebrated collaboration with the journalist Adolphe Smith Street life in London 1878) and it was under his instruction that many RGS Fellows set of to photograph the furthest reaches of the known world.

Such work helped to underpin the use of the camera—alongside the sextant, compass and sketchpad—as an essential part of any explorer's equipment. While the aesthetic nature of photography was ever present there was burgeoning interest in its application for the scientific documentation and recording of the world. As Thompson noted *"the faithfulness of such pictures affords the nearest approach that can be made towards placing the reader actually before the scene which is represented."*

Photography's New Place in Exploration

Throughout the Victorian period expeditions continued to be documented both through existing forms—such as the sketch pad and oil paints—alongside the recent introduction of the camera. The tensions between these two forms can in part be seen in David Livingstone's Zambezi expedition 1858–64.

Livingstone was accompanied by his brother Charles—who was the expedition's photographer—

R. Allen & Sons. A group consisting of T. S. and Miss Livingstone, James Chumah and Susi and the compiler of MSS discussing the journals, maps and plans of the late Dr. Livingstone.
R. Allen & Sons (Nottingham) 1874. Royal Geographical Society.

alongside Thomas Baines an accomplished artist. Bain's and Charles Livingstone soon argued, and following a contrived story of the theft of a bag of sugar Baines was expelled from the expedition.

The animosity between these two visual professional is reflected in Baines's painting of the rapids on the Zambezi River in 1859. Baines is pictured centrally, striding purposefully across the scene sketch book in hand. However, the expedition's photographer is depicted as a diminuative, shrouded figure isolated and seemingly of little consequence.

Records of Hidden Histories

The photographic archive of exploration also reveals the hidden histories of individuals whose lives may have so easily been lost to history. For example, many may be familiar with the story of how after Livingstone's death the African members of his expedition carried his body, alongside his equipment and papers, back to the coast for where it was returned to England, However, what do we know of these Africa individuals?

Much is revealed in the following photograph showing James Chuma and Abdullah Susi (centre left and right) both members of Livingstone's expedition. As Dr Caroline Bressey notes, in a rereading of this image, it illustrates an uncommon scene of a white Victorian man—Rev Horace Waller (the editor of Livingstone's papers) looking up at two Black African individuals who are centre stage in the scene's composition. It was Waller who, when the RGS presented Chuma and Susi with medals recognising their contribution said; *"These faithful companions of Livingstone were able to give an intelligible account of every river and mountain and village in the regions they had passed through; and such aid as they could give was of the first importance to Mr. Livingstone in preparing the work on which he was engaged."*

It was only with some trepidation that the Society embraced the new technologies of lenses, blackout tents, chemicals and glass plates. For example, Hugh Mill wrote, in commenting of the use of images projected by lantern slides in the 1880's, that *"the proposal to illustrate papers read at the evening meetings by lantern slides was scoffed at by some who said it would lower the Society's discussion to the level of a Sunday School treat with a magic lantern."* However, the Society's growing enthusiasm for this new technology resulted in its purchase—albeit under the guise of how the images enhanced the 'scientific' value of lectures—of its own lantern in 1890.

In addition, a chapter on photography appeared in the second edition of the Society's *Hints to Travellers* (1865)—alongside sections on 'Outfits for an Explorer,' and 'Latitude and Longitude.' Professor Pole the author wrote that, "*any traveller or tourist, gentleman or lady may, by about a quarter of an hour's learning, and with the amount of apparatus that would go into the gentleman's pocket or lady's reticule, put him or herself into the position (to take a picture).*"

148/9 "the Society by degree added instruction in photography, geology, natural history and other subjects so that the traveller who took the whole course and

profited by it could start on his exploration with a full scientific equipment"

Conclusion

Today we may marvel at the lengths to which our Victorian ancestors toiled to gather photographs of their world. The Royal Geographical Society was central to the promotion, use and collection of photographs that recorded the global reach of Victorian Britain. Indeed, it was the Society's central concern—that of geography—than underpinned how it promoted photography. As James Ryan has argued, *"much Victorian colonial photograph, from travel and topography to natural history, was broadly about geography."*

Time may not have diminished the beauty of these photographs and we can continue to revel in their aesthetic qualities. However, perhaps of greater importance is that in their glass plates and sepia tones these 19th century photographs have captured an irreplaceable record of the world' people, places and environments.

ROYAL PHOTOGRAPHIC SOCIETY

The world's oldest national photographic society, the Royal Photographic Society of Great Britain, formed in 1853 as *The Photographic Society*, was not the world's first photographic organisation. That distinction goes to *The Edinburgh Calotype Club* established by a group of amateurs in 1841. Like the *Société héliographique française* founded in France ten years later, the Edinburgh club was a relatively informal grouping, and survived until 1856 and the formal establishment of the Photographic Society of Scotland. The *Société héliographique française* was disbanded in 1854, its place taken by the more formal structure of the *Société française de photographie* which still exists today.

The genesis of the *Photographic Society* can safely be traced back to the discussions in 1851–52 which prefaced the organisation of the world's first exclusively photographic exhibition at the Society of Arts in London in December of that year. By that time, surprisingly in advance of London, a photographic society had already been established in Leeds, and friendships developed through the informal *Calotype Club* in London in the 1840s had also surely underlined the value of such groupings.

The pivotal moment in the organisation of photography in 1852 brought together the leading amateurs and professionals of the day, under the leadership of Roger Fenton, to organise and mount a huge international showcase for the new medium. Seven hundred and eighty four exhibits from seventy-six named photographers and several more un-named were displayed at the Society of Arts from December 22nd 1852 until the end of January 1853. Significantly that event brought together most of those who would figure centrally in the first meetings of the new photographic society.

One figure surprisingly missing from the list of 1852 exhibitors was Antoine Claudet, a key figure in the establishment of the Photographic Society of London. Despite the widespread published attribution of the idea of forming a photographic society in London to Fenton, researches have significantly raised the importance of Claudet's input into the project.

An undated document exists in the National Museum of Photography, Film & Television, Bradford, England, titled *Photographic Society* which can tentatively be dated to some time in 1851. Recent researches (Kamlish 2002) strongly suggest that this document—which significantly predates Fenton's involvement with the idea—was written by Claudet.

The document opened

> It is proposed to establish, in London, a Photographic Society on the same principles as the Heliographic Society which has just been formed in Paris by a number of Gentlemen.
>
> The Object of this society is the advancement of the Science of Photography, and the diffusion of all the improvements made in the different countries where the art is practiced with some success.
>
> Every particular branch of science has in London a centre of action, a place of meeting where its followers can be brought in contact one with another, where they may be helped in their private research by the research of others where they can learn new discoveries as soon as they are published. It is time after ten years of unconnected and separate labours that Photography should take a rank among the most important Sciences. It is time to erect its temple.

Kamlish argues that Claudet's motivation was not entirely altruistic, that he had recently acquired premises at 107 Regent Street which were too large for his immediate needs, and that the establishment of such a centre for the promotion of photography would be an appropriate and profitable use for that space.

For whatever reason, Claudet's proposal remained unpublished, and probably circulated only to a very few people. Thus, no action was taken for at least a year. Claudet's right to be recognised the originator of the idea seems well made. Certainly, in Fenton's obituary (*Photographic Journal,* Sept 15 1869, 126) he, Fenton,

is recognised only as "one of the early promoters of the Photographic Society."

Fenton's enthusiasm for such an organisation was fuelled after he had become directly involved with members of the *Société héliographique française* during a visit to Paris in late autumn 1851—meeting with Gustave le Gray and others—and had been impressed both by the society itself, and its pioneering publication *la Lumière.* He published an account of his visit in *The Chemist*, February, 1852, making a particular point of praising the vision of the French in establishing their society—and using the readership of the journal as a conduit for promoting the idea more widely in Britain. In the following issue, March 1852, he published his "Proposal for the formation of a Photographical Society."

Kamlish postulates that Claudet—who had by 1852 become a near neighbour of Fenton's with a home in Gloucester Road—may have passed his proposals to Fenton in the hope that Fenton would be better able to promote them. That would be at odds with the relative photographic status of the two men at that time—Fenton a newcomer to the medium, and Claudet already recognised as one of the major players with ten years experience, a thriving London business, several important published papers on the science of photography, and a number of patents to his name. In any event, in his address to the inaugural meeting of the society in spring 1853, he reflected on the original ideas which had been mooted "in the winter of 1851–52."

Whatever the circumstances, Fenton's published proposal was pivotal, and was doubtless translated into a practical proposition during the preparations for the Society of Arts exhibition. In it he set out many of the tenets that drove the society for the following century and a half—many of them also contained within the Claudet document of a year earlier. Only a few of his proposals proved short-lived.

> As the object proposed is not only to form a pleasant and convenient photographic club, but a society that shall be as advantageous for the art as is the Geographical Society to the advancement of knowledge in its department, it follows necessarily that it shall include amongst its members men of all ranks of life; that while men of eminence, from their fortune, social position, or scientific reputation, will be welcomed, no photographer of respectability in his particular sphere of life will be rejected.
>
> The society, then, will consist of those eminent in the study of natural philosophy, of opticians, chemists, artists, and practical photographers, professional and amateur. It will admit both town and country members.
>
> Despite that proviso, and although the name adopted was *The Photographic Society*, it was often referred to as *The Photographic Society of London* reflecting the predominantly metropolitan make-up of its founding membership.
>
> Like Claudet, Fenton believed the society should have 'appropriate premises fitted with laboratory, glass operating room, and salon in which to hold its meetings. It would be some considerable time before that was achieved, the ordinary meetings throughout the early years being held at The Society of Arts.

Again, like Claudet, Fenton also proposed the regular publication of the society's proceedings, and the establishment of a library, but while Claudet proposed the establishment of a Permanent Collection and a Museum of Photography, Fenton's paper proposed an annual album of members' work. Despite annual albums being produced in the early years, it was Claudet's idea for a permanent collection which endured and which grew into the huge world-class RPS Collection which is now housed in Bradford at the National Museum of Photography Film & Television.

At about the time the proposal appeared in *The Chemist* in March 1852, Fenton and others met and formed a Provisional Committee to drive the idea of a society forward. They met frequently throughout the spring and autumn, and in an unusual choice of words, these meetings were reported as being held "with a view of organising a Society of those to whom such a *re-union* would be acceptable." Fenton became honorary secretary of the provisional committee, and his role was pivotal in spreading news of the new initiative as widely as possible. Throughout that period he was also actively involved in the proposed exhibition at the Society of Arts, the two parallel engagements giving him regular access to like thinkers.

The provisional committee, which had met regularly at the offices of the *Art Union* journal in the spring, suspended its activities in the summer, as one of the stumbling blocks in the formation of the society, which they had to consider and deal with, was the existence of William Henry Fox Talbot's calotype patent—the restrictions it placed on the development of photography was seen as incompatible with an independent photographic society. After representations by Sir Charles Eastlake and Lord Rosse, Talbot's agreement was reached to relax the patent, at least for amateur users, and progress towards the establishment of the society was restarted with a further series of meetings in autumn 1852.

The Inaugural Meeting of the new Society was held on January 20th 1853 at the Society of Arts—a few days before the exhibition closed—with Sir Charles Eastlake in the Chair, who opened his address by confirming that the chairmanship had initially been offered to Talbot, but that the inventor had declined.

The inaugural Council of the new society included, amongst others, such luminaries as Charles Wheatstone, Sir William Newton, Hugh Welch Diamond, Fenton as Secretary, Peter le Neve Foster, Peter Fry, Robert Hunt, John Dillwyn Llewelyn (whose name was recorded

as 'Lewellyn'), the Count de Montizon, Hugh Owen, Alfred Rosling, Charles Vignoles, several of whom had also exhibited at the Society of Arts at the end of the previous year. In his eloquent introduction to the catalogue for that exhibition, Fenton had written that the society "will be the reservoir to which will flow, and from which will be beneficially distributed, all the springs of knowledge at present wasting unproductively."

The first issue of the *Journal of the Photographic Society* was published on March 1st 1853, and with only minor interruptions, has been published ever since. Despite having a membership a little shy of four hundred by the mid 1850s, the popularity of the journal amongst the entire photographic community meant that it was producing four thousand copies per issue. Its founding premise—that it would serve as a conduit for an interchange of ideas and successes amongst photographers in all countries—has held good ever since.

The topics covered in early editions of the journal ranged from transcripts of lectures given at meetings, and in-depth discussions on the chemical composition of sensitising and developing baths, to the rolling controversy over whether photography was an art of a science. Reprints of articles published in *la Lumière* were also included, as were reports on the proceedings of regional photographic societies, and transcripts of key lectures given in Liverpool, Manchester and Edinburgh. A thriving letters column soon became a mainstay of the publication, allowing both town and country members to share their experiences, their difficulties, and their discoveries.

Within six months of the formation of the society, Queen Victoria and Price Albert had agreed to become patrons, initiating a Royal association with the society which has endured to this day and which, in 1894, culminated in the change of name to the *Royal Photographic Society of Great Britain.* It was Prince Albert who, unwittingly, resurrected Claudet's idea of a permanent collection of members' works in 1854, but several years passed before the idea was acted upon. In the meantime, infrequent albums of members' work were produced and circulated by groups within the society, operating under the names of *The Photographic Club*, and *The Photographic Exchange Club*.

One of the initiatives contained within both Claudet's and Fenton's proposals was the mounting of an annual exhibition, and the first such display opened at the Society of British Artists, on London's Suffolk Street, with an evening soirée on 3rd January 1854. The Annual Exhibition remains a focal point of the Society's year today. In those Victorian exhibitions, the majority of the works were for sale, the society augmenting its funds by taking a 10% commission off the sale price.

By the end of the first year, with professional photographers assuming a greater influence over the proceedings of the society, the first Annual General Meeting in February 1854 voted, by show of hands, to exclude all professional photographers and photographic dealers from sitting on Council of holding office within the society. Fenton, at the end of his first year as secretary of the society he had helped form, informed the meeting that were this to be implemented, he would feel obliged to resign—he was at the beginning of his own eminent career as a professional photographer. After further discussion, the meeting was persuaded of the folly of such a move, and the vote reversed. The Photographic Society was not unique in having to learn to live with the uneasy marriage of amateurs and professionals.

But it was the presence and the influence of the scientists and the professionals who drove much of the important early work undertaken by the society's various ad hoc committees.

Most significant amongst those committees was what became known as the 'Fading Committee' chaired by Fenton in 1855, and set up to investigate the apparent impermanence of both salted prints and albumen prints. Under the chemical direction of T. F. Hardwich, the committee came up with sound recommendations for the avoidance of the problem—specifically using fresh hypo, and gold toning. Hardwich had correctly identified that sulphur compounds in the prints, caused by over-used fixer were a primary cause of the problem—eliminated by using fresh fixer—and that sulphur in the atmosphere exacerbated fading, a factor reduced by toning with gold chloride.

Other committees played important roles in the further understanding of the chemistry of the collodion process, and very significantly, in moving towards the establishment of realistic copyright protection for photographs and photographers.

These scientific and legal engagements did much to raise the public profile of the society, but beneath the surface, the ongoing debate about the status of photography within the worlds of art and science continued. The uneasy marriage of photographic artist and photographic scientists continued throughout the society's first forty years until, in 1892, the Vice President Henry Peach Robinson, frustrated by what he saw as a lack of recognition of the art of photography, led a breakaway group to leave the society and establish what became known as the Brotherhood of the Linked Ring. Their manifesto stated that the breakaway group had been established "as a means of bringing together those who are interested in the development of the highest form of Art of which Photography is capable," and was a direct response to their belief that the society's direction was biased against them. The recently elected President, Sir William de Wiveleslie Abney was one of the leading (and most opinionated and widely published) photographic scientists of his day, with a declared lack of interest in

the creative side of photography. He remained President until 1894, was re-elected again in 1896, and again in 1903, serving until 1905.

The society, in its first half-century had been led by a succession of eminent scientists, and clearly the photographic artists felt they were not receiving equal recognition, and that the society's leadership showed little sympathy towards their aspirations. Sir Charles Eastlake had been succeeded in 1855 by Sir Jonathan Frederick Pollock MP, barrister and mathematician, who held the presidency until 1869. He was immediately followed by James Glaisher, one of the society's founder members, who remained in office until 1892. Then came Abney, and all three had emphasised in their various presidential addresses that they saw the advancement of photographic science as being a far more important pursuit than the development of the art. Indeed, going back to Claudet's original proposal, he suggested only that the society's primary object should be "the advancement of the Science of Photography." It was Fenton who first broadened the brief and Sir Charles Eastlake whose introductory address first embraced the value of photography "both to Science and to Art."

In the 20th century, the recognition of disparate groups within the society, each focused on a specific aspect of photographic art or science, defused such potential minefields and ensured that the broad diversity of photography proposed by Fenton almost a century earlier were equally and individually represented.

Over the first seventy years, the society's collection of photography developed in an unstructured manner, dependent upon gifts from members rather than a focused gathering together of a representative cross section of the images produced. Thus, when John (J) Dudley Johnston decided to focus on the society's history in his Presidential Address in 1923, he found few examples of past members' work with which to illustrate his lecture. Roberts (2001) notes that he was able to find only about one hundred images in the attic of the society's house, many of the early works having either been damaged or, simply, lost. It is thanks to Johnston's zeal—as Honorary Curator from 1927 until 1955—that the society developed its unique collection, retrospectively acquiring prime examples of 19th century work as well as gathering the best contemporary work available. Roberts notes that over 70% of the work in the collection was produced by members of the society.

It was, therefore, towards the middle of the twentieth century before Antoine Claudet's 1851 suggestion—that the society should gather "specimens of the art contributed by members or procured from different countries"—became a valuable reality.

ROYAL SOCIETY, LONDON

The Royal Society of London for Improving Natural Knowledge was founded in 1660 and established by Royal Charter in 1662. It is the world's oldest scientific society in continuous existence and today acts as the UK's national science academy. It is an organisation of Fellows, currently numbering around 1300 of the world's leading scientists.

The Society and its Fellows had a longstanding interest in the component parts of what in the 19th century became photography: light, optics and chemistry. Early opportunities to develop photographic technique occurred on the fringes of the Society: for example, in solar printing experiments by Thomas Wedgwood and Humphry Davy (a future Royal Society President). J.N. Niepce approached the Society, apparently with the intention of submitting a paper on his work, but did not do so. These episodes in photographic pre-history led to no practical Royal Society involvement in scientific research on the subject.

However, from 1833, the problem of recording an image from life by camera was being considered in a serious if intermittent way by William Henry Fox Talbot FRS (1800–1877). Talbot had already written on mathematical and optical subject, thus earning election to the Royal Society's Fellowship in 1831. He had early contact with intellectually sympathetic Fellows such as John Herschel and David Brewster and the former would provide crucial support following the first announcement of Talbot's research interests in his paper 'Some account of the art of photogenic drawing' which was read to the Society on 31 January 1839.

Remarkably, Talbot's paper was not published in full in the Royal Society's *Philosophical Transactions*, but was abstracted. However, it, and news of L.J.M.

Daguerre's work in France generated a wave of interest in photographic science, particularly on the part of Sir John Herschel FRS, who had followed newspapers and other printed accounts of the new inventions. Herschel quickly provided his own important contributions to both Talbot and the wider world, most importantly on the use of sodium thiosulphate as a fixing agent. His photochemical experiments were published by the Royal Society in three major papers as were basic coinages such as 'photography,' 'positive' and 'negative.' These terms were in circulation amongst the Fellowship well before their first appearance in print. Herschel himself developed several novel photographic processes which were communicated to the Royal Society, notably the chrysotype and cyanotype and remained for some time an unofficial consultant and prime mover on matter concerning photography.

As knowledge of the new images gained currency among Britain's scientists, other important photographic researches were relayed to the Society, often encouraged or mediated by Herschel. Thus, Robert Hunt FRS (1807–1887) published not only in the *Philosophical Transactions*, but also produced the first important popular digest on photographic technique. Joseph Bancroft Reade FRS (1801–1870), meanwhile, investigated and to an extent repeated his peers' work on the usefulness of gallic acid in developing latent images, reporting on his work to the Society. In addition to improving elements of processing, Fellows also looked almost immediately for applications of the photograph to scientific work. As early as 1839, the use of sensitized paper as a recording medium for barometric and meteorological instrument observations was being discussed by the circle of Robert Were Fox FRS (1789–1877).

It was not just the scientific elite who were caught up in the excitement of photography. The formal development of photographic science was accompanied by popular interest, the general currency of which owed much to the personal networks of the Society's Fellows. Thus, for example, the first serially-published photographic book (and one with serious natural history intent) was Anna Atkins' *British algae*. Atkins (1799–1871) adopted Herschel's blueprinting technique for the purpose; her father was John George Children (1777–1852) a Fellow of the Royal Society and chairman of the 1839 meeting of the Society at which W H F Talbot had described his process for the first time.

That Royal Society's scientists themselves played a role in popular photography is evidenced by the work of Sir Charles Wheatstone FRS (1802–1875) and Sir David Brewster FRS (1781–1868) on stereoscopic photography, a popular offshoot of a development which had serious scientific merit. In the aftermath of the Great Neapolitan Earthquake of 1857, for example the Society (via Robert Mallet FRS) financed the gathering of damage evidence and earth movement using, in part, stereo photographs and these were also used for astronomical purposes. However the greatest single contribution of the Society and its Fellows in this respect was in the relaxing of Fox Talbot's calotype patents. Many of the Society's principally-concerned Fellows provided evidence on the merits of the patents and on the history of Talbot's researches, while the Society's then-President, William Parsons 3rd Earl of Rosse (1800–1867) cowrote a crucial letter to Talbot in 1852 which had significant impact on his relenting in aspects of his claims.

The Society continued to be interested in scientific applications of photography in the 1850s and 1860s. Many of these are very well-known. Warren de la Rue FRS (1815–1889) took important steps in astronomical photography. His initial work on the moon was privately conducted, inspired by daguerreotypes he had seen at the Great Exhibition of 1851 and such images proved more useful than the human eye in resolving lunar features. His solar work, particularly the cost of producing regular photo-heliograph images at Kew, was underwritten by the Royal Society and results were the subject of a Royal Society Bakerian Lecture by de la Rue in 1862. At the opposite scale, the Society provided research support to the physician Richard Leach Maddox (1816–1902), then producing photo-micrographs as illustrative material for paper submissions to the Society. Maddox would later perfect lightweight gelatine plates for photographic use.

An under-researched aspect of the Royal Society's role in promoting photography lies in the organisation's regular use of images at its annual exhibitions of science. In the 19th century these were known as soirees or conversaziones. At these events the latest developments in scientific research were (and still are) presented to invited audiences and in their earliest incarnations, photographs were themselves the subject of display. One famous later Victorian participant was the photographer Eadweard James Muybridge (1830–1903) who in 1889 presented his instantaneous photographs of animal motion. The event concealed an episode that reflected very badly on the Society. Muybridge had submitted a paper on 'Animal locomotion' for publication by the Society in 1883 but its author was quite unfairly suspected of plagiarism and it remained unpublished, thereby temporarily damaging Muybridge's reputation as the originator of motion photography.

As the 19th century drew to a close, the use of standard photographic methods in support of scientific work and publication became a matter of routine and the Society's immediate involvement in photography waned in favour of more specialist organisations. To put this into perspective, photography was a relative novelty in scientific travels of the 1850s, such as Mallet's work in Naples and that by Charles Piazzi-Smyth FRS

(1819–1900) in Teneriffe in 1856. But even by the time of the pioneering oceanographic expedition undertaken by HMS *Challenger* in the years 1872–1876, initially championed by the Royal Society and led by its Fellows William Benjamin Carpenter FRS (1813–1885) and Charles Wyville Thomson FRS (1830–1882), things were changing. The expedition had its share of 'firsts' (including images of iceberg) but more important were the large numbers of photographs taken as an integral part of the expedition scientific record, in the same manner as note-taking, specimen collection and instrument readings.

RUDGE, JOHN ARTHUR ROEBUCK (1837–1903)

English photographer

Born in Bath, England, 26 July 1837. His father Henry Rudge, a wood carver, and his mother Christiana, were middle-class reformers. By 1861 Rudge was lecturing on electricity, experimenting with an electric model train and an electric boat, and in 1863 was listed as a "philosophical instrument maker." In the 1860s or 70s he projected simple silhouette moving images with a "Wheel of Life" lantern slide. In 1875 Rudge created the Biophantic Lantern. A carousel with seven slides moved intermittently around the lamphouse. Rudge became associated with portrait photographer William Friese-Greene, and probably initiated Friese-Greene's interest in motion photography. They produced various motion effects with glass slide sequences.

Rudge's "Jumbo Funniosities" (c.1882), projected on a more developed machine, featured sequentially posed photographs of a toy elephant; a precursor of stop-motion motion picture animation. Another device featured four converging lenses to project a static slide bearing four portrait photographs. A rotating shutter directed the light to each one in turn, creating a limited movement effect. About 1887 he screened with his last machine, the Biphantascope, a motion series of 12 photographs of 'A Boy in an Eton Collar.' A lifelong bachelor, Rudge died in Bath on 3 January 1903.

STEPHEN HERBERT

RUSKIN, JOHN (1819–1900)

Art critic and social commentator who took a keen interest in photography

John Ruskin was, and still remains, best known for his art criticism and social commentary. His many artistic pursuits including drawing and watercolour painting, designs of various kinds, poetry and other literary works, have been assimilated into a cannon that reveals the breadth and depth of Ruskin's originality. His first four major publications, volumes one and two of *Modern Painters* (1843 and 1846), *The Seven Lamps of Architecture* (1848) and *The Stones of Venice* (1852), established his reputation as a writer of powerful intellect and rare ability to convey both the experience and the significance of the act of seeing. These publications also demonstrated Ruskin's commitment to the social responsibility of art. Ruskin was a prolific writer as the 39 volumes of his 'Works' testify but he was also an eloquent public speaker who lectured on a dazzling array of subjects, both before and after he became the first Slade Professor of Fine Art at Oxford in 1869. Writing almost a century later in 1964, Kenneth Clark pronounced that merely to read Ruskin was accepted proof of possession of a soul and, from the numerous editions of his publications, he was read extensively. His legacy extends to such different individuals as Oscar Wilde, Alfred Milner, Arnold Tonybee, Cecil Rhodes and the numerous realist landscape artists of the second half of the nineteenth century. Ruskin's importance to the history of photography is that he made many references to it during a period of over sixty years, he employed it intermittently in his publications and lectures, he recommended it as a drawing aid, he purchased photographs and, during the

late 1840s, 1850s and possibly beyond, he was closely involved in their production. Over 200 daguerreotypes mainly of Alpine subjects and architectural details are attributed, directly or indirectly, to Ruskin. 125 of these are extant and have been connected to Ruskin for some time. A further 121, possibly dating from Ruskin's visits to Venice in the late 1840s up to 1852, together with 14 salt prints, which surfaced in 2006.

John Ruskin was born on 18th February 1819 at 54 Brunswick Square, London. He was the sole offspring of a wine merchant father and an Evangelical mother. As a youth he was privately tutored at home, visited a number of art masters, developed a passion for the works of Turner and travelled in Britain and Northern Europe with his parents. In 1836 Ruskin became a Gentleman Commoner at Christ Church, Oxford, which considerably extended his education and social circle. He won the prestigious Newdigate Prize for Poetry but poor health delayed his graduation. However by 1843, the first volume of *Modern Painters* had been published by "A Graduate of Oxford."

Ruskin had an extraordinarily large and varied network of associates and followers, a significant number of whom were involved in photography. One of these associates was John Henry Parker, an antiquarian who sold photographs of archaeological investigations in Rome to Ruskin in 1874, which subsequently featured in Slade lectures. For a substantial period Dante Gabriel Rossetti, a founder member of the Pre-Raphaelite Brotherhood, was an ardent follower of Ruskin. Rossetti, similarly to Ruskin, used photographs as visual aids and, at his family home in Chelsea, posed with Ruskin and the artist William Bell Scott for William Downey on 29th June 1863. Despite the appearance of relaxed conviviality suggested by many of the photographs from this sitting, Ruskin expressed his dissatisfaction with his appearance and Scott later candidly revealed his dislike of Ruskin in his 1892 autobiography. Some of the many others whom Ruskin knew included Jemima Blackburn (née Wedderburn) who conducted early experiments with photography and Richard Calvert Jones who, like Ruskin, was taught drawing by James Duffield Harding.

In large part because Ruskin was passionate about art and traditional crafts and turned his visually attuned mind towards mineralogy and botany among other subjects, he had an aversion to the idea of progress expressed in Thomas Macaulay's *History of England* (1843–60), the geological revelations in Charles Lyell's *The Principles of Geology* (1830–33) and the ideas of history contained in Charles Darwin's *Theories of Evolution* (1859). Although early photography was a fundamental breakthrough, Ruskin was able to embrace it because it was tangible rather than theoretical and, above all, it captured the kind of singular detail that Ruskin craved in art, architecture and landscape scenery.

In a letter to his father in October 1845, Ruskin described the daguerreotype as a blessed invention. He was purchasing daguerreotypes by the end of his Normandy tour in 1848 and took his own photographic equipment to Switzerland in 1849 and, with his new wife Euphemia (née Gray) to Venice in 1849–50. On 24th February 1850 she described Ruskin in St. Marks's Square "with a black cloth over his head taking daguerreotypes" (Mary Lutyens, *Young Mrs Ruskin in Venice*, New York: Vanguard Press, 1965, 146). At this time Ruskin was assisted by his factotum John (known as George) Hobbs (later Hobbes) who was in Ruskin's service until 1854. In Hobbs' notebook entry for 1st May 1849, there is a suggestion that he not only carried the photographic equipment for Ruskin but also prepared and developed the plates. This may have been a pattern that Ruskin continued with his new factotum, Frederick Crawley, who was photographing with Ruskin in the Alps in 1854. This would have freed Ruskin to select viewpoints, consider compositional matters and check focus. However it is possible that Ruskin was more involved in photography than this interpretation allows.

Typically these dDaguerreotypes are 6" × 8" and there is at least one example, Richard St. John Tyrwhitt's painting *Mer de Glace* of c. 1859, that was almost certainly based on a Ruskin daguerreotype. Whether Ruskin was the first to photograph the Matterhorn, as William Gershom Collingwood claimed in 1884 is debatable but in *Praeterita* (1885–89) Ruskin stated that he was among the first. Looking back over almost forty years he discovered that his daguerreotypes recorded the ebbing of glaciers. In a similar vein, the 1883 Epilogue to *Modern Painters* contains Ruskin's observation that photographs of St. Mark's in Venice demonstrated that his own "careless" sketch for plate VI of *The Stones of Venice* had omitted the entasis of the tower.

Ruskin recommended photographs as an aid to drawing and cited Charles Thurston Thompson's reproduction of Raphael's *St. Catherine* as a model. He also included photographic reproductions in some of his publications such as the Autotypes in the 1890 edition of *Val D'Arno* and Carlo Naya's photographs of paintings in the 1890 edition of *Giotto and his Works in Padua*. However Ruskin could be critical of photography, remarking in *The Elements of Drawing* (1857) that shadows were rendered much darker than they should be. He was also concerned that colour photography would also bring further distortions.

The 1870s brought Ruskin joys and sorrows. He moved to Brantwood, an idyllically situated house in the Lake District. However the deaths of his mother in 1871 and, in 1875, the death of Rose La Touche, the young woman he had hoped would become his second wife, signalled Ruskin's gradual retrenchment from intellectual life. Between these two bereavements, in September

1873, Frank Meadow Sutcliffe photographed Ruskin, followed by Lewis Carroll in 1875. William Jeffrey captured an early Ruskin portrait in 1856 and Ruskin sat for Caldesi in 1862. By the time John McClelland photographed him in the 1890s, Ruskin had been broken by a legal battle with Whistler but had completed his autobiography. Ruskin died in 1900 and was buried at St. Andrew's in Coniston. He is commemorated in Poet's Corner, Westminster Abbey.

JANICE HART

Biography

Ruskin was born in London in 1819, the sole offspring of a wine merchant father and an Evangelical mother. As a youth he was privately tutored in art and a wide range of subjects and travelled widely in Britain and Europe with his parents. He went on to Christ Church Oxford in 1836, won the Newdigate Prize for Poetry but sat for his degree much later than expected because of ill health. In 1843, inspired by the works of Turner and the new generation of Pre-Raphaelite artists, he produced *Modern Painters*, the first of five volumes of art criticism inflected, like most of his later writing, with social commentary. He was a prolific writer, eloquent lecturer (both before and after he became the first Slade Professor of Fine Art in 1869) a productive artist and an occasional designer. He also took a keen interest in photography producing (or overseeing the production of) upwards of 200 Daguerreotypes, many taken in Italy during an 1849–50 a tour with his new wife Euphemia (née Gray). The trajectory of Ruskin's interest in photography began with the Daguerreotype and, over a period of sixty years encompassed photography's numerous technical, artistic and social transformations. Ruskin's early enthusiasm for photography's ability to render singularity of detail, particularly architectural and landscape detail, gave way to a criticism of photography's tonal rendition and later, a questioning of photography's capacity for artistry and an apprehension concerning the likely distortions of colour photography. These shifts in opinion give considerable interest to Ruskin's various references to photography because he can be seen as a barometer, if an idiosyncratic and sometimes aberrant one, of changing public attitudes. Ruskin occasionally included photo-mechanical prints in his publications such as the Autotypes which appear in the 1890 edition of *Val D'Arno*. Ruskin also sat for a large number of photographers including William Jeffrey, William Downey and Frank Meadow Sutcliffe. The ill health that troubled him whilst an undergraduate student developed into a number of physical and mental complications, particularly from the 1870s following the deaths of his mother and the woman he had hoped would become his second wife, Rose La Touche. Ruskin went into semi retirement in the last decade of his life at Brantwood, the house he purchased in the early 1870s. He died there in 1900, one of the indisputable sages of the nineteenth century. He is buried at St. Andrew's at Coniston and commemorated at Westminster Abbey.

RUSSELL, ANDREW JOSEPH (1832–1909)

American photographer

The building of the first transcontinental railroad by the Union Pacific and Central Pacific Railroads generated an enormous interest among the American public creating both a market for photographic images of Western America and a means for photographers to transport bulky equipment to remote regions. Andrew Joseph Russell was the official Union Pacific photographer in 1868 and 1869 and one of many to follow who took advantage of this interest in the railroad and the sights along the line. He took over 250 large-format glass-plate negatives and 500 stereo-view negatives mostly in Nebraska, Wyoming, and Utah. Some of these images are classics of 19th Century American photography including one of the best-known images in American history (for years misidentified as a C.R. Savage photograph) of the two

Russell, Andrew Joseph. Slave Pen, Alexandria, Virginia. *The Metropolitan Musuem of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 (2005.100.91) Image © The Metropolitan Museum of Art.*

locomotives of the Union Pacific and Central Pacific Railroads coming together at Promontory, Utah at the Golden Spike Ceremony.

Russell was the natural choice when the Union Pacific decided to photographically document, The Work of the Age. Russell was a New York State native who moved from Nunda, New York to New York City in 1859 where he was a painter and portrait photographer. During the Civil War he was assigned as a special assistant to the Military Railroad Construction Corps for the Union Army. Most of his images documented the construction of military railways and his photographs were often rushed by special messenger to Secretary of War Edwin M. Stanton in Washington D.C. Russell as well photographed the battle of Fredericksburg and took a few stereo-views, and some Russell photographs have mistakenly been attributed to Matthew Brady.

After the war Russell returned to New York City to resume his work as a portrait photographer and artist. For whatever reason, Russell was not hired immediately after the war and the Railroad used the Chicago, Illinois photographer John Carbutt instead. Given, however, Russell's background in railroad photography and the fact that most of the Union Pacific executives were former Union Army officers, he must have seemed a better fit. Russell began photographing the Railroad headquarters in Omaha, Nebraska in early 1868 and he caught up with the construction crew in Cheyenne, Wyoming. He followed its frenzied pace across Wyoming, into Utah, and finally to the site where the Union Pacific and Central Pacific lines came together at Promontory, Utah on May 10, 1869. There were three photographers (the other two being C.R. Savage and Alfred A. Hart) at the Golden Spike Ceremony. The photographs taken were, not surprisingly, mostly devoid of the workers who built the railroad (Irish-Americans for the Union Pacific and Chinese-Americans for the Central Pacific). Instead they show the railroad officials, financiers, and dignitaries who were invited to the event. Afterwards Russell traveled to Sacramento along the Central Pacific line taking a handful of images as he went. Before returning to New York City, he photographed across Utah and Wyoming again, but this time at a more leisurely pace.

Russell showed a great deal of flexibility as a photographer. The twenty-three large-format images published by the Union Pacific in *The Great West Illustrated in a Series of Photographic Views Across the Continent* (only a handful of which exist today) portray the builders of the railroad in heroic terms. They evoke awe of the work done and convey both movement and power. The thirty images utilized in a book published by geology professor Ferdinand Hayden one year later entitled *Sun Pictures of Rocky Mountain Scenery*, however, are not dramatic images but instead are scenes of geological interest. Hayden was in charge of the U.S. Geographical and Geological Survey and wanted to promote the study of geology in Western America. Most of these photographs were taken after the joining of the rails when Russell had more time to pick and choose his subjects. In these photographs nature is not an obstacle to be overcome, but a source of interest to the traveler. Neither of these books, however, had a wide distribution and the general public viewed the building of the transcontinental railroad through stereo-view series published by Russell initially and later without attribution by Stephen Sedgwick and O.C. Smith. These images are surprisingly mundane.

Taken as a whole, however, the stereo-views create a visual catalog of the workers, tunnels, bridges, buildings, railroad engines, and new towns of the Union Pacific and satisfied the demand by the public for photographs instead of artwork (whose accuracy was suspect to many Americans) of the American West.

Russell's artistic background is shown in his large-format views by the careful composition and thoughtful placement of the railroad within its natural surroundings. The images provide a human perspective on what for Russell must have seemed an impossibly forbidding landscape. A number of photographs show figures contemplating the railroad from a high vantage point. These views reinforce the idea of the railroad as conquering the great distances of the American West, but also in a precarious balance with the natural forces surrounding it. Russell was, as well, a pioneering photographer. Although his equipment did not allow him to stop action, he did attempt to set up scenes as if he were capturing the daily work of the laborers. Many of his photographs were, as well, made into wood-cut illustrations and printed in weekly magazines.

Russell was the first of many photographers, including William Henry Jackson, Charles Roscoe Savage, Carleton Watkins, and Eadweard Muybridge who photographed both the Union Pacific and Central Pacific Railroads. Russell provided scenes which were bought by an Eastern audience eager for images of what was still then considered an exotic and romantic place. Surprisingly, however, there is no evidence that Russell ventured to Western America again in his lifetime.

DANIEL M. DAVIS

Biography

Andrew Joseph Russell was born on March 20, 1829 and grew up in Nunda, New York. As a young man he was a painter and a teacher at the Nunda Literary Institute before moving to New York City in 1859 where he worked as a panorama painter and a portrait photographer. During the Civil War, Russell became the official railroad military photographer for the Union Army. He returned to New York City after the war, but soon thereafter traveled west to start documenting the construction of the Union Pacific Railroad through Nebraska, Wyoming, and Utah. He is best known for the 250 large-format images he took of the building of the transcontinental railroad in 1868 and 1869 including one of the most famous images in American history, that of the two railroad engines of the Union Pacific and Central Pacific coming together at Promotory, Utah. He also took over 500 stereographic negatives during these two years that were actually seen by a larger audience at the time. Russell earned a good salary from the Union Pacific for over two years, yet others gained more materially from his images as his stereo-views were later issued without attribution. In the 1960s a cache of glass-plate negatives were discovered at the American Geographical Society and his large-format views became better known. After photographing the railroad, Russell returned to New York City and worked as a portrait photographer as well as an artist for the magazine *Leslie's Illustrated*. He died on September 22, 1902.

RUSSIAN EMPIRE

The first information about the invention of Daguerre reached Russia already on 4th January 1839 (according to the Julian calendar). It was followed by active discussions in the press of the future perspectives of photography. A special emphasis common for all participants to these discussions was made on the documental character of daguerreotypes. But the evaluations were in fact different. The new invention did not fail to interest the scientists from St. Petersburg Academy of Sciences. In April of 1839 academicians (biologists) Karl-Ernst Bar (1792–1876) and Fyodor Brandt (1802–1879) asked the corresponding member of the Academy of Sciences, Josef Hamel (1788–1862) to get acquainted with the new invention in the course of his business trip abroad.

First Hamel went to London and got acquainted with Talbot and his invention. In May of 1839 Hamel sent to the Academy the description of Talbot's method and a couple of photos, which were of bad quality. The Academy Assembly therefore committed a task to Julian Frizshe, an academician (1802–1871) to survey the calotype method. The academician informed on the results of his research work on the 23rd of May of 1839 and demonstrated the picture of herbarium, which he made by using the method of photographic recording (photogram). In the course of his work on these pictures

he streamlined the method. This was the first scientific research of photography made in Russia.

Meanwhile, Hamel moved from London to France and got acquainted with Daguerre. He sends to the Academy the description of daguerreotype method along with the equipment necessary for making photos, including the camera, before the sale of these things started. The discussion devoted to this technology in the academy of sciences was held on the 6th of September of 1839. In 1839–1841 Hamel recurrently sent to St. Petersburg new photos, including those made by Isidore Niepce—these were the views Louvre and other buildings. Later in 1850 Hamel received from Isidore Niepce the originals of documents (168 in number) on the history of inventing photography, which after Hamel's death in 1862 were transferred to the Academy Archive.

In Russia, like everywhere in the world, daguerreotypes gained great popularity. The first daguerreotypes brought to Russia were exposed in shop-fronts and attracted the interest the of public at large. In 1839 the first booklets by Nickolai Stepanov appeared describing the methods of Daguer and Talbot, the cameras, and other necessary photographic equipment went on sale. One of the first photographic amateurs to appear was Franz Teremin (1802–?), a lieutenant colonel of the Ministry of Lines of Communication, was interested in daguerreotypes, and made a photograph of the Isaac Cathedral in St. Petersburg with 25 minutes time-exposure in October 1839. In 1840s Count Alexei Bobrinski made a photograph of the conservatory in his house in St. Petersburg. In 1843 Sergey Levitski (1819–1898) being on a trip made photographs of views of the Caucus. In mid-1840s an unknown photographer recorded the sculptures by Ivan Vitali before they were mounted onto the facade of the Isaac Cathedral.

Since 1840s professional daguerreotype studios for making portraitphotographs started to appear. The style of these works was predetermined by the style of painted miniatures, which were very popular at the time. The latter was imitated in daguerreotypes decoration and in by-hand colouring of the black and white photos. The genre of photo-portraits formed the commercial basis for future development of photography.

The first professional daguerreotype specialists working in Russia came from abroad. All of them had already worked in various cities of Europe. They were, Josef Weninger from Wien, the Schneider brothers and Carl Dautendey from Germany and among others.

Some of them set up permanent studios, while others traveled round the country. For instance, D'Avignon made several trips to far away cities of Russia in 1843–45s. In 1845 he made photo-portraits of insurrectionists against the emperor in December of 1825 who spent their life banishment in the suburbs of Irkutsk in Siberia. As this information reached the Third Department of the Emperor's Office (dealing with state crimes and prisoners) the photographer was arrested for making photographs of state criminals. Soon afterwards the photographer was released, the daguerreotypes were confiscated and destroyed and since then taking photographs of criminals was strictly prohibited. However some of the daguerreotypes preserved by some miracle are now part of the collection of the Historical museum. Thus, the authorities estimated the documentary value of photography very high right from the beginning.

Among the first Russian professional photographers one could name Alexei Grekov, who opened a studio in 1840. He made and sold self-constructed daguerreotype apparatus, he employed Boris Yakobi's method for silver-plating copper and brass photo-plates. Such photo-plates were cheaper than the ones completely made of silver. At the meeting of Paris Academy of Sciences in November of 1840 Arago made a report on his method of producing photo-plates.

Most of the Russian professionals in daguerreotype started to work in 1850s and by 1860s they fully replaced the foreigners. Many of the Russian daguerreotype masters were graduates of the Emperor's Academy of Fine Arts, which produced high artistic value of the works. The industry of the studio portrait actively developed in Russia.

In 1850s the wet collodion photo-process started to be widely used in Russia and soon enough it ousted daguerreotype although this was the way people continued to call it: a daguerreotype on paper. In 1850s Andre Disderi started to make cartes de visite, which made this genre extremely popular with the public. It became popular in Russia to have an album of photographic family portraits.

In 1850 Andrei Denier (1820–1892), a graduate of St. Petersburg Academy of Fine Arts opened his famous studio. He became a true master of photo-portraying; the artists Ivan Kramskoi and Petr Sokolov worked in his studio for some time as retouchers. In 1865–1866s Denier publishes photographic albums of portraits of famous people (Russian writers, artists, scientists, etc.) 12 photographs in each and this was one of the first photographic editions in Russia. The aesthetics of painting, which was then applied to photography, called for a soft optical image. In order to achieve it Denier worked out an original technique of printing from two negatives of different density. He patented this technique in 1873 for three years. Recent researches made it clear that this method had been employed by foreign photographers earlier (which proves that Denier's invention was not the original) but nevertheless Russian photographers keep calling it "Denier's effect"and prominent Russian masters of photography, such as Sergei Levitski (1819–1898), Andrei Karelin (1837–1906), used the method successfully.

The thing of particular interest at present is the early outdoor works. Despite the considerable technical problems accompanying outdoor photography, photographers were often asked to join scientific expeditions to do the job previously assigned to artists. They were to record the results of research, photograph the nature, the nationalities inhabiting the region, to work in the combat area documenting the ongoing events.

Widely known are the photographs made by Roger Fenton: he photographed the Russian fortifications being destroyed during the Crimean War of 1854–1855s. The Russian photographers also made photographs of the aftermath of the battles, scenes in the camps. C. Kolpaktchi, for instance, made a panorama of destroyed Sevastopol consisting of several photographs.

The work which attracts much attention is the one by an unknown photographer who made a photography of a church procession in Moscow Kremlin in 1858. In this work there was something of a photo-report—a recording of an interesting event.

The main task of outdoor photography was to record the scene or object as closely to the reality as possible. The photography was a assigned the auxiliary role of a scientific document. In 1850–1860s Nikolai Vtorof, an ethnographer, applied photography to create an ethnographic map of Voronezsh region (he invited Michail Tulinof (1823–?)to do this job for him). Vtorof presented the results of this work at the meeting of Russian Geographic Society in 1857. In 1867 The Natural Science Society of Moscow Emperor's University organized an all-Russia Ethnographical Exhibition. This exhibition housed more than two thousand photographs of different nationalities, scenes of their life and views of the region. Photographers joined expeditions and missions were recording of the events was needed.

In 1858 in the course of the diplomatic mission to Khiva and Bukhara second lieutenant Anton Murenko (1837–1875) made photographs that composed a unique album "From Orenburg through Khiva and to Bukhara." Here were the scenes of life of the mission on trip, scenes of life of local people and the surrounding landscapes. For this work Murenko was awarded a silver medal of Russian Geographic Society and afterwards he became a professional photographer. Then Murenko got a task from Russian Geographic Society to compose albums of ethnography and views of different regions of Russia. On opening a studio in Saratov in 1861 he was the first to start purposefully making photographs of Povolzshje.

In the second half of the 1860s a Russian photographer Michail Nastjukof made lots of photographs of the Volga region and in 1866–1867s he issued an album "Views of Volga from Tver and up to Kazan."

More and more photographers started to make outdoor photos. An interesting ethnographic photo-work was carried out by W. Carrick (1827–1878) in 1870s. In the 1870s ethnographic photography was also practiced by J. Raoult, a photographer from Odessa. He worked in Simbirsk region, made photographs of inhabitants of Moldova and Ukraine. A huge photographic collection of valuable material on Central Asia was composed under the supervision of A. Kun, a researcher, in 1874. The album comprised four volumes and contained over 1200 photographs. For this album the author won one of the highest awards at an International Geographic Exhibition in Paris in 1875.

All these works were applied in science and their value depended on the exactness of rendering of this or that object or scene by means of photographing. The emergence of association for mobile exhibitions (the so called peredvizhniks trend in art) in 1870 conduced to finding artistic value in documental photography as these artists in the majority of their pictures recorded some moments of real life as if fixed down with a photo-camera.

Thus photographs made in 1869 by Josef Migurski a fellow member of French photography society, the author of the first textbook on photography in Russian in 1859, made photographs of construction in Odessa, which echo the paintings by Konstantin Savitski "Repairs at the railway," 1874.

Nevertheless it should be mentioned that artistic photography is a term more applicable to studio photography (including studio photographic portraits). The photographer arranged the setting in accordance with the laws of painting, achieved the desired lighting through a complex system of reflectors, used a variety of studio accessories, strived for the ways of making the image softer at the expense of documental exactness, and at times just copied famous paintings.

A widely acknowledged master of Russian pictorial photography of the second half of the 19th century is A. Karelin. His followers and students, like for example Stepan Solovjov (?–1908) and others searched for the expressive means in photography taking the aesthetics of painting as a starting point.

The static character of studio photography had to be overcome. The attempts to do it were made by Konstantin Shapiro (1840–1900). In his photo-series devoted to the novel by Gogol "Notes of a madman" he recorded performance by Vasili Andreev-Burlak. Each photography in the series corresponded to a definite moment in the context of the monologue. The album was published in 1883, it consisted of 30 photographs and today we perceive it as a set of expressive shots from a silent film with titers.

A considerable progress in the development of photography, the documentary photography in particular, was prompted by the emergence of dry bro-gelatine plates in late 1870s. The events of the Russian-Turkish war of 1877–78s were recorded by such photographers

as A. Ivanov, M. Revenski, D. Nikitin, V. Barkanov and others. In the 1880-s photo-recording of various events became quite frequent. Alexei Ivanitski made a photographic document of the crash of the Tzar train in 1888. But these works were a long cry from the real photographic reports. Photographers kept concentrating on static scenes. Their attempts to reflect the dynamics of the event were still rather shy.

Lieutenant N. Apostoli made marine photographs with the help of a double camera he constructed in 1890. Apostoli outlined his experience in the "Guidance for studying practical photography for naval officers and tourists."

The documentary photographs were badly needed by the illustrated. At that time they still published photographs engraved by artists. But even in the copies made by artists one could easily trace the photographic basis. The demand for such photographs went steadily up. The photo-images were often used by artists involved in battle painting: they introduced some of the documental details rendered by photographers into their works.

In the 19th century painting in Russia the peredvizhniks were obviously domineering. This surely told on photography: the leading tendency consisted in rendering the surrounding world realistically by purely photographic means. The concept of free photographic setting kept gaining weight. The plots were often taken from regular life of common people, not necessarily some extraordinary scenes but also a most routine ones.

One of the prominent proponents of realistic photography was Maxim Dmitriev (1858–1948). The most outstanding of his works was the album "Year of Poor Crops of 1891–1892 in the Nijnij Novgorod Province." The woes of people suffering of severe drought and epidemics of typhoid and cholera were the center of the first photo-publicist report in Russia.

The method similar to photo-documentary was also employed in literature. It helped to transmit the realistic message and make the plot more close to reality. Thus, for example, the famous Russian writer Anton Chekhov (1860–1904) visited Sakhalin in 1890 and in his literary work "The Island of Sakhalin" first published in 1895 the writer rendered with photography-like exactness all the details of the way of life of convicts and exiles. The basis for this description was laid down by his observations and a series of photos.

In 1890s Alexei Kuznezov (1851–?) a convict confined to ten years in the Zabaikalje region for revolutionary activities, created an album called "Views and Types of the Nerchinsk Servitude." Documentary photographs of the late 19th century made Dmitri Jermakov (1845–1916) one of the first photographers of Georgia. His diverse photographic legacy included landscapes, architectural monuments, scenes of life of different nationalities from Georgia, Armenia, Persia. His studio on Tiflis (at present Tbilisi) one might consider a prototype of a photo-agency of today. In 1896 Jermakov issued his "Catalogue of photographic views and types of the Caucus, Persia, The European and Asian parts of Turkey." It comprised over 18 thousand images and anyone could order the view he liked for a fee. Jermakov made studio ethnographic photos: the sitters dressed in the national costumes played the moments of their real life. The photographer admired both the picturesque moments and the routine situations and fixed them down in a short period of time.

In all these works one could trace the starting point of the contemporary understanding of photography. According to this understanding the realistic rendering is an artistic document, which does not simply reflect but influences the reality. Masters like that were the ones who predetermined the concept of specifics of photography.

A considerable part of photographic legacy is constituted by landscape city shooting. Many photographers especially from 1870s on recorded the sights of the home town. The photographers were particularly attracted by large cities such as St. Petersburg, Moscow, Nizhni Novgorod and some others.

A large-scale shooting of Moscow and its suburbs was carried out by Albert Meighm in1870–1880s under the task of one of the Moscow leading bourgeois, Nikolai Naidenov. As a result an album appeared, which comprised the photographs of architectural monuments and vies of the streets in the city. It should be mentioned that these works were not aimed at rendering the city's life. In 1890–1900s Petr Pavlov carried out a shooting of Moscow; he focused primarily on genre and view photography. In his works architectural monuments were recorded on the background of the vigorous city life.

In the 19th century photography was actively used to solve scientific problems and execute applied tasks. The first Russian photographer who made photographs of Russian style buildings and period pieces was Ivan Barschevski (1851–1948). He made a great number of photographs of architectural monuments, archeological objects and different ancient pieces from museums for the purpose of future scientific research.

Another vivid example of applied use of photographs is the research works by Jevgeni Burinski (1849–1912), who employed photography in court litigation. In 1886 he worked out a method of layer by layer restoration of image (colour-separating method), which allowed to read spoiled manuscripts and inspect the documents if there is a doubt in their authenticity. In 1894 he used this method in his work in the Emperor's Academy of Sciences—he studied leather documents of the 14th century.

Pictorial photography in Russia was also pushed forward by amateurs (first amateurs appeared already

in 1839). The number of photo-amateurs went up rapidly in the 1880–1890s, which is connected with wide spreading of brom-gelatine plates and simplification of the process of photography. Since 1890s lots of societies of photo-amateurs of different levels emerged in Russia. By 1917 they amounted to over a hundred.

Many of the amateurs were also keen on music, painting, literature, which had an impact on their creative work as photographers and formed the basis for a homogeneous cultural environment of the nation.

One of the first and the most respected photo-amateurs was Ivan Nostits (1824–1905), count and lieutenant general. He started to go in for photography in 1839; he later made photo-portraits of the Emperor's family, ships, landscapes, architectural monuments. In 1859 he made the photographic portrait of the famous prisoner, the Chechen imam Shamil. He tested photo-apparatus and published the results of his research works in special journals. In 1896 he issued an album "Photographs by count Nostits." The earnings he donated to the fund of the Penkov orphanage in Yekaterinaslav region.

The problems of photography were the topic of several works by an outstanding Russian scientist and evolutionist Kliment Timiryasev (1843–1920). He drew parallel between photography and the process going on in leaves o plants. Besides he was among the first ones to realize how important foe physiology was the invention made by Hermann Wilhelm Vogel—his optical sensibilizators. Timiryasev used to say that the most fascinating photo-process is the decomposition of carbon dioxide and the formation organics in the plants under light and the sensiblizator—chlorophyll. The scientist was also a passionate photo-amateur, he was knowledgeable in the theoretical as well as in practical achievements of photography. He pictured landscapes and was a master of the genre. By the best of his works he proved that photography is an art.

Among Russian photo-amateurs Alexei Mazurin(1846–?) is most widely known in Europe. In 1890s his works were published in journals of Germany, Great Britain and other countries. He was one of the Russian pioneers of pictorialism, the leading trend in photography on the verge of the 20th century. He learned how to perform positive printing, got acquainted with the gum dichromate and the pigment method.

There were women photo-amateurs, for instance Natalia Nordman-Severova (1863–1914), the wife of a famous Russian artist Iliya Repin. She was the head of the Ladies' photographic society. Her amateur photographs were used by Repin in creating the great painting "The State Council."

Leo Tolstoy's wife Sophia was an amateur photographer, so she made a photographic chronicle of the writer's life.

The thing that contributed to the spreading of knowledge of photography was the photo-periodicals. This can be subdivided into issues of public photographic organizations, independent editors, journals of trading firms, non-photographic journals, which published materials on photography.

The majority of articles tackled the technical problems of photography. The question of the artistic value of photography was less widely discussed also there were several declarative publications stating that photography was a form of art.

The aesthetics of photography started to gain prominence in the end of the 19th—the beginning of the 20th century especially as soon as pictorialism spread in the country.

Photography was first used as an illustration by an artist Vasili Timm (1820–1895), who published from 1851 to 1862 the so called "Russian Pictorial Gazette," although the photographs were copied by hand. In Russia there were photo-journals: "Svetopis" (Photography) issued in 1858–1859s; "Fotograf" (Photographer) issued in 1864–1866; "Fotograficheskoje obozrenije" (Photography review) issued in 1865–1870s.; the "Fotograf" journal (1880–1884s) was an organ of the fifth department of the Emperor's Russian Technical Society (ERTS; there was also "Fotograficheski Vestnik" (Photography Gazette) issued in 1888–1897s; "Fotograf Ljubitjel" (Amateur photographer) issued in 1890–1909. The best artistic and theoretical journal, "Fotograficheski Vestnik" was a press organ of Russian Photography society in Moscow in 1907–1918s. The journals housed publications on new achievements of photographic process, events in the life of Russian and foreign photography, reviews on photographic literature, information on exhibitions and other important things. The journals not only unified the Russian photographers, they also kept society informed on culture-specific questions.

In 1890s photography started to be actively used in periodicals, which entailed the emergence of photographers oriented on making reports. The considerable sums of money they got as honorariums allow them to go in for this kind of photography.

The title of the king of report is best suited to Karl Bulla (1853–1929). Together with his sons he made photographs for journals and news-papers rendering the events that were taking place in St. Petersburg. Over 100 thousand negatives made by the Bulla family reflect the way Russia lived in the end of the 19th—the beginning of the 20th century. They did not lie in the advertisement that ran as follows: "An experienced photographer-illustrator, K.Bulla, St.Petersburg, Nevsky 48. Makes photographs for illustrates on the current events. Makes photography of anything you might need, anywhere, feeling free in any surroundings be that a region, a build-

ing, be it in the day-time or at night." The exactness of a photographic report was socially relevant and more convincing than a verbal description. That's why the public kept demanding for more and more photographic information.

The 19th century is the time of emergence and maintenance of photography all over the world and in Russia in particular. Besides it is the time when photography gained the status of a form of art.

In the end of the 19th century and the beginning of 20th century (up to the revolution of 1917) there were two trends for development of photography in Russia. The bulk of photographers believed in the principles of realistic photography, employing the latest achievements of photographic technology. The proponents of the trend, and Sergei Prokudin-Gorski most active among them, called to stay documental and use natural colours. The latter worked on a large project—a series of coloured photographs of Russian sights. The results of the work were used for studies as well as for research.

Another trend especially active in the beginning of the 20th century was the pictorial photography. Within the framework of this trend the photographers studied the problems of creating an artistic image, worked on such matters as composition and lighting. The photography developed on the background of changing priorities in Russian painting, These trends formed the basis for the Soviet photography of the 1930s, which combined expressive imagery and documental exactness.

Russia before the revolution of 1917 was integrated into the world economy, politics and culture and carried out one of the leading functions in the development of the world. That is why Russia had a worthy position in the global process of photography development.

RUTHERFURD, LEWIS MORRIS (1816–1892)

He was born in New York City and graduated in Laws from Williams University in 1834. Between 1837 and 1849 he practiced as a lawyer. He was a passionate amateur in astronomy, and has a special place in both histories of photography and astronomy as a pioneer of the photography as a tool of the astronomer. The beginning of spectroscopy (1830) and photography (1839) opened the horizon of astronomy, that traditionally studied the position of the stars. From that moment a new branch was inaugurated, the physical astronomy, or more commonly known as astrophysics.

With this starting point, chemists and physists began to point instruments at the stars searching for new data and the photography was called to play a fundamental role, when allowing a faithful, reliable and lasting registry of the celestial phenomena. Today this period of astronomy is known as "New Astronomy"; and Rutherfurd was one of its pioneers, together with Norman Lockyer (1836–1920) in England, Jules Janssen (1824–1907) in France, father Angelo Secchi (1818–1878) in Italy and Hermann W. Vogel (1834–1898) in Germany. Rutherfurd developed special lenses, altogether with the optician and daguerreotypist Henry Fitz. This allowed to focus on the wavelengths involved in the photochemical process of the humid collodion plates, that is the blue, the violet and the ultraviolet.

In 1860 he established in New York an observatory with a great equatorial refractor telescope, with an objective of 33 cm of diameter and a camera for humid colodion plates. He obtained photographic images of the solar disc, as well as of the Moon, some planets, stars and constellations. His images of the Moon became famous at the Universal Exhibition of Paris, in 1867. Some were reproduced in stereoscopy and in woodburytype, illustrating treatises of astronomy or photography (Flammarion, 1878 and Vogel, 1875) and a few in albumen paper, in great size—approx. 42 cm × 57cm—which were distributed to the main scientific centers and to celebrities and astronomers of the world.

When the American astronomer Benjamin A. Gould (1824–1896) accepted the invitation of the President of Argentina, Domingo F. Sarmiento to direct an observatory in the mediterranean city of Cordoba, Argentina, Rutherfurd trained the future Gould' assistant, a German scientist, Carl Schultz-Sellack to obtain photographs with his system, and gave Gould the first compound lens that were used in that observatory. (Ferrari, 2001).

Rutherfurd donated his instruments and photographs to the University of Columbia, of which he was a benefactor (1858–84).

RYDER, JAMES FITZALLEN (1826–1904)

American photographer

James Fitzallen Ryder, an American photographer for most of the second half of the 19th century, learned the daguerreian process in his hometown of Ithaca, N.Y. from a self-styled "Professor" Brightly, who "assured me that I was a promising subject and would make a mark as a daguerreotypist," Ryder wrote in his memoir.

In partnership with Brightly, Ruder operated daguerreian rooms in Ithaca, then became a traveling daguerreian in southwestern New York, Pennsylvania and Ohio. He opened a gallery in a vacant Mormon temple in Kirtland for a time, and worked in Elyria, Ohio during the winter of 1850. He then settled in Cleveland, where he introduced the ambrotype to the city in 1855.

In 1862, under the commission of the Atlantic and Great Western Railway, Ryder produced a two-volume album of 129 photographs of the landscapes, towns, stations and sheds, bridges, cuts, and tracks associated with the company. By the late 1860s, Ryder was Cleveland's leading photographer.

In 1868 he helped introduce negative retouching to the United States when he brought a retoucher from Germany to the United States. Ryder was a founding member of the Photographers Association of America and became the group's first president in 1880.

BOB ZELLER

S

SABATIER-BLOT, JEAN-BAPTISTE (1801–1881)

French painter and photographer

Appearing among the most famous portraitists of the Parisian daguerreotype of the 1840s, Jean-Baptist Sabatier is still today a poorly known figure among the historians of photography. There was a burst of production, accompanied by the absence of sources of files relating to him, and a scarcity of his name in the press, which make writing on him difficult.

He was born on January 31, 1801 in Lassur in Ariège. His parents wanted an ecclesiastical career for him, but his fragile health obliged them to withdraw him from seminary. Afterwards, he developed his artistic talents and became a miniaturist, located in Paris at 50 Palais Royal, exhibiting to the Salon on several occasions since 1831 (1835, 1837, 1839, 1841, 1843), always showing portraits of women. In 1838 he married Miss Blot and in 1839 their only daughter, Maria, was born; throughout the years of the 1840s, both were his favored models for daguerreotype portraits.

From the beginning of the 1840s he seemed to become part of the many painters of miniature attracted by the new medium of daguerreotype. During this period he became the pupil of the friend, Daguerre with whom he created at least two portraits, around 1844 (Rochester, George Eastman House and Société française de photographie). It is from 1842 that we find the name "Sabatier-Blot" on the reverse side of a plate of daguerreotype. The following year this name appeared for the first time under the heading "painter-artist," with "Palais Royal, 137." It was probably then that, assisted by his wife, Sabatier simultaneously practiced the two techniques, daguerreotype and miniature, even if the latter had become less favored. That year, Sabatier presented miniatures to the Salon for the last time however, he continued to be presented as "a painter in miniature, making portraits with the daguerreotype" until the 1850s.

Sabatier-Blot presented daguerreotypes at "l'Exposition publique des Produits de l'Industrie" ("Public exposition of Products of Industry") the following year and, according to its publicity, was awarded an honorable mention. The same year, "Sabatier-Blot" appeared for the first time with the heading "Daguerreotypes" and a different address (Palais Royal 163). He was explicitly mentioned as specialist in portraits.

He seemed to have been one of the most sought after portraitists of the capital in the second half of the 1840s. His works, abundant and scattered, are difficult to locate in their totality. They reveal a good technician, famous for perfectly polished plates, which were obtained using a machine of his own invention. Also demonstrated is a certain skill of composition which sometimes distinguished him from his competitors. Sabatier-Blot had access to the traditional accessories of the portrait studio of this period such as the pedestal table covered with a tablecloth or a carpet. The plain backgrounds made it possible to center the attention on the character and to cut out its silhouette more significantly. Perhaps the naturalness of the poses, often less stiff than in the majority of the works of this period, is particularly noticeable in the series of portraits which he left to his daughter and his wife and can explain the success of his studio.

At the end of the 1840s, Sabatier-Blot was still located at the Palais Royal but at a different addresses: Palais Royal 137 and Valois 27 (1848) then Palais Royal 129 (1849–58). The other addresses however appear on the back of various plates signed with his name: Palais Royal 43 or Palais Royal 132. In 1849 he presented portraits at the exposition of the Products of

Industry. His production was rewarded, even though the jury mentioned that the effects of light were too complicated, which harmed the simplicity and the clarity of the images.

The last exposition in which he seemed to have taken part was that of the Hook Deluxe hotel of 1851 where he presented only one portrait. The same year, he became a member of the new Société heliographique. At the time when the technique of collodion was established, his name was rarely mentioned: three years later, he appeared among the first members of the Société française de photographie although he did not take part thereafter in any of its expositions. He seemed nevertheless to continue to express interest in the photographic medium, and its technical aspects in particular. In 1857 he acquired a patent for an instrument that was easier to manipulate as it was "so simple that one hour is enough to learn photography." Then in 1863, he developed another apparatus to operate in the open air. Moving once again, his studio from to 1861 was located at 25 rue Neuve des Bons Enfants (25 street Neuve of the Good Children), and then from 1863 to 1871, at Valois 37. He continued to make portraits, in particular calling cards, and ended his activity at the beginning of the 1870s. He died in 1881.

Since his large body of work is very scattered today, the most substantial collection consists of a little less than thirty plates belonging to the George Eastman house in Rocheste. These images came from the collection of Gabriel Cromer, a member of family of Sabatier-Blot's daughter who married, in 1865, to another photographer, Victor Laisné. With the study of this collection, it appears that the best of his work was carried out in margin of his commercial activities such as a portrait of the chemist Jean-Baptist Dumas, probably from 1849–1850, and the many portraits, sometimes with the format full plate, which he created of his daughter and his wife starting from the middle of the 1840s. Sticking more to the expression and the character of his models than with their social status, these images are among the greatest successes of the portrait to the French daguerreotype portraits.

SACHÉ, ALFRED (c. 1853–1885)

India-based photographer

Commercial photographer, eldest son of John Edward Saché by his first wife, Alfred joined his father's photographic studio at Nainital in 1872, where he worked as an assistant till 1874. Working on a seasonal basis, he also opened his own premises in Benares in 1874, which he managed for one season till March 1875. The following month, he established another studio in the hill station of Kasauli, where he also became agent for the sale of his father's photographs. Between 1876 and 1881, Alfred's professional activity remains uncertain; the birth of his first child in March 1876 in Amballa and his second child in 1880 in Lahore suggests he may have worked as a photographer in both cities. In 1881, he opened a studio in Dalhousie, which he ran for a few years before traveling to Lahore again, where he possibly established the firm A. Saché & Co before he died in 1885. The firm continued till 1895, possibly run by his half brother John, who was John Edward Saché's son by his second wife Annie, and managed a studio in Lahore between 1886 and 1895. From 1896, the business A. Saché & Co was renamed Saché & Co and remained in activity till 1900.

Stephanie Roy

SACHÉ, JOHN EDWARD (1824–1882)

Prussian-born, Indian photographer and studio owner

Commercial photographer, born in Prussia as Johann Edvart Zachert, Saché arrived in Calcutta from the United States in late 1864, and entered into partnership with W. F. Westfield. Member of the Bengal Photographic Society, the firm Saché & Westfield won the silver and bronze medals at the annual exhibition of the Society, respectively in 1865 and 1866. While in partnership with Westfield, Saché opened his own independent studio at Nainital in 1867. He subsequently went into a brief partnership with a Mr J. Murray in Bombay in 1869. The same year, he made an expedition into the Himalayas, following Samuel Bourne's example. By 1870, Saché had ended his association with Westfield and concentrated on the running of season-based studios until his death in 1882: Mussoorie (from 1876) and Nainital during the hot months, Lucknow (from 1871) during the cooler months. In 1873–74, Saché made a series of views of Kashmir, which was to be the last group of topographical images he produced. Between 1874 and 1876, additional seasonal studios were opened in Meerut, Cawnpore and Benares, the latest being

managed by his eldest son Alfred. A number of talented photographers worked in Saché's studios, including G. W. Lawrie, with who he went into partnership as Saché & Lawrie between 1880 and 1882. During his twenty years in India, Saché traveled extensively throughout northern India, covering major sites and towns, and produced an accomplished collection of images, proving himself a master of the picturesque composition.

STEPHANIE ROY

SALTED PAPER PRINT

More concisely known as the salt print, the name implies the method of its preparation: fine quality paper was soaked in a dilute (ca. 1–2%) solution of common salt (sodium chloride) and dried. One side was then brushed over with a concentrated (ca. 20%) solution of silver nitrate, thus precipitating light-sensitive silver chloride within the paper fibres. Exposure to sun- or daylight through a contact negative caused a positive image in silver to print-out as minute particles of the metal trapped within the fibres of the paper surface. Such photographs on plain paper therefore carry no significant layer of colloidal binder; their matte surface distinguishes salt prints from those coated with glossy layers of hardened colloid, such as albumen, gelatin, or collodion**,** to bind the silver particles in suspension. Between these extremes there also exist intermediate examples of lightly colliferized prints.

The light sensitive chemistry of salt prints is essentially that of the first successful photographic process on paper: the photogenic drawing paper (q.v.) invented by William Henry Fox Talbot in 1834. The term 'salt print' is a later neologism (Hardwich 1855). Talbot originally stabilised his photogenic drawings with fixing agents—either saturated (ca. 32%) sodium chloride, or (ca. 2%) potassium iodide—but rather ineffectively, because the residual silver chloride remained slightly light-sensitive. Fixation with these halides was soon displaced by 'hyposulphite of soda' (still used today as 'hypo,' but properly, sodium thiosulfate), Sir John Herschel's innovation of 1839, which completely removed the excess silver chloride.

Salt prints fixed in a fresh hypo solution have a reddish- or yellowish-brown color that is affected by the paper sizing agent: the animal gelatin used for British papers afforded warmer image tones than the starch sizing of French papers. Such colors were commonly considered unpleasing, but with continuing use any hypo fixer bath was seen to yield more satisfying print colors of rich brown, as silver salts accumulated within it. This observation, publicised by Louis-Désiré Blanquart-Evrard in 1850, caused photographers to age their hypo baths artificially, by deliberately adding silver nitrate. The same effect was discovered in some cheaper substances: nitric acid, iodine, and iron(III) salts—all are oxidising agents that convert thiosulfate into polythionates, capable of *partially* sulfiding the silver image, to good effect. However, the optimum point of this procedure was very critical: if the paper were not fully washed free of excess fixer, it slowly converted the entire image to silver sulfide, with consequent fading

Benecke, Ernest. Vie de Gebel Mousir & Il Cataract du Nil regardant au nord-Nubie 72.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

to dull ochre. The enthusiastic but careless employment of these inexpensive "old hypo fixing and colouring baths" proved disastrous for the permanence of many salt prints.

A better procedure for toning salt prints had already been proposed in 1847 by P. F. Mathieu, who employed *sel d'or*—a complex thiosulfate of gold(I)—to protect the silver image with a deposit of gold metal, as used for gilding daguerreotypes since 1840. Encouraged by Gustave Le Gray's recommendation in 1850, many French photographers took to gold-toning, but its benefits were only publicised in Britain much later in 1855, by Thomas Sutton. His energetic advocacy in the *Photographic Journal* won over the leading photochemist Thomas Hardwich, who repudiated his earlier recommendation of the 'old hypo bath,' in the second edition of his *Manual of Photographic Chemistry* in 1855. In the same year, the Photographic Society set up a committee with the remit "to take into consideration the Question of the Fading of Positive Photographic Pictures upon paper." This so-called "Fading Committee" recommended—though not unanimously—that gold toning be employed. The 'old hypo bath' was not finally discredited until *ca.* 1858. By then, the fading of salt prints had become a chronic problem; for instance, those printed by Nicholaas Henneman from 1844 onwards, for Talbot's publication *The Pencil of Nature*, suffered from the use of 'old hypo' at the Reading Establishment, where inadequate washing procedures were occasioned by the intermittent and impure water supply.

Greater success with salted paper printing was enjoyed by the circle of Scottish amateur photographers based in St. Andrews, and by their professional brethren in Edinburgh, David Octavius Hill and Robert Adamson. Between 1843 and 1847 this uniquely fruitful collaboration produced thousands of salt prints of rich color that survive well today. Edinburgh Old Town was then affectionately known to the Scots as "Auld Reekie" and the ingress of the sulfur-polluted atmosphere sometimes caused fading at the margins, but the body of the print was usually unattacked. The stability of Hill and Adamson's salt prints may be attributed to their use of dilute fixer and very thorough washing—24 hours was usual—to ensure complete removal of residual thiosulfate.

Three other improvements to Talbot's original formulation for photogenic drawing paper have proved worthy of note:

1. The 'ammonio-nitrate of silver paper' devised by Alfred Swain Taylor in 1839, which yielded a more neutral print color, and was easier to fix.
2. The inclusion of sodium citrate in the salting solution to absorb the chlorine produced photochemically, which otherwise reversed the reaction by re-oxidising the silver image; this became a standard additive to all later printing out papers.
3. Immersion in dilute sodium chloride before the hypo fixation bath, to precipitate any remaining soluble silver nitrate, which could otherwise cause brown stains of silver sulfide by oxidising the thiosulfate.

Salted paper was the principal medium for photographic printing throughout the 1840s and 1850s; but it was slowly displaced by a shift in public taste towards albumen paper, which had first emerged around 1853, and achieved commercial dominance by the end of the decade. From an esthetic viewpoint, the salt print was seen as the positive complement to Talbot's calotype paper negative process, thus sustaining the artistic ethos of 'photography on paper' as the medium of the gentleman-amateur. The fibrous paper substrate had the optical effect of diffusing the image to a softened 'impressionistic' look, much favoured for landscape. On the other hand, the sharp albumen print was the ideal positive counterpart to the highly resolved wet collodion negative on glass, and the medium of choice for portraiture by professional photographers. The artistic sentiments attaching to plain paper photography may also have stimulated the temporary revival of the salt print beween 1895 and 1912, contemporaneous with the newly-perfected platinotype process and its perfectly matte 'engraving-like' surface, which was challenging—as one detractor put it—the "sharp and slimy" albumen print.

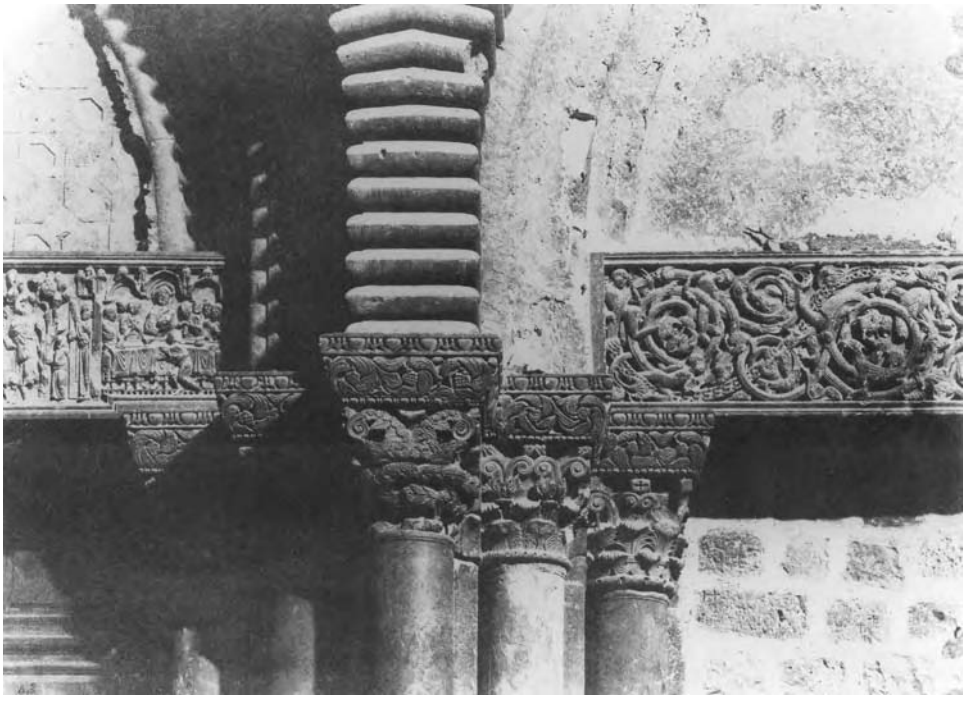
SALZMANN, AUGUSTE (1824–1872)

Archaeologist and painter

Impassioned by the early East, Auguste Salzmann went to Italy (1844) and Algeria (1847) with his friends Gustave-Henri Salzmann (a homonym) and Eugene Fromen-



Salzmann, Auguste. Jerusalem, Saint Sepulcre, Details de Chapiteaux. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 (2005.100.373.86) Image © The Metropolitan Museum of Art.*

tin. The company Schoengauer de Colmar provided the financial assistance for them stay in Egypt at the time of the excavations of Mariette (1851). This environment stimulated Salzmann's learning for archaeology, so he documented the architecture by means of photography. At the end of 1853, he left for the Holy Land to photograph the monuments studied by archaeologists two years earlier. In June 1854, he brought approximately 150 negatives from Jerusalem although his partner Durheim remained there after his departure, and produced around fifty more, which he published in 1856 in the form of album that he dedicated to Saulcy.

The *Jérusalem, époques judaïque, romaine, chrétienne, arabe; explorations photographiques* contains 174 prints obtained using paper negatives and 92 pages of text (Museum of Orsay: donation Robien de Bry; BNF; private collection). This work, printed by Blanquart-Evrard and published by Gide and Baudry, constitutes a luxurious album published in the early years of photography. The print quality gave the images relief and a particular intensity.

At the end of 1857, Salzmann left for Rhodes where he remained for several years, in particular to excavate the necropolis of Camiros (1858–1865). In 1863, he set out again for the Holy Land with Saulcy to undertake more thorough research. He brought back from this second campaign a set of salted paper prints on (approximately 26 × 32 cm) which were then reproduced in the form of photolithographies, in the workshops of Joseph Lemercier. These images were intended to illustrate the articles of Félicien Caignart de Saulcy.

These two voyages made Salzmann an occasional photographer who seized the appropriateness of the new medium to serve his scientific goal. He fully explored the malleable possibilities of photography just as well as other photographic professionals. Salzmann took part in the very first exposition organized by the Société française de photographie in 1855, with a panoramic view of Jerusalem, which was noted for the skill of execution (however, he was never a member of the SFP).

The views of the first voyage were among the most beautiful images of Jerusalem, and of a very poetic range, in spite of the scientific approach that inspired them. Salzmann studied ruins according to a rigorous approach, similar to that of Henri le Secq for Mission Héliographique. Le Secq's countryside images of Alsace was perhaps what inspired Salzmann to photograph the general and in contrast, the individual as well, creating overall sweeping images of the Valley of Josaphat, juxtaposed to images of enclosing walls, and drains. Salzmann photographed whole monuments as well often finding focus in the details. The project emphasized the closer details (apparatuses, ornaments) and points of view, namely all that the traditional artist did not have time to draw. The strongest images were indeed those which favored the large layout, which were unusual at that time.

In the foreword of the album, Salzmann wrote: "the photographs are not any more of the accounts, but of many gifted facts of a brutal conclusiveness." From this point of view, the Jerusalem album offers a successful application of the paper negative to the challenge of illustrating archaeological remains. Salzmann's images were used as a way to report and testify to the reality of the archaeological vestiges. In that, these views fulfilled the goal of photography assigned by Arago, which was to reproduce testimonies of the history of humanity. However these images go well beyond mere representation, glorifying the stones and the architectural and sculptural reliefs in a controlled play of light and shade. By their character of immediacy, the images acquired a great effectiveness. With the effects of the subject matter, Salzmann perceived with acuity the possibilities of the photographic medium. The power of certain images is accentuated by the fact that the town of Jerusalem was in ruins, and therefore uninhabited.

With the photographs of 1854, Salzmann takes his place in the role call of eminent travelers in the east, consisting of painters and draughtsmen, then photographers. From 1840, Egypt in particular and then other regions were regularly visited by the followers of the new medium. In the known body of photographs taken in the East between 1840 and 1855, Salzmann occupies quite a particular place, which one could consider a personal esthetic. Surpassing simple representation, his work offered a fresh vision in the field of archaeological photography.

SAMBOURNE, EDWARD LINLEY (1844–1910)

Edward Linley Sambourne was one of the most eminent British cartoonists and illustrators of the late nineteenth century. For over forty years, from 1867 onwards, his work appeared in nearly every issue of *Punch* magazine, where he succeeded Sir John Tenniel as chief cartoonist in 1901. A gifted and skilful draughtsman, some of

his best work appeared as book illustrations, such as his drawings for Charles Kingsley's *The Water Babies* (1885). Sambourne was also an enthusiastic and prolific photographer, relying heavily on photographs to support his draughtsmanship and building up a reference collection of around 30,000 images.

Sambourne first took up photography in the early 1880s, attracted like many others by the increased ease and convenience offered by the recently introduced gelatin dry plates. However, unlike the vast majority of these new amateur photographers, Sambourne's motivation for becoming a photographer was primarily pragmatic and utilitarian rather than recreational. Over the years, Sambourne had amassed a huge collection of commercial photographs and magazine cuttings to use as visual references for his drawings. However, the tight deadlines he had to work to meant that it was often impossible for him to find commercially produced images which exactly matched his needs. Photography provided Sambourne with the perfect means of obtaining precisely the image he required, exactly when he needed it. Many artists, of course, have made extensive use of photographs, but most were reluctant to admit the debt that they owed to photography. Sambourne, to his credit, was refreshingly candid and open about his working methods. In two interviews he gave in 1893 he explained: 'I do not agree with those artists who codemn the aid of photography altogether. On the contrary, I consider it a very useful and valuable adjunct to art.' and, more revealingly, 'You see, I don't believe in drawing out of my head, as people call it. I go to Nature herself, and that must be better art than working from mere recollection—at least, that is my opinion. I'm always on the look-out for people, objects and scenery to photograph...' Soon, rather than being merely a 'valuable adjunct,' photography became an indispensable tool which came to dominate his working practice. Indeed, a fellow *Punch* cartoonist, Harry Furniss, later described Sambourne as 'a slave of the camera and mere copyist'—a charge which Sambourne fiercely refuted. Even a superficial study of Sambourne's photographs and cartoons, however, reveals just how dependent on photography he became.

At his home in Stafford Terrace, Kensington, London, Sambourne photographed himself, members of his family, friends and servants in poses and attitudes reflecting the requirements of his weekly cartoon for *Punch*. He also made frequent use of a huge variety of props and costumes. The resulting negatives were processed by Sambourne in his home darkroom which he converted from a bathroom and contact printed to produce cyanotypes or platinum prints. These prints were then traced to form the outline of the cartoon. Indeed, many of Sambourne's drawings are direct transcriptions of his photographs down to the smallest detail.

In 1893 Sambourne joined the Camera Club—a sign of his growing interest in photography that now transcended his work-related activities. The Camera Club had recently moved to new well-appointed premises on Charing Cross Road and Sambourne made full use of the facilities offered, attending meetings and lectures and using the darkrooms and studio. Many of his photographs taken at the Camera Club reflect Sambourne's main area of photographic interest—the female nude. Whilst some of these studies were genuine *aides-memoire* for his drawings, the sheer volume of nude photographs, combined with the nature of the poses implies that their motivation was primarily private rather than professional. They can be viewed as both artistic and erotic with many transcending the boundary into the fetishistic and mildly pornographic. For his nude photography Sambourne used professional models and usually worked at the Camera Club. On rare occasions, however, he would invite the models into his home—making sure that his wife was safely out of the way, staying at the family house in Ramsgate.

In 1905 the Camera Club closed temporarily. This coincided with a change in direction for Sambourne's photography. Whilst continuing to photograph nudes as well as the tableaux which formed the basis of his work for *Punch,* he now began to devote time to exploring the possibilities of the snapshot. He had bought his first hand camera in 1892 and relished its potential for 'candid' photography. Sambourne's favourite subjects were schoolgirls that he photographed in the streets of Kensington, using a detective camera disguised as a pair of binoculars that took a photograph at right angles to the direction in which it appeared to be pointed. Despite the unpleasant connotations clearly implicit in these photographs, there is no denying their freshness, vitality and spontaneity and they represent some of his most interesting work.

It is, perhaps, significant that this, the last expression of Sambourne's continuing and at times all-consuming enthusiasm for photography, should also embody an element of subterfuge and secrecy. In his photography, as with so many aspects of his personal life, Sambourne seemed able to keep the various strands of his public and private persona detached and separate. He remained a public figure with very private passions—a man of contrasts and contradictions, a man who despite the huge amount of time and energy he devoted to it, could still reply, when asked if he was fond of photography: 'No, I can't honestly say that I am.'

Sambourne died in 1910. His house is Stafford Terrace is preserved and is open to the public as a unique

example of a late Victorian townhouse. The family archive, including Sambourne's photographs, is held at Kensington Central Library.

SANDERSON, FREDERICK H. (1856–1929)

English photographer and inventor

Frederick Sanderson was born in July 1856 to a long established Cambridge family. He started work as a cabinet maker and as a wood and stone carver and became interested in photography in the 1880s. He took a leading role in his local photographic society. Photographic retailing was added to his cabinet making business.

Sanderson had a particular interest in architectural photography and, unable to find a camera to meet his needs, he set about designing one. The outcome of his work was the subject of British patent number 613 of 10 January 1895. The patent described a method of supporting the front or back of a camera which allowed them to be fixed at any angle. In practice the design was incorporated into a double strut on each side of the front standard which could be locked into any position. The patent also referred to a rotating lens panel into which the lens was mounted eccentrically and bellows which tapered on their lower side to aid the extreme movement available with the strut arrangement.

Sanderson licensed the design to George Houghton and Son of London who initially had the camera made for them by Holmes Brothers. Holmes Brothers were incorporated into Houghtons Ltd in 1904 and the camera was subsequently made and sold by them or their selling company Ensign Ltd until its demise in 1940. The camera was popular and the original field camera model, made in a variety of plate sizes. A hand and stand model was offered from 1899. The hand camera underwent a process of continual improvement with further patents from Sanderson and others. It was last listed in Ensign's 1938 catalogue by which time upwards of 26,000 examples of the sixty distinct models of Sandersons had been made.

Frederick Sanderson does not appear to have made any further significant contribution to photography. He died on 9 July 1929 leaving an estate valued at £1887 12s 3d.

MICHAEL PRITCHARD

SARONY, NAPOLEON (1821–1896) AND OLIVER FRANÇOIS XAVIER (1820–1879)

The Canadian brothers, Napoleon and Olivier Sarony, earned their respective reputations on opposite sides of the Atlantic—Napoleon becoming New York's pre-eminent 19th century theatre photographer while his older brother operated the most successful portrait studio in the north-east of England.

The sons of an officer in the Austrian army who had moved to Canada after Waterloo, the brothers moved to New York with their parents in 1831, and by 1841, both had become enthused by photography, with Oliver operating daguerreotype studios briefly in both New York and Quebec. Napoleon, however, initially trained as a lithographer and worked for a time with the eminent American print-maker Nathaniel Currier before setting up his own lithographic business in partnership with James Major in 1843. By 1857 the company had acquired another partner and traded as Sarony, Major & Knapp. Despite his later success with photography, he retained a profound interest in lithography.

In 1843, the year Napoleon established Sarony & Major, Oliver had emigrated to England, and spent several years as an itinerant daguerreotypist in eastern England. Early advertisements list him in the 1840s and early 1850s operating studios in towns and cities in Yorkshire, Nottinghamshire, and Lincolnshire. Given the attempts by Richard Beard to retain tight control over the use of the daguerreotype in England in the 1840s through his patents and licences, it can be assumed that Oliver was using the process unofficially.

By 1854, he was operating a mobile studio throughout Cambridgeshire and Norfolk, eventually opening a permanent studio in Scarborough, Yorkshire, in 1857. This represented a complete change of direction for Oliver, as itinerant photographers were usually at the lower end of the market, while advertisements for the Scarborough studio emphasised the quality of his work, and were priced accordingly. Before the end of that year he briefly opened another studio in Newcastle, and returned to Scarborough in July 1858 to open Gainsborough House, a custom-designed studio built to his own specification at South Cliff, and he remained at that address until his death in 1879. Many of the studio's cartes-de-visite bore the address 'Sarony Square, Scarborough.'

Oliver Sarony was not only a fine photographer, he was an innovator as well, with a keen business eye. Several of his innovative ideas were patented—with two

Sarony, Napoleon. Oscar Wilde.
The Metropolitan Museum of Art, Gilman Collection, Purchase, Ann Tenenbaum and Thomas H. Lee Gift, 2005 (2005.100.120) Image © The Metropolitan Museum of Art.

patents (1858 No. 725, and 1858 No. 1501) covering aspects of studio practice and the coloring of prints, and another in 1862 for an improved combined posing chair and head restraint.

He employed painters and colourists to produce large portraits from his photographs, and opened and developed an art gallery selling paintings, lithographs, and his own photographs of royalty and celebrities. His fame drew a visit by the Prince of Wales in 1869, resulting in a sitting which further extended Sarony's.

In his obituary (*Anthony's Photographic Bulletin*, September 1879, 287) his Scarborough operation was described, at its height, as having 98 rooms and employing 110 staff.

By the late 1860s, Sarony & Co. was offering for sale a range of studio backdrops—reportedly painted by his brother Napoleon who had, by that time, opened a photographic studio in New York.

By 1864 he had been joined in England by Napoleon, whose Birmingham studio, Sarony & Co., operated from premises in New Street from 1864 until after 1880. The *British Journal of Photography* in its issue of April 28 1865, 222, reported Napoleon's patent 'Improvements in the Production and Treatment of Photographs.' A few weeks earlier, the *American Journal of Photography and the Allied Arts & Sciences*, Feb. 1 1865, 351–352, had commented on Napoleon's new techniques for vignetting being used in the Birmingham Studio, and in May 1866, The *Art Journal* reported that he "is one of the best photographers [working] in Birmingham" and that he "uses the 'rest' invented by his brother, of Scarborough."

But the Birmingham venture was not his first. Napoleon Sarony's first studio is believed to have opened in Yonkers in 1857, where he was listed as a daguerreotypist, at which time he was still involved with the lithographic business of Sarony Major & Knapp. The fact that Knapp joined the partnership at that time may have been as a result of Napoleon's decision to change professions. The studio is not listed after 1858, and he is believed to have left for a tour of European lithographic companies some time before 1860, arriving in England in 1863. With the Birmingham studio established, however, he returned to America, and his New York in Union Square studio opened in 1866 or 1867. Over the following thirty years he is reputed to have photographed every major star on the New York stage.

Napoleon was a major influence in the emerging use of publicity photographs in the theatre. In addition he photographed many writers and celebrities. By the time of his death in 1896, the studio is believed to have amassed an archive of over forty thousand negatives.

Napoleon was at the centre of a celebrated court case in 1883, over the unauthorized duplication and publication of one of his portraits of Oscar Wilde. The case of *The Burrow-Giles Lithographic Company against Napoleon Sarony* was heard first in a District Court, and subsequently argued in the US Supreme Court in December 1883. It centered on whether or not the copyright protection granted to photographers under the US Copyright Act of July 1870 was constitutional. The question related to whether or not the photograph existed separately from the person it portrayed—and as Oscar Wilde's physical appearance was not copyright, nor could be a photograph of him. In 1884 the Supreme Court found in favor of Sarony, but conceded that all photographs might not necessarily be thus protected. Central to this definition of copyright was the ideal that the photograph should be *"entirely from his own mental conception"* and that the photographer must be responsible for *"arranging the subject so as to present graceful outlines, arranging and disposing the light and shade,* [and] *suggesting and evoking the desired expression."* Thus, this ruling constitutionally defined a

photograph was being the work of an author, as original as the written word—a major milestone in copyright protection.

The character of Julius Bianchi in the 1902 novel *The Fortunes of Oliver Horne* is believed to have been based on Napoleon Sarony.

SAUNDERS, WILLIAM THOMAS (1832–1892)

English photographer

William Saunders, one of the finest nineteenth-century photographers of China and Japan, operated a studio in Shanghai from around 1861 until at least 1887. Like Felice Beato in Japan, Saunders' success was built upon the production of souvenir albums of Chinese scenery and *genre* studies for foreign residents and visitors. Much of this work has survived and his talent is self-evident. His Chinese landscape portfolio of Shanghai, Ningpo and Foochow was supplemented by views of Peking and Japan. He made his first photographic tour to Japan in 1862, accumulating some 90 images but, surprisingly, only a few of these have so far been identified and are in the Worswick Collection, Tokyo. In May, 1863 Saunders offered handcolored photographs and may well have been the first commercial studio in the Far East to do so. Apart from his larger-format work, which also included multi-plate panoramas of Chinese and Japanese towns and cities, Saunders also sold *cartes de visite* and stereoviews.

Having enjoyed considerable commercial success, he sold all of his stock and equipment in 1871 and returned to England to marry. Perhaps his marriage failed because, by the following year, he was back operating his studio in Shanghai. His wife died in England in 1887 and shortly afterwards he decided to retire and went home. Returning to Shanghai on a visit in 1892, he caught bronchitis and died.

TERRY BENNETT

SAUVAIRE, HENRI (1831–1896)

French photographer

Henri Sauvaire was born in Marseille. Raised by his Uncle Marius, a merchant who often dealt with the Near East, he soon became familiar with Orient. As Henri de Clercq (1836–1901) or Gustave de Beaucorps (1825–1906) he was among those talented amateur photographers fond of Orient. He certainly learned photography in France in the mid-fifties and practiced it during thirty years along with a successful diplomatic carrier started in 1857 in Lebanon, as a *drogman* in Beyruth, and ended in 1885 in Morocco as the French consul. He then came back to France, near Marseille, where he died.

Unfortunately only some of his photographs are still kept today (the Musée d'Orsay received in 1995 from René and Bernard Sauvaire a very important gift of 160 prints, both from paper and glass negatives). Most of the remaining prints have been taken between 1860 and 1866 in Lebanon, Syria and around the Bosphorus. Henri Sauvaire was a fine observer of oriental life and landscapes. He revealed his sense for artistic composition as well as his technical abilities in large Beirut panoramas, sad views of the Christian quarter in Damas burnt down after the civil war in 1860 as well as in beautiful prints of the famous Damas Omayad mosque.

Familiar with occidental circles in Lebanon he also did several photographs of Camille Rogier (1805–1870) studio. Painter and illustrator—he has illustrated the first French edition of Hoffmann's tales; Rogier was close friend to Théophile Gautier, Gérard de Nerval and Gustave Flaubert. Even if he almost left his artistic carrier for a more lucrative position in postal administration, Rogier stands in front of Sauvaire's camera as a painter, before a white canvas, surrounded by friends. The *tableaux vivants* Sauvaire composed in the eccentric French man studio show the photographer sense of humor as well as his mastery of lightening. His soft portraits of women whose beauty is enhanced by the sumptuous fabrics of their Turkish clothes underline Sauvaire's delicacy.

In 1866, Sauvaire traveled with Christian Edouard Mauss around the Dead See thanks to an archeological expedition supported by the Duc de Luynes. He took there almost one hundred prints to be published by Melchior de Vogüé in 1875. The views of the ruined crusaders castles gave him first rank, along with Auguste Salzmann (1824–1872), as masters of early archeological photography. Fine scholar, experienced numismatist, Sauvaire then published and translated several books on Oriental civilization.

DOMINIQUE DE FONT-RÉAULX

SAVAGE, CHARLES ROSCOE (1832–1909)
American photographer

Charles Roscoe Savage's beginnings were modest. He grew up in a poor Southampton neighborhood and as the son of a gardener received very little schooling and was expected to contribute to the family finances at an early age. He did, however, have an interest in religion and in 1848, despite his family's objections, he converted to the Church of Jesus Christ of Latter-Day Saints (the Mormons). In 1855 Savage left England for New York City. Although he was interested in photography while still in England, only when he reached New York did he begin his study in earnest. He found the trade to be very secretive and had difficulty in receiving training of any kind. Eventually, through reading, experimentation, and paid lessons he became quite competent.

In 1860 he arrived in Council Bluffs, Iowa (then the main departure point for the Overland and Oregon Trails) where he set up a crude darkroom and gallery. He was able to earn enough money to buy and outfit a wagon for his small family for the trip westward. On August 28, 1860, Savage finally reached the Mormon Zion in Utah. At first his business was almost exclusively devoted to portraiture, but Savage soon went outdoors by photographing the buildings of Salt Lake City as well as the mountains and small towns of Utah. After several years, though, Savage felt more and more isolated from other progressive photographers and from the latest developments in the art. In 1866 he came up with a daring plan to travel 9,000 miles from Salt Lake City to San Francisco to New York and then back to Utah that would plunge him deeply in debt, but which began his rise to national prominence as a Western photographer.

Savage left Salt Lake City for San Francisco, California by stagecoach. He visited with a number of photographers while in the city including Carleton Watkins. He then took a steamer down to Panama, crossed the Isthmus and took another boat north to New York City. In New York he bought photographic supplies from the E. and H.T. Anthony Co. and visited with several publishers before traveling to Philadelphia to pick up a wagon similar to the darkroom wagons used by Civil War photographers. He shipped the wagon by boat and rail to Nebraska City, Nebraska. He then traveled across the Plains, into the Rocky Mountains, and back to Salt Lake City (of course photographing the more famous places on the Oregon Trail as he went). Savage made a number of contacts on this voyage and soon after his images started showing up as lithographs in *Harper's Weekly* and *Leslie's Illustrated* and were marketed on the East Coast through the New York firm of Fowler and Wells. Savage also subsequently published articles in *The Philadelphia Photographer* and *Humphrey's Journal of Photography and the Allied Arts and Sciences*.

In 1869 when the Union Pacific and Central Pacific Railroads were scheduled to come together at Promontory, Utah, Savage was asked to join Andrew Joseph Russell and Alfred Hart to photograph the final drama of "The Work of the Age." This event opened doors among the railroad companies and for the next 30 years Savage enjoyed free passes and sometimes even private luxury cars on several lines. Savage's photographs encouraged tourism for the railroads while providing him the means to travel about the West photographing the landscape and its diverse peoples. Savage also benefitted from interest in the Mormons of Utah. Americans had a morbid curiosity about polygamy (Savage himself would eventually marry four women), with the worship of a living prophet, and with the Mormon theocratic government. After the railroad was completed, greater number of tourists visited Salt Lake City and a stop at Savage's studio became almost mandatory.

In 1869 Savage also met (presumably for the first time) two of the best known photographers of the American West, William Henry Jackson and Timothy O'Sullivan. Although at the time they could not know it, these three would introduce the country to the scenic Western landscape long before Buffalo Bill peddled the mythic West of cowboys and Indians. Whereas O'Sullivan and Jackson would travel to the most remote areas of the West, Savage stuck to the more traveled byways, using wagons and trains rather than mules and makeshift boats. And although Savage had an appreciation for wilderness, he did not embrace it as did O'Sullivan and Jackson whose photographs celebrate the breathtaking landscape and majestic scale of the West. In comparison with these two, Savage's photographs focus on development. Upon first seeing what would later become Zion National Park Savage wrote, "From a picturesque point of view, it was grand, sublime, and majestic, but as a place of residence, lonely and unattractive, reminding one of living in a stone box; the landscape, a skyscrape; a good place to visit, and a nice place to leave" (Richards, 66).

In part due to this ambivalence towards nature, Savage's images have never received the critical attention of Jackson and O'Sullivan. Certainly he is not put in the same category as Carleton Watkins or Edweard Muybridge whose subtle experiments with unconventional views and composition are lacking in Savage's work. He did, however, document an important sub-culture (the Mormons) and his relentless travels around the West ensured that he would be remembered among the major names of nineteenth-century Western photographers.

Savage was also a savvy businessman, one who did not succumb to the bleak financial fate of so many other Western photographers. He was successful in part because his photographic studio was also a general art store that sold various photographic and artistic supplies, periodicals, books, craft goods, and miscellaneous novelties. He had a variety of contacts on the West and East coasts through which he could market his photographs and stereo-views and who would, in turn, provide him with merchandise to sell at his "Art Bazar." Despite a few setbacks (his gallery burned down in 1883) his business continued to grow over the years. As amateur photography grew increasingly popular in the 1880s and 1890s, Savage moved into photo finishing and camera sales. After the turn of the century, Savage devoted more and more of his time to various philanthropic events and to the Mormon Tabernacle Choir. In fact, when he died of a heart attack on February 3, 1909, he was almost as well known for his generosity as for his photography.

Biography

Charles Roscoe Savage was born on August 16, 1832. He grew up in a poor Southampton neighborhood but moved to New York City in 1855. Savage began his study of photography in New York and opened his first gallery in Salt Lake City, Utah in 1860. He started with portraiture, but quickly branched out to photograph buildings, towns, mines, newsworthy events, and landscapes in Utah. In 1866 a trip to New York and Philadelphia brought attention to the young photographer, but it was not until he attended the joining of the Union Pacific and the Central Pacific Railroads at Promontory Point in 1869 that Savage became a recognized name. After 1869 he would travel throughout the West (with free passes from the railroads) shooting scenes of interest along the lines. In comparison with his peers such as Carleton Watkins, Timothy O'Sullivan, and William Henry Jackson, Savage was not as ambitious about seeking out new photographic opportunities, nor did not embrace the western landscape as they did. He did, however, document an important sub-culture (the Mormons) and he was one of the first photographers to provide images of the American West to eager Eastern audiences. Savage was also a savvy businessman whose profits from a successful art store in Salt Lake City allowed him to continue his photographic career. Unfortunately, only a few original Savage negatives exist today because of two devastating fires in 1883 and 1911.

SAVILLE-KENT, WILLIAM (1845–1908)

English naturalist and photographer

Saville-Kent (also known as Kent) was born in Sidmouth in Devon, England, on 10 July 1845 to Samuel Savill Kent and Mary Ann Kent. After studying at King's College, and the Royal College of Science under T.H. Huxley, he initially pursued a career in natural history museums, including the British Museum. In 1873, he accepted the position of resident naturalist at the recently opened Brighton Aquarium. Similar roles followed at other public aquaria until he was appointed Superintendent of Fisheries in Tasmania, Australia, in 1884. Saville-Kent's research into marine life and its commercial applications, including pioneering work in pearl culture, earned him a number of advisory roles for the Victorian, Queensland and Western Australian colonial governments from 1887. These provided him with opportunities to travel to some of the farthest regions of the continent and adjacent islands. During this time he took up photography and produced remarkable coral reef views and studies of natural history specimens. Saville-Kent published numerous scientific studies throughout his career, however he is best known for two, more popular, natural history monographs from that latter period in Australia—*The Great Barrier Reef of Australia*, 1893, and *The Naturalist in Australia*, 1897—both extensively illustrated with his photographs. He developed various techniques for photographing natural history subjects and experimented with colour processes, exhibiting his photographs at the Royal Society in 1891 and the Royal Photographic Society (RPS) in 1906. The latter, shown by invitation of the RPS Council, included over eighty natural colour transparencies prepared by the Sanger-Shepherd trichromatic process with modifications, and were presented as lantern-size plates, half and quarter-size plates and stereos. Following a sudden illness and bowel surgery, Saville-Kent died in Bournemouth, England, in 1908.

KATE DAVIDSON

SAWYER, JOHN ROBERT MATHER (1828–1829) AND CHARLES (1861–1914)

English photographers

John Sawyer was born in Sheffield, but started his career as an optician in Norwich. He opened a studio on Regent Street, London in 1871 with Walter Strickland Bird (1828–1912), later admitting Edward William Foxlee (1832–1913) to the partnership. At the same time, the partners took an interest in the recently established Autotype Company, operating out of Ealing.

In January 1873 John Spencer (manager of the chemical department), and Bird bought out the Company together with its London Gallery at 36 Rathbone Place, St. Marylebone. A modification by Sawyer of the carbon process was patented in 1874, as "flexible temporary suppor,t" paper coated with gelatine rendered insoluble by means of chrome alum, followed by a second coat in soda and borax. Sawyer's son Charles joined the Company shortly before his father's ill health forced a premature retirement. John Sawyer died at sea in sight of Naples harbour January 21 1889, while on a health cruise.

Charles was sole manager of the Autotype Company after Bird's mental health deteriorated, forcing him to retire in 1900. Sawyer, whose main interest had always been with the technical manufacture of the carbon printing, himself died prematurely after a long illness September 22, 1914.

David Webb

SAWYER, LYDDELL (1856–c. 1908)

English photographer

When the photographer Lyddell Sawyer joined the Brotherhood of the Linked Ring in November 1895, he took the pseudonym of 'Sheriff.' Despite having been one of the original 'secessionists' from the Photographic Society of Great Britain (today the Royal Photographic Society) in 1891, the association which became known as the Linked Ring was three years old before he formally became a 'link.'

Originally from the north east of England—he is believed to have been born in Sunderland, and to have worked in a professional studio in Newcastle before establishing his own studio in the town in 1885—'Lyd' Sawyer had quickly earned for himself the reputation as one of the finest 'art photographers' in late Victorian England, and was a friend of such other eminent practitioners as Frank Meadow Sutcliffe and Henry Peach Robinson. From 1896 he operated a portrait studio in Regent Street, London.

Given the importance of his contribution to the development of photography as an art, surprisingly little is known of his life and work. A staunch advocate of the idea that a photographer should 'make' rather than 'take' pictures, his images have a lyrical narrative quality.

His images appeared in several influential publications, including *Sun Artists* (vol. 4), 1890, and *Photographs of the Year,* the published catalogue of the Photographic Society's 1891 exhibition, with a text by H P Robinson.

He left the Linked Ring in 1901, and continued to operate a studio in Maida Vale until at least 1908.

John Hannavy

SAXTON, JOSEPH (1799–1873)

American Photographer

Joseph Saxton is credited with creating the oldest extant American-made photographic image. Taken from his window at the Philadelphia mint where he served as curator of weights and measures, the daguerreotype captured the cupola of Central High School and a portion of the State Armory building on a silver plate used to cut coin blanks. The actual date of the image has been disputed as several accounts of the Daguerre's process were available in the United States in September and October of 1839. The earliest published reference to Saxton's daguerreotype is a description that appeared in the *United States Gazette* on October 24, 1839. Best known as a talented machinist, instrument maker and inventor, Saxton constructed and improved upon a wide variety of scientific and practical devices. He was a member of the American Philosophical Society, the Franklin Institute, and the National Academy of Sciences. Born in Huntington, Pennsylvania on March 22, 1799, Saxton spent his early career in Philadelphia employed as a clock and watchmaker. He lived in London for nearly a decade where he was affiliated with the Adelaide Gallery of Practical Science before returning to Philadelphia in 1837 to accept the position at the mint. He served as chief mechanic in the Office of Weights and Measures of the U.S. Coast Survey from 1843 until his death on October 26, 1873 in Washington, D.C.

Jenny Ambrose

SAYCE, B. J. (1837–1895)

The name of B.J Sayce first came to national prominence within the photographic community with the publication of the paper 'Photography Without a Silver Nitrate Bath' in *The British Journal of Photography* on September 9th 1864. That article effectively marked the end of the wet collodion era and prefaced the dawn of modern photographic materials.

Although his name usually follows that of William Blanchard Bolton in histories of photography—'Bolton and Sayce' being given joint credit—Bolton himself acknowledged that it was Sayce's understanding of chemistry which drove the development of photography's first true emulsion.

Sayce's quest for an emulsion which could simply be poured on to a plate and then exposed clearly places the genesis of the idea in the wet collodion era. From initial experiments in 1859, it took five years of development before the announcement of a working collodio-bromide emulsion in 1864.

The emulsification of silver bromide in collodion removed the need for the separate silver nitrate bath, and was the forerunner of all the dry plate emulsion technology which followed. For several years, Sayce's discovery was known as the Liverpool Process.

Always an amateur photographer, Sayce was a founder member of the Liverpool Amateur Photographic Association, and one of the instigators of the first International Photographic Exhibition held in Liverpool in 1888.

JOHN HANNAVY

SCHAEFER, ADOLPH (c. 1820–1853)

Dutch photographer

Started original as a painter and according an advertisement in the Journal of The Hague in the Netherlands he worked there as a photographer from January 1st until the 14, 1843. He was befriended with Philipp Franz von Siebel who wrote at Leiden on May 1, 1843, a letter of recommendation to King William II of the Netherlands to ask the King if Schaefer could work in the Indonesia to work for the Ministry of Colonies to photograph the historical buildings and places for the government. In 1844 he traveled to Indonesia to replace Jurriaan Munnick, as the Dutch Government was not pleased with the results of Munnick's work.

Before he left he bought on November 3, 1843, photographic equipment from Hottinguer & Comp. in Paris for for 8882 Dutch guilders.

After his arrival Schaefer made more then 5000 pictures of many Indonesian monuments and geological places in the West Indies in order of the Dutch Government. He used daguerreotype and later albumin types. Most of his work in preserved at the Tropical Institute of Amsterdam, some is preserved in the collection of art at the Rijksmuseum in Amsterdam. In 1849 Schaefer opened a studio in Semarang on the Isle of Java and also gave lessons in photography.

After this time Schaefer disappeared. It could be the result of his debt of 6073,53 guilders to the Dutch Government.

In Dresden a men named Schaefer died in 1853, leaving behind a widow and a son.

PETRA NOTENBOOM

SCHEELE, CARL WILHELM (1742–1786)

Swiss chemist

The chemist Carl Wilhelm Scheele was born in Stralsund, then part of Sweden, now Germany, and was one of a number of eminent scientists whose work predicted and laid the foundations for photography. His research in 1777 into the blackening effect of light on silver salts confirmed the earlier findings of Johann Heinrich Schultze, and progressed scientific understanding of what would become photographic chemistry.

Scheele's significant discovery was that the blackening effect of light on silver chloride—he had isolated and identified the element chlorine in 1774—was due to chemical reduction, and that the result of that reduction was black silver metal. His recognition that silver chloride blackened more quickly when exposed to light at the blue and violet end of the spectrum was a significant contribution toward understanding that spectral sensitivity.

In so doing, he coined the expression 'chemical rays' to denote those wavelengths of light which has actinic properties.

That ammonia dissolved silver chloride was already known to chemists, but Scheele's application of that knowledge to remove the silver chloride which had not been affected by exposure to light predicted the 'fixing' process upon which permanent photography would later depend.

He is credited with the identification of citric, malic, oxalic and gallic acids—the last also a key chemical in early photography—and was the first to recognise that air is predominantly made up of two gases, oxygen and nitrogen.

JOHN HANNAVY

SCHLAGINTWEIT, HERMANN (1826–1882); ADOLPH (1829–1857) AND ROBERT (1833–1885)

German explorers and scholars

The five Schlagintweit brothers—Hermann, Adolph, Eduard (1831–1866), wrote an account of the Spanish expedition to Morocco in 1859–60, Robert and Emil (1835–1904), and specialized in Tibetan studies—also worked in Europe and Asia. Hermann's first scientific mission, in association with his brother Adolph, was conducted in the Alps between 1846 and 1848. Subse-

quent expeditions in the same region, in which Robert took part, confirmed their reputation as scientific explorers. In 1854, the East India Company commissioned the three brothers to pursue a magnetic survey of India on the death of surveyor Charles Elliot. During 1854–57, they traveled throughout the Deccan and the Himalayas, and at some occasions, beyond the frontiers of the Company's territories. Hermann and Robert were the first Europeans to cross the Kunlun Mountains in China, for which Hermann received the title *Sakünlünski*. During these travels, Robert took a number of ethnographical and topographical photographs. Upon their return in Europe in 1857, the two brothers published *Results of a Scientific Mission to India and High Asia* (4 volumes, 1860–66). Adolph pursued his research in Central Asia and was put to death by the Amir of Kashgar on 26 August 1857. Hermann settled in Jägesburg and devoted himself to writing. Robert was appointed professor of geography at Giessen in 1863 and traveled widely to America between 1867 and 1870, where he lectured and traveled along the Pacific coast, publishing his research between 1870 and 1876.

STEPHANIE ROY

SCHNAUSS, JULIUS KARL (1827–1895)

German photographer, photo-chemist, and photographic writer

Julius Karl Schnauss was born in Weimar on 7 July 1827 to the court advocate Carl August Constantin Schnauss. Being deaf since his childhood he primarily received a private education. From 1847 to 1849 Schnauss studied physics and chemistry at the University of Jena but experimented mainly in his own laboratory. After gaining his doctorate in chemistry, Schnauss began photographing, opening a portrait studio in Jena in 1852. In the same city, he founded one of the first photographic schools in Germany, the *Photographisch-Chemische Institut* in 1855 where he taught photo-chemistry and practical photography and also sold photographic equipment. Schnauss also tried to establish photography as a discipline at the local university, but without success. In 1858 he was co-founder of the Allgemeiner Deutscher Photographen-Verein [General German Photographers' Association]; in conjunction with this initiative he became editor of the professional journal *Photographisches Archiv* [*Photographic Archive*], together with one of his pupils, Paul Eduard Liesegang. Schnauss closed his school and the studio in the midst 1860s, concentrating on his career as a writer. He published a number of popular manuals and treatises and regularly in photographic and chemical journals. Schnauss also made important contributions to photo-chemistry. He died in Jena on 6 December 1895.

STEFANIE KLAMM

SCHNEIDER, TRUTPERT (1804–1988), HEINRICH (1835–1900), AND WILHELM (1839–1921)

German daguerreotypists

Trutpert Schneider was born 13 March 1804 in Bollschweil (then Bollschweil-Kukucksbad) . Like his namesake, St. Trudpert, the seventh-century Catholic missionary who settled in Baden, he called the scenic and multi-lingual area around Freiburg his home. He was trained to be a cabinet maker by his father Mattäus Schneider, and in 1831, married Regina Locherer and established his workshop in her parents' house in Ehrenstetten. Schneider's fine woodwork and elaborate designs won him an excellent reputation and and a loyal circle of customers including the local landed gentry as well as wealthy residents of the city.

Early in 1847, an itinerate daguerreotypist named Joseph Broglie arrived in Freiburg, having lost his plate holders in transit. He was sent to Trutpert Schneider who fashioned the replacement holders to Broglie's exacting specifications. Broglie, in thanks, made a daguerreotype of the family Schneider: Trutpert, his wife Regina, and three sons, Karl (b. 22 December, 1833), Heinrich (b. 9 October 1835), and Wilhelm (b. 10 October 1839). Trutpert Schneider was instantly captivated by the daguerreotype process and assisted Broglie for a very short time, learning the methods of polishing, fuming, exposing, and developing daguerreotypes. He sketched the dimensions of the camera, the fuming and developing boxes, and all that was necessary to construct his own daguerreotype apparatus. Plying his new trade among his enthusiastic customers, Schneider began his career as a daguerreotypist, offering not only photographs, but boxes adorned with daguerreotypes.

Rather than setting up a studio, Schneider decided to follow the model of an itinerate photographer. Unlike most itinerate photographers, however, Schneider and later his sons Heinrich and Wilhelm travelled from one lucrative city location to another, stopping in the country only to photograph estates and castles, usually by invitation. By 1848, Trutpert and his middle son, the 13 year old Heinrich, had embarked on perhaps their first daguerreotyping tour. It followed a path which they would often take, through Donaueschingen, Heiligenberg and Karlsruhe. Although many of the daguerreotypes made by Schneider and his sons have been dispersed or lost, it is apparent that even in this very early stage, they were much in demand. Trutpert himself and both his sons Heinrich and Wilhelm spoke German, English, Italian, and French, and could accomodate not only tourists, but travel and work easily to the North, South, East, or West.

These small tours continued for several years, during which Trutpert Schneider refined his technique

and began to make stereo daguerreotypes, filling the demand for photographs in three dimensions. It was one of several distinctive characteristics of the Schneiders' photography that they not only made such a large quantity of stereo daguerreotypes, but that they appear to have refused to make any 'studies,' the usual title for nude and often pornographic stereo daguerreotypes. Having begun to daguerreotype at the height of the industry, Trutpert Schneider and his sons adhered to their successful medium, only occasionally making Ambrotypes, and much later, learning the wet plate and dry plate processes. Their lack of novel innovation does not appear to have injured their business or slowed the demand for their photographs.

In 1852, Trutpert and Heinrich Schneider began a much longer tour, on foot, through Switzerland, and over the mountains to the region of Lombardy, which was under Austrian control at the time. It was here that the Schneiders first met the Prince Karl von Baden, whose acquaintence would aid their later work in Russia. The sitting calendar shows that father and son travelled and photographed in Como, Brescia, Verona, Venice and Vicenza. They kept a tight schedule, moving from one place to another, but still there were times when no appointments were made, and to fill the time and his purse, Trutpert offered instruction in his own method of penmanship. In 1854, they were again on the road, this time to Vienna, where they remained a year. This pattern of travel was followed by the brothers Wilhelm and Heinrich when they succeeded their father in the business.

It may have been as late as 1856 that Wilhelm first joined his brother and father in photography. The Atelier of T. Schneider & Sons was firmly established from the year 1858 onwards, when the Schneider brothers kept an orderly record of their portrait sittings. Trutpert, who would live to very advanced age, continued actively in the partnership but more and more remained at home in Ehrenstetten while Wilhelm and Heinrich widened their circles of travel and their fame. They would establish themselves in a city for a certain time, taking rooms that would be made into a temporary and often luxurious studio, and photograph until it was time to move on to the next city. In this way, they daguerreotyped in Cologne, Frankfurt, Bonn, Hamburg and Berlin.

It was in Berlin in 1859, that Wilhelm and Heinrich plied their daguerreotyping skills to great effect, achieving a level of fame that was previously unknown to them. They photographed notables from His Majesty the Prince Regent (preparing and developing the plates in his highness's bedchamber, much to the titillation of the press) to the Lord and Lady Bloomfield. They would return to Berlin several times, documenting not only the wealthy and famous people, but the architecture as well—of which beautiful examples exist in stereo. After their success in Berlin, the Schneider brothers never wanted for work, and indeed they earned enormous sums of money in each city they worked.

In late May 1861, the brothers arrived for their first daguerreotyping tour of Russia. St. Petersburg, still in the grip of winter, was only a short layover before they continued on to Moscow. In Moscow, they were treated like visiting dignitaries, allowed access to the royals, given transportation and an escort, and housed in the Kremlin. On this first visit, the brothers remained less than a month, returning to St. Petersburg, where they stayed a year. They returned to Moscow again in the summer of 1862, and photographed in Königsberg and northern Prussia on their way back to Berlin, returning home finally in 1863.

Although the brothers continued to travel the length and breadth of Germany for several years, they were thinking of settling back near their hometown. They finally opened a newly built photographic studio near the train station in Krozigen in 1867. Trutpert Schneider lived on until 27 December 1899, long enough to see his sons turn first to wet plate, then to dry plate photography. Wilhelm Schneider outlived Heinrich, who died only six months after their father. But when Wilhelm also died in 1921 the era of T. Schneider & Söhne came to an end.

KELLEY WILDER

Biography

Trutpert Schneider (13 March 1804–27 December 1988), and his two sons Heinrich (9 October 1835–13 May 1900), and Wilhelm (10 October 1839–21 January 1921), from near Freiburg in Breisgau, operated a daguerreotype and photographic studio from 1848–1921. For many of these years it was a travelling studio, not only within Germany, but in the neighboring lands of Austria, Italy, and Russia. They refined the art of the itinerate photographer, however, and created an event of their arrival in each city, often photographing the most famous and wealthy inhabitents. From 1859–1863 the firm enjoyed considerable success, spending a great part of the time in Berlin, Moscow and St. Petersburg. Most distinctively, the Schneider Atelier continued to make daguerreotypes and stereo daguerreotypes long after the invention of the wet plate. The daguerreotypes were often hand colored, and the stereos were famous for their plasticity. In 1867 the brothers opened their first fixed studio in Krozigen, incorporating first the wet plate and later dry plate for their photography.

SCHOTT, FRIEDRICH OTTO (1851–1935)

German glassmaker and chemist

Born in Witten, near Essen, Germany, Schott came from a family of glassmakers. After studying chemistry at Aachen and Wurzburg, he graduated at Leipzig in 1875 with a thesis on 'Defects in the manufacture of Window Glass.' He experimented with new types of glass, using previously unemployed elements such as lithium, boron and phosphorus. In 1879 Schott sent some samples to Ernst Abbe at the Zeiss factory in Jena. Abbe was so impressed that the pair began to collaborate and, in 1882, Schott moved his laboratory to Jena in order to continue his experiments. In 1884, Schott set up the Schott and Genossen glass factory with Abbe, Carl Zeiss and Roderich Zeiss. This glassworks specialised in new forms of optical glass, many of which were previously unknown. Their first catalogue, published in 1886, listed no fewer than forty-four different types of glass. In 1889, along with Abbe, Schott formed the Carl Zeiss Foundation. He succeeded Abbe as the foundation's manager, a post he held until 1927.

Colin Harding

SCHRANK, LUDWIG (1828–1905)

Ludwig Schrank was born on August 24th, 1828 in Vienna. He studied chemistry, physics, mineralogy and geology at the technical university and was in the service of the "K.K. Bergwerksprodukten Verschleiß-Direktion." Until his retirement he remained busy in government service. His interest in electroplating led him to photography. In 1854 he established a studio, in which he worked part time as a portrait photographer. After the doors of his first studio were closed, he established another studio in1868 with Franz Xaver Massak, which was successful from 1870 to 1873. In 1861 Schrank was one of the first establishing fathers of the "Photographische Gesellschaft" Austrias first photographic association. In 1864 he and photographic dealer Oskar Kramer, established the "Photographische Correspondenz." This magazine was appointed the organ of the "Photographische Gesellschaft" a while later. Schrank remained the publisher and editor of the magazine, imtermittendly during the years 1870 to 1885 up to his death. By the mid 1870s, Schrank ended his very active career as a photographer, however, he continuted his publishing and editorial activity for decades. Beside numerous articles in domestic and foreign technical periodicals on topics such as practical and aesthetic topics, he also wrote a practical manual for photographers and a publication discussing copyright in photography. Schrank died on May 20th, 1905, in Vienna.

Astrid Lechner

SCHULTZE, JOHANN HEINRICH (1687–1744)

German chemist

Johann Heinrich Schultze, born in Colbitz, Magdeburg, was a German chemist and polymath, a Professor of Chemistry and Anatomy—and later also Greek and Arabic—at the University of Altdorf near Nuremberg. He was also one of a number of eminent chemists whose work predicted and laid the foundations for photography.

While engaged in chemical experiments in 1725 seeking to produce phosphorus, Schultze discovered that chalk—which by chance also contained traces of silver—impregnated with nitric acid, turned dark under the action of sunlight. Further investigations confirmed that it was silver nitrate—produced by a reaction between the acid and the silver—which had had that effect, and his continued experiments resulted in the creation of impermanent photograms of stencils, letters and other objects laid on the chalk.

His significant discovery was that it was light rather than heat which was creating this effect—a point picked up by his 1907 biographer Josef Maria Eder, who, with an almost apostolic zeal, declared him the true 'inventor of photography.' While Schultze recognised the purely scientific importance of his discovery and communicated his findings to the Imperial Academy at Nuremberg, he did not, however, recognise its future as the basis of an imaging system. That step would be made almost three quarters of a century later by, amongst others, Thomas Wedgwood.

Schultze died in Halle in 1744.

John Hannavy

SCIENCE

Towards the science of photography

Until the advent of today's digital age, the science of photography has predominantly been concerned with harnessing, exploiting, and controlling the effect of light upon silver salts. The science of photography, as it emerged throughout the nineteenth century, was concerned with expanding the understanding of both the physics of light and optics, and the chemistry of sensitive materials and their processing, maximizing the effect of light upon those salts. That photographic materials progressed, by 1900, from experimentation by enthusiastic individuals to mass production my multinational companies, underlines both the importance of the medium, and its commercial value. It also stands as a testament to the commitment of the early pioneers to share information, exchange ideas, and offer innovative suggestions to move scientific understanding forward.

For practical photography's first four decades, the picture-maker was also manufacturer and chemist, seeking to produce photographs using homespun chemistry which by its lack of consistency, introduced an almost infinite range of variables. Yet in so doing, the great photographers of the mid-Victorian era overcame major difficulties, and applied their limited technical and chemical understanding to the production some of the medium's most beautiful and enduring images.

In seconding the motion "That a Society now be established to be called 'The Photographic Society'" at the Photograph Society of London's inaugural meeting on 20th January 1853, Robert Hunt accurately summarized the importance of a forum for the exchange of scientific knowledge in the development of photography. His comments were reproduced in the first issue of the *Journal of the Photographic Society*:

> Mr Hunt, in seconding the motion, dwelt at some length on the importance and even the necessity of a Society to ensure the future progress of photography. He considered such an Association of practical men would be the best and most efficient mode of publishing and comparing the results of their numerous mutual trials, and pave the way for new discoveries. However rapid and satisfactory may have been the improvements in this science, much yet remained to be done. Reference was made to several phenomena, hitherto unexplained and still obscure, attendant on the results of photographic operations; for instance, it is known that the prepared paper is not acted upon by the yellow rays, while these rays do act upon glass prepared with collodion.

Hunt's account, while correctly identifying that the science of photography was, as yet, in its infancy, underlined that lack of understanding by incorrectly suggesting that the wet collodion plate had some sensitivity to yellow. Yellow sensitivity would, in fact, not be achieved until the early years of the 20th century when the introduction of dye sensitizers finally made a truly panchromatic emulsion possible. What Hunt was probably observing was limited green sensitivity manifesting itself as fogging under an imperfect yellow glass in the darkroom.

If the experiments of Thomas Wedgwood between 1795 and 1802 are taken as a starting point, photography, at the time Hunt was writing, was already more than half a century old—yet an understanding of the underpinning science was only in the very earliest stage of emergence. Wedgwood's inability to fix his pioneering images is often cited as an early example of poor photographic research—given that the ability of a range of chemicals to arrest the darkening effect of sunlight on silver salts had been identified by Carl Wilhelm Scheele and others much earlier. So, from photography's earliest days, an organized dissemination of relevant scientific knowledge would have been beneficial.

Robert Hunt was, himself, one of the leading figures in the advancement of the science of photography. His *Popular Treatise on the Art of Photography* had first been published in 1841, and he had completed work on the third edition of his *Manual of Photography*, first published in 1851, by the time of the Photographic Society's inaugural meeting.

The early years of photography were punctuated by a number of radically different approaches—independent inventors pursuing their shared goal by seeking to exploit fundamentally different chemistries.

Wedgwood and Davy opened the century with their experiments—reported in June 1802 in the *Journal of the Royal Institution* and later recounted by Henry Snelling in his groundbreaking 1849 book, *The History and Practice of the Art of Photography* (New York: G.P.Putnam, reprinted New York: Morgan & Morgan 1970).

> A piece of paper, or other convenient material, was placed upon a frame and sponged over with a solution of nitrate of silver; it was then placed behind a painting on glass and the light traversing the painting produced a kind of copy upon the prepared paper, those parts in which the rays were least intercepted being of the darkest hues. Here, however, terminated the experiment; for although both Mr. Wedgwood and Sir Humphrey Davey (sic!) experimented carefully, for the purpose of endeavoring to fix the drawings thus obtained, yet the object could not be accomplished, and the whole ended in failure.

While that report mentions that Wedgwood and Davy experimented with several different materials on which to brush their chemistry, only paper is specifically cited. Their other experimental surfaces included leather, and they noted that

> White paper, or white leather, moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but, on being exposed to the day light, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black …

and indeed their experiments proved markedly more effective with leather than with paper, due in part to chemicals contained within the tanned leather about which they knew nothing at the time. It would be a further thirty years before William Henry Fox Talbot demonstrated the practical application of their ideas, by recognizing the initial production of a 'negative proof' from which a 'positive proof' could be made by contact.

In 1816, Joseph Nicéphore Niépce, experimenting with silver chloride, got no further than had Wedgwood and Davy, again due to an inability to arrest the darkening effect of light. He too got within touching distance of producing the first photographic negative. Silver nitrate—the chemical Niépce abandoned—would later play a crucial role in the evolution of photographic materials. A decade later he turned his attention to a range of

chemicals which were physically hardened by the action of light and so, eschewing silver salts about which so much was already known in favour of bitumen of Judea, coated on to a sheet of glass, hardened by long exposure to light, and the unhardened areas then dissolved with oil of lavender. By 1826 he had moved to a pewter base and had announced his findings and produced what survives as the world's oldest photographic image.

By 1828 he had migrated from pewter to the silvered copper plate which would later become the base of the daguerreotype, and had returned to exploring the effect of light on silver salts—in this case silver iodide. Niepce's process, however, used iodine to darken the areas of silver where the bitumen had not been hardened by the action of light.

The daguerreotype evolved directly from the collaboration between Niépce and Daguerre, and after Niépce's death in 1833, between Daguerre and Isidore Niépce. Since Isidore's first attempts in 1840, many in the history of photography have sought to clarify the importance of Joseph Nicéphore Niépce's role in the evolution of the process which would help make photographic portraiture ubiquitous.

While the daguerreotype bears the Frenchman's name, the process which achieved such worldwide popularity progressed well beyond its inventor's achievements. The science of the daguerreotype was advanced significantly by many practitioners and scientists. Experiments by Antoine Claudet, for example, increased the sensitivity of the plate considerably, while arguably the most significant advance was John Frederick Goddard's discovery of the accelerating effect of employing bromine—reducing exposures for portraiture from the impractical to the practical. Despite the significance of his discovery, Goddard did not profit from his scientific breakthrough, and unlike Daguerre who received a French government pension, Goddard lapsed into poverty, saved only by a public appeal—promoted by John Werge and Jabez Hughes—which raised enough money to sustain him into old age.

In the 1840s, scientific innovation had no commercial value without the protection of a patent, and Goddard had not sought such protection, although arguably it was his innovation which ensured the daguerreotype's long popularity.

In a series of parallel developments,Talbot's experiments had taken him first to photogenic drawing and then to the calotype, establishing the negative/positive process as the ideal foundation for the development of photography as a low-cost and easily duplicated medium. Talbot's chemistry was simple, but by the early 1850s, albumen-on-glass, waxed paper and wet collodion had all brought both new refinement to the production of the negative, and a widening range of chemicals being used.

There was often little understanding of the role of each additional chemical—just a belief that adding them improved the reliability of the negative medium, and the consistency of the results.

Thus, in the first issue of the *Journal of the Photographic Society* for 1854, Washington Teasdale from Leeds published a comparison chart showing the differences and similarities between eight different versions of le Gray's Waxed paper process. The chart demonstrated the huge variations between the strengths of the chemicals employed by the process's main proponents—including Vicomte Vigier, Sir William Crookes, Roger Fenton, and le Gray himself. Teasdale's table and accompanying notes showed there was huge variation in the chemical composition and chemical strength of the different versions, the recipes ranging from a single chemical—potassium iodide on its own—in Crookes' version, to eight in Teasdale's, while the iodide in Fenton's published account was three times the strength of le Gray's original formulation. Such variations go a long way towards explaining why some users found le Gray's process unreliable and slow while others found Fenton's to be almost assured of success.

Variations in the chemistry of the waxed paper process was by no means unique. Every process had its advocates and its critics. With Frederick Scott Archer's wet collodion process, there were ultimately almost as many versions as there were users! As long as the manufacturing of the negative material was in the hands of the user, such wide variation in formulae was inevitable, as was the vigorous support each user gave to his 'improvement.'

In addition to claims about the performance of individual chemicals, there was often significant debate over who had prior claim to a particular process. Niépce's claim in France for a share of Daguerre's fame was mirrored in Britain by the Rev J. B. Reade's claim for priority over Talbot in the invention of the paper negative. At the time of Frederick Scott Archer's publication of the wet collodion process, Gustave le Gray, himself the inventor of the waxed paper process, claimed to have proposed—and used—a wet collodion process at least a year before Archer. (Like Goddard, Archer's generosity in seeking no financial reward for his process left him penniless, and after his untimely death in 1857 a fund had to be established to raise money for his widow.) Talbot, for good measure, claimed his patents gave him control over any process in which a negative was created from which prints could be made.

By the mid-1850s, however, photographic science entered a period of calm, with most patents being allowed to lapse, and the photographic community showing increasing altruism in sharing ideas and experience.

Many photographers soon appreciated the need for a measure of consistency in their chemistry, and

initiated self-imposed quality control and testing in their manufacture. In the 1850s, after preparing a new batch of waxed paper negative papers, the British photographer Samuel Smith, of Wisbech, Cambridgeshire, for example, would use the front of his house as a test subject to determine the sensitivity of the new material, and thus the exposure required. Collodion users would go through a similar routine to test the rapidity of each new mix of chemicals.

Despite the primitive chemistry and unsophisticated technology of the day, the quality of surviving imagery from the mid-Victorian period is a testament to the skill of the early photographers, despite the lack of sound scientific underpinning.

However, a widespread lack of understanding of the relationship between the colour temperature of the exposing light source, the spectral sensitivity of the emulsion, the exposure given to the negative, and the processing to which it was subsequently subjected, resulted in a range of visual phenomena in the negatives and resulting prints for which photographers had no ready explanation.

In the absence of simple measuring devices which would aid the estimation of accurate exposure, development was, invariably, continued 'until the image was brought out fully,' however long that might take.

An appreciation of the importance of consistent developer temperature, did not gain widespread acceptance until the end of the century. Despite recognition in the 1860s that the activity of the developer changed with the seasons, no connection was made between that and the importance of temperature consistency. Instead, it was suggested (Towler 1864) that a stronger developer was needed in the winter than in the summer, and that a more acidic developer was preferable in the summer, as the acid slowed the developer action down.

The combination of lower actinic values in winter daylight—causing under-exposure—and cold and under-active developers, resulted in many negatives which required considerably extended development until a printable density was achieved. This introduced increased fog levels, significant loss of shadow detail, and a loss of the subtle tonality which those same photographers could produce in summer.

Perhaps surprisingly, failure to recognize the cause of the problem persisted into the closing years of the century with Wall (1897) noting that 'speaking very generally, it may perhaps be estimated that development takes about twice as long in winter as in summer." Wall did, however, observe correctly that "under-exposure should always be avoided, as with these plates or films a considerable amount of over-exposure can be controlled in development, but if the light has not acted sufficiently on the plate no process of development can possibly make a good negative of it." In Wall's 1897 dictionary, he devoted several pages to 'Thermometers and Thermometry,' but included nothing of their application to photographic processing! The chemical composition of the developer, its strength and its rate of activity were all issues about which individual practitioners held strong views.

In many instances, good science emerged from heated debates between practitioners with opposing points of view, conducted in the meetings of photographic societies and literary and philosophical societies, or in the pages of the emerging photographic press. Often deteriorating into very personal attacks, these very public spats helped to progress scientific understanding, with the protagonists returning to their experiments to test and re-test their theories. The gentleman scientist—the enthusiastic amateur—seemed willing to endure the opprobrium of his peers in the cause of defending his point of view. There was little tangible benefit to the protagonists, except by being proved correct, but their perseverance eventually led to significant progress and enhanced understanding.

It was only with the advent of industrialization in the manufacture of photographic materials that good science acquired a commercial value. Once the manufacture of emulsions and materials moved from kitchen-sink to manufactory, consistency and reliability assumed a greater importance.

Amongst the first to produce ready-to-use gelatin-bromide dry plates were Wratten & Wainwright in London. Along with several other manufacturers, their 'repaid' dry plates went on sale in the late 1870s, and were initially met with 'scepticism and conservatism by the most eminent photographers' used to preparing their own materials from start to finish (Werge 1890). Initial reluctance, on the part of photographers, to abdicate their responsibility for emulsion preparation and coating to industrial concerns, was only overcome when those emerging manufacturers could demonstrate that their products offered benefits which the homemade preparations could not. Those benefits—initially more promised than actual—only really came to be understood and appreciated once the many chemical and physical components of photography were recognized as a single system rather than a number of disparate and unrelated elements.

Key to persuading professional users of the benefits of pre-coated plates was the introduction of scientific control over emulsion preparation, and the design of coating machines to ensure batch-to-batch consistency. Manufacturers such as Cadett & Neal, Marion & Company, and others, quickly recognized the commercial value of emphasizing the high quality of their materials and the consistency of results which their careful use brought to the user.

In working towards an understanding of the holistic

nature of the photographic process, the pioneering work of Ferdinand Hurter and Vero C. Driffield in England was pivotal. Their work on the relationship between development rate and temperature led them to recommend that 65ºF be adopted as the optimum standard, thus removing, at a stroke, the idea that development time should be extended in cold weather. Intriguingly, their recommendation was published in the journal *Photography* in 1893, four years before Wall's *Dictionary of Photography* perpetuated the idea of doubling time in winter!

But Hurter and Driffield's most significant and enduring contribution was the recognition that photography needed to be considered as a *system* where each component and each action was interdependent—that a deviation in any one aspect had an impact on the character of the final negative. While their proposal was not widely accepted or understood at the time, the various suggestions they made about standardisation, consistency, accuracy and repeatability established the foundation not only for the science of sensitometry, but also for a much wider appreciation of the physical and chemical inter-relationships upon which photography depends.

Their H&D speed system, based on the placing of the full tonal range of the subject on the straight line portion of the *characteristic curve*, came at the same time as a range of devices for estimating the actinic value of the illuminating light source. Thus, as the century came to a close, improved consistency in plate manufacture, coupled with reasonably accurate estimation of exposure and accurate processing, took photography into a whole new realm of consistency.

A number of actinometers were on the market by the 1890s, most using albumen printing-out-paper, and basing exposure on the time taken for the paper to darken to a pre-determined tone. The importance of such instruments as Green and Fuidge's Actinometer, Wynne's Exposure Meter, Watkins' Exposure Meter, and similar devices by Reid, Stanley, and Watt, cannot be underestimated—despite the fact that they used a blue-sensitive printing-out-paper to estimate the exposure required for orthochromatic emulsions—a problem noted by Werge without explanation.

The introduction of the Kodak camera in the late 1880s marked the birth of modern photography—with, for the first time, the science of manufacture and processing effectively separated from the art of photographic picture-making.

SCIENTIFIC PHOTOGRAPHY

"Magnificent," declared *The Photographic News*, referring to Professor Owen's opening address to the British Association in 1858:

> Photography is now a constant and indispensable servant in certain meteorological records. Applied periodically to living plants, photography supplies the botanist with the easiest and best data for judging of their rate of growth. It gives to the zoologist accurate representations of the most complex of his subjects, and their organisation, even to microscopic details. The engineer at home can ascertain …the most complex works on the Indian or other remote railroads. The physician can register every physiognomic phase accompanying the access, the height, decrease, and passing away of mental disease.

The speaker had been very prescient and within a few years, other writers echoed his words. In 1860, F.F. Statham referred to "the handmaid of the sciences," and four years later, a reviewer described photography as "the child of science," emphasising the freedom from fallibility in observations. Praise continued because of photography's ability to preserve a faithful image. "The sensitive photographic film is the true retina of the scientist," declared the eminent French astronomer, P.J.C. Janssen at a meeting of the Société Française de la Photographie in June 1888. The potential of photography to the scientific disciplines had been present from the beginning. In 1839, William Henry Fox Talbot had anticipated future developments by challenging his "photogenic drawing" to capture the image within his solar microscope. Many other investigators soon exploited the advantages of photography, and their research benefited from sharing reliable results with other practitioners.

In France, the daguerreotype process was also used with the microscope and, in spite of the lack of rapidity in the plate, Alfred Donné obtained satisfactory images

for demonstration to the Academy of Sciences in 1840. His philosophy was summarised: "… we shall let Nature reproduce herself … with all her details and infinite nuances." The poor response of his plate to daylight, however, prompted him to develop alternative lighting forms, and he successfully adapted the oxy-hydrogen torch as a light source for his microscope. By 1845, Donné and Léon Foucault had published an illustrated atlas of histological photomicrographs intended for teaching—"it is so to speak the object itself which will be placed before the eyes and in the hands of the audience."

There was no formalised programme for developing photography as a tool of the sciences. Whilst others accepted photography as an art form, the scientific practitioners welcomed photography as an aid to their work, and used it in different ways. Some realised that emulsion sensitivity extended beyond the boundaries of human vision and that it was possible, for example, to probe the night sky and secure ocular proof of their observations. At times, it was possible to dispense with lenses and optics, but instead, to build equipment designed to "write" direct to sensitive plates. At an early stage, analyses of solar and other spectra benefited by having images for comparison with other versions.

Practitioners in medicine, natural history and crime recognised the potential for creating standardised records, records that provided an image, which was adequate to serve as the original. Botanists were prompt to recognise the advantages over drawing, and when Anna Atkins made cyanotypes in 1843, she overcame difficulties "in the interest of the botanical value." Robert Hunt declared, "Specimens may be copied with a fidelity which cannot by any other means be obtained." At Surrey County Asylum Hugh W Diamond believed photographic evidence of his suffering patients would contribute to improvements in treatment. Staff at London Zoological Gardens undertook to compile a catalogue of "type specimens" from the animals in their collection and in 1871, unwittingly created a photograph of the last surviving quagga. Police services recognised the merits of "the rogues gallery" when a police sergeant from Bristol was able to identify "a hardened offender" in Birmingham.

Other disciplines of a scientific nature also annexed photographic techniques for recording aspects of their pioneering work. Liberated from free-hand drawing, archaeologists utilised photographic prints in lectures, in exhibitions and in publications. Space saving was welcomed by travellers. Prior to the use of photography, expeditions had relied on casting plaster images of the faces of native tribes. Photographic prints would serve ethnology just as well, stated *The Photographic News*. On any Arctic voyage, space was at a premium, but the merits of securing permanent records of the explorations were seldom overlooked, in spite of the hardships to be endured by the photographic officer, who was obligated to work in difficult conditions.

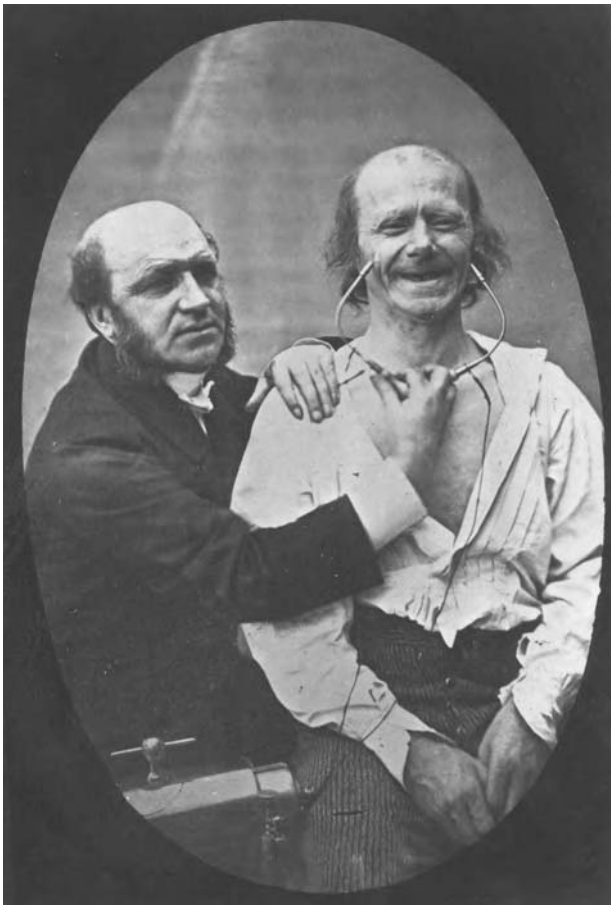
In astronomy, photographic recording became such an asset, that many of the astronomers made important contributions to photographic science. Janssen advised on good laboratory practice for photographing with the telescope, and valued photography—"[it] gives us today images of the sun in such perfection that they permit us to employ them in work of the greatest precision." For twenty years, he had cherished a belief that "a photograph … offers for purposes of measurement and examination such previous details that they surpass in value the observations of the most skilful astronomer."

At the observatory in Bonn in 1894, the first assistant, Dr. Julius Scheiner, devised a sensitometer for establishing reliable plate speeds for his photographic exposures, which subsequently evolved as the Scheiner speed system. Regular adjustments to equipment and techniques sometimes revealed the need for improvements to sensitised materials. For example, in 1884, Josef Marie Eder proposed a formula for orthochromatic plates, colour-corrected to improve rendition of yellow-greens. Early in the twentieth century, further improvements delivered the panchromatic emulsion.

The single astronomical record was valuable, but photography was a tool that could be applied to a constructive purpose. In 1882, some observers agreed to document stellar positions, but by 1891, eighteen worldwide observatories were working in co-operation to assemble a comprehensive dossier of the night sky. Such was the authority of the assemblage that the undertaking was not repeated until 1949. Similarly, in medicine, the compilation of an "atlas" of conditions often provided confidence to diagnostic procedures.

The applications of photography multiplied for two reasons. It provided results in a permanent form, and some techniques could be adapted to reveal data that were otherwise undetectable. Talbot's use of the solar microscope in 1839 had been successful, but within three years, he was demonstrating polarising microscopy, and showing its potential for crystallographic studies. In combining his enthusiasm for pictorial photography with his studies in crystallography (1853), Sir William Crookes admitted his motive had been to "retain in a more tangible form the well-known beautiful figures observed…" (That is, the distinctive ring structures that permitted identification of crystals.) However, Crookes' results provided a welcome surprise; his photographic plate revealed more than four times what he had expected from his visual observations, which, in turn, initiated further enquiries within the scientific community, and the evolution of standardised techniques.

The possibility of recording beyond the limits of the human eye was considered possible. Sir John Herschel had succeeded in identifying infrared radiation



Duchenne, Guillaume-Benjamin. Mechanisme de la Physionomie Humaine ou Analyse Electro-Physiologique de *l'Expression des Passions.*
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

by observing temperature change, and he forecast the likelihood of detecting energy in the "lavender" region of the spectrum (i.e., ultra violet radiation.). When the ultra violet spectrum was eventually recorded in 1864, it was the precursor for twentieth-century studies in atomic structure … and later, in 1935, ultra violet radiation was supplanted by the electron beam and a new style of microscopy evolved.

In 1851, Talbot demonstrated "an instantaneous photogenic image" to the members of the Royal Institution by exposing a page of *The Times* (which was fastened to a rotating drum) to the light from an electric spark. The relationship between photography and time now developed in different ways. High-speed photography had its derivation in the pistol camera of Thomas Skaife who made modifications that allowed him to capture what he termed the "epochs of time, inappreciable to our natural unaided organ of vision …"

Advances to the dry plate fulfilled the specification for recording shock waves. In 1888, Ernst Mach adapted August Töpler's schlieren layout and succeeded in preserving the distinctive patterns of currents that surrounded a bullet in flight. In 1893, CV Boys was engaged in studies intended to demonstrate the effects of a projectile (bullets) striking different materials, such as glass and metal. Photography was now providing a range of ideas on which to base experiments, to record sequences, and to compare results, all with certainty and confidence.

Photography offered other ways of capturing time. Experiments, which preceded the development of cinematography, exploited the ability to capture movement, and Eadweard Muybridge used photography when he set up a series of cameras in 1872 to study the motion of a horse. Success encouraged him to reduce exposure times and thus eliminate blur, by improving his chemistry and equipment. By 1878, he had secured sequences of horses walking, trotting, and galloping, men running and leaping, women dancing, doves in flight, water splashing and sufficient experience to synthesise his multiple images into an apparent single moving picture.

In France, Etienne Jules Marey, a physiologist, improved the idea and designed cameras for recording sequences on a single plate. His "chronophotography" was applied to many motion studies—locomotion, aerodynamics, vibration, blood circulation and heartbeats. When the Englishmen, William Frieze Greene, modified a magic lantern around 1886, he introduced a rotating shutter and four lenses to capture images, which gave the impression of movement.

Subsequent improvements to emulsions, to lighting and to timing equipment provided the basis of scientific techniques that continued into the heart of the next century, but some nineteenth-century investigators struck out in a different direction. They had realised the merits of using sensitised photographic material as a "self-recording" method, which would automatically indicate changes to the quality of light and other phenomena. Captain William de Wiveleslie Abney equipped a "sunshine recorder" with a discrete hole through which sunlight smeared its image on slowly-moving piece sensitive paper. To analyse the quality of daylight, Vero Charles Driffield modified the actinometer patented by his colleague, Dr. Ferdinand Hurter, and collected "daily diagrams of light" for twelve months during 1885 and 1886. From the mass of data, now accumulated on bromide paper, the two men designed the Actinograph exposure calculator.

Anxious to explore the solar spectrum (and improve the characteristics of dry plates for solar photography), Abney registered evidence of infrared radiation by directing sunshine, *via* the spectroscope, onto his photographic plate (1880). He had been confident "there are some faint rays which lie below the limit of the red." Eventually (1930), special plates were sensitised for infrared photography.

The x-ray, possessing unusual properties but detectable on conventional plates, was discovered by Wilhelm Röntgen in 1895. Working with a luminescent screen and a cathode ray tube, the hitherto unrecognised rays revealed themselves "by making darkness visible," when Röntgen placed his hand in the ray's path and revealed the internal bone structure. X-ray techniques opened the way to non-invasive probing of the soft tissues of the human body, teeth, fractured limbs, Egyptian mummies, precious stones, machinery and metal castings. The applications in medicine alone prompted *The Lancet* (1896) to describe the technique as "the searchlight of photography." It was seen as "photography of the invisible." Relishing the chance to photograph the invisible, Josef Maria Eder teamed up with Eduard Valenta in 1896 to produce a series of radiographic studies, that were acclaimed for their artistic content as much as the scientific disclosures.

Once the value of x-radiography was accepted, progress was swift. Exposures of quarter an hour were reduced to a few minutes and the nineteenth-century pioneering efforts contributed substantially to the twentieth-century techniques of ultra-sound, pulse echo recording, and tomography based on positron emission. Radiotracers were employed on cadavers in 1896 but by 1927, the technique of angiography had become an *in vivo* procedure. The first autoradiograph emerged in 1904, and in 1912, x-rays were used to produce diffraction patterns of crystals.

Not all the applications of photography were successful and many ideas for taking advantage of photography either failed to materialise, or did not fulfil the requirement. In a review of progress in 1888, Dr. C.H. Bothamley deplored the lack of "scientific method." His thesis was that few people had the ability to plan satisfactory experiments, and some research failed to establish "the existence of a given set of phenomena." In his opinion, investigators sometimes drew incorrect conclusions from their data, and Bothamley criticised results that did not distinguish between "that which is actually established and that which is only rendered probable or possible." His remedy was "systematic and somewhat severe training."

He recommended the photographic literature of the day, and accepted "progress must necessarily be slow until a better knowledge of the art of experiment … become more widely diffused…." The journals fulfilled their responsibility by publishing papers from the universities, academies and institutes in Europe and America. Just as important were the abstracts and reprinted texts from overseas journals, such as *La Nature* (France), the *Bulletin de la Société Françoise de Photographie, the American Journal of Photography,* and the *Philadelphia Photographer* (USA). *The Photographic News* included regular features from correspondents in Germany and France, and *The British Journal of Photography* maintained a column of continental notes and news.

Photography made satisfactory contributions to nineteenth-century science for three reasons:

- It was welcomed as a means of securing reliable proof that had a degree of permanence and could be distributed among colleagues
- It documented phenomena and scientific events in ways that replaced the need for human observations
- It could be allied to existing optical equipment, and could be incorporated in the design of new apparatus.

In making use of photography for constructive purposes, progress was never in doubt and a secure nineteenth-century foundation provided confidence for twentieth-century investigators, who then achieved advances as new materials, methods and techniques were introduced.

SCOVILL & ADAMS

Photographic apparatus and supply firm

Scovill & Adams, a photographic apparatus and supply firm, succeeded the photographic division of the Scovill Manufacturing Company in 1889 with Washington Irving Adams (1832–1896) serving as President, Treasurer, and Secretary. The firm, which evolved from a company with a diverse history, originated as a gristmill on the Mad River in Waterbury, Connecticut in 1680. The mill, converted in the early 19th century to the gilt and brass button manufactory of Abel Porter & Co., was purchased by James Mitchell Lamson

Scovill (1789–1857), Frederick Leavenworth, and David Hayden in 1811. In 1827, Hayden and Leavenworth retired and James's younger brother, merchant William Henry Scovill (1796–1854), purchased the men's interest in what had become one of the two most prominent button factories in the country. Under the brothers' leadership, the firm, renamed J.M.L. & W. H. Scovill, grew in success and divisions, including an expanding auxiliary business of rolled brass and plated metal.

In 1842, J.M.L and W.H. Scovill became the first and largest manufacturer of daguerreotype plates in the United States after perfecting a plate that was flat and of a better quality than the popular French imports. According to the company papers at Harvard University, the company supplied such prominent daguerreians as Samuel Broadbent, Jeremiah Gurney, and A. Southworth & Co. To remain competitive over the next decade, the company expanded their photographic products line to include gilded metal mats, preservers, and cases. The New York City salesroom established in 1846 made over $60,000 a year in sales on mats and preservers alone. By 1851, the firm was advertised as a dealer of daguerreotype materials and promoted such novelties as a folding case for family portraiture and a case for sepulchral daguerreotypes.

In 1850, all the company interests, including the photographic division, were incorporated under the Scovill Manufacturing Company, which continued to grow in market outlets, production plants, and profits. In 1851, company agent Samuel Holmes established Western markets as far away as California. In 1857, the firm bought the factory of S. Peck & Co. in New Haven, Connecticut, which produced plastic photograph cases and camera parts, and in 1867 acquired the American Optical Co., a manufacturer of cameras and other photographic apparatus in New York. By 1873, company growth had led to the establishment of a branch of the photographic division in Birmingham, England and the completion of a new warehouse in New York City at 419–421 Broome Street containing offices, salesrooms, storage, and a darkroom for customers. By 1874, the profits of the photography division totaled over $1,000,000.

In 1868, Frederick J. Kingsbury accepted control of the company following the deaths of the Scovill brothers and the retirement of Scovill Buckingham, the Scovills'nephew. Under Kingsbury's administration, the photographic division of the firm prospered through the ingenuity of company upstart Washington Irving Adams. Adams, a former daguerreotypist, entered the employ of the Scovill Manufacturing Company as an entry clerk in 1858 and quickly acquired increasingly influential roles and responsibilities. Between 1870 and 1871 Adams assumed the leadership of the American Optical Co. and founded the company periodical, *Photographic Times*. In 1875, Adams became president of the S. Peck & Co. and in 1878 became the company agent in charge of the New York business. Adams also served as the first Vice-President of the Centennial Photographic Company and was a Chairman of the Executive Committee of the National Photographic Association.

Throughout the 1870s and 1880s, under Adams's guidance during the peak of a rivalry with E. & H.T. Anthony & Co., Scovill's interest in the photographic market diversified even further. In the early 1870s, prolific advertisements in the company periodical and the *Philadelphia Photographer* promoted apparatus and materials for every aspect of photography, including tripods, lanterns, developers, rollers, trays, negative frames, and studio props. The company also introduced the Scovill Photographic Series of training manuals. With the introduction of a multiplying camera in 1878, Scovill became synonymous with cameras as well. The company's cornering of the market in competition with Anthony & Co. progressed even further when around 1881 Scovill became the sole distributor of Carbutt dry plates, a move that signaled Adams's business savvy in anticipating the growing amateur market. Consequently, in 1882 the Scovill Manufacturing Company began advertising cheap amateur outfits that included camera, dry plate holder, tripod, and lens. In 1885, the Waterbury view camera was introduced as a part of the profusely advertised outfits and quickly became an American classic. During this time, the company also displayed its photographic equipment at several exhibits, including annual exhibitions of the National Photographic Association and the Photographic Association of America as well as the Centennial Exhibition of 1876, where the company received an award for photographic apparatus.

Given the success of the photographic department and following George Eastman's 1887 rejection of a Scovill offer to consolidate photographic businesses, Scovill Manufacturing Co., opted to form an independent firm, Scovill & Adams, which manufactured, sold, and acted as agents for photographic equipment and supplies. With the creation of the new firm in 1889, Scovill & Adams became a leading innovator in camera design and earned several patents related to camera construction. Between 1891 and 1898, the company introduced the Henry Clay folding camera, one of the first self-casing, folding bellows cameras; the Solograph folding plate camera; a spy camera; and a panoramic camera equipped with a swinging lens. The new firm continued to publish the *Photographic Times* and the renamed Scovill & Adams Photographic Series of training manuals. It also remained a leading supplier of photographic equipment and apparatus nationally and internationally, including Central and South America.

Adams ran Scovill & Adams until his death in 1896, whereupon his son Washington Irving Lincoln Adams, editor of *Photographic Times*, assumed operation of the company. Under the younger Adams, the firm entered into the manufacturing of roll film in 1899.

On December 23, 1901, Scovill & Adams and their main competitor of fifty years, E. &H.T. Anthony & Co., merged and formed Scovill & Anthony with a joint capital stock worth $2,500,000. In 1902, the firm relocated principal operations to Binghamton, New York, and, in 1907, changed its name to Ansco. In 1928, Ansco merged with the film company Agfa, and the new company focused on the manufacture of film. In 1939, General Aniline & Film Corp, known as GAF, merged with Agfa-Ansco and the company, later renamed Anitec, continued operation until 1998.

SCOWEN, CHARLES T. (active 1873–1890)

English, photographer and publisher, active in Ceylon

Charles Scowen arrived in Kandy, Ceylon (Sri Lanka) in early 1873. He worked as a clerk for some period of time but by 1876 he had opened a photographic studio. In 1885, the firm which bore his name, Scowen & Co. had studios in Kandy and Colombo. Scowen & Co. offered an extensive catalogue of sensitively photographed studies of native people, as well as the antiquities and landscapes of Ceylon. During its existence, there appear to have been several Scowens involved in the operation of the studio—Charles T. Scowen returned to England in 1885, and C. Scowen was listed as proprietor until 1891, M. Scowen was proprietor in 1893 when the firm changed hands and the companies stock, including negatives, was taken over by the Colombo Apothecaries Co. Photographs credited to Scowen & Co were used as illustrations in a number of books about Ceylon and the tea trade.

KATHLEEN HOWE

SEARS, SARAH CHOATE (1858–1935)

American photographer and painter

Sarah Choate Sears was born in Cambridge, Massachusetts, in 1858 to Elizabeth Carlisle and Charles Francis Choate, a lawyer. In 1877, she married the wealthy real estate magnate Joshua Montgomery Sears and became a prominent member of Boston Society. She studied painting at the Cowles Art School and the Museum of Fine Arts School in Boston during the 1870s. She began to receive recognition for her watercolors by the 1890s. In the next decade she turned her attention to photography, producing portraits and still lifes in the pictorialist style. She became active in promoting photography as an aesthetic medium along with Frederick Holland Day and was influential in ensuring photography's inclusion in Boston's Society of Arts and Crafts inaugural show in 1897. She was granted a solo exhibition at the Boston Camera Club in 1899. She was also a member of the British pictorialist association, the Linked Ring and the Photo-Secession. After her husband's death in 1905, she abandoned her work as an artistic photographer and dedicated herself to collecting contemporary art and supporting the work of other photographers, particularly the photographers of the Photo-Secession. She died in West Gouldsboro, Maine, in 1935.

ANDREA KORDA

SEBAH, JOHANNES (JEAN) PASCAL (1823–1886) AND JOAILLIER, POLICARPE (1872–1947)

The Constantinople-based photographic studio Sebah & Joaillier—formed from a partnership between Johannes (Jean) Pascal Sebah and Policarpe Joaillier which dates only from 1890, but from its establishment, took over the marketing of the catalogue of fine images produced in Turkey and Egypt by Pascal Sebah. Sebah operated a studio in Constantinople from the 1860s, and also worked in Egypt from 1873. The same images, therefore,

have been marketed by the studio at various times as being the work of P. Sebah, J. P. Sebah, or Sebah & Joaillier.

Folowing Pascal Sebah's death in 1886, the Turkish studio was operated by his brother Cosimi for a time, who also trained Pascal's son in the art of photography. Johannes, known as Jean, reputedly joined the business aged 16, took it over at aged 18, and immediately entered into a partnership with Policarpe Joaillier. Joaillier returned to France in 1910, but with subsequent partners, Jean Sebah remained actively involved with the studio until 1943.

From the 1870s, Sebah, and later Sebah and Joaillier, were major suppliers of evocative imagery to the increasing number of people who to undertook the Victorian Grand Tour. Their studio images of Egpytians and Nubians in 'traditional' costumes and undertaking 'traditional' tasks were highly popular, and indeed had been Pascal Sebah's *Les Costumes Popularies de la Turquie* published to critical acclaim in 1873.

JOHN HANNAVY

SEDGEFIELD, WILLIAM RUSSELL (1826–1902)

English photographer

William Russell Sedgefield was born in Wiltshire, England, in 1826, and by the age of sixteen had applied to Talbot for a licence to practice the calotype as an amateur, while at the same time pursuing his training as an engraver. He progressed from calotype to waxed paper and both wet and dry collodion, and in a lifetime devoted to the medium, became one of the most critically acclaimed photographers of his generation. His acquaintances included the great publishers of photographic views Francis Frith and Francis Bedford.

Amongst his publications were *Photographic Delineations of the Scenery, Architecture and Antiquities of Great Britain and Ireland*, published in several parts in 1854, and *The Thames Illustrated with Photographs*, also in several parts (1866). He contributed works to several photographically illustrated books, most notably William and Mary Howitt's *Ruined Abbeys and Castles of Great Britain* in 1862 where his images appeared together with contributions by Bedford, Roger Fenton, George Washington Wilson, and others.

Sedgefield exhibited his work at many exhibitions from 1854, and from 1859 his many series of stereoscopic views were widely distributed. He continued in professional photography until his retirement c.1890, with premises in various locations in the London area, but the topographical nature of his most important work took him all over England and Wales.

JOHN HANNAVY

SELF-PORTRAITURE

The first photographic self-portrait was made just weeks after Arago announced Daguerre's invention in the French Council of Deputies in 1839. Like Niepce, Daguerre, and Talbot, Hippolyte Bayard had labored for some time at inventing a permanent photographic image. He was on the verge of success when Arago made his dramatic announcement, which conferred fame, as well as a sizeable monetary stipend, upon Daguerre. Bayard's response was a remarkable self-portrait in which he depicted himself in the nude as a drowned man. On the back of one print he wrote a note explaining that the drowned man had ended his life in despair after learning that Daguerre had beaten him to the acclaim and the money. He pointed out that the discoloration in his face and hands were signs of the flesh's deterioration, and warned the viewer of the corpse's odor. This first self-portrait was groundbreaking in several respects. It is the first known self-portrait in the nude by any artist since Durer (Durer's 1503 drawing is full frontal nudity, while Bayard's groin is covered.) Moreover, there is a self-directed humor in Bayard's image that many subsequent photographers would echo. To our eyes, Bayard's picture seems prophetic not just regarding the images that other 19th century photographers would produce, but for the performance art that emerged later in the twentieth century.

Many photographers, including Bayard, made more conventional self-portraits in which they presented themselves as serious people deserving of respect. Photography was revolutionary in its ability to make likenesses of people that would outlive them, a privilege that had previously been reserved for those very few who could afford to commission their own portraits. Photographers were no less prone to desires for immortality than anyone else, and accordingly self-portraits flourished. In addition, photographers, like painters, seized upon the genre as a way of advertising their abilities, often posing themselves beside their cameras or photographs. Photographers presented themselves as serious image-makers, and adopted the head and shoulders, direct gaze conventions of formal portraiture. Self-portraits became one mechanism through which photographers presented themselves as deserving the status of artists.

However, the self-dramatizing and playful elements that Bayard introduced also recurred throughout the 19th century. One is tempted to suggest that there is something in the photographic process itself that encourages this kind of plasticity and role-playing. These behaviors were not, of course, the exclusive prerogative of photographers, as they predated the birth of photography by many centuries. Rembrandt's self-portraits, for example, portrayed a man moving through a variety of social stations, as signaled by his amazing array of hats,

gold chains, and cloaks. Jan Steen portrayed himself as an anti-hero, often occupying the central position in paintings that depicted the chaos of unruly households, taverns, and debauchery in general. And when Caravaggio depicted David holding Goliath's decapitated head in triumph, he modeled the ogre's head after his own. But photographers of the 19th century approached the genre with an exceptional degree of freedom and experimentation. Among others, Charles Negre, Roger Fenton, Antoine Samuel Adam-Salomon, and Francis Frith enjoyed donning costumes and posing as various Romantic and exotic figures.

Nadar's and O. G. Rejlander's self-portraits are especially notable cases in point. Nadar made numerous self-portraits throughout his lengthy career, including straightforward head and shoulders images and family portraits with his wife and son. He sometimes donned outrageous costumes and wigs, probably chosen from the compendious wardrobes he kept in his studio. Nadar also photographed himself as part of two of his many entrepreneurial projects. He made at least one self-portrait in the Paris catacombs as part of a series on the expansive underground network in Paris. These photographs represented the first underground photographs as well as one of the earliest successful efforts to use artificial light in photography. The process of sitting for the catacomb self-portrait, which among other things provided a sense of scale for the unfamiliar underground setting, proved to be an especially arduous undertaking because of the very long exposure time and the cool and damp conditions. In a subsequent picture, Nadar spared himself the inconvenience and used a dummy rather than himself. Nadar was also an investor in the development of hot air ballooning, which became something of a passion for him. He used it as an opportunity to make the first aerial photographs, and also to pose himself (looking not entirely comfortable) in the gondola of one the balloons.

Across the English Channel, O. G. Rejlander was no less eclectic and eccentric in his interests. He posed himself in various guises, ranging from Greek philosophers to Garibaldi. He included himself in several humorous tableaus. In one scene, Rejlander scratches his head in confusion as a gypsy peddler tries to con him with an array of products, while in another image he whispers gossip into another man's ear about an unseen young woman. In several of the illustrations for Darwin's *On the Expression of the Emotions in Man and Animals* (1872), Rejlander used himself as a model, histrionically posing in images that supposedly represented indignation, surprise and other emotions. He used the combination printing technique that he pioneered in the mid 1850s to create a self-portrait of himself presenting an alter-ego version of himself as a militiaman. In *Happy Days*, Rejlander and his wife Mary smile broadly as they embrace one another, an unusually upbeat depiction of middle-aged love. There is a *joie de vivre* in Rejlander's self-portraits that is rare not only in 19th century photography, but in the entire history of the genre. Both Rejlander and Nadar in large measure reject the melancholic and self-important postures that many self-portraitists adopted, in part, one senses, because they were simply having too much fun playing with the photographic possibilities.

Some of the same elements continue through memorable American self-portraits near the turn of the century. In a dizzying photograph, William Henry Jackson posed himself at the edge of a high and precipitous rock outcropping in Yosemite (c.1895). The legs of the tripod are spread to the extreme edges of the small rock as Jackson studies the canyon on the ground glass. In dramatizing the considerable risks that many landscape photographers undertook in the practice of their art, such images valorized the courage of the photographer.

In 1898, F. Holland Day took different kinds of risks when fasting for several weeks in order to depict himself as Christ in a crucifixion series. The series includes close-ups of Day's head, topped with a crown of thorns, as well as photographs of his emaciated, nearly naked body nailed to the cross. These self-portraits are extraordinarily realistic, which accounts for some of the controversy that they occasioned when first exhibited in Boston.

Two other pairs of self-portraits are emblematic of how the genre developed in the late nineteenth century. Edward Steichen made numerous self-portraits throughout his long career, but two of his earliest are among the strongest in the medium's history. In one, made in Milwaukee in 1898, a young, casually dressed Steichen stands near the edge of the picture's frame, peering rather uncertainly into the camera. Beside his head hangs a small empty frame on an otherwise blank wall. The picture has a tentative quality to it, suggesting a young man who is just beginning to emerge as a distinct personality. The other self-portrait was taken four years later, after Steichen had moved to Paris. Now Steichen depicts himself as a painter (which in fact he was at the time), applying a brush to a palette in a beautifully composed and heavily worked photograph. He is dressed in sumptuous clothes worthy of a Rubens self-portrait. In this picture, Steichen presents himself as the very picture of success and self-assurance. Whether these two photographs represent an actual metamorphosis in Steichen's personality is open to question, but there is little doubt that the two *projected* selves could not be more different.

Similarly, Frances Benjamin Johnston constructed two very different selves in 1896. In *The Proper Victorian*, Johnston, in her early thirties, poses herself as a society matron, a genre in which she had developed

a considerable reputation amongst political and high society women in Washington. She is decked out in furs and an elaborate hat, her head resting on an elegantly gloved hand as she peers directly into the camera with an expression combining haughtiness, intelligence, and perhaps just a hint of vulnerability. Her expression is accentuated by the carved human head on her chair, which glares at something beyond the picture's edge. In the other self-portrait, Johnston is the "Proper Victorian's" polar opposite: she sits before a fireplace holding a beer stein in one hand and a cigarette in the other. Her legs are casually crossed, prominently displaying petticoats and an ample sweep of calves. She looks away from the viewer with a strong, unsmiling mien. The lack of eye contact reinforces the impression of a tough, no-nonsense woman making her way in a man's world. There's nothing seductive or feminine about her. This woman is fully self-contained, breaking the rules without a hint of apology.

Steichen's and Benjamin's self-portraits at the dawn of the twentieth century may be seen as efforts not just to reflect or project themselves through self-portraits but also to construct multiple selves using the photographic medium. From the first self-portrait of Bayard onwards, photographers were often drawn to the plastic and theatrical possibilities that they discovered in photography. Photographers during the nineteenth century increasingly used the medium to examine and portray the multiplicity of selves that would come to preoccupy psychologists, sociologists, historians, and countless artists in the century to come.

DAVID L. JACOBS

SELLA, VITTORIO (1859–1943)
Italian photographer

Vittorio Sella was born on 28th July 1859 in Biella, where his father, Giuseppe Venanzio, a scientist and photographer, founded one of the most important Italian woollen manufactures. In 1856 he published *Il Plico del Fotografo*, the first Italian treatise on photography. Vittorio's uncle, Quintino, a government minister, founded the Club Alpino Italiano in 1863. Vittorio attended a scientific high school and afterwards he worked in the family firm. He learned photography from his father and thanks to him he also became interested in exploring and mountaineering. In the course of his life he took thousands of photographs of the Alps. From 1879 he worked with scientific rigour on many extraordinary photographic *reportages*, taken while climbing in the Italian Alps. He also travelled abroad; in 1889, 1890 and 1896 he was in the Caucasian mountains; in 1897 he took photographs during an ascent of the mountains of Alaska with the Duke of the Abruzzi. In 1899 he was in Sikkim in Nepal, and in Africa with the Duke of the Abruzzi again. He made ascents in the Himalayas (1899, 1909) and took photographs during a trip to Morocco. His photographs were widely circulated for their quality and variety and they were found useful by geographers, topographers and alpinists. Vittorio Sella died in Biella on 12th August 1943.

SILVIA PAOLI

SENSITOMETRY AND DENSITOMETRY

When Hubert Davy repeated the experiments of Thomas Wedgwood in 1802, he attempted to convey the rapidity of his photosensitive preparations and stated, "… the part concealed by it *[the light]* remains white, the other parts speedily become dark." Some years later, William Henry Fox Talbot also found the need to indicate the speed of his materials, and he quantified an experiment by combining the intensity of the light ("I employed the full sunshine") and the time of exposure—"*half a second*" (Talbot's italics).

In the same year (1839), Mungo Ponton drew attention to a "cheap and simple method" that relied on the behaviour of light on potassium bichromate to form an image. He claimed his material was "equally sensitive with most of the papers prepared with salts of silver" but admitted, "it is not sufficiently sensitive for the camera obscura …" He had already identified that "the active power of the light … resides principally in the violet rays" by an experiment using light filtered to violet, yellow and red.

Antoine Claudet initiated experiments in 1848 that he hoped would increase the sensitivity of the daguerreotype process to daylight. In order to quantify the response of his plates, he built a device that he called the Photographometer, and which provided controllable conditions of exposure. Like other workers, Claudet relied on assessing his results by eye.

Unwittingly each of the early practitioners had provided the basis for the subsequent study of sensitised materials. Sensitometry became particularly important when photographers no longer prepared their own materials but relied on plates manufactured by a third party. The introduction of dry plates brought a need for reliable testing in the factories, and a means to audit the claims for improved speed. Consequently, the role of sensitometry took on an importance that led to continuing improvements in the practice of photography. For example, an understanding of the behaviour of sensitised materials contributed to the design of actinometers to improve exposures during carbon printing, and to the accuracy of exposure calculators, which replaced exposure tables.

As a rule, three requirements were required for a sensitometric study:

- Equipment for making a consistent exposure to a plate,
- Implementation of an agreed development protocol,
- A means of accurately measuring the ensuing densities.

The designs of the first sensitometers incorporated ingenious exposing devices. Leon Warnerke relied on an energised phosphorescent block of calcium sulphide for his exposing source. James Spurge (working with J.D. Mucklow) proposed a system of tubes that channelled controlled amounts of daylight onto the test plate. Exposing through "a screen" (a step wedge) impressed a set of numbers on the negative and, after development, the first identifiable number established the rapidity of the plate. For example, in 1890, Marion & Company advertised their Ordinary dry plates as "Averages 19–20 Warnerke's Sensitometer" and advised users to "double the exposure of the Instantaneous," which had an average rapidity of 24–25 (on Warnerke's scale).

Before then, however, some workers had encountered conundrums, which were not resolved until sensitometry improved. In 1874, William de Wiveleslie Abney noticed a disparity between time of exposure and intensity of light whilst examining the opacity of his negatives. By the time he had solved the riddle, he had developed his own method for measuring the deposits on negatives and was confidently testing photographic materials objectively.

To measure the transparency (or the opacity) of a negative, Abney used the shadow photometer that Benjamin Thompson (Count Rumford), had designed to compare the strength of different forms of artificial lighting in 1793. Although Abney introduced improvements to the instrument by inserting rotating sectors (i.e., a system of variable apertures), which were positioned in front of one of two light sources, he retained Rumford's principle of balancing the intensities of the two shadows projected on a screen. The amount of adjustment that was necessary to achieve the match indicated the opacity of the deposit.

A limitation of the method when applied to photographic work was the need to use relatively large specimens. Warnerke's sensitometer and Abney's photometer for measuring density (that is, a densitometer) were pragmatic solutions devised to solve specific questions as they occurred. When practitioners appreciated the value of sensitometry and densitometry, the techniques improved and evolved as an important branch of photographic science.

By 1888, Ferdinand Hurter and Vero Charles Driffield had begun to collaborate on experiments in photographic chemistry. The initial work had been undertaken with a view to improving the calculation of camera exposures, but their investigations were later directed towards understanding the action of light on photographic emulsions. To make their studies comprehensive, Hurter and Driffield standardised their tests by exposing plates to the light of a standard candle, modulated by a rotating disk designed to control the amounts of light reaching the plate. They also specified a standard developer (ferrous oxalate) and described apparatus they had made for making measurements.

Hurter and Driffield also introduced the word "density" to describe the individual amounts of silver that were produced during development, and by plotting density measurements against the given exposures, they constructed a curve, which displayed the characteristics of the sensitised material being examined. Hurter and Driffield formed their conclusions from a range of density readings, (instead of the single number obtained by Warnerke), and their technique was consequently more reliable. From their characteristic curve, they were able to determine the sensitiveness of plates, and by the end of the 19th century their method was recognised and accepted as the H & D Speed System.

A contemporary of Hurter and Driffield, Henry Chapman Jones, described his densitometer in 1895, which he claimed as an improvement on other designs because he had been "desirous of getting a more simple arrangement." His achievements were to eliminate the need for two light sources (the reference beam and the measuring beam), to reduce the loss of light in the optical system and to measure in "one simple movement.." Jones's densitometer remained popular until improved designs were introduced in the 20th century.

SEVASTYANOV, PETR IVANOVITCH (1811–1867)

Archeologist, traveler, photographer

Petr Sevastyanov was born in 1811 to the family of merchants who were honorary citizens of the town Krasnoslobodsk in the Penza province. In 1831 he graduated from the Moscow University. Commissioned by the Ministry of Justice he worked in Perm, Tiflis (T'bilisi), and St. Petersburg. In 1852 he was honored with the title of the Full Secret Counselor. While staying in Paris in 1858, Sevastyanov took lessons in photography for a month from the photographer Belloni preparing himself for an expedition to Athos.

Sevastyanov organized two expeditions to Athos. The first important series of photographs devoted to the Holy Mountain was taken during the first expedition in 1857; the second expedition lasted for 14 months (1859–1860). Painters, architects ,and photographers took part in these expeditions. Sevastyanov photographed the rare manuscripts and icons of the Athos monasteries. He brought 1300 negatives back with him. Sevastyanov's prints made it possible to read the manuscripts' faded ink texts. This was the first instance where photography aided the restoration of such rare documents.

In February 1858 Sevastyanov made a report "On photograpy in application to archeology" in Paris on the basis of the first Athos expedition. In 1861 and 1862 Sevastyanov's prints were a success in St. Petersburg and Moscow exhibitions. Sevastyanov was the first to use photography to the document research on Athos monasteries.

Sevastyanov died in St. Petersburg in 1867.

ALEXEI LOGINOV

SHADBOLT, GEORGE (1819–1901)

English

North London timber merchant George Shadbolt was an early experimenter in micro-photography and a leading figure of the Microscopic Society.

He was a founder member of the Photographic Society and exhibited many subjects at its 1854–1857 exhibitions using wax-paper, wet-collodion and his own 'collodion honey process' to produce his favored matt salt prints—he disliked the 'glare' of albumen paper. He was also a member of the Photographic Exchange Club.

Shadbolt's earliest exhibits were portraits, some enlarged from small negatives (he appears to have used his camera as a form of enlarger, using gaslight to make the prints). His later studies were all views made in and around Hornsey, North London, which then was then quite rural.

Shadbolt contributed several articles to the *Journal of the Photographic Society* and the *Liverpool & Manchester British of Photographic Journal* which later became *The British Journal of Photography*. He was also vice president of the North London Photographic Association and a member of the Amateur Photographic Association.

He seems to have retired from photography around 1864, however, his son Cecil became a pioneer aerial photographer, taking vertical pictures from a balloon in 1883. C.V. Shadbolt also photographed the Holy Land, illustrating H. A. Harper's *Walks in Palestine,* published in 1888. He was killed in a ballooning accident in 1892, his father died nine years later.

IAN SUMNER

SHERLOCK, WILLIAM (1813–1889)

English

Sherlock was born at Lambeth, South London, in 1813, his father, also William, was a solicitor and William junior followed his father's profession. In 1843 Sherlock wrote to William Henry Fox Talbot requesting permission to open a London photographic portrait studio. After several exchanges, Talbot offered the concession for Bristol, but Sherlock declined.

Sherlock contributed over 40 photographs to the 1852 Society of Arts London Exhibition, all but one from paper negatives. The subjects depicted rural scenes: A Group of Peasants, Pollard Willows and Rustic Bridge were typical titles. By 1855 he was using wet-collodion to produce his negatives, printing on salted paper.

Sherlock's large body of work was originally attributed to John Whistler but as Ken Jacobson has shown in his 1996 work *Etude d'Apres Nature*, this was an incorrect assumption due to a large number of his works in the collection of the Whistler family.

In exhibitions between 1852 and 1859 Sherlock showed almost 200 rustic studies, many entered by the print seller J.Hogarth. His work has also been confused with that of the French master Humbert de Molard and much of his work is in the French style. He gave up his profession as an attorney and became a full-time photographer in the late 1850s and moved from London to South Devon, where he lived until his death in 1889.

IAN SUMNER

SHEW, WILLIAM (1820–1903)

William Shew first made his mark as a daguerreian artist and case maker in Boston before moving to California, where he took photographs for more than 50 years.

Born near Watertown, New York, he began making daguerreotypes there in 1841 with his three brothers after learning the process directly from Samuel F. B. Morse. The four brothers moved from Watertown to Ogdensburgh to Rochester and to Geneva, New York, establishing galleries in each city, before settling in New York City.

From 1841 to 1844, Shew managed John Plumbe, Jr.'s Boston gallery. Around 1844, he began making miniature cases and continued in that line of work for several years. From 1849 to around 1851, he resumed taking daguerreotypes in Boston.

Shew arrived in San Francisco by ship around 1851 and established a portable gallery that he operated until moving into more permanent quarters on Clay Street. He was burned out of this location and moved to another on Montgomery Street, where he remained for 20 years. He was also active in local politics and served on the local Board of Education. In 1901, more than 50 years after settling in San Francisco, Shew was still operating a photo gallery on Kearny Street.

BOB ZELLER

SHIMOOKA RENJØ (1823–1914)

Japanese photographer

Shimooka Renjø is generally thought of as one of the "two fathers of Japanese photography," along with Ueno Hikoma. Shimooka was born as Sakurada Hisanosuke in Shimoda in 1823. His father was an official shipping agent for the Tokugawa military rulers. Shimooka moved to Tokyo at the age of thirteen to seek training as an artist. He later served an apprenticeship with a master of the traditional Kanø painting school, Kanø Tøsen. He may have first seen foreign daguerreotypes while serving as a guard at the Shimoda artillery battery in the 1850s. He was so impressed by their realism and detail that he decided to learn photography. Shimooka acquired his first formal training in the medium around 1860 from an American photographer in Yokohama named John Wilson. When he left Yokohama in 1861 or 1862, Wilson also gave Shimooka his first camera in exchange for a painting. In 1862 Shimooka opened a studio in Yokohama, one of the first Japanese-run photography businesses. He produced studio portraits primarily for foreign tourists, as well as staged photographs of locals that also appealed to foreign tastes. He later managed a number of studios in both Yokohama and Tokyo, and trained many of Japan's early photographers. By 1877, Shimooka no longer worked as a photographer, though he continued to paint photographic backdrops and panoramas. He died in 1914.

KAREN FRASER

SIDEBOTHAM, JOSEPH (1824–1885)

Calico printer, botanist and entomologist, pioneer photographer

He was involved with several early experiments in the search for stable dyestuffs for textile printing and had an enduring interest in microscopy. Sidebotham was a prime mover in the establishment a 'microscopical section' in the Manchester Literary & Philosophical Society in the late 1850s (becoming its Vice-President), and a photographic section in the 1860s. Through the 'Lit & Phil,' he became acquainted with John Benjamin Dancer (qv)—from whom he purchased microscopes and developed an interest in micro-photographs—James Mudd (qv), Alfred Brothers (qv) and many other early photographers. He was a long-serving member of the Manchester Photographic Society, and a regular speaker at the society's meetings. One of the earliest demonstrations of the workings of a rotary camera shutter was that given by Sidebotham in 1856. He served as the society's Vice-President from 1861 until 1865. With James Mudd, he experimented with variants on the waxed paper process in the 1850s.

Sidebotham lectured and wrote extensively on photography and his essays on the collodio-albumen process, and on contemporary printing processes published in *Recreative Science: A Record and Remembrance of Intellectual Observation, Vol. II.* (Groombridge and Sons, London, 1861), were considered important contributions to the published account of photography.

JOHN HANNAVY

SILVESTER, ALFRED (UNKNOWN)

Alfred Silvester's blindstamp can be found on some of the most elaborate and beautifully tinted genre stereocards of the 1850s and 1860s, yet the only record of his studio at 118 New Bond Street, London is from an 1864 trade directory. No personal details have yet been located.

His exhibition record comprises two portraits by wet collodion shown at the 1855 Exhibition of the Photographic Society, and forty of his celebrated stereographs at the 1858 Edinburgh exhibition of the Photographic Society of Scotland.

Silvester's stereos were usually produced in small sets of three or four cards, or in much larger series, with a strong moral theme and narrative character, and they could be purchased either card mounted for viewing by reflected light in the drawing room stereoscope, or as tissues for viewing by transmitted light. Themes like *The Hero's Wife* and *The Dream of the Wedding* were popular entertainment. *Look Before You Leap* linked sound advice with a strong Masonic theme, and depicted aspects of Masonic ritual, while his most celebrated genre card, *Guardian Angels* was one of his most overtly religious. Similar treatments of many of the themes in Alfred Silvester's stereographs were published by his major rivals John Elliot, and the London Stereoscopic Company.

JOHN HANNAVY

SILVY, CAMILLE-LÉON-LOUIS (1834–1910)

French photographer

Camille Silvy was born at Nogent-le-Rotrou, a market town to the west of Chartres, on May 18, 1834, to Marie Louise and Onésipe Silvy, descendents of a notable Provençal family with possible Italian roots. When his father, mayor of Nogent, was appointed director of a Paris bank in 1835, he moved his family with him.

As a child, Silvy was taught drawing by Hippolyte Lalaisse, a teacher, lithographer, and painter of portraits, genre scenes, and animals. Silvy studied law and graduated in 1852 taking up a minor diplomatic post. He took up photography when he took a trip with Lalaisse to Algeria in 1857 and realized his inadequacy at obtaining exact views of the places he traveled through. He made photographs and drawings on this trip, particularly of Kabylia, newly conquered by France.

Silvy joined the Société française de photographie in 1858 and exhibited at the Salon the following year. Silvy was one of a number of photographers who donated prints to be sold to raise funds for the organization. Most of the views he exhibited at the Salon were taken close to his birthplace, at Gaillard at La Croix-du-Perche or in Nogent-le-Rotrou. Like those of many of his contemporaries, Silvy's photographs were made from large, wet collodion glass negatives which most likely processed his plates in one of the family's houses in the area.

Silvy's most well known photograph was taken near Nogent-le-Rotrou of the river Huisne in 1858, and is known today as "River Scene, France." The version in the Société française de photographie, where Silvy exhibited the print for the first time in 1859, was originally given the title "Vallée de l'Huisne."

Although it was made just a few years following the inauguration of the Grande Ligne de l'Ouest from Paris that passed through Nogent, "River Scene, France" gives no indication of this new industrial access to Paris. The scene is one of quiet, picturesque contemplation where one's eyes can explore the intricate and carefully composed details in the middle ground where riverside houses, boat docks, and trees are reflected in the smooth mirror-like surface of the river. The glass negative allowed a greater sharpness as well as faster exposure speed. The people positioned along the riverbank in *River Scene*, though staged, did not have to stand stiffly in order to be rendered. The composition is reminiscent of topographic prints of the time, aimed at creating picturesque views of leisuring tourists in a landscape. However because Silvy's photograph lacks picturesque monuments such as the nearby Romanesque castle and a church, he seems to be more interested in the scene as that of local residents, enjoying their own beautiful spot.

Because clouded skies were challenging in early photographs, Silvy used a method first invented by Hippolyte Bayard and made famous by Gustave Le Gray that is to take a separate negative of a cloudy sky and splice it with the negative of landscape in the printing stage. In addition, Silvy had to paint in parts of the main cluster of poplar trees as well as along the horizon in order to blend the two negatives. Because of his success with these techniques as evident in "River Scene," Silvy is recognized as one of the great craftsmen of photographic printing.

In a review of the exhibition at the Société française de photographie, Ernest Lacan praised Silvy's landscapes: "These are ravishing *tableaux* which have the merit of being as true as nature herself, while borrowing from art a glamour which gives poetry to the most ordinary places" (*Photographic News*, July 9, 1859, 1). Such critical acclaim along with the writings of Louis Figuier, a well-known science journalist, who declared Silvy's photographs to be ". . . true pictures in which one does not know whether to admire more the profound sentiment of the composition or the perfection of the details . . ." (L. Figuier, *La Photographie au Salon de 1859,* Paris, 1859, 9) placed Silvy at the head of the modern French landscape school.

In addition to landscapes, Silvy also made still-lifes, such as *Trophées de chasses* of rabbits, game birds, and fish hanging symmetrically like realist still-life paintings of the time. In 1859 a wood engraving for the weekly *L'Illustration* was made after his photograph of a group of citizens in Paris gathered around a posting put up by Napoleon III before his departure for Italy to join the

Silvy, Camille. Les Petits Savoyards (Street Musicians).
The J. Paul Getty Museum, Los Angeles

fight against Austria. The image combined reproductive technology, politics, and a moment of history in the making. Silvy was also meant to travel with the Italian campaign to make photographs but the French army succeeded in their mission before Silvy could receive his papers to go.

In 1859, Silvy moved to London and established a portrait studio. There he made carte de visites, recently patented by the Frenchman Disderi, which makes him most likely the first *carte-de-visite* photographer in London. Soon Silvy moved to a large and spacious portrait studio in Porchester Terrace, Bayswater. Within two and a half years he had taken close to seven thousand portraits of famous and upper class citizens. He photographed individuals and groups in elaborate studio settings as well as arrangements of figures in landscapes.

Beyong the studio, Silvy continued to be inventive with the medium. In the late 1850s he created a series of studies of light and weather as well as a series of street scenes. Silvy made photographic reproductions of early manuscripts, particularly the "Sforza Manuscript" in which he discovered that photography, because it could capture yellow ink and render it as black, could also play a restorative role as well as a documentary one. When a major controversy over whether photography could be exhibited in the Fine Arts section of the 1862 International Exhibition occurred, Silvy, who was a member of both societies, stood in favor of photography's industrial classification. Silvy was also an inventor of machines, such as a cylindrical camera body that could house a rolled waxed-paper negative and in 1867 he made a panorama of the Champs Elysées to demonstrate his invention. He invented the idea of a tripod that could keep a lens horizontal to the ground for surveying. Silvy experimented in making print runs of photographs in ink and worked in photoceramics and photographed tombs in the Dreux chapel in Normandy by magnesium light.

As the *carte-de-visite* phenomenon died down, Silvy ended his portaiture studio in London in 1868 and moved back to France. He took up the post of *agent consulaire* of the French government at Exeter from 1868 to 1870 but returned again to France when the Franco-Prussian War broke out, and served as a lieutenant in the Eure-et-Loir department. He later published two pamphlets describing the campaign. Like many workers in photography in the nineteenth century, Silvy's life was ended prematurely by cyanide of potassium poisoning. Silvy entered an asylum in 1881 and died there in 1910.

KAREN HELLMAN

Biography

Camille Silvy was born at Nogent-le-Rotrou, France, on May 18, 1834. Silvy studied law and graduated in 1852 taking up a minor diplomatic post. He took up photography during a trip to Algeria in 1857. Silvy joined the Société française de photographie in 1858 and exhibited at the Salon the following year. Like those of many of his contemporaries, Silvy's photographs were made from large, wet collodion glass negatives. Silvy was known primarily for his landscape scenes taken around his native town in France but he also made still life studies. In 1859 he moved to London and established a portrait studio where he was possibly the first carte de visite photographer in London. In the late 1850s he created a series of studies of light and weather, a series of street scenes, and several photographic reproductions of early manuscripts. In the 1860s Silvy invented a cylindrical camera body that could house a rolled waxed-paper negative and in 1867 demonstrated his invention with a panorama of the Champs Elysées. He also invented the idea of a tripod that could keep a lens horizontal to the ground for surveying. In 1868 Silvy closed his studio and moved back to France. He took up the post of *agent consulaire* of the French government at Exeter from 1868–1870 but returned again to France when the Franco-Prussian War broke out, and served as a lieutenant in the Eure-et-Loir department. Like many workers in photography in the nineteenth century, Silvy's life was ended prematurely by cyanide of potassium poisoning. Silvy entered an asylum in 1881 and died there in 1910.

SIMPSON, GEORGE WHARTON (1825–1880)

Editor and writer

George Wharton Simpson succeeded Thomas Sutton and Editor and Proprietor of the fortnightly journal *Photographic News* in 1861, a position he held until his death in 1880.

A prolific writer, he contributed essays, in addition to his own journal, to *Photographic Notes, The Photographic and Fine Arts Journal* and the *British Journal of Photography.* His writings were reprinted extensively in *The Philadelphia Photographer, The American Journal of Photography and the Allied Arts & Sciences, Humphreys Journal* and *Photographic World* amongst others.

He wrote two important books—*The Photographic Teacher: or What to do in photography, and How to do It: a Clear and Concise Compendium of the Collodion Process* was published in 1858 by H Squire & Co of London, and *On the production of Photographs in Pigments: containing Historical Notes on Carbon Printing and Practical Details of Swan's Carbon Process* was published by T Piper in London in 1867.

He became Vice President of the Photographic Society of Great Britain, and was also elected to the same post at the South London Photographic Society.

In his obituary, (*BJP*, January 15 1880) his early career as Editor of the *Darlington & Stockton Times* is mentioned, as is the fact that he practised as a professional photographer 'for some years' before taking over the editorial chair at *Photographic News*.

JOHN HANNAVY

SKAIFE, THOMAS (1806–1876)

English photographer and studio owner

Thomas Skaife was born in 1806, marrying circa 1829 and having one son, Wilfred (1830–1862). He operated photographic studios at various addresses in London from 1860 until 1867 and exhibited as a miniature painter at the Royal Academy from 1846 to 1852.

He took up photography in early 1856 and in June patented a rubber-band powered flap shutter to facilitate instantaneous photography. He became increasingly attracted to instantaneous photography and he produced a series of stereo photographs for the War Department showing the trajectory of the shell from a mortar.

His most prominent contribution to photography was the introduction of his Pistolgraph camera in 1859. Skaife, inspired by a suggestion made by Thomas Sutton in the *Photographic Journal* of July 1858, designed a camera fitted with one of his own flap shutters. He re-designed the camera in 1859 to make use of 1 inch

square glass plates. The camera was called the Pistolgraph. Skaife's camera was sold with several types of lenses including a wide aperture Dallmeyer f/1.1 portrait lens. The plates could be enlarged successfully 10 to 15 times by projection, by enlarged negative or by use of a solar camera.

Skaife's camera attracted much interest in the photographic press and Skaife licensed the use of the camera to other photographers to produce 'pistolgrams' or 'pistolgraphs.' It was deemed particularly applicable for taking portraits of children, old people, and animals.

Skaife died on 18 November 1876 at Preston, near Steyning, Sussex, aged 68.

MICHAEL PRITCHARD

SKEEN, WILLIAM LOUIS HENRY (d. 1903)

English, photographer, publisher

William Louis Henry (W.L.H.) Skeen was the proprietor of a large commercial photographic company active in Ceylon (now Sri Lanka) from the late 1860s through 1903, with studios in Colombo and Kandy. His father William Skeen, the first official government printer for Ceylon, purchased a studio for his son after he his return from photographic training in London. During its existence, W.L.H. Skeen & Co was the premier photographic firm in Ceylon. The company offered an extensive catalogue of views of landscapes, studies of tribal peoples and ethnic groups, and documented the tea plantations and spice works. Skeen & Co. held commissions to record many of the major construction projects—railway projects and the construction of the Colombo Breakwater in the 1880s. The company published J.W.W. Birch's photographs of Polonnaruwa around 1876. Skeen & Co. received the coveted "photographers by appointment to the Duke of Edinburgh" during his tour of 1870. In addition to views of Ceylon, in the 1890s the firm offered a series of views of India—Bombay, Jaipur, Delhi, Agra, Darjeeling—probably acquired through purchase or trade with another commercial studio. Skeen & Co. photographs were exhibited at major international exhibitions from 1870 to the end of the century and its operations. It appears the Platé & Co. acquired its negatives when it closed in 1920.

KATHLEEN HOWE

SKY AND CLOUD PHOTOGRAPHY

Photography was invented as the meanings and uses of sky and cloud in art were in flux. In paintings, skies were once typically conveyed as the realm of gods; cloudless, infinite and timeless, often blocked out with celestial gold. If a cloud was present, it was a symbol of divine wrath. From the early Renaissance artists began to fill images of skies with clouds and birds, seeking to evoke a specific space and time. By the nineteenth century, sky and cloud in art could be romantic, evoking emotional states or spirituality, but could also be scientific or realist, used to image atmospheric effects, highlight the time of day or document nature.

At a time when the West was surveying unknown lands, it was also exploring the infinite, daunting sky. Photography played a role in the demystification of sky and cloud, providing what was considered objective evidence of natural processes. In 1896, the *International Atlas of Clouds* was published, incorporating photochromatypes of different types of cloud, by the international meteorological committee—a concern thus spanning the entire century. However, it was actually in the early 1900s Jean Baptiste Lamarck and Luke Howard worked on classifications for clouds.

The night sky was also documented. Lunar daguerreotypes of George Philips Bond and John Adams Whipple were shown at the 1851 Great Exhibition at Crystal Palace, London, and were so popular that they went on tour in Europe. The subsequent wet-plate collodion prints by Warren De La Rue, along with Lewis Morris Rutherford's albumen print 'The Moon, New York' (1865) continued to spark the interest in lunar photography. As well as looking to the skies from Earth, Gaspard Félix Tournachon, or Nadar, famously took his camera up in the hot-air balloon, attempting 'aerostatic photography' from 1858 to record the earth from the sky.

Cloud and sky were aesthetic as well as scientific subjects. In nineteenth-century art the empiricist doctrine of depicting a specific place at a specific time, and aiming to show atmosphere, was pursued by artists such as Claude Monet, John Constable, Joseph Mallord William Turner and James McNeil Whistler. Images recording 'effect' gained scientific value and appeared more 'truthful' and desirable. Summing up mid-nineteenth-century art, Ruskin stated in 1856, that 'if a general and characteristic name were needed for modern landscape art, none better could be invented than "the service of clouds".' Photographs were used as an aid to drawing and painting natural landscapes. Many people considered them equivalent to a sketch, although less subjective and less artistic. In the 1870s for example, the French artist Gustave Courbet was concentrating on skies and seas, making photographs on which to base his paintings.

Skies could be cloudless for both technical and aesthetic reasons. From the 1840s skies in photographs were often blank due to the fact that the material's sensitivity was selective and restricted, which prevented the photographer to acquire detail in a dark foreground (for example 'At Compton, Surrey, 1852–54' by Ben-

jamin Brecknell Turner). Often photographers tried to achieve an empty sky for stylistic reasons. Japanese photographs were closely linked to the woodblock tradition that made use of large single-tone spaces: Kusakabe Kimbei's 'Fujiyama' (c.1880) is a coloured albumen print with a flat sky. The empty sky in Carleton E. Watkin's 1860s photographs (of the type to be disseminated as artistic prints and postcards), highlights the sublime in the iconic landscape of the American west at Yosemite. In the 1890s, the British photographer Peter Henry Emerson sometimes used a white, blank sky to evoke distance and fin-de-siecle emptiness (for example 'The Bridge,' a photo etching from *Marsh Leaves*, 1895).

J. M. W. Turner, discussing paintings, breached the artistic concern of making an opaque two-dimensional surface reflect light. In photography, the appearance of the sky depended on the characteristics of the methods and paper used, and how light would reflect off the surface. The mirror surface of the daguerreotype reflected light and added interest to void skies (Horatio Ross's daguerreotype 'Craigdacourt,' 1848, for example). Watercolourists and calotypists both used Turkey Mill paper to render the sky mottled and interesting. Hill and Adamson's work reveals the blurred effect, creating texture and shape, caused by the way in which the paper absorbed chemicals. Journals suggested improving blank, white skies when using a paper negative by blackening the verso with ink, and when using a glass negative by painting the verso red or yellow.

Imaging clouds demanded technical skill and astounded viewers, who were unused to seeing romantic symbols in such a scientific context. It was a technical challenge until photographic papers became more reactive than the early albumen papers of the 1850s, and so alternative methods were used. Clouds were often painted onto the backs of negatives. Farnham Maxwell Lyte revealed in 1861 that tufts of cotton could be placed the glass negative and the printing frame to achieve clouds. Alternatively, the part of the negative showing the sky could be covered during exposure in the darkroom, so that the detail was not lost.

It became common practice to superimpose one negative of clouds onto a negative of a landscape, creating a photomontage to achieve detailed sky and land in one photograph. Frenchmen Camille Silvy and Gustave Le Gray, and Englishmen F. M. Lyte and Roger Fenton were amongst the nineteenth-century photographers who used this innovation. Silvy's 'River Scene, France' (1858), is an early example of this technique, and was praised in *The Photographic Journal* (5, 1859) for its 'exquisite and varied detail,' although Silvy was also criticised for using 'artifice to make picture, not take a picture" (Paris review by Louis Figier, 1859).

Roger Fenton's study 'September Clouds' (1859), emulating Constable's paintings of clouds, was used in a number of different landscapes to give a model sky to each image. His photographs were first shown in Britain and sold well to an international market. The blatant manipulation of superimposing negatives to artistic ends was a concern for Le Gray, who insisted that photographs preserve the 'truth' but who also used photography as an artistic printmaking process, as in 'The Solar Effect—Ocean' (1857). Sky and cloud made Le Gray famous; his many seascapes selling well.

Nineteenth-century photography of sky and cloud was caught between the contemporary concerns of art and science. Echoing the painterly obsession with imaging the atmosphere, it acted as a catalyst for technical innovations in the 1800s, and the development of scientific skill and artistic taste. Photographs of sky and cloud sold brilliantly to a large market as fine art prints, postcards, or stereoscopic views. The subject was used to varying effect in different situations: highlighting majesty of mountains, emphasising vastness of land or sky, contributing to propaganda of empire, documenting new theories and discoveries, aiding explanations of natural processes, and advancing photography as an art.

SLINGSBY, ROBERT (d. 1895)

English photographer

Robert Slingsby was a professional photographer working in Lincoln from circa 1859 where he was also described as a stationer and dealer in artistic supplies. He joined the Photographic Society in 1869 and was a regular exhibitor of work in the Society's annual exhibition from 1863 initially showing examples of his portrait work and local views but gradually showing more staged genre and art studies.

Slingsby contributed a number of articles to the British photographic press usually addressing portraiture and matters of interest to the professional studio photographer. In his 1873 piece entitled 'A few notes on portraiture,' he described his method of sensitising plates, his studio and posing methods and later pieces commented on backgrounds and the need for an orderly routine in the studio, all based on his own experiences. He had two patents granted in 1875 and 1876 relating to the use of skylights in photographic studios.

In 1880 H. Baden Pritchard visited Slingsby's Lincoln studio and reported on the visit in detail for the *Photographic News*. He noted that Slingsby's photograph *Alone* which had been exhibited at the Photographic Society's exhibition had earned him £450 and was continuing to sell. The article described Slingsby's studio and working methods in some detail.

Slingsby's more important contribution to photography was his work on the development of flash light for photography. As early as 1869 he had a photograph reproduced in the *Illustrated London News* that had been produced using artificial light and between 1890 and 1891 he was granted four patents relating to the use of magnesium for flash photography one of which related to a shutter that could be synchronised to the discharge of magnesium.

Robert Slingsby died in Lincoln on 16 August 1895 leaving an estate totalling £1552 13s 10d.

MICHAEL PRITCHARD

SMEE, ALFRED (1818–1877)

The scientist, ophthalmic surgeon, and metallurgist Alfred Smee was an important and prolific writer on electricity and electro-biology, and was an early pioneer in the understanding of the electrical stimulation of nerves and muscles.

Smee, a fellow of the Royal Society, was co-founder of the London Opthalmic Hospital, and ophthalmic surgeon to the Bank of England, and a friend and collaborator with Charles Babbage. Recent researches have confirmed him as an early pioneer of the concept of artificial intelligence.

He was also interested the potential value of batteries in the electrolytic preparation of chemicals, and, in 1842, supplied Sir John Herschel with some of the potassium ferricyanide—a key chemical in Herschel's cyanotype process—which he had made from potassium ferrocyanide by what he termed 'electrolytic oxidation.' Several surviving letters from Smee to Herschel attest to his wide interest in the chemistry of early photography.

An article by Smee "Photogenic Drawing" was published in *The Literary Gazette and Journal of Belles Lettres* on May 18, 1839 (314–316). In that article Smee recognised the future value to photography of gallic acid, and also predicted the importance of iron proto-sulphate, observing that "photogenic paper may be blackened" by a dilute solution of the chemical. Iron proto-sulphate, or ferrous sulphate, was later recognised, by Robert Hunt in 1844 as a developer.

In his book *Elements of Electro-Metallurgy* (Longman, Brown, Green and Longman, 1841), Smee included a chapter 'On Multiplication of the Daguerreotype' (134–135).

JOHN HANNAVY

SMILLIE, THOMAS W. (1843–1917)

American photographer

Washington, D.C., photographer Thomas W. Smillie served as the Smithsonian Institution's first photographer when hired part-time beginning in 1869. Educated in chemistry, Smillie pursued his passion for photography at the Institution while continuing to work as a commercial stereo photographer. By 1871, Smillie's position was made full-time with responsibilities to photograph and document museum collections, buildings, and scientific research. He developed traveling exhibitions, the first for the Ohio Valley Centennial Exposition at Cincinnati in 1888. Smillie arranged for this display by acquiring or borrowing historic and contemporary photographs and camera equipment, such as Samuel F. B. Morse's daguerreotype camera and accessories, and the 1888 No. 1 Kodak camera. He continued to correspond with working professional and amateur photographers, and manufacturers to record the history of the science, technology and art of photography. In 1896, Smillie was named the first honorary custodian of the newly formed Section of Photography at the Smithsonian, the first such unit in an American museum. Smillie maintained an active collections and exhibitions program while remaining staff photographer. As a mentor, he taught photography to many apprentices preparing them for work with U.S. government agencies. In 1913, Smillie opened the first Hall of Photography in the Smithsonian's U.S. National Museum. He remained at the Smithsonian until his death in 1917. Today, this important collection is housed in the Smithsonian's National Museum of American History, Photographic History Collection.

MICHELLE ANNE DELANEY

SMITH, BECK & BECK

The firm of Smith, Beck and Beck dates from 1857. Its origins lie with James Smith (died 1870) an optician and optical turner working from 1826–1847 who had made the brass work for Joseph Jackson Lister's (1786–1869) achromatic microscope. Smith took Lister's nephew

Richard Beck (1827–1866) as an apprentice and they commenced a formal partnership in 1847 which continued until 1857 when they were joined by Beck's brother Joseph Beck (1829–1891), who had been apprenticed to the important optician and instrument maker William Sims.

The Smith, Beck, and Beck company was primarily an optician and optical instrument maker with microscopes being a particular speciality. As Smith and Beck the firm introduced stereoscopes to the range of goods it produced including a top-loading hand-held model. The firm's most successful viewer was based on Joseph Beck's patent number 2112 of 15 September 1859 which described a viewer designed for viewing paper stereo pairs either mounted on card or in books. The open-body viewer was sold as the Patent Mirror Stereoscope.

A refined version was produced with solid sides which inverted into it's own box and was sold as the Achromatic Stereoscope in either walnut or mahogany. Various designs of cabinets to hold the viewer in its box and stereographs were produced. The viewer was very effective and consequently became very popular with over 3000 being produced. It was still being advertised in 1890.

Alongside the stereoscopes Smith, Beck and Beck was also publishers and retailers of photographs including cartes-de-visite portraits and they claimed to keep in stock 'some thousands' of stereoscopic views with others readily obtainable. The most notable of the stereographs published by the firm was Warren de la Rue's celebrated series of lunar photographs taken on his reflecting telescope and enlarged by Robert Howlett. These were sold as both paper and glass stereographs.

Smith retired from the partnership in 1865 and c1867 the firm began trading as R and J Beck, becoming a limited company in 1895. Joseph's son, Conrad, was apprenticed to the firm in 1879 and later ran the company and published several books on optics. Thomas Smithies Taylor was also apprenticed to the company in 1879 and in 1886 he founded his own firm which was to become Taylor, Taylor and Hobson of Leicester, another successful photographic lens manufacturer.

By the 1880s R. and J. Beck's photographic lenses were mainly being exported to the United States and by the end of the decade they had doubled manufacturing capacity to meet the demands of the home market. The company was the first to fit an iris diaphragm on a regular basis to its rectilinear lenses from 1887. Although the firm manufactured some Voigtländer lenses under licence and a limited range of its own quality lenses it increasingly produced lenses directly for camera makers such as W Butcher & Sons, Newman and Guardia and others.

The company made several distinctive cameras. The first true twin lens reflex camera was made by R. and J. Beck for G. M. Whipple (1842–1893), superintendent of the Kew Observatory to his own design, in 1880. It was designed for cloud photography. A later cloud camera was made by Becks to Robin Hill's patent in 1924. From 1892 Beck introduced a successful range of cameras under the Frena name with the third thousand being supplied in 1894. The camera was based on Joseph Thacher Clarke's patents and held one or two packs of twenty cut-films, specially made for them by Ilford Ltd, which were changed by rotating a handle on the outside of the camera. Further models were made through to the early 1900s.

During the twentieth century, the firm increasingly focused on supplying lenses and specialist optical instruments before moving away from photographic optics. It underwent several mergers but remains in existence as Coherent Ealing (Europe) Ltd producing specialised high precision opto-mechanical assemblies.

SMITH, JOHN SHAW (1811–1873)

Irish amateur calotypist

John Shaw Smith belonged to the Anglo-Irish landed gentry, born in Clonmuth, County Cork, South Ireland, on October 18, 1811, the fifth of eight sons of John and Mary Richardson Smith. He settled in the family's house of Fairy Hill in Blackrock, on the seaside north of Dublin, and in 1839 he married his first cousin, Mary Louisa Richardson, from whom he had two children, John Augustus (born in 1840) and Florence (born in 1844). His life ended tragically on January 29, 1873, when he shot himself.

His work with the calotype process stands out in the early history of photography in Ireland for the extensive photographic tour that he took along the Mediterranean shores, between December 1850 and September 1852. Before taking this trip, he practiced the calotype process in Ireland, documenting the ruined landscape scenery of his surroundings—the Celtic Graveyard at Blackrock, the monastic settlement at Glendalough—and taking a short trip to Paris, in August 1849. It is not documented whether he had any personal contacts with the French calotypists, but his Parisian views reveal his awareness

of their work, as well as of Lerebours' *Excursions Daguerriennes* (1842–1843). It is likely that Shaw Smith was exposed to photography from its beginnings, as the new invention was announced in 1839 in the "Proceedings of the Royal Irish Academy." Possibly, he knew the work by Scottish calotypists Captain Henry Brewster (Sir David Brewster's son), in Dublin in 1842, and John Muir Wood, in Ireland in the late 1840s. The work of Irish gentleman William Holland Furlong, corresponding with Talbot in the early 1840s, might have also come to his attention.

John Shaw Smith mastered the calotype process, reading a paper about his modification of Blanquart-Evrard's wet-paper process for use in hot and dry climates, at the Dublin Photographic Society in April, 1857 (published in the *Journal of the Photographic Society* on April 21, 1857, and in the *Liverpool and Manchester Photographic Journal*, on May 15, 1857). His modification consisted in adding "bromure d'iode" to the iodizing bath in preparation of the calotype negative (using Whatman's paper and, for higher temperatures from 70 to 85 degrees, Canson's paper). The addition of "bromure d'iode" caused the time exposure to be longer but allowed the paper to remain in good condition for a whole day in high temperatures. The paper was excited in the morning and developed the same evening. The geography he toured along the Mediterranean shores elicits comparison with similar itineraries taken by Calvert Jones (1841, 1845–1846), George Wilson Bridges (1846–1852), and the French calotypists in Egypt, beginning with Maxime Du Camp in 1851.

He photographed the monuments and sceneries of Italy, Greece, Turkey, Egypt, the Sinai peninsula, Palestine, the ruins of Petra, Lebanon, Syria, Malta, and, on his way back, Switzerland. He carefully documented this trip, writing date and location on each negative, organizing each group with geographical headings, and keeping also a travel diary. After 1861, he printed his calotype negatives of Egypt as albumen prints in a two-volume album of seventy-two views with autograph text pages. The photographs of Shaw Smith's tour were not published, and were exhibited only once in his lifetime, in the photographic section at the Dublin International Exhibition in 1865, together with works by Antoine Claudet, Julia Margaret Cameron, O.G. Rejlander, Thomas Annan, Francis Frith, Francis Bedford, where Shaw Smith was awarded an honorable mention for "good productions from paper negatives."

The Grand Tour of John Shaw Smith began in December 1850 in Rome, where he made eighty-one photographs (the largest group in his trip together with those made in Egypt), which followed a preconceived iconography of the Catholic-Roman capital, and sought for picturesque sceneries along the Tiber River, and the surroundings of Tivoli. He was one of the last amateurs who yielded to the lure of Italy with the paper negative, and it is likely that he gathered with the international group of artists and photographers at the Caffe' Greco. He continued the trip south, reaching Naples and Pompeii, taking pictures of the ruined landscape with the Vesuvius in the distance, which echo Calvert Jones' earlier calotypes as well as Charles Dickens' literary observations.

He traveled by steamboat between Naples and Athens, with a stop in Malta, quarantine station between Europe and the Eastern countries. The photographs of Athens reveal his political involvement with the romantic figure of Lord Byron, searching for the house where this hero lived and died during the Anglo-Greek war, and looking for traces of British power over Greece. He continued to Constantinople and Alexandria, stopping in Smyrna, Cairo, and taking a boat-trip along the Nile. He approached the Egyptian ruins in a similar way he photographed the Roman sites, visiting the monument in its architectural context and making progressive sequences that presented each structure and views from a variety of perspectives.

Many photographs taken in the Eastern countries (Petra, Jerusalem, Baalbec) recall his work in Ireland, where ruins are enmeshed in a quiet and deserted landscape, with atmosphere of spiritual and natural decay. The aesthetic rendering of the texture of the stones into the fibers of the paper negative reached its peak in the records of the tombs of Petra, where he arrived as earliest calotypist in history. As for many early photographic travels, the one by the Irish John Shaw Smith raises questions about his own personal engagement with the sites, his cultural and political background, and a growing tradition of organized itineraries, guidebooks, and architectural documentation.

The whole extent of John Shaw Smith's calotype work (346 calotype negatives and 191 salted paper prints) is conserved in two major photographic collections—the Harry Ransom Humanities Research Center at the University of Texas at Austin (from the collection of Helmut Gernsheim) and the George Eastman House in Rochester (from the collection of Alden Scott Boyer)—and, in minor part, in the Photographic Society of Ireland in Dublin.

Maria Antonella Pelizzari

Biography

John Shaw Smith is the only known Irish calotypist who took an extensive trip along the Mediterranean, in Italy, Greece, Turkey, Egypt, the Sinai peninsula, Palestine, Lebanon, Syria, Malta, and Switzerland, between 1850–1852. A smaller body of work documents Irish Celtic ruins, and a trip to Paris. He was born in Clonmuth, County Cork, South Ireland, on October 18,

1811, and was part of the Anglo-Irish landed gentry. His relationships with Scottish, Irish, and French calotypists of his time are possible but not documented. He used Blanquart-Evrard's wet-paper process, improving it for the use in hot and dry climates, and he was a member of the Dublin Photographic society, founded in 1854. His work was not published and was exhibited only once, at the Dublin International Exhibition in 1865. He ended his life tragically, when he shot himself, on January 29, 1873. His large body of work reveals an amateur skilled at the early photographic process, with a good knowledge of other calotypists' works in Europe and the Near East.

SMITH, SAMUEL (1802–1892)
English

Samuel Smith, known locally as 'Mr. Philosopher Smith' on account of his amateur enthusiasm for all things scientific, lived much of his life in Leverington near Wisbech, Cambridgeshire, England, where he 'retired' in the late 1840s after a short but successful career as a timber merchant. He was an amateur astronomer, geologist, microscopist and microscope-maker, and photographer.

He developed his interest in photography c.1851, and between 1852 and 1864, produced a remarkable body of work using le Gray's waxed paper process, sometimes working with Thomas Craddock. His subjects were the ships, buildings and industry of Wisbech, and despite the challenges of the slow waxed paper process, his images present an evocative picture of the Cambridgeshire town.

He prepared his waxed paper negative materials in batches, testing each new batch by photographing Malvern House, his Leverington home. Several of Smith's negatives bear annotated exposure details, confirming exposure times of between ten and fifteen minutes. Thus, for his many views of sailing ships on the River Nene, low tide was the only time photography was practicable.

There is no evidence that Smith ever used wet collodion. He stayed with the waxed paper process until the mid1860s—making him one of the last photographers in the country to employ paper negatives. After 1864, he abandoned photography to pursue his other interests.

JOHN HANNAVY

SMITHSONIAN INSTITUTION

The Smithsonian Institution was established by act of the United States Congress in 1846. Although this legislation provided for scientific and cultural research with a library, a museum and an art gallery proposed, much of the research and collecting for the first decades of the Institution focused on the scientific interests of Secretary Joseph Henry. Photography was first displayed at the Smithsonian during an 1869 exhibition documenting Native American delegations visiting Washington, D.C., Ferdinand V. Hayden of the U.S. Geological Survey and William Blackmore were influential in supporting the exhibition. Alexander Gardner and Antonio Zeno Shindler of Washington photographed many of the nearly four hundred portraits which became part of the Natural History collections. In the same year photographer Thomas W. Smillie was hired as an independent contractor to document buildings and specimens in the Smithsonian. By 1871, Smillie was appointed the first photographer for the Smithsonian and given a staff position to run the photography unit in the Department of Preparation.

Smillie, with the support of Smithsonian officials like Secretary S.P. Langley, Assistant Secretary G. Brown Goode, and Graphic Arts Curator Sylvester R. Koehler, expanded the scope of his work to include preparing Smithsonian traveling exhibitions related to the history of photography. The first of these exhibitions was sent to the Ohio Valley Centennial Exposition in Cincinnati in 1888. Smillie sought examples of photographs and apparatus from individual photographers (both professional and amateur) and commercial manufacturers to illustrate the technical history of the field and contemporary advances. With a broad vision for the newly formed U.S. National Museum (1881), Assistant Secretary G. Brown Goode supported collecting efforts documenting present and past technologies as well as cultural artifacts

from everyday life. Objects for display in 1888 included Samuel F. B. Morse's daguerreotype camera, the first in America; a portrait of Morse, a plate holder, and a fuming box purchased from the National Photographic Association. William Bell and S.R. Seibert donated additional pieces of apparatus for display. Commercial contributors included George Eastman and the Eastman Dry Plate Company, William Kurtz and the Scovill Manufacturing Company.

Following the close of the Cincinnati exhibition, some of photographic items were retained by the Smithsonian as the start of its photography collection. Work on traveling exhibitions and collecting artifacts for a history of photography collection continued over the next decade. Friends to the collection like John Wesley Powell, of the U.S. Geological Survey and later the Smithsonian's Bureau of American Ethnology, and photographer Frances Benjamin Johnston, who apprenticed with Smillie, were influential in bringing significant acquisitions to the growing collection. In 1896, a Section of Photography was recognized within the Division of Graphic Arts, and established as the first unit of its kind in an American public museum. Smillie was given the title of "honorary custodian" of the photography collection while continuing his work as official Smithsonian photographer; he retained both titles through long career. He died in 1917 while still supervising the photography collection.

The 1896 Washington Salon and Photographic Art Exhibition, sponsored by the Camera Club of the Capital Bicycle Club, presented an opportunity to for Goode and Smillie to expand the national collection of photography to include its first examples of the pictorialist, or art photography. Fifty of the 345 works on exhibit at the Washington Salon where purchased for the Smithsonian's new Section of Photography. The selection of platinum and carbon prints represented work of notable photographers such as Philadelphia photographers Alfred Clements, Clarence Moore, and Henry Troth; New York photographer Charles I. Berg; female photographers Mary Bartlett, Sarah Eddy, Emma Fitz, Emma J. Farnwsorth, and Frances Benjamin Johnston; and many amateur photographer members of the Washington Camera Club. Alfred Stieglitz did not submit any of his own photographs to the 1896 Salon but acknowledged the effort of the U.S. National Museum as a step forward in the acceptance of photography as art. Smillie's later correspondence with Stieglitz result in a purchase of twenty-seven photographs from Stieglitz's personal collection of his own work and that of his contemporaries for the installation of the first Smithsonian Hall of Photography in June 1913. The exhibit presented to the visiting public the history of the science, technology and art of photography, select inventors, professional and amateur photographs and equipment, and the beginnings of the motion picture.

Only four men have followed Thomas Smillie as custodians to the unit: Loring Beeson (1917–1920), A.J. Olmsted (1920–1946), Alexander Wedderburn (1946–1960), and Eugene Ostroff (1960–1994). Wedderburn and Ostroff held the title of curator. Important materials accessioned reference the various processes and formats of photography and significant collections of individual photographers William Henry Fox Talbot, J.W. Osborne, Dr. John W. Draper, Peter Neff, Eadweard Muybridge, H.H. Bennett, Frederic Ives, Ansel Adams, Victor Keppler, Richard Avedon, Elliott Erwitt, and Edward Weston. Works by Washington, D.C. photographers are collected, such as Mathew Brady, Alexander Gardner, William Henry Jackson, William Towle, the Bell and Scurlock families, and Fred Maroon. Strengths in the apparatus collection are the U.S. Patent Model collection, stereoscopic cameras and viewers, the GAF collection and still camera collection, the printing and processing collection, and early motion picture apparatus dating from 1895–1915.

More than one hundred years have past since the inception of the Smithsonian's collections pertaining to the history of photography. Now referred to as the Photographic History Collection within the National Museum of American History, the unit's mission focuses primarily on American photography encompassing social history, technical innovation and aesthetic values. Yet, the Collection has maintained a holistic approach to document the history of the field, study the effects of time, and collect best works of both professional and amateur photographers. The Collection has increased to 150,000 photographs and 10,000 pieces of photographic apparatus.

The Smithsonian Institution now administers sixteen museums each with photograph collections pertaining to its holdings. The African Art Museum, Cooper-Hewitt Museum of Design, Freer/Sackler Gallery of Asian Art, Hirshhorn Museum and Sculpture Garden (modern art/international scope), National Museum of American History, National Museum of American Indian, National Museum of Natural History, National Portrait Gallery, Smithsonian American Art Museum, and Smithsonian Archives all offer rich research opportunities in the study of photography.

SNAPSHOT PHOTOGRAPHY

Before it acquired the photographic meaning with which it is now primarily associated, the word 'snapshot' was originally a hunting or shooting term describing a shot taken quickly, without careful aim or preparation. In 1850, for example, *Blackwood's Edinburgh Magazine* wrote of intrepid African explorers pressing on 'without pausing in their route, even to take a snap-shot at a crocodile basking on a sand-spit' (*Blackwood's Edinburgh Magazine***,** August 1850, 231). During the 1850s, when 'instantaneous' photography first became a technical possibility, the term seems to have first begun to be used in a photographic context. Certainly, by 1859, a report of a demonstration of Thomas Skaife's Pistolgraph camera in *The British Journal of Photography* describes how the camera operator 'was directed to snap his camera at the skylight' *(BJP*, 1 July 1859). In this case, of course, the link with firearms is implicit in the name Skaife chose to give his camera. However, the term was also open to a broader interpretation. The following year, for example, writing in *The Photographic News*, Sir John Herschel referred to 'the possibility of taking a photograph, as it were, by a snap-shot—of securing a picture in a tenth of a second of time' (*The Photographic News*, 11 May 1860). On the basis of this remark, Herschel is usually credited with coining the term 'snapshot' to describe a photograph taken with a very brief exposure. However, it is quite possible, that he was simply echoing what was already current usage.

Herschel's comments, whilst prophetic, did not reflect photography's capability at the time. Although 'instantaneous' photographs were indeed produced during the 1860s—often as stereoscopic pairs—it was not until the introduction of much more sensitive gelatin dry plates in the late 1870s that the practice became widespread. Dry plates not only made possible the pioneering chronophotography of Muybridge, Marey and Anschutz but also profoundly affected the work of amateur photographers by extending greatly the range of subjects available to them. Their introduction also had a radical effect on camera design. For the first time, exposures were now brief enough to allow cameras to be held in the hand when taking a photograph. Freed from the need for a tripod, a new generation of hand-held box-form cameras appeared in the 1880s. Because of their comparatively inconspicuous appearance and speed of operation, which made 'candid' photography possible for the first time, these were popularly known as 'detective' cameras—a term coined by Thomas Bolas in 1881. Most were simple wooden boxes, sometimes covered in leather or brown paper, so as to resemble bags or parcels. Some were disguised as books or watches, hidden in ties, hats or walking sticks or intended to be worn, concealed beneath a waistcoat. Most 'serious' photographers rejected the term 'detective' since they felt that it damaged both their individual reputations and that of photography as a whole. They felt that it encouraged the popular notion of the 'camera fiend' who took people's photographs without their knowledge or consent. Henry Peach Robinson, for one, considered that: 'There is something in the sound of the word so mean, sneaking and unutterably low-down that it quite choked me off having anything to do with the whole concern**'** (*The Amateur Photographer*, 27 March 1896, 270). Robinson's preferred term was the less sensational and more accurate 'hand' camera.

The idea of hidden cameras, of observing without being observed and of being photographed unawares, certainly caught the imagination of the general public. The ubiquitous 'camera fiend' turns up frequently in contemporary cartoons, newspapers and popular magazines. In 1895, *The Amateur Photographer* magazine (founded in 1884 and a manifestation of the rapid growth of photography as a hobby) complained: 'We are gradually beginning to think that when a man gets hold of a hand-camera he loses some of his moral balance, and he does things which otherwise he would not think of doing; and unless he recognises this and pulls himself up short, he degenerates into that worst of all types—the snap-shot fiend' (*The Amateur Photographer*, 19 July 1895, 34). Three years later, when hand cameras were a little less of a novelty, *The British Journal of Photography*, could still write: 'One often hears and reads of the 'hand-camera fiend' who 'snap-shots' (sic) ladies as they emerge from their morning dip at the seaside, or loving couples quietly reading under a shady rock' (*BJP,* 23 December 1898, 818). By the 1890s, then, the term 'snapshot,' whilst still referring to a photograph taken with a brief exposure, had acquired a second and more widely-used meaning as a 'candid' photograph taken without the subject's knowledge or permission. The lure

of covert photography was deemed to be so tempting that even members of reputable clubs and societies had to be warned about succumbing to its attractions. In 1892, a speaker at a meeting of the West Surrey Photographic Society hoped that members of his audience 'would not at any time bring discredit upon hand-camera work by 'snap-shotting' (sic) persons under conditions which might cause unpleasantness' *(BJP*, 11 November 1892, 732). The appropriate choice of subject was not the only cause for concern. The convenience, flexibility, cheapness and comparative ease of use of hand cameras challenged photography's status both as an 'art' and as a 'craft' requiring skill and dedication. As *The Amateur Photographer* observed in 1894: 'The hand-camera has not exercised a most salutary influence on the status of photography; the use of the instrument, the cheapness of some forms too, tending to produce a careless haphazard style of working in which 'flukes' are sure to be occasionally successfu.' (*The Amateur Photographer*, 5 January 1894). Alfred Stieglitz, despite being an early advocate of the hand-camera as a creative tool, concurred: 'The placing in the hands of the general public a means of making pictures with but little labor and requiring less knowledge has of necessity been followed by the production of millions of photographs. It is due to this fatal facility that photography as a picture-making medium has fallen into disrepute' (*Scribner's Magazine*, November 1899, quoted in Nickel, Snapshots, 11). Indeed, since snapshots are usually taken by people with little or no technical knowledge or aesthetic sensibility—with predictable results—the word has also acquired a pejorative association. This seems to be a comparatively recent interpretation. Paul Martin, for example, usually described his photographs as 'snapshots' or even 'snaps' and even called his 1939 autobiography *Victorian Snapshots*.

Confused and threatened by such rapid change, some photographers looked back at what they perceived as a lost 'golden age': 'In the good old time of collodion and silver baths, amateur photographers were comparatively few, and they were looked up to by their friends as being far above ordinary mortals, owing to their knowledge of the black art…They had to do all the work themselves…and felt rewarded for all their trouble by their intense pride in the result. Now, alas! All that is changed, the amateur photographer is everywhere; he knows nothing of the troubles of his predecessors and has no respect for the old amateur…who often finds that he has to take a back seat to make room for the man who, only last week, bought a 'complete outfit' for a guinea, 'directions for use' included' (*BJP Almanac*, 1890,p446). Some die-hard conservatives refused to compromise. Colonel Joseph Gale, for example, when asked whether he would consider doing some hand-camera work, replied, 'I have not descended to level yet.' (*The Photographic Journal*, July 1934, 345). Others, however, such as Paul Martin, actively embraced the new and exciting possibilities offered by the dry plate and hand-camera, capturing the world of the 1890s with his trusty 'Facile' camera, tucked under his arm. Discovering the delights of candid photography, he later enthused, 'It is impossible to describe the thrill which taking the first snap without being noticed gave one' (Paul Martin, *Victorian Snapshots*, 22). George Davison, who as well as being a leading pictorial photographer was also a director and assistant manager of the Eastman Photographic materials Company, managed to persuade several of his photographic friends, including Eustace Calland, J. Craig Annan and Frank Meadow Sutcliffe, to try out Kodak rollfilm cameras so that the results could be used for advertising or promotion. In 1897, in another initiative to promote the legitimacy of the hand-camera, Davison organised the first public exhibition of snapshot photography. As well as amateur work received as entries for an international competition, the exhibition also included an invitation section of work by leading pictorial photographers and a selection of work by Royal photographers, including Princess Alexandra. The exhibition was a great success and after its three-week run at the New Gallery in London's Regent Street transferred to the National Academy of Design in New York.

The success of the Eastman Exhibition was a measure of the extent to which snapshot photography had caught the interest of the public. Whilst the debate about snapshot photography rumbled on in the photographic press and in club and society meetings, the public had, it seemed, already made up its mind, knowing little and caring even less about the opinions of the likes of Colonel Gale or Alfred Stieglitz. Events had conspired to overtake matters. For in the wider world a revolution was taking place. A revolution that was to fundamentally alter the nature of amateur photography; A revolution that had been triggered in 1888 by the appearance of a 'detective' camera named *The Kodak*.

Marketed with the famous slogan 'You press the button, we do the rest,' the Kodak was simple enough for anyone to use. Eastman claimed: 'We furnish anybody, man, woman or child, who has sufficient intelligence to point a box straight and press a button…with an instrument which altogether removes from the practice of photography the necessity for exceptional facilities, or in fact any special knowledge of the art. Significantly, the camera formed merely part of a complete system of amateur photography that was to revolutionise photography. The Kodak camera was pre-loaded with film. After this had been exposed, the entire camera was returned to the factory for the film to be developed and

printed. The camera, reloaded with fresh film, was then returned to its owner with their negatives and a set of prints. For the first time, the act of picture-*taking* was separated from that of picture-*making.* Contemporary observers soon realised the significance of the Kodak System. Reviewing the Kodak, *Scientific American* magazine concluded that 'it promises to make the art of photography well nigh universal.' Ironically, of course, in making photography universal it also directly challenged its claim to be regarded as an 'art.' How could such a democratic and quotidian medium whose subjects were largely drawn from the trivial and banal have any pretensions towards 'Art'?

Crucially, the Kodak was not aimed at existing photographers but at a vast new untapped market that Eastman had created for photography. As *The Photographic News* was quick to realise: 'The Kodak is intended…to bring into the ranks a new class—those who do not wish to devote the time and attention which is necessary to really practice photography, but who desire to obtain records of a tour, or to obtain views for other purposes' (*The Photographic News*, 14 September 1888, 578). Eastman's own advertising copy put it more succinctly—'Anybody can use it. Everybody will use it.' With cameras placed in the hands of people who were not perceived to be 'photographers,' the word snapshot took on its third and current definition, meaning a photograph taken by an unsophisticated amateur, using a simple camera. Today, it is the intent of the photographer rather than the exposure time or choice of subject that best serves to define the snapshot. Whilst the majority of snapshots are taken with comparatively brief exposures, some are not. Moreover, whilst the word also implies a degree of spontaneity, many snapshots are the result of considerable preparation and arrangement of the subject. The fundamental characteristic of the snapshot is that it is a 'naïve' document motivated solely by a personal desire to create a photographic record of a person, place, or event with no artistic pretensions or commercial considerations.

Following the success of the Kodak, the rapid introduction of ever-cheaper camera models, culminating in Eastman's introduction of the Brownie camera in 1900, removed many of the financial as well as the technical constraints that had delayed the popularization of photography. For the first time, photography became truly accessible to millions of people. In 1896, even before the appearance of the Brownie, the writer, J. Ashby Sterry, wrote about 'these days of the universal Kodak and perpetual snap-shooter' (J. Ashby Sterry, *A Tale of The Thames*, 1896). In 1899, *The New Penny Magazine* in an article entitled 'Snap-Shot Photography' could confidently claim that 'Almost everyone now has some idea of the taking and making of a photographic picture' (*The New Penny Magazine*, 1899, 282). The snapshot had come of age.

SNELLING, HENRY HUNT (1817–1897)

The History and Practice of the Art of Photography, published in 1849, was the first book from the pen of Henry Hunt Snelling, who would go on to establish, edit, and publish the influential *Photographic Art Journal* in 1851.

A writer, editor and photographer, Snelling was born in Plattsburg, New York, on November 8, 1817, where his father, a colonel in the US Army, was stationed. He spent much of his childhood travelling to new postings with his parents, eventually settling in Detroit with his mother in 1829 after his father's death.

After a number of generally unsuccessful business ventures, Snelling, in 1847, took up a position with Edward Anthony, then the major manufacturer and supplier of photographic materials, equipment and accessories. Questions about technique from customers reputedly encouraged Snelling to believe that there was a market for instruction manuals, and *The History and Practice of the Art of Photography* appeared within two years.

It was, however, the monthly publication of *The Photographic Art Journal*, renamed in 1854 *The Photographic and Fine Art Journal*, which established Snelling as perhaps the most authoritative voice on the development of American photography at the time. Two further books, *A Dictionary of the Photographic Art* (1854), and *a Guide to the Whole Art of Photography* (1858) further cemented his reputation.

SOCIÉTÉ FRANÇAISE DE PHOTOGRAPHIE (SFP)

French organization, 1854 to present

The Société française de photographie (SFP) was founded November 15, 1854, by seventeen former members of the Société heliographique (SH) (1851–53) and a number of prominent figures in the sciences, the arts, government, and society—non-photographers as well as practitioners. The character of the earlier Société heliographique, a rather relaxed, genteel group with meeting rooms in the home of its president, Colonel de Montfort, intimate photographic soirees in private homes, and a self-described identity as an organization for "those looking in their leisure time for the charm of a noble interest and the attraction of an elevated preoccupation" (Janis 1983, 42) was that of an exclusive group of enlightened amateurs. The SFP adopted a more formal structure appropriate to a learned society organized on the model of the French Academies. The precise connections between the earlier organization and the SFP have yet to be traced. Although many former SH members became members of the SFP, the SFP was not a continuation of the earlier organization. In fact, prominent members of the earlier group are notable in their absence, for example, Henri LeSecq and Ernest Lacan, while others, such as Eduard Baldus only joined later.

The Société française de photographie defined itself under its organizing statutes as "an artistic and scientific association of men studying photography." Membership was limited and exclusive. By charter there would be two hundred regular members, and an additional two hundred corresponding members from outside Paris; a membership number no doubt based on the model of the two hundred member Institut de France. Ten of the founding members of the SFP were members of the Institut de France, including the first president Victor Regnault. They also counted among their founders, members of the nobility, i.e., Count Aguado, Baron Gros, and Baron Humbert de Molard. Included among the ninety-three founders were representatives from the arts—Eugène Delacroix, Vallou de Villeneuve, Louis Robert, Eugène Durieu and Eugène Cuvelier—and sciences—the botanist Brébisson, naturalists Geoffrey-Saint-Hilaire and Louis Rousseau, and physicist Léon Foucault. Several members came from the mid and upper ranks of the Second Empire bureaucracy. And, of course, a number of photographers associated with the Société Heliographique—Hippolyte Bayard, Gustave LeGray, Charles Nègre, Blanquart-Evrard, Léon de Laborde—were also founding members. Victor Regnault, a physical chemist, director of the Imperial Porcelain Manufactury at Sèvres, and a photographer, served as the SFP's first president, a position he held until 1868. By 1855 membership had grown to 165 members. The aspirations of the organization were defined in the first issue of the *Bulletin de Société Français de Photographie* (January 1855) which explicitly denied "any consideration foreign to purely scientific and artistic goal[s]…[other than] the pure love of the photographic art and science" (McCauley 1994, 41). McCauley identified a strong anti-commercial bias in the membership and program of the SFP and notes that during a period characterized by the explosion of commercial photography studios and the firms serving them (1850–1870), relatively few commercial operators were to be found in its membership rolls.

The SFP's administrative committee comprising fifteen members and officers organized regular bimonthly meetings which were conducted under formal rules of order like those governing the Academies. Committees were established to investigate reports, review scientific submissions—generally to do with innovations in processes and equipment—and to vet technical communiqués. Meetings and the work of the committees were reported in the *Bulletin de Société Français de Photographie,* which also announced competitions, almost exclusively of a scientific or technical nature, and published the prize-winning submissions. The secretary carried on lengthy correspondence with a number of foreign photographic societies excerpts of which appeared in the *Bulletin*. The *Bulletin* quickly settled into a dual role as the means of communicating the work of the SFP and its members, and a journal devoted to the scientific and technical aspects of photography. Issues that might have been of interest to commercial photographers—laws governing photographic rights, or advances specifically geared to commercial interests in the rapidly industrializing practice of photography—were not addressed. It was no doubt due to the lack of support for commercial interests that in 1859 Ernest Mayer, of the firm Mayer frères et Pierson, founded the Union photographique as a mutual aid society for photographic workers.

Within months of its founding, the SFP began to organize photographic exhibitions; the first opened in September 1855 and coincided with the Paris Universal Exposition which featured a remarkably strong showing of photographic work. Between 1855 and 1876, the SFP organized eleven photographic exhibitions—1857, 1859, 1861, 1863, 1864, 1865, 1869, 1870, 1874, and 1876—a continuous program of exhibitions which roughly coincided with the Paris painting salons. Exhibitions were open to members and non-members, and to foreigner practitioners. The SFP's exhibitions quickly achieved the status of the photographic salon on the order of the official paintings salons. The 1859 SFP exhibition was held in the Palais des Champs-Elysées in rooms adjacent to the Salon, the government sponsored

painting exhibition. Subsequent exhibitions opened on the same day as the *Salons,* which rejected all submissions in photography. The Société's exhibition committee also organized French representation in exhibitions in other countries. SFP members exhibited as a group in Brussels in 1856, in a large space dedicated to French photographic achievement. This was also the case in reciprocal arrangements the SFP entered into with the Royal Photographic Society (RPS) of England; in the RPS exhibitions of 1858 and 1863, SFP members were accorded their own section or rooms.

By far the most press recognition and critical attention accorded to photography was directed to the exhibitions of the SFP. With the exception of the 1855 exhibition, every later exhibition was accompanied by a catalogue which listed photographers by name and nationality, described the subject of submitted images, and identified both negative and print processes. They constitute an invaluable resource for researchers. In addition, the *Bulletin* devoted extensive coverage and detailed reviews to all of the SFP exhibitions, as well as the photography sections of the Universal Expositions of 1855 and 1867, and international exhibitions of photography in Brussels, London, Edinburgh, etc.

The scientific focus came to dominate the SFP to the exclusion of the arts towards the end of the nineteenth century. Within the *Bulletin* there are fewer references to artistic projects by members; discussions of issues of aesthetics, never prominent, disappear. The criteria for evaluating work presented in the SFP exhibitions increasingly focused on technical competence. As the nineteenth century drew to a close, the SFP came more and more to function as a scientific academy in which scientific and technical issues could be presented and debated, and as a repository for technical examples. Prizes for technical innovation were offered under the aegis of the Société and a number of technical challenges were posed by the Société with awards determined by committees made up of members with scientific backgrounds. This insured that important innovations were presented first to the SFP for publication in the *Bulletin.* Scientific and technical submissions ranged from that of Edmund Becquerel, a founding member, who published the results of his experiments with heliochromy, or recording the colors of the light spectrum on daguerreotype plates, to Alphonse Poitevin's presentation of a photolithographic printing process. But the SFP's preoccupation with scientific and technical questions created an increasing sense of disenfranchisement for members who aspired to artistic photographic practice. Ultimately, although some maintained membership in what was clearly the most prestigious photographic organization in France, they and others formed organizations that reflected more closely their interests. Such an organization was the Photo-Club de Paris, founded in 1894 by SFP member Robert Demachy and others, to address the interests of artistic photographers. The Photo-Club's first exhibition (1895) was titled the First Exhibition of Photographic Art, a rather heavy-handed effort to distinguish their program from the exhibitions of the SFP. This division of artistic practice from the overwhelmingly scientific and technical bent of photographic organizations, such as the SFP, was echoed by similar organizations in London—Linked Ring Brotherhood—and Vienna—Das Kleeblatt (The Clover Leaf)—and New York—The Photo-Secession.

Société française de photographie continues to this day as a research center. Their holdings include superb collections of images—contemporary and historic, examples of rare photographic processes and types of equipment, as well as members' archives which include papers and photographic prints and negatives. The Société maintains a library devoted to historic and contemporary photography. In 2006, they list their holdings at 10,000 books and five hundred photographic journals from twenty-four countries. This includes extensive holdings of early photographic journals from around the world. The collection of early photographs can be counted among the most important of French photographic collections. Publication of the *Bulletin* continues, and is joined by a journal devoted to historical and critical research, *Études photographique.* The SFP continues to promote the study of photography—both its history and contemporary use—through lectures and its collection.

SOCIÉTÉ HÉLIOGRAPHIQUE

In the early stages of the history of photography, many people were experimenting with the new medium. The calotype process, which is a paper negative process, was one of the most important techniques of the time.

In 1851, a group of artists, writers, and photographers got together and formed the first photographic society in the world: the Société héliographique française. The creation of this photographic society was a landmark moment in the evolution of photography and important for its history. It was a network of people excited about the possibilities of the calotype and interested in exchanging both chemical and artistic skills, which contributed to the expansion and development of photography through exhibitions, members' projects such as La Mission Héliographique, and the review, *La Lumière*.

The 1850s was a time when many different groups were being established and efforts were being made to legitimize the new medium. The objective of the society was to unite those involved in the new process and to exchange ideas. The Société héliographique was an important development for the growth and recognition of photography because it promoted the medium.

The society was formed by Baron de Montfort in January of 1851 in Paris, France and its first president was Baron Gros, a diplomat and photographer. The group was made up of mostly photographers, amateur and advanced, as well as painters, writers, scholars, and public figures. The society's board included Hippolyte Bayard, Edmond Becquerel, Benjamin Delessert, Eugène Durieu, Mestral, Léon de Laborde, Claude-Marie-François Niépce of Saint-Victor, Jules-Claude Ziegler and Baron de Montfort himself. Many of master photographer Gustave Le Gray's students, as well as students of painter Eugène Delacroix's, were members; both of these artists were also members. Additional members included Olympe Aguado, Arnoux, Aussandon, Edouard Baldus, Barre, Champfleury, Charles Chevalier, Cousin, Desmaisons, Fortier, Count of Hassounville, Horeau, Lemaître, Henri Le Secq, Noël-Marie-Paymal Lerebours, Leisse, Frédéric Bourgeois de Mercey, Montesquiou, Prince of Montléart, Emile Peccarère, Viscount Adolphe of Poncéau, Peuch, Puille, Victor Regnault, Schlumberger, FrançoisAuguste Renard, Viscount Joseph Vigier and Francis Wey.

The headquarters of the society was at Baron de Montfort's home, 15 rue de l'Arcade in Paris. The top floor of the building contained meeting rooms as well as rooms closed off for developing and experimenting in the new medium and an outside terrace for members' use. The building also had a shop, owned by Mr. Peuch, which sold photographic materials.

Members were united with a common cause which was to endorse photography through exhibitions, share technical information, publish reviews and more. They met frequently to work on developing the technique. Lengthy discussions took place and served as a way to pass along skills and knowledge of the technique. Beyond the regular informal get-togethers, the society had "photography soirées" at the Baron de Montfort's home or at other members' homes.

The society also held exhibitions, notably an opening exhibition in January of 1851 as well as an exhibition which included a portfolio "intended to illustrate the best French photography" by Charles Nègre titled *Little Ragpicker* (Pare, 228). The society also assembled a collection of photographs in the form of albums.

The weekly magazine, *La Lumière*, was a significant part of the society and prospered even after the society ended. Under the direction of both Francis Wey, who served as head of the society for part of its existence, and Ernest Lacan, *La Lumière* reviewed exhibitions as well as members' work and even recorded the society's meetings. While reporting on photographic projects of the time, *La Lumière* expressed the great enthusiasm for the medium that the members shared in the Société héliographique. The magazine existed from 1851 to 1860 and remains a very important document for the medium's history of the time period, and certainly for the history of the Société héliographique.

Since the 1850s was an important time for the advancement of photography, the Société héliographique played an important role in its progress. For example, five members of the society—Gustave Le Gray, Mestral, Édouard Baldus, Hippolyte Bayard and Henri Le Secq—became the group that formed the Mission Héliographique, commissioned by the government's Commission of Historical Monuments. One of the leading members of the Commission, Léon de Laborde, was also a member of the Société héliographique. The mission's goal was to send these five photographers across France to document important French architectural structures. This effort, a large proportion of which was produced by using le Gray's waxed paper process, was an attempt to record French cultural heritage and began shortly after the foundation of the Société héliographique. *La Lumière* reported with great fervor and praise for the project.

British photographer, Roger Fenton who had studied in Paris under painter Delaroche from 1841–1843, went back to France in 1851 to study the structure and organization of the newly created Société héliographique. The following year he drafted a proposal for a photographic society back in Britain and eventually founded the London Photographic Society in 1853.

The Société héliographique française dissolved in 1854 and became the Société française de photographie which still exists today. As for the end of this group, photography historian Michel Frizot explains in "Calotypists circles," that "this "secession" may be related to the change in technique from paper to glass negatives and the need for better organization of meetings, which remained informal and friendly" (*A New History of Photography*, Frizot, 70). The group was informal

but then as the medium became more complex, it was necessary for a more disciplined approach to exploring its complexities. The Société héliographique published reviews, held discussions and exhibitions related to promoting the technique, and served as a model for future organizations. The society still remains an important step in the evolution of the photographic medium.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN ASIA (EXCLUDING INDIA)

The photographical technique was a blend of various inventions stemming from diverse origins. Soon after its first public circulation in August 1839, photography freely entered the commercial field. The ability, open to everyone, to daguerreotype was the key to success. Photography then spread through Europe, America and few years later throughout the world. The spread of photography in Asia, as elsewhere, does not only come from the novelty of the process. It also benefited from the commercial expansion of western countries through eastbound sea routes and first appears in Asia in coastal towns open o foreign trade.

Photography also reached the orient with the various diplomatic or military expeditions, as they often included an amateur or a professional photographer.

Soon, many adventurers, attracted by the chance of fortune, would try to establish photographic studios in Asia. Singapore—first trading post in 1819, then crown colony in 1867—had its first documented photographer in 1843. The economic growth of the colony attracted many studios such as August Sachtler, 1863, and G.R. Lambert & Co, 1867. The enthusiasm of the foreign community both drew new photographers to Singapore and urged them to get organized. The first official society was the Strait Photographic Association, created in 1887 at Hill Street. The first president was D.C. Neave, founder o the F&N Company. As soon as 1894, members of this association took part in international photographic competitions and won prizes in Jakarta.

In the same period, China was compelled to open Canton (Guangzhou), Amoy (Xiamen), Foochow (Fuzhou), Ningpo (Ningbo), and Shanghai to foreign trade and cede Hong Kong, following the signature of the Treaty of Nanking on 29 August 1842. It allowed British merchants to establish "spheres of influence" in and around the ports and permitted the installation of occidental newcomers (merchants, soldiers, traders, diplomats, adventurers etc.) and with them along came photography. Jules Itier took the first documented daguerreotypes of Macau and Canton in 1844. He was a member of the French embassy of Théodose de Lagrenée, who signed the treaty of Whampoa (24 October 1844) between France and China.

The arrival of photography depended on the opening to foreign trade of the coastal owns of southern China. However the first photographers society was founded only in 1937, it was The Photographic Society of Hong Kong. It also followed the route of military expeditions, as the armies took photographers along. Felice Beato would go further in land in 1860, taking pictures in the trail of the Anglo-French force, which invaded Peking and burnt the famous Summer Palace.

Photography reached Japan in much the same way. From 1853 onward, Japan, closed to all foreign trade since 1639, started to open its ports under the pressure of western countries. Ports as Yokohama, Nagasaki, or Kobe were then open to westerners. The first known daguerreotype of Japan dates from 1857, but professional studios appear only a few years later. Charles Wirgman, sent to Japan as a correspondent of *The Illustrated London News* as soon as 1861, invited Felice Beato to join him in 1863. Together, they founded in 1865 their first commercial venture, a studio in Yokohama. It is significant that when the second owners of this firm were still westerners, Stillfried & Andersen, the next one was a Japanese, Kusakabe Kimbei.

The further improvement of photographical techniques increasingly mastered by Japanese would foster amateur practice. The first society, the Nihon Shashinkai was created in 1889 by William Burton, a professor at Tokyo's imperial university, Ogawa Kazumasa, and other native and foreign photographers. Ogawa's friend, Japanese Viscount N. Okabe was an amateur

photographer too and through his wealth and position could help the development of photography in Japan. As a president of this society Enomoto Takeaki, an influent member of the Meiji government, tried to promote photography as an artistic medium. Other photographic societies emerged at the turn of the century, such as the Tokyo Shayu –kai, founded by Osaki Koyo, or the Toyo Shashin-kai, by Miyauchi Kotaro.

In south-east Asia, the lead of Thaïland in the adoption of photography must be noted. It is due first and foremost to the implication of King Rama IV. The king created a royal department of photography in his government and had the queen and himself portrayed. The French bishop Pallegoix, leader of Siam's Catholic Church, introduced daguerreotype a mere few years after its invention. According to a 1905 edition of the Sayam Prabhet newspaper, the country's first native photographers were Pallegoix's students, Phraya Kasapkijkosol, Phra Preechakolkarn and Luang Akaneenaruemitr, who is best known today as Chit Chitrakanee or Francis Chit.

In other parts of south-east Asia, the British colonial administration sent various archeological or artistic surveys, often with a photographer, such as the one sent to Burma in 1855 to document the ancient town of Ava.

Photographers reached Indochina and other French colonies or protectorates following the progression of troops in Cochinchina. Emile Gsell was the first to settle in Saigon and have his studio there from 1866 to 1879. The progression of the troops in the north—Annam and Tonkin—allowed photography there too. Hocquart, a military doctor, illustrated through his photographs the progress of French colonization. But no real organization dedicated to photography was established before the beginnings of twentieth century. The EFEO—French school of far-eastern studies—established in Hanoi in 1900, was the first body to launch extensive photographic campaigns.

Documentation about societies, groups and exhibitions of photography in far-east Asia is very scarce and few historians have so far had either the ability or the will to search through the subject. The broad outline as it appears today is that of a parallel progression of photography, trade, military conquests, religious missions and industry. The countries where a strong political system, and the social elites, were willing to adopt the new technologies brought from the west, such as Siam and Japan, were the ones where amateur and professional photographers first got organized in societies or government bodies. Many foreigners were also probably members of photographic societies in their home countries. Elsewhere the societies seem to appear only in the twentieth century. It is likely that the exhibitions or fairs dedicated to industry and trade also played a role in the diffusion of photography but they are yet to be studied. It would be interesting to compare the case of far-east Asia to that of India, where photography rose fast and strong in the nineteenth century.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN AUSTRALASIA (INCLUDING NEW ZEALAND AND PACIFIC)

Nineteenth-century Immigrants from Great Britain who chose to settle in Australasia may have been surprised to find that once they'd settled into their new homes, they had on their doorstep some refinements which hitherto may have been denied them because of their status in society. These were learned institutions which went under a multiplicity of names like the Philosophical Society or the Mechanics Institute. Some of these may have been fostered by those who were responsible for organising their passage in the first place. For instance, the New Zealand Company, largely responsible for the settlement of Port Nicholson, saw to it that a consignment of books was dispatched to the colony. For an annual membership fee, immigrants could join these groups and participate in the exchange of information on a myriad of topics, especially the arts and sciences.

Wellingtonians for instance, were able to boast a Mechanics Institute in a temporary dwelling which was purchased for £30 in 1842, barely two years after the settlement was established. This housed a library and a selection of (unspecified) scientific instruments which had been purchased in London prior to the departure of the first immigrant ships that left England in September 1839.

Institutions like this became a conduit which saw the dissemination of knowledge including the virtues of the daguerreotype and other photographic improvements which followed at a rapid pace. It may come as a surprise to known that Australians and New Zealanders were more than familiar with the theoretical workings of the daguerreotype and the calotype well before a decade had elapsed after their discovery. Wellington's Mechanics Institute represents just one of many fledgling institutions that developed throughout Australasia.

Of course anyone involved in the arts and sciences in mid-Victorian times was eagerly sought to give ad-

dresses to its members. In August 1848, the daguerreotypist H.B. Sealey was invited to become a member of the Mechanics Executive Committee after he had presented an address on the daguerreotype.

Elsewhere in the South Pacific, with smaller centres of population, it would be difficult to maintain anything approaching a society or an institution.

However, as missionaries were very active with cameras, it may have occasioned an instance whereby one of their party may have given a talk or demonstration of their skills. Their audience may have included land owners, government employees and traders. For instance, the French settlement in New Caledonia saw a number of photographers from 1848.

After the discovery of gold in payable quantities, some cities like Melbourne in Australia and Dunedin in New Zealand's South Island, demonstrated their wealth with trade exhibitions. These colonial events attempted to follow that which had been established in London in 1851 with The Great Exhibition. They were ideal platforms for displaying photographs and elicited great attention whenever they were staged. Dunedins' first exhibition was in 1865 and it was repeated again in 1889/90, when it carried the more impressive title of title of the New Zealand and South Seas Exhibition.

Gradually, as some of the wrinkles were removed from photography an ever growing number of educated people began to take up the craft as a recreational pursuit. Some of these amateurs formed themselves temporarily into groups like those who met on 8 December 1858 in Sydney under the auspices of the Philosophical Society of New South Wales.

This may well have been the first such group in Australasia. As amateurs tended to push the boundaries of photography, there eventually came a need to show their handiwork to a wider audience. The amateur photographer Rev. John Kinder (1819–1903) exhibited a selection of his photographic views at two exhibitions run by the Auckland Society of Arts in 1870 and again in 1873. Despite these developments, photographers in Australasia had to wait many years before anything resembling a photographic society of some significance got off the ground.

In New Zealand the first photographic organisation to appear on the scene was the Amateur Photographic Association of 1882, which met on a monthly basis and had its base in Wellington. A prominent member of this Association was Arthur Thomas Bothamley (1836–1948), a civil servant who played an important role in New Zealand's exhibit at the 1876 International Exhibition in Philadelphia. Also active about this time in the Association was an amateur who went on to become a member of the New Zealand's Parliament, William Thomas Locke Travers (1819–1903). In 1871, Travers read an important paper to the Wellington Philosophical Society on "Out-door photography," a report which drew attention to some photographic characteristics peculiar to this part of the world, like the effect of ultra violet light on photographic emulsions which had been devised mainly for use in the northern hemispheres.

The 1890s witnessed a period of tremendous expansion as easy-to-use cameras of all description became available at low cost. Photographic clubs and societies were formed in nearly every major settlement. A highlight in their annual calendar of events was the Intercolonial Exhibitions which saw entries from both sides of the Tasman Sea gathered together where they were judged and awarded medals and certificates.

Attempting to bond these widely spread groups into a united front fell unwittingly into the lap of several publications which were established in the early 1890s. Two of these were Australian journals. They were *Harrington¹s Photographic Journal* which, though printed in Australia, was also released in New Zealand. It was founded in 1892. Similarly, the Australian Photographic Review also found its way across the Tasmanfrom 1894. In New Zealand, *Sharland's New Zealand Photographer*, also commenced publication in 1892. This was edited by Josiah Martin, (1843–1916) a commercial photographer who amongst other things opposed soft focus photography and actively campaigned for a number of matters which identified injustices to photographers when it came to government agencies who were undercutting professionals who were involved in supplying prints for the lucrative tourist market.

As the nineteenth century came to a close, New Zealand photographers were able to measure themselves for the first time against their overseas counterparts. A British annual called *Photograms of the Year*, which published a yearly survey of fine art prints from around the world, despatched a folio which included examples by H.P. Robinson. These were toured in Australasia by photographic clubs and societies in 1896.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN AUSTRIA

Among the most important places and proliferation of early photography in Austria is Physikinstitut der Wiener Universität, das Polytechnische Institut in Wien (1815 an engineer created academy, which is called today the University of Vienna) and the Niederösterreichische Tradesman's Union (which was a 1839 union of the industrial middle class with financial support from Viennese aristocracy circles, and is known today as the Austrian Tradesman's Union). Andreas von Ettingshausen was chair of physics at the Viennese university since 1834, and was a reader of the publication of the Daguerreotype in Paris 1839. Von Ettingshausen and his nephew William Burger gave lectures on photography between 1863 and 1867. From 1896 to 1930 these types of lectures were given by the photographer Hugo Hinterberger who specialized in photomicrographs. Johann Joseph Prechtl (supervisor from 1815, and until 1849 was the director of the school) and the chemists Anton von Schroetter and Joseph Johann Pohl were the main figures responsible for supporting photography at the polytechnic institute. On Prechtls suggestion Anton George Martin (initially an assistant at physical Institut, starting from 1843 as the librarian of the polytechnic institute) and the others began to experiment with photography.

Under Anton of Schroetter general guidance, the school's own Chemistry institute developed a laboratory equal to that of several photographic pioneers, under the direction of Andreas Groll and Johann Natterer, and particularly Joseph Johann Pohl, who became coworkers of Anton George Martin in 1846. He also, in 1858, gave relevant lectures on photography and micro photography at the polytechnic institute and became a professor of chemical technology (1862–1895) and later a teacher of Josef Maria Eder.

Among other famous photographers was Wilhelm Horn, who before he opened his studio in Prague in 1841, was the publisher of the first photographic technical periodical in German-speaking countries (photographic journal) from 1854 to 1865, and the founder of the first Central European photography wholesale business.

Andreas von Ettingshausen, Johann and his brother Joseph Natterer, and August Artaria were considerable representatives of the Niederoesterreichi Tradesman's Union who represented Simon Ploessl and Wenzel Prokesch, the art dealer and publisher. The association secretary, William Horn, who had been in this postion since 1841, traveled to Paris to establish an exchange between Austrian and French photographers and was a general manager of the world exhibition of 1873 in Vienna. From the Niederoesterreichi Tradesman's Union, various initiatives proceeded for the establishment of public technological-historical collections after 1873 in addition to the efforts started in 1908 of the establishment of the Gründung des Technischen Museums Wien, which opened in 1918. In its exhibition contents among other things, valuable photographic historical pieces from the collection of the poly-technical institute were displayed.

The earliest association which centered on the application of photography in Austria has traditionally been the Fürstenhofrunde, which existed from 1840 to 1842. At first this organization was more informally a club of photographic pioneers consisting of Josef Berres, Anton George Martin, Josef Maximilian Petzval, Joseph Johann Pohl, Wenzel Prokesch, Peter Wilhelm Friedrich von Voigtländer, and August Artaria, which met at the Naturwissenschaftlern, Technikern und Medizinern, Künstlern und Gewerbetreibenden zusammengesetzter Klub von Fotopionieren. They also met at the house of the painter Carl Schuh zu Fachgesprächen or in the building of the Fürstenhofs in Vienna to discuss common experiments. The testing of Petval's revolutionary lens design of 1840 is probably the group's most significant experiment.

An outstanding instance of the early paper photography in Austria embodied the photographic studio of K.K. Hof and the state of printing, which increased in 1841 under the direction of Alois Auer who was the director until 1866. In the 1850s and 1860s one of the best innovations created were the print manufacturing plants of Europe. Many aspects of public research and development focused on visual presentation because these plants were able to produce large sized architecture and panorama photographs, expedition reports, photomicrographs and first photo-mechanical pressures through unusually systematic and effective production lines, allowed the variety of reproduction methods and picture documentation to be widely distributed with relative ease and conformity.

Legal restrictions concerning copyrights were introduced to Austria in 1861, which led to the establishment of a photographic copyright association. The photographic society in Vienna remains today the oldest and most long-lived interest agency of photography in German-speaking countries. This association at first was

Antoine, Franz. Hermine Antoine. *The Metropolitan Museum of Art, David Hunter McAlpin Fund, 1948 (48.83.21) Image © The Metropolitan Museum of Art.*

mainly modelled after the Société française de photographie, however the state-conformed civil organization nevertheless was somewhat dominated by the same stucture existing in the country's government.

The first president of the society however was Anton George Martin (elected in 1861 until 1865, then again from 1868 to 1870). He was followed by the chemist and school teacher Emil Horing (president 1866 to 1867 and 1870 to 1883) and the officer and reproduction technician Ottomar of Volkmer (president 1885–1901). Furthermore among the group's members were Ludwig Angerer, Rudolf Eitelberger, Josef Maximilian Petzval, Joseph Johann Pohl, Ludwig Schrank, Anton von Schroetter and Wilhelm Schwarz-Senborn. The society pursued commercial goals and offered advertisements in their association magazine *Photographische Correspondenz* (from 1864 to 1971 since from 1956, the official scientific organ came from the Sektion der Deutschen Gesellschaft für Photographie in Cologne) however, *Photographische Correspondenz* was always also a current, supraregional and effective forum for the broader proclamations of scientific-technological innovations. In addition it was prominent in the organization of exhibitions in 1864, in Vienna as the first specialized photographic exhibition in German-language countries. This exhibition provided a historical sample and apparatus collection as well as a library of relevant international specialized publications, recently located at Graphischen Lehr- und Versuchsanstalt but today, on loan to the Fotosammlung der Albertina in Vienna). The purpose of Österreichischern Museums für Kunst und Industrie (1864 opened; first director: Rudolf Eitelberger) was to provide a platform for central discussions reagrding modern visual culture, similarly fashioned after that of the larger model of the South Kensington Museum. The integration of photography into this discussion was helped along through the establishment of the museum's own photographic studio, led by the renowned photographer Ludwig Angerer. Further support of photography within the museum included comprehensive photograhic exhibitions, one of which took place in 1871 and was called grafische, reproduktionstechnische und fotografische Sektion im Rahmen der Eröffnungsausstellung im Museumsneubau am Wiener Stubenring; then in 1875 consisting of the internationale Ausstellung der Photographischen

Gesellschaft; and in 1888 with erste Ausstellung des Clubs der Amateur-Photographen in Wien, and again in 1891 with the Club der Amateur-Photographen in Wien—Internationale Ausstellung künstlerischer Photographien.

The opening of Eröffnung der K.K. Lehr and Versuchsanstalt für Photographie und Reproductionsverfahren in Vienna, today Höhere Graphische Bundes-Lehr- und Versuchsanstalt (GLV) was in 1888. This fully equipped technical school worked in Austria to maintain the tradition of photography as a discipline of civil buergerlich-gediegener handicraft and engineer art. The establishment of the GLV was known world-wide and received their international reputation for the work completed during the term of photo chemist Josef Maria Eder who was the first director from 1888 to 1923. Industrial magnates of photographic production did not develop in Austria as dynamically as in other countries. In the last quarter of the 19th century however from 1882 to 1918 and still under the monarchy, the very active protogewerkschaftlichen initiative came into being, which later became Verein photographischer Mitarbeiter.

Finally in 1887, the earliest association of moderately active photographer collectives in Europe was the Club der Amateur-Photographen in Vienna (renamed Camera Club in 1893,) stressed and aimed for an artistic dynamic. The first large exhibition in the Austrian museum for art and industry was organized by the "club." In 1888 they held a show, the first of which was for amateurs only. Doing this was enough however to shake up some members of the established photographic community in Vienna. More specifically, in exhibiting their photographs in this unusually, selectively arranged international exhibition, the amateur photographers challenged the aesthetic guidelines established by the contemporary painters and commercial artists. Most notable were the images that came from English photographers such as Peter Henry Emerson and George Davidson. It was from their design principles in the "Paysage Intime" that the idea was had to minimize the hole though which light came, later becoming known as small apertures and extended depths of field. The most consistent representatives of these techniques were Hans Watzek, Hugo Henneberg and Heinrich Kühn as well as the American art photographer, Alfred Stieglitz all of whom crucially changed the international photography scene circa 1900.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN BELGIUM

The multiple and potentially protean nature of photography is clearly reflected in the broad range of institutions which assisted the introduction of the new medium to Belgium—artistic, technological, and learned. the patrons of the fine arts were the first to witness a public display of daguerreotypes in Belgium at the triennial exhibition held in Brussels in September 1839. the crowded walls of competing portraiture, landscapes, and history paintings also welcomed five daguerreotype plates—two by Daguerre (who had presented them to King Leopold I), and three local views by rival Brussels pioneers Jean Baptiste Jobard (1792–1861), inventor and journalist, and Antoine Dewasme (1797–1851), lithographer and director of the Société des Beaux-Arts.

Simultaneously, the country's leading learned society, the Académie royale des Sciences et Belles-Lettres (Royal Academy of Science and Literature), was called upon to evaluate a paper process invented by Albert Breyer (1812–1876), a medical student, whose Breyerotype was a form of reflectography or photocopy enabling direct positive prints of engravings, drawings, and written documents. the Académie would reprise this role in the 1840s and 1850s, when work by W.H.F. talbot, Abel Niépce de Saint-Victor, Guillaume Claine and Edmond Fierlants was submitted for opinion, in the latter two cases within the context of grant applications made to the Belgian government. Furthermore, photography featured in one of the prize essays set by the Académie in 1847, on a topic covering "les avantages et les inconvénients de la découverte des procédés purement mécaniques" (advantages and drawbacks of the discovery of purely mechanical processes).

Another semi-official body to take a sustained interest in photography in the early decades was the Musée de l'Industrie, headed by Jean Baptiste Jobard in the 1840s. Despite its name, the Musée was more a technology centre and forum for the dissemination of inventions. As such, the progress of the new medium was monitored by the institution, a process culminating in the association of Gustave De Vylder (1824–1895),

engineer and teacher at the Ecole industrielle de Gand (Ghent Industrial College), where he gave public courses in photography for over thirty years, beginning in 1862. One of his pupils, Léonce Rommelaere (1839–1887), was appointed chemist at the Musée de l'Industrie in 1870, where he too instituted the practise of free public lessons in photography.

Very soon after its foundation in 1854, the Société française de photographie, pre-eminent in France, became a natural focus for the aspirations Belgian photographers eager to prove themselves on an international level. Many leading practitioners joined, such as Chevalier L.Pt. Dubois de Nehaut, Edmond Fierlants, and the great specialist in micro- and astronomical photography Adolphe Neyt (1830–1892). And it is thanks to membership of the Société française de photographie that the work of Louise le Ghait, the only significant woman calotypist in Brussels, has been saved from oblivion.

The French body also contributed to the success of the earliest photography exhibitions held in Belgium in 1856 and 1857. Photography had previously occupied a minor place in the state-sponsored trade fairs run under the aegis of the Association pour l'encouragement et le développement des arts industriels en Belgique (Association for the promotion and development of industrial arts in Belgium). Fearing that local production was lagging behind the international competition, Edouard Romberg, director-general for fine arts in the interior ministry, took the initiative to transform the event into a full-fledged photography exhibition for two years running. The 1856 exhibition, at which the Sociéte française de Photographie exhibited collectively, had a considerable impact. The purpose of stimulating local production was implicit in the nature of the trade fair, as one commentator observed: "Belgian photographs have been far surpassed by those from other countries… Belgium will derive most benefit with regard to photographic progress, from the lessons given by her neighbours" (Thomas Phipson, "Universal Exhibition of Photography, Brussels," *Journal of the Photographic Society [of London]*, 3 (21 October 1856): 146, reprinted from *Cosmos*, 9 (3 October 1856): 345).

Belgium had to wait nearly twenty years and the creation of its first photographic society before an exhibition of equal significance would be organized. The Association belge de Photographie was founded in 1874 as a national and official body with King Leopold II as patron. The initiators were De Vylder and Rommelaere, who were appointed respectively first president and general secretary, and two young engineers, Paul Davreux (1845–1905) and Léon Laoureux (1845–1915). A founding membership of 143 grew steadily decade by decade, from 200 in 1880 and 381 in 1890 to 650 in 1898 and 727 in 1905. It would remain a strong (if latterly less predominant) force in the domain in Belgium until the outbreak of the second world war, when its collections and library were dispersed.

Throughout its existence, the Association belge de Photographie remained true to its twin purpose of acting as a springboard for artistic creation and scientific advance. Article 2 of the articles of association reads: "Son but est purement artistique et scientifique. Elle poussera au développement des progrès scientifiques par des réunions périodiques, des communications, l'essai des nouveaux procédés, des expositions, et si les ressources le permettent, par la publication des faits les plus intéressants" (Its purpose is purely artistic and scientific. It will promote the development of scientific progress by means of regular meetings, communications, experimenting new processes, exhibitions, and, if resources allow, by the publication of news reports.) Despite the explicit disavowal of commercial interest, the Association was a broad church, counting many professional photographers and owners of supply houses amongst the membership and officers, such as Joseph Maes, president from 1889 to 1895. Its breadth of membership and scope proved an advantage, enabling many functions to be delegated and practical work to be carried out at monthly meetings of the regional sections—initially Brussels, Liege, and Ghent, followed by Antwerp in 1890, Namur in 1893, and Mons in 1901. Given the centripetal force of the Association, the few independent local clubs set up in the wake of the growth in amateur photography in the 1880s made little impact. Exception may be made for the Cercle Photographique de Bruges, founded in 1887 as an offshoot of the Excelsior literary society, in a part of Belgium which failed to produce a regional section of the Association, and the Photo-Club de Belgique, founded in 1895, an amateur body of excursionist tendencies and a total membership of around 100.

The Association belge de Photographie, in fulfilment of its mission, organized international exhibitions of photography, both images and material, in 1875, 1883, and 1891. It was also present at the jubilee fair held to celebrate fifty years of nationhood in 1880 (and at which Désiré Van Monckhoven was honoured with a display of his publications) and the international exhibitions held in Antwerp in 1885 and 1894, and Brussels in 1888.

With its presiding spirit of internationalism, the pictorialist movement quickly gained ground in Belgium, influenced both by proselytising of the Linked Ring and by adherents of the Photo-Club de Paris, where Edouard Hannon (1853–1931) regularly exhibited. the Linked Ring counted two Belgians among its members—the multi-talented Brussels professional Alexandre Drains (1855–1925), and textile merchant Hector Colard (1851–1923), whose international outlook made him an ideal intermediary for interpreting and presenting, to a Belgian audience, the diverse intellectual and aesthetic

currents of the so-called French and English schools. the Association belge de Photographie, having hosted a well-received exhibition of British pictorialists in 1892, briefly lost the initiative when an independent Salon photographique was co-organized by Hannon at the Cercle artistique et littéraire [Artistic and Literary Circle] in Brussels in 1895, at which prints by leading lights of French pictorialism such as Demachy and Puyo featured alongside Belgian work. Henceforward, the Association belge de Photographie regained and maintained momentum, organising major salons in 1896, 1898, and 1902. Its size in Belgium and reputation abroad enabled it to overcome with ease the threat posed by the small secessionist movement L'Effort, active 1901–1905 around interior designer Léon Sneyers (1877–1949) and photographic supply-house owner Léon Bovier (1865–1923). Other leading pictorialists in Belgium, notably Gustave Marissiaux and Léonard Misonne, remained loyal to the Association.

The increase in the medium's popularity and profile at the turn of century gave rise to two very different institutional initiatives in photograph collecting. As a sign of pictorialism's social acceptance, a photography section was established within the Musées royaux des arts décoratifs et industriels [Royal Museums of Applied Arts] in Brussels in 1896. the Musée photographique, as it was known, purchased a total of 68 exhibition prints shown at pictorialist salons in Brussels between 1895 and 1901, 27 of which remain in the holdings of the Cinquantenaire Museum up to the present day. With the waning of pictorialism, the will to pursue the acquisition of photographic prints as artworks dissipated in Belgium. A Musée belge de Photographies Documentaires (Belgian Museum of Documentary Photography) was founded in 1901 as an offshoot of the Photo-Club de Belgique, along the lines of Léon Vidal**'s** Musée Documentaire in Paris. It was reported shortly afterwards that the Museum possessed 23,000 items. Renamed the Institut International de Photographie in 1905, the fate of this body's collection is unclear.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN CANADA

Professional Organizations

Given Canada's small population spread out over a large geographic area and the existence of only a handful of professional photographers in any one urban centre up until the 1890s throughout the country, many Canadian professional and amateur photographers took out memberships in United States and international associations such as the National Photographic Association (founded 1868) and its successor the Photographers Association of America (established 1880). Montreal's Alexander Henderson in 1859 was the first member from North America of England's Stereoscopic Exchange Club. Lacking a local social or business outlet other than newspapers and short-lived magazines, commercial photographers regularly communicated information about their business (and sometimes personal) issues. Montreal's William Notman started in the 1860s with *The Philadelphia Photographer* and *Anthony's Photographic Bulletin*. Victoria's Hannah Maynard submitted samples of her own and her husband Richard's work in the 1880s and 1890s to the *St. Louis and Canadian Photographer*.

Many commercial photographers worked in isolation and, except for the most successful, appear to have mistrusted one another. Some of the newspaper advertising was extremely vitriolic. One of the initial attempts at a formal organization for professionals, the Toronto Photographic Society, lasted about a year from its start around March 1869. The society formed to battle price cutting. The St. John Photographers' Association made an even briefer appearance on the scene; its president, Carson Flood, is listed in an 1871 national business directory. The Photographic Association of Canada, centred in Ontario, organized on

24 January 1884 and was later known as the Ontario Society of Photographers; among its first leaders was Toronto photographer S.J. Dixon. The PAC's first president was R.D. Bayley, who as president of the Huron Photographic Association helped initiate the PAC. It survives today as the Professional Photographers of Ontario which is part of the Professional Photographers of Canada.

Amateur Associations

The earliest formally organized associations of Canadian amateur photographers, generally known in 19th century Canada as camera clubs, were established in the 1880s. The first independent camera club in Canada was the Quebec Amateur Photographers' Association located in Quebec City (1884–1886). The Quebec Camera Club, also in Quebec City, was founded 8 February 1887 and disbanded in May 1896. The Montreal Camera Club, preceded by the Montreal Amateur Photographic Club (1886–1889), organized in 1890 and incorporated two years later. The Montreal Camera Club still operates. Rivalling the province of Quebec as an early centre of amateur associations is Ontario. The Toronto Camera Club began on 23 February 1887 as the Photographic Section of the Royal Canadian Institute. The club went its own way on 17 March 1888 as the Toronto Amateur Photographic Association, then changed its name on 7 December 1891 to the Toronto Camera Club, followed by incorporation in 1893. The club celebrated its official centennial in 1988 and continues to exist. The Hamilton Camera Club started as the Hamilton Scientific Association, Photographic Section on 18 April 1892, and was followed by the Camera Club of Ottawa in 1894 and both are into their second century. Several other camera clubs in Ontario are noted in Koltun (1984).

Attempts to organize amateurs in other urban centres did not fare as well as Quebec and Ontario where the bulk of the Canadian population resided and still does. Sprange's *Blue Book for Amateur Photographers* (1895) reported the Winnipeg Camera Club, begun on 27 September 1892, as defunct. The Saint John Camera Club was organized on 9 June 1893 and lasted at least into the mid-1910s. The Halifax Camera Club was organized in March 1896. There were two efforts to create camera clubs in Vancouver, the first in 1895, the second in 1897. The later Vancouver Camera Club had 56 members in March 1897, but appears to have disbanded by 1899 or 1900. One of the last Western Canadian amateur associations to organize in the 19th century was the Associated Photographers of Manitoba and Northwest Territories which met on 13 July 1899 in Winnipeg, Manitoba, for its first annual meeting. When women applied for membership in the camera clubs, only the Toronto Camera Club is known to have debated the issue and agreed to admit them in November 1895.

Associations composed primarily of artists or those broadly interested in the arts, especially after the Kodak revolution, such as the Vancouver Art Association (founded 1890) and Vancouver Arts and Crafts Association (established 1900) also included amateur photographers and exhibited their works. The Canadian Lantern Slide Exchange (1893), centred around Toronto, Hamilton and Montreal in Ontario and Quebec, was modelled on the American Lantern Slide Interchange (1885). The amateur clubs often included professional photographers among their membership. William James Topley maintained a membership in the Camera Club of Ottawa, likely from its start in 1894 until 1921, three years before his death. Other professional photographers such as Les Livernois firm in Quebec City, Quebec, and the Edwards Brothers in Vancouver, BC, played an important role in helping manage the amateur revolution in photography brought about by Kodak roll film. They rented or sold cameras and supplies, helped process dry plates or film, and, most importantly, offered space and darkroom facilities for amateur organizations to meet and hone their technical skills.

Public and private art galleries, museums, libraries, religious organizations (chiefly in Quebec), private societies, companies such as the Canadian Pacific Railway, and academic institutions all played a significant role in preserving Canada's early photographic history before the establishment throughout the 20th century of government-operated archives by provincial and local jurisdictions. Some camera clubs, such as the Toronto Camera Club, maintained their own records back to their origins and only deposited these with national or other archives in the 20th century well after their founding. Several major collections by 19th century Canadian professional photographers such as William Notman, however, were preserved as business records and donated or sold in the 20th century to public institutions. Some studio collections by 19th century photographers, primarily in the Maritime Provinces (New Brunswick, Prince Edward, Nova Scotia and Newfoundland), continue to remain in private hands into the 21st century. Prints from Isaac Erb's (1846–1924) negatives, a New Brunswick landscape and industrial photographer beginning in the 1870s, are sold on the Internet through the collection owner Vintage Photo & Frame Ltd.

Of the provinces which were a part of the Confederation of Canada in the 19th century, only British Columbia and Nova Scotia appear to have had publicly accessible government archives prior to 1901. While all the provinces and their colonial predecessors had records-keeping operations, these were mainly paper-based. Historic photographs, where still used in the course of a government agency's work, such as the

Geological Survey of Canada, may not yet be transferred to an archives. The Canadian Archival Information Network or CAIN is a national database describing archival records, including photographs, at the fonds or collection level. All 13 provincial and territorial archival computer networks are linked to CAIN.

The National Archives of Canada (formerly the Public Archives of Canada, founded 1872) did not establish its Picture Division until 1907, but had acquired photographs a decade earlier. As of March 2002, the National Archives holds over 21 million of photographs dating back to the earliest days of photography. About 400,000 online descriptions of photographs preserved by the National Archives are linked to nearly 4,000 digital images in its online, Web-based research tool ArchiviaNet. The National Archives also issued research guides to its photographic collections and published the *Guide to Canadian Photographic Archives* (1984), a union list describing publicly accessible photo collections across the country.

The National Gallery of Canada (founded 1880 and officially opened 27 May 1882) contains an international collection of around 20,000 photographs dating back to 1839, descriptions of which, along with selected digital facsimiles, are available through its CyberMuse Web site. Although the NGC exhibited photographs as separate art forms beginning in 1934, its own Photograph Collection was not established until 1967.

As of March 2002, provincial and territorial government archives in Canada with active photograph digitization programs containing 19th century photographs (not for online exhibits) are, in chronological order, the British Columbia Archives (1993), the Archives of Ontario (1998), the Northwest Territories Archives (ca. 2000), and the Nova Scotia Archives & Records Management (2001).

First established in 1894 as part of the Legislative Library, the BC Archives began collecting historical records, including photographs, in 1898. Today it preserves the largest number of 19th century photographs of the province. Some of the significant 19th century photographers represented in its holdings are Frederick Dally, Francis George Claudet, Richard and Hannah Maynard, and Edward Dossetter. As of March 2002, the BC Archives Web site describes over 110,000 photographs linked to over 65,000 digital images.

The Notman Photographic Archives, operated within the McCord Museum, McGill University, Montreal, provides Web-based access to 24,000 digital photographs from among the 1,000,000 photographs by the William Notman firm and other photographers.

The other significant public collection of 19th century digital photographs is available through the privately funded Glenbow Library and Archives Web site. Part of the Glenbow Museum, the Glenbow Library and Archives collection of online photographs (nearly 60,000 digital images and descriptions) are also searchable through the Images Canada Web gateway. The Glenbow Library and Archives preserves over one million photographs.

Canadian photographers, like their counterparts around the world, used their own business spaces from the very beginning of photography to exhibit their work. The first daguerreotypes of Canada taken in early 1840 by Hugh Lee Pattinson may have been exhibited the same year in London or Paris by Antoine-François-Jean Claudet and Noël Marie Paymal Lerebours. Works by Canadian photographers were formally exhibited at international world's fairs in Paris, London and other European urban centres, as well as the United States. The first international exhibition at which Canadian photographers were represented was the 1855 Paris Exhibition. Thomas Coffin Doane (1814–1896) from Montreal, Quebec, and Eli J. Palmer from Toronto, Ontario, the only two Canadian photographers exhibiting, received honourable mention for their work. At the 1862 London International Exhibition, William Notman was awarded a medal and Francis George Claudet, the youngest son of Antoine-François-Jean Claudet, received an honourable mention for his landscape photographs of New Westminster, BC. Claudet's father was one of the judges, but whether he excused himself is not known. Some of the portraits on patent leather exhibited by George Robinson Fardon at the 1862 world's fair were discovered late in the 20th century by the Victoria and Albert Museum and their identity verified by the author in 1999 as Fardon's work. Examples of other international exhibitions at which Canadian photographers were represented are the 1865 Dublin International Exhibition (J.B. Livernois of Les Livernois), the 1867 Paris Exposition Universelle (Wellington Chase; J.B. Livernois of Les Livernois; William Notman), the 1876 United States Centennial (International) Exhibition (J.S. Climo; Alexander Henderson; William Notman), the 1878 Paris Exposition Universelle (J.E. Livernois of Les Livernois [ed. Note: this is J.B. Livernois' son]; William Notman), the 1886 Colonial and Indian Exhibition London (Mrs. R.E. Carr; Richard Maynard; William Notman), the 1888 Barcelona World's Fair (S.H. Parsons), and the 1893 World's Columbian Exposition Chicago (W.H. Boorne; Les Livernois). Governments, both national and provincial, also commissioned photographs or purchased existing images which were incorporated into international exhibition displays as a means of illustrating and promoting their regions.

At the national level, there were no competitive exhibitions consisting solely of photographs as an art form until 1934 when the National Gallery sponsored the Canadian International Salon of Photographic Art. Prior to this time, the camera clubs and photographers

such as Vancouver's John Vanderpant organized open and invitational photography salons. The first Canadian camera club exhibit was staged by the Toronto Camera Club in 1891. Prior to this, industrial or agricultural fairs at the provincial or local level were the primary venue for the competitive exhibition of photographs by professionals and amateurs. Possibly the earliest such instance in Canada was the display of daguerreotypes at the Nova Scotia Industrial Exhibition in October 1854. Among the first Canadian art exhibitions which included photography was one hosted by the Art Association of Montreal (now the Montreal Museum of Fine Arts) in 1865. Works by William Notman and Alexander Henderson were on display that year and by the latter in 1867. The Royal Canadian Academy of Art (established 1880) did not begin to recognize photography as an art form until at least the 1960s when it awarded Ottawa's Yosuf Karsh its RCA Medal (1964). Some of the founders of the RCA, however, utilized photography in their landscape painting.

All Canadian societies and groups who sponsored exhibitions saw steady growth and interest in photography in the first decade of the 20th century as the Pictorialism tradition blossomed. As noted by H. Snowden Ward, co-editor of *Photograms of the Year*, based upon his 1899 visit to a Toronto Camera Club meeting:

> The Canadian amateurs … feel their somewhat isolated position … but by means of careful study and discussion of the articles and reproductions in the journals, as well as by very frank, breezy criticisms at their own lantern-slide evenings, they are doing all that lies in their power to remedy these deficiencies.

SOCIETIES, GROUPS, AND EXHIBITIONS IN FRANCE

The birth of the French photographic institution followed the development of the scientific and historical academies in the country. The same cultural phenomenon took place in all European countries as well as in their colonial territories.

The photographic societies were associations whose purpose was to ameliorate photography and diffuse it to the majority.

During the 19th century, "in science, if the lonely genius make the most important discoveries, the scientific societies (…) make them understandable, propagate and improve them." ("Si c'est le seul génie qui fait dans les sciences les grandes découvertes, ce sont les sociétés savantes (…) qui éclaircissent les découvertes, qui les répandent et les perfectionnent," Dictionnaire de la langue française, Littré, 1863–1871)

This century has been considered as the century of technical discoveries. Diffused by specialized newspapers, Expositions universelles and academies, sciences became a new subject of interest, the beginning of their democratization.

The photographic academies were very different by their members' type, their research field, even their philosophy. The technical societies were the most important by the number of their members because they

were opened for all amateurs and professionals. Almost all artistic societies were dedicated to amateurs. The professional associations considered themselves as genuine companies union.

Most organizations developed themselves after 1875, following the simplification of the photographic techniques, particularly the introducing of the gelatin-silver bromide. As Jean-Pierre Chaline, the French historian, exposed, in France, academies grew up between 1875 and 1884. The expansion of the photographic associations' foundation took place later than the development of classic academies. For the photographic societies, this happened above all between 1887 and 1896.

These societies or associations established the scientific or artistic studies like a bond of the nation. Upper classes people gathered themselves to exchange on scientific or artistic experiments and knowledge. The first photographic society was called the Société héliographique, created in 1851 to develop photography and its applications but dissolved in 1853, the same year the Royal photographic Society was founded in Great Britain. One year later, in 1854, a new society, also based in Paris, called the Société française de photographie, replaced it.

Founded on the Académie des Sciences exemplification, this society was much more science-oriented: its aim was to ameliorate and diffuse photographic techniques (See Articles of association, *Bulletin de la Société française de photographie*, January 1855). They met each month to talk about both little improvements and important discoveries. As its model, practice was the only way to recognize a new technique. Researchers came to present their invention before the Society. Then, a little group (five or six people) formed a commission to experiment the novelties. One month later, they had to give their conclusions and judge them in a report. This account was published in the Bulletin de la Société française de photographie, the Society's journal released every month for the members since January 1855. Most of them were amateurs: they did not live of their passion but had enough time to experiment and devoted their life to photography.

At this time, knowledge was freely diffused and scientists offered to the community the results of their researches, based on common exchange. Transmission was the main way to evolve. This society became the pattern for all others. The Société boulonnaise de photographie located in Boulogne, in North of France, in 1856, even asked to use its status as a model.

The centralized organization of French politics probably influenced the creation of the photographic sociability: the most important of them, and the first, was located in Paris. Each town wanted to have its own scientific or historical academy. In the French countryside, photographic associations have been principally founded by a member of this main society: opened to every kind of members, often with a library, a laboratory and a newspaper dedicated to the photographic news and the life of the association.

As time went by, the addressed subjects evolved. At the beginning, before the 1870s, the different techniques—the collodion process, the negative albumen process, the collodio-albumen process—and the different cameras were the most important questions. With the gelatin-silver bromide's arrival, new topics appeared, such as picture quality, snapshot speed, and above all the recognition of the photography as an art and not only as a scientific help.

More than the professional photographers, the amateur members of these groups contributed to ameliorate and diffuse the techniques. The photographic societies organized courses and lectures—notably from the 22 November 1891 to the 10th of April 1892, at the Conservatoire national des Arts et Métiers, in Paris—explaining the processes, the best way to choose the camera, and how to use the best technique at the best moment.

Most of the members used to write books and articles to spread photography to the general public. One of the best known popularizer in France was Albert Londe, publisher of The snapshot photography (La photographie instantanée) in 1886 and The modern photography (La photographie moderne) in 1888. The will of the French photographic society was to give a status to photography, between science and art.

In the 1890s, the French society changed: entertainment became part of life not only for the upper classes, but for middle classes as well. With the gelatin-silver bromide and the reducing size of the camera—the most known, but not the only one, was probably George Eastman's Kodak box, photographic democratization was on its way. Photography was used during a jaunt, a trip, or to capture the most important life times of the families.

Following these changes, appeared a new kind of association led by Albert Londe, Maurice Bucquet, and Gaston Tissandier. Its name was the Société d'excursions des amateurs photographes created the 4th August in 1887. Its purpose was to "organize excursions and practical lectures for the development and the diffusion of the photographic knowledge" ("Société ayant pour but d'organiser des excursions et des conférences pratiques en vue du développement et de la diffusion des connaissances photographiques," in the first article of association). Several societies of this kind were created in France, in almost every department.

At the same period, another type of photographers' group appeared. Their members were also amateurs, but with a different aim. These artistic societies, the photo-clubs, existed since 1888, date of the Photo-club de Paris birth. One more time, this association was the

pattern for the others. The photo-clubs were associations where the members were strictly amateurs. Principally, these associations requested the recognition of the photography as an art.

First, members of the Photo-Club de Paris and the Société d'excursion des Amateurs photographes were almost the same, including Maurice Bucquet, Albert Londe and Jules-Etienne Marey. Quickly, theses societies' respective positions became diametrically opposed. The Excursion society lauded photography as a healthy entertainment—it was most of time combined with sports like bicycle or walk—when the Photo-club exalted photography as an aesthetic and conceptualized art. In fact, the Photo-club recommended the pictorial photography.

In 1892, they presented in the "first international photographic exhibition and the linked arts" (Première exposition internationale de photographie et des arts qui s'y rattachent) a new aesthetic. They showed staging images, playing with lens aberrations to give an ethereal and vaporous touch similar to drawings, mostly printed with gum-bichromate. Pictorial photography was an international movement first represented by British photographers like Peter Henry Emerson or Julia Margaret Cameron. This photographic practice was known in France thanks to universal exhibitions and books, notably "Naturalistic photography for students of the Arts" written by Emerson and published in 1889.

In France, the photo-club members had a particular position because they struggled for the photographic recognition as art, and also for the amateur status. According to Paul Gers in 1889, the 12th December, concluding on the Exposition universelle in Paris, "the artistic value of their (the amateurs) works, (could) compete with the specialist's one, the professional's one ("la valeur artistique de leurs travaux, lutter avec succès contre les spécialistes, les professionnels," in Photo-Club de Paris, Séance du 12 décembre 1889, Journal des Sociétés photographiques 1890–1892, 31).

Then, the amateur could have been considered as a better artist than the professional, whose sole purpose was to make money with his practice. They refused little camera boxes, choosing the camera obscura, refusing the instant photography and choosing the staging photography, in fact refusing technical progress.

These pictorial photographers proposed to consider a kind of hierarchy in photographs: their practice would have been the most important, as the noble one, whereas the excursionist's practice would have been seen as an entertainment able to give travel impressions and the professional practice would have been despised because of making money.

In France, particularly in Paris, photographers had to choose their side: excursionist or pictorialist. However, the splitting was not that strong in the countryside where some associations like the Photo-club rouennais, located in Normandy, belonged to both sides. Created in November 1891, its presidents were scientists like the naturalist Henri Gadeau de Kerville (1891–1892) or the physician Abel Buguet (1893–1900) but the association was opened to "excursionists and pictorialists" (See articles status of the Photo-Club rouennais, 1891).

However, these organizations had a common fight, and to give them coherence, the Union Nationale des Sociétés photographiques de France was created in 1892. Every year, a congress was organized by the Union in a different city, working on technical, artistic or juridic subjects.

From the very beginning of the photography, the pictures display, especially during the Expositions universelles, was considered as the best way to introduce techniques' newness. Actually, photography was held as a scientific technique, so processes were the most important distinctiveness.

To present their researches, the societies and the photo-clubs used the same methods: the exhibition. The societies proposed to the spectator a presentation copied on the fine arts Salon. Another pattern was probably the exhibition of the Society of Arts in 1852 (or 1851) in London composed by Joseph Cundall, member of the Calotype Club with the help of Roger Fenton, active member of the future Photographic Society of London.

The first exhibition was organized by the Société française de photographie in 1855, from the 1st August to the 15th November. The photographs were divided in sections: the different processes as salted paper print, albumen paper print, daguerreotype, and then by subjects like portrait, landscape and scientific photography. The foreign photographers were accepted for the second show, in 1857. Several countries were represented and a jury awarded some of the photographers, like the Universal exhibitions did.

For the first edition, the amateurs were more important in numbers, but two years later, professionals were represented almost as much as the amateurs. The Société française de photographie made these shows approximately every two years.

The Expositions universelles were the occasion to show the new photographic techniques and processes. There were also exhibited ancient techniques as a kind of summary. One of the great wills of the societies and the photo-clubs was to give credibility to the photography as an art. They all tried to make the government understand the importance to give them an exhibition place in the fine arts section, not in the techniques' one: this request provoked a great scandal in 1900. Foreign photographers—principally pictorialists—refused to come and expose their production at the exhibition in Paris because it was scheduled in the Education palace and not in the art one.

Societies and photo-clubs in France, as well as their lectures and publications, have been prevailing in the fight of the photography's recognition. They allowed the grouping of different kind of people in the same purpose. The photographic institution, which had been divided in the 1890s, recovered its unity after 1900 and gave birth to the first section dedicated to the photography in a museum in 1926, in the Conservatoire national des Arts et Métiers, a technique museum, in Paris. At last, one of the ultimate purposes was accomplished.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN GERMANY

Throughout the 19th century the German speaking countries hosted more than 100 photographic societies, mostly on a local basis but aiming at a greater public, too. The first group of practitioners met regularly as early as 1840 in the studio of Carl Schuh in Vienna but there were no significant implementations until 1857 when three German photographers called for the foundation of a Society of German Photographers (Allgemeiner Deutscher Photographen-Verein) following French and English examples. Formally founded by more than 40 participants the society seemed to flourish within the next years, including the initiation of its own journal *Photographisches Archiv* edited by the founding fathers Julius Schnauss and Eduard Liesegang. But in 1863 the society ceased to exist and was basically replaced by the freshly inaugurated Berlin Society for Photography (Photographischer Verein zu Berlin) which was founded by Hermann Wilhelm Vogel. He split this society into a German Photographic Society (Deutscher Photographen-Verband) by 1867 which existed—due to political as well as internal reasons—only for another year on a national basis. For the next 30 years, all attempts to organize an annual conference of German photographers or found another society for the interests of all photographers were condemned to fail. Only in 1897, the newly released copyright law forced 2500 photographers to constitute a Law Protection Committee of German Photographers (Rechtsschutzverband Deutscher Photographen) which finally turned into a Central Committee of German Photographers (Centralverband Deutscher Photographen) in 1902. The Austrian history is different as the Photographic Society of Vienna (Photographische Gesellschaft in Wien), installed in 1861, gradually grew into the official function of uniting all Austrian photographers and industries of the field.

There were numbers of smaller societies and interest groups among photographers, too. Besides local groups, of which those in Berlin, Hamburg, Frankfurt on Main, Weimar, and Chemnitz were the most active ones there were groups of theater-playing photographers, of photographic industries, of suppliers of photographic materials, and of photographic assistants. Although 10% of all photographic employees in the late 19th century were female there has been no group or society to pursue their interests. As early as the 1850s there were smaller local groups in amateur photography but there were societies in amateur photography before the foundation of Society for the Improvement of Amateur Photography (Verein zur Förderung der Amateur-Photographie) in Berlin in 1869. The German Society of Friends of Photography (Deutsche Gesellschaft von Freunden der Photographie) set up in 1887 had to prepare the big exhibition for the celebration of photography's 50th anniversary, and a Free Photographic Society (Freie Photographische Vereinigung) was the first attempt in the creation of a pressure group in Fine Art Photography.

Setting up institutions in photography seemed a lot more complicated. In 1853, Hermann Krone in Dresden launched his first school of photography offering more than the average basic courses as given by nearly every daguerreotypist before. This private institute was converted in 1869 into a part of the Dresden polytechnicum, and Krone became the first official instructor in photography on a technical basis. The first class and laboratory in photochemistry was installed at the Berlin University in 1884, Hermann Wilhelm Vogel the first to hold the seat being followed by Adolf Miethe, Otto Mente, and Erich Stenger. By 1888, Joseph Maria Eder had founded the Higher Institute of Graphic Arts (Hoehere Graphische Lehr- und Versuchsanstalt) in Vienna which was to be followed in 1900 by a similar institution in Munich; the Lette school in Berlin specializing in teaching women created a class in photography in the same year. In 1885, the architect Albrecht Meydenbauer had set up the Prussian Institute for Photogrammetry

(Preussische Messbildanstalt) in Berlin to produce and catalogue photogrammetric data of buildings to be preserved.

Exhibiting photography started with its own birth: In fall 1839, there were a number of exhibitions showing Daguerreotypes from Paris in all big cities of the German speaking countries. The first one-man travelling show was installed in 1840 by Johann Baptist Isenring from the Swiss Schaffhausen but shown mainly in Southern Germany. Although the Germans were slow in presenting themselves at the World Fairs of 1851 and 1855 in London and Paris, photography had been present in both apparatus and images at all of the German industrial fairs from 1840 onwards. Permanent exhibitions in showrooms common in the USA since the 1850s only appeared irregularly in Vienna and Berlin in the 1860s. A special form of exhibiting stereo photographs was patented and installed by Ernst Fuhrmann in 1877 named the Emperor's Panorama (Kaiserpanorama).

Exhibitions of photographc images flourished for a relatively short time after photography's 25th anniversary in 1864. The same year, Anton Martin from Vienna had curated an exhibition on early photography and shown some work of his contemporaries; the German photographers concentrated on having a banquet with a burlesque comedy accomanying it. In 1865, Hermann Wilhelm Vogel and his Berlin society tried to establish an annual show of photography but these efforts ceased within three years. But by 1889, photography's 50th anniversary was the occasion for installing huge exhibitions of both images and apparatus in Berlin and Vienna. The Berlin exhibition held in the Prussian War Academy was the first to show the greater importance of amateur photography over the average craftmenship practised so far; the best featured exhibitor was a 25-year-old student of Hermann Wilhelm Vogel: Alfred Stieglitz. By this time Alfred Lichtwark had already been established as head of the Hamburg Art Hall (Kunsthalle); he started the annual exhibition of Fine Art Photography in 1893. A last instauration of the year 1895 combined all efforts described here: The South German Association of Photographers (Sueddeutscher Photographen-Verein) was founded to hold annual exhibitions for the sake of photographic art and artists in a Secessionist manner, it helped to instigate the Munich school of photography, it collected a large number of images to set the ground for a National Museum of Photography, and by a pilgrimage to Pope Leo XIII. in Rome, it installed Saint Veronica as the holy guardian for all photographers and their necessities.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN ITALY

At the beginnings of photography, in 1839, Italy was not yet a unified state. In the months following the Arago announcement, daguerrotypy was presented in a number of the most prestigious scientific institutions and rapidly spread through the various states of the country, with different outcomes according to the different cultural influences. Even in unified Italy, however, the Italian photographic associations continued to maintain strong local characteristics.

The first photography associations were established primarily around the practice of calotypy, and were often also composed of foreign artists traveling in Italy on the classic grand tour. One of the first was the Circolo di calotipisti set up in Rome (1850–52) on the initiative of Count Frédéric Flachéron. The meetings were attended by Prince Giron des Anglonnes, Eugène Constant, Henri Peach Robinson, and Giacomo Caneva.

In March of 1888, the Associazione degli Amatori di Fotografia was established in Rome, presided over by the Duke of Artalia. The founders included Enrico Valenziani and the engineer and architect Giovanni Gargiolli. The latter, who had already founded the Società Amici della Fotografia in Naples in 1887, subsequently played an important role in the debate on the use of photography in an area traditionally covered by engraving, i.e. the reproduction of works of art, a sector in which Italian photography would always be extremely prolific. Obstructed in his project to create a photogravure laboratory at the National Copper-engraving Institute in Rome, he set up the Royal Photography Laboratory at the Ministry of Education (1892), which definitively established the use of photography in art reproductions.

Another active center was the city of Turin, which was particularly favorable to the diffusion of photography

also because of its geographical and cultural vicinity to France. Here the Unione Fotografica Italiana had been in existence since 1879, a longstanding association, whose activity was widely known.

The work of these first associations was mainly geared toward promoting meetings and information exchanges, particularly regarding technical innovations, as well as the dissemination of treatises and publications and the organization of training courses. The latter activity turned out to be essential, especially due to the absence of any official photography schools. Apart from some sporadic private initiatives, such as the Photographic Institute of Brindisi founded by Antonio Montagna, the teaching of Antonio Chimenti at the University of Rome (as of 1842), Semplicini in Florence (around 1850), and Ottavio Baratti at the Technical Institute of Milan in 1865, and the "Municipal evening school in chemistry for factory workers" in Turin, an authentic School of Photography was only established in Florence in 1905, following more than two decades of discussion, supported by the Società Fotografica Italiana.

The year 1887 was decisive: in Florence, during the works of the jury of the 1st Italian Photography Exposition, the foundations were laid for the constitution of the first national association. The Società Fotografica Italiana (SFI) was officially inaugurated two years later. The founders included many professional photographers, including Vittorio Alinari, Carlo Brogi (member of the Board of Directors), and the senator Paolo Mantegazza—known for his use of photography in a series of studies in anthropology and ethnology—who became its president. In October 1889, the SFI began publishing its own Bulletin, which continued until 1914.

One of the most important activities of the SFI was the organization of annual conferences, where participants discussed topics related to the history and technique of photography, its applications in a broad range of disciplines, and its relationships with art and custom. Both at the central level and through local groups, the SFI organized "photographic walks" and projections, and systematically collected Italian and foreign publications dedicated to photography. One of its most ambitious projects was to create a national museum of photography. Success came in 1902, with the opening of a Photography Archive at the Royal Uffizi Galleries in Florence, promoted by Corrado Ricci and encouraged by the Touring Club Italiano.

Around the SFI, many amateur photography clubs began to appear, often frequented by professional photographers as well.

In 1890, the *Circolo* Dilettanti Fotografi was set up in Turin, and many of its members were present at the photography exhibit in Venice in 1891. In 1892, the club participated in the organization of the Exhibit for the Promotion of the Fine Arts in Turin, in which over fifty photographers participated. The following year, in conjunction with the Turin branch of the Club Alpino Italiano (CAI), the association opened an exhibit of the works of amateur photographers, members of the CAI and other touring clubs from various Italian regions. In this regard, it should be underscored that photography assumed growing importance in the life of this type of association (CAI, Touring Club, Unione Escursionisti, and so on), and that these organizations, through the creation of thematic archives, expositions, and particularly magazines with a wide circulation, made a substantial contribution to the creation of a new image of the Italian landscape. No traces remain of the activity of the Circolo Dilettanti Fotografi after 1895, but it is known that many of the members converged, together with a group of professionals, in the more important Società Fotografica Subalpina. Founded in Turin in 1898 during the 1st National Congress of Photography, the Society was composed of about fifty members.

A branch of the SFI, composed of amateurs and professionals, was established in 1892 in Bologna, followed in 1896 by the Società dei Dilettanti Fotografi. The dissolution of these associations spawned the Circolo Fotografico Bolognese in 1900, the oldest body still in existence today.

Similarly, in Milan, the Circolo Fotografico Lombardo (1889) was established, as well as the *Associazione Lombarda*, which in 1893 numbered as many as four hundred members. In Milan, an important industrial and commercial center, the first national journal of photography, *La Camera Oscura*, began publication in 1863, directed by Ottavio Baratti and subsequently by Luigi Borlinetto. The journal published essays by Italian and foreign scholars, with a prevalently technical-scientific orientation, though often included topics of a political-cultural nature as well. But the experience that left the greatest mark on photography in Milan in the second half of the 19th century, in terms of both technical research and interest in the new creative languages, was *Il Progresso Fotografico,* a periodical created by Mario Gandini and Rodolfo Namias. By 1894, Namias had published more than thirty manuals and in 1895 he organized the Laboratory School of Applied Photochemistry.

In all the major expositions and conferences dedicated to photography in the last two decades of the century, the Istituto Geografico Militare was a constant presence. Its Photography Department was set up only in 1896, but the collections made by the military contained a large number of photographs made prior to that date, added to which was a large quantity of documentary material of geographic and ethnographic interest.

The involvement of Italian photography in exhibition events began with a sporadic presence in the general expositions, in which photography was initially exhibited

as a technical "marvel" rather than as a possible means of artistic expression.

In the pre-unification period, Bologna, the second most important city in the Papal state, could offer an emblematic example. In the 1850s, while the first studies and stable photographic production were beginning, the local administration attempted to foster the participation of local artisans in the Universal Expos of London and Paris. In parallel, exhibitions of a regional nature were promoted—occurring for the first time in the Agricultural, Manufacturing, and Industrial Exposition of 1856—in which photography was one of the products on display. In 1857, the official regulations of the exposition included a section of "Examples of Photography and Daguerrotypes," shown separately from the copper engravings and lithographs.

At the first Italian Exposition, held in Florence in 1861, all the important names in local photography participated. Most of the images displayed were portraits, while the large studios took the first steps in the sectors in which they would subsequently specialize: landscape photography and art reproduction.

Within important traditional events, such as the Italian General Exposition of Sacred Art in Turin, photography was not only widely present but the subject of a lively debate centered mainly on its artistic potentials (1898), leading to the creation of the important journal *La fotografia artistica* (1904–1917). In the General Exposition of Turin of the same year, "Photographic Art" appeared among the "Liberal Arts" and attracted a large number of visitors. At the end of the 19th century, Italian photography periodicals bore witness to the fact that discussions within the associations centered on issues analogous to those confronted in the other European countries: artistic photography, its definition as a cultural heritage, the genres, and the relationship with the applied arts, academy cultures, and the cultures of the secessionist movements.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN RUSSIA

Photography became very popular in Russia in the 19th century. Thus, in St. Petersburg alone, according to the population census of 1881, photography involved 382 out of 668,000 citizens, and according to the census of 1890 it involved 443 out of 954,400 citizens. Such large cities as Moscow, Kiev, Odessa and others also functioned as photography centers. Fairs housed mobile photo studios in which the technology of ferrotypes was primarily used.

The first photo amateurs were often rich or born noble. As the photo technology became simpler and cheaper, many middleclass amateurs became involved, often using photography as a means of self-expression. The self-expression through photography is why the amateur photographical societies appeared. Studying and analyzing the achievements of contemporary photographers and exchanging experiences were especially valuable for the provincial amateur photographers. Before the revolution of 1917 the number of photographic societies, although varying in size and cultural significance, amounted to more than 100.

The first decades of the development of photography were marked by a specific emphasis on the equipment. The first photographic societies were technical societies. The basis for the first large photographic society was formed by the Russian Emperor Technical Society (RETS) established in St. Petersburg in 1866. The RETS consisted of several branches. It comprised such

departments as chemistry, electricity, air-drifting, etc., which facilitated the inclusion of the use of other scientific findings in photography. The RETS established a fifth department in 1878, it was called the Photography Department. This initiative was headed by outstanding scientists like D. Mendeleev, photographers like L. Levitsky, I. Boldyrev, V. Carrick, and even artists like landscape-painter I. Shishkin and other prominent figures in Russian culture.

RETS' goals included the development of the technical, scientific and artistic aspects of photography, the establishment of theoretical and practical lecture courses the organization of nationwide photo exhibitions, and the establishment of a museum for photographic pictures. RETS had over thirty affiliates in various cities, including Moscow, Nizhni Novgorod, Odessa, Vyatka, Kiev, and others.

The leaders of the photography department in RETS, S. Proskudin-Gorski being one of them, believed that photography was documental by nature. In fact, he published articles on pictorial photography in *Fotograf Lyubitel* (*Amateur Photographer*) of which he was the chief editor. He stated that photography functioned as a way to fix surroundings in natural colors. After the revolution of 1917 the organization changed its name to Russian Technical Society (RTS). RTS organized a couple of photographic events and it fell apart in 1929.

In 1872 another special department for photography within a technical society was established in Moscow. The Society for Technical Ideas Dissemination (STID) developed out of need, a photographic society. The department's activities became obvious in 1883 due a general increase of interest in photography. The photo department of STID fostered the development and dissemination of artistic and technical ideas related to photography. The department was formed by such outstanding figures in Russian photography as E. Mattern, D. Yezuchyevski, and V. Vulfert. As the members of the society grew in number and the scale of activities became larger, it became clear that an independent photographic society was needed. So, in 1894 Russian Photographic Society (RPS) was established. It played a great role in the development of photography in Russia. As of the 1st October 1901 the number of its members amounted to 1,113. In 1899 a famous Moscow Photographer K.Fisher was elected the chairman of the society. The society set up a charity fund for those photographers who could no longer work due to an illness or a tragic accident. The meetings of the society were held in the Polytechnical Museum. At these meetings the members of the society used to discuss not only organizational matters and the latest photography related news but also scientific issues that were of general interest. Members of the society also used to demonstrate new photo equipment. Those who were interested, but not members of the society gladly visited the meetings, often totaling hundreds at times. The RPS organized out-of-town photo sessions in the beautiful suburbs of Moscow and nearby small towns. Often, this was followed by exhibitions and contests. The meetings of the society, as well as the journals, were full of heated debates on photography, its place in culture, and the direction of further development of photography. N. Petrov, a person knowledgeable on foreign photography and various theoretical and practical issues of photography, was a vigorous advocate of pictorial photography. He kept promoting the aesthetic concepts of pictorial photography in his speeches and articles for *Vestnik Fotografii* (*Photography Magazine*). He also tried to familiarize the Russian readers with the works by western masters. By 1930 the RPS had become dislocated and ceased to meet further.

The Photographic Society of Odessa (PSO) was founded in 1891. By January 1, it had 192 members. PSO studied theoretical as well as practical aspects of photography and gave an opportunity for the amateur photographers to travel for artistic and scientific purposes. The society members provided opportunities to photograph rare antiques and remarkable pieces of architecture. The PSO also held many of photo exhibitions. Additionally, the PSO established a commission for photo inspections that were needed for litigations.

There were also, among other societies, the Tiflis Society of Photo Amateurs, the Baku Photo Coterie, the Artistic and Photographic Society of Moscow, and the Saint Petersburg Photography Society.

The societies' major activities included the organization of photo exhibitions and providing support for members' participation in exhibitions held by other societies. Russian photographers took part in lots of international exhibitions, like the World Exhibition in London in 1863 and the International Exhibition in Berlin in 1865. Their works were an organic part of the world's art of photography. The works of Russian photographers were often prize-winning. The All-Russia Photographic exhibition in Moscow in 1867 housed over two thousand photos of typical Russian characters, scenes of folk life, and landscapes. Photography formed a large part of the International Polytechnic exhibition in Moscow in 1872. In 1882 a remarkable event in the history of Russian photography took place in Moscow, an All-Russia exhibition within the framework of a RETS session was held. Naturally the session included the photography department as well, thus setting into existence the first photographer's session in Russia. The exhibition prodded and worked to understand photo activity. The first specialized exhibition was held in Saint Petersburg in 1888 with 138 photographers participating and 820 photos exhibited. To mark 50 years since the invention of photography in 1889 the RETS organized exhibitions in Saint Petersburg and in Moscow. At the

St Petersburg exhibition there were some participants from abroad were invited by a commission of experts, such as F. Nadara.

Maxim Petrovich Dmitriev presented some of his works that later became a sensation of the Moscow exhibition. These photographs were some of his Volga sights, portraits, and genre scenes. In the 1890s international photographic exhibitions were no longer something extraordinary. At the Moscow International exhibition of 1896, organized by RPS, the foreign participants claimed all four contest nominations. Photographers from Denmark, Germany, France and other countries won gold and silver on equal terms with their Russian colleagues. Russia came to be fully integrated into the international photography process. The Session of Russian photographers and other specialists in the field synchronized to this exhibition a study of the key issues of Russian photography. The most salient question was of copyright for photographic works and products of photographic and mechanical processes. The law was proposed to the State Duma in 1908. Before the revolution of 1917, large photo-exhibitions took place in Russia like the International Photo Salon of Photography in Kiev in 1911, and a full-scale exhibition in St. Petersburg in 1912.

The societies and the exhibitions fostered the process of theoretical conceptualization of the artistic abilities of photography. The articles on this theme started to appear in Russia in the later half of the 1850s. The photographers and art critics wrote about the artistic potential of photography. However, these articles were not numerous and did not influence the world's photographic process.

During meetings of photographic societies, the question or problem that photography influenced life, or that life influenced photography was frequently discussed. For example, M.Dmitriev's album The Year of Poor Crops of 1891–1892 in the Nijnij Novgorod Province caused much influence on the public opinion and contributed to the activation of the government's aid to the ones who suffered from drought, typhus and cholera. It was this album that caused many photographers to begin to emphasize social problems in their work more often.

Many more heated debates on the specific features of photography, its language, the aesthetics of the art of photography, and the analysis of the achievements of world photography. In the beginning of the 1900s, a sharp debate arose in the photographic sphere regarding pictorial photography. This debate grew into an analysis of the nature of the artistic photographic image in general. Even though the works of the Russian photographers could not already influence the world's pictorial photography, it played an important role in the development of the Russian photography.

After 1932, all the artistic societies ended to create a space for the style of "soviet" realism.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN THE NETHERLANDS

The first encounters the Dutch had with photography probably took place in Paris where they went in the 1840s for equipment, or in London where they visited the International Exhibition of 1851. A few years later, in 1855 the Dutch for the first time had the opportunity to attend an exhibition of international photography in their country. It was the Exhibition of Photography organized by the prestigious Vereeniging voor Volksvlijt (Society for Industry), initiated by amateur photographer Jan Adriaan van Eijk, which was held in the center of Amsterdam in the building of the artists' society Arti et Amicitiae on the Damrak. It was quite similar to the exhibitions held this same year and a year later in Paris and Brussels, with more or less the same photographers and comparable contributions. 65 contributors send more than a seven hundred photographs to Amsterdam—photographers, societies and publishers alike—mainly from France, but also from England, Germany and the Netherlands itself. Photographs by the Dutch photographers Eduard Isaac Asser and his friend the chemist Eugene Bour were hung next to contributions by Charles Nègre, Henri Le Secq, Charles Marville, Edouard Baldus and the Comte the Montizon. The same exhibition was held a second time, two months later in The Hague, inaugurated by the king.

In 1858, 1860, 1862, and 1865 similar exhibitions, the first three also in the building of Arti and Amicitiae in Amsterdam followed: showing photographs by Gustave Le Gray, Philip Delamotte and Nièpce de St. Victor alike. The Dutch were a little more oriented towards France than towards Britain. It must have been the same mixture of art, experiment and industry as

elsewhere. The photographs were offered for sale and the catalogues mention ' import duties' and names of dealers as well. Benjamin Brecknell Turner's views of Amsterdam for instance were not exhibited in 1858 by the photographer himself but by the Amsterdam publisher W. Kirberger. The 1865 International Exhibition for Arts and Industry took place in the newly built Dutch Crystal Palace, the Paleis voor Volksvlijt in Amsterdam. Nadars mammoth photograph of a Japanese was being shown to the Dutch public, as well as his images from the Paris' catacombs. Maxwell Lyte for instance presented his landscapes from the Pyrenees and Wilhelm Hammerschmidt Egyptian views.

In those first 26 years since photography was introduced, the Dutch didn't have proper photographic societies, nor organized groups of photographers. Manuals and treatises from everywhere were translated for the amateurs who were interested in the new technique of image making. Some magazines for fine arts or industry translated articles from European origin and off course many read journals from France, Great Britain and Germany. The Dutch periodicals *Algemeene Konst- en Letterbode* as well as *Album der Natuur* regularly mentioned exhibitions, technical innovations and details in the field of photography. The 1860s saw the rise and spread of commercial and professional photography. This took place on a far smaller scale however than in the larger European countries. The first magazine exclusively concentrating on photography, *Tijdschrift voor Photographie*, was introduced in this period, again initiated by J.A.van Eyck, and leaded by a captain in the army L.P. van Beek. In 1864 it appeared for the first time and it lasted until 1866. Another photographer needs to be mentioned here. The German Julius Schaarwachter emigrated from Berlin to Nijmegen and started his De *Navorscher op het gebied der photographie, Tijdschrift voor photographie en aanverwante wetenschappen* between 1865 en 1876. He was a strong protagonist of the founding of a society or union for professional photographers, which he however never effectuated. In general the journals mainly had a 'technical' character. Other known platforms for exchange were the gentlemen's societies of art, architecture and antiquities.

It lasted until 1872 before the first *photographic* society, the 'Amsterdamsche Photographen-Vereeniging,' was founded with A. Haakman as its president. The society had its own journal, like the first Dutch journal also mentioned *Tijdschrift voor Photographie*. Only 45 photographers joined the club. The members exchanged photographs and technical details and held lectures, as we can read in its minutes in the *Tijdschrift voor Photographie*. In 1887 this rather subdue society was dissembled. Within a year a new society for *amateur* photographers—for 'dilettantes'—under the name of 'Helios,' with a journal with the same name was founded in Amsterdam. Pioneer photographer Asser was one of its active members. In 1889 or 1890 the 'Nederlandsche Fotografen Vereeniging' was founded, which however didn't last long and of which we virtually know nothing.

The Amsterdam society was the first in a long row of local amateur photographer societies which were based in virtually every city, from Groningen to Arnhem, from The Hague to Maastricht. In the 1890s throughout the country a vast amount of international exchange took place by means of international exhibitions of the pictorialists. Foreign publications such as *Die Kunst in der Photographie*, *Camera Work,* and *The Studio* were well known. The work of British, American and German photographers, among them Alfred Stieglitz and Heinrich Kühn was often shown to the Dutch photographers and public. *Lux* (1889–1927) was an important monthly photography journal. Little known—only two numbers survive—was the journal *Lumen*, 'Magazine for Photography, Projection and Cycling,' founded by the Amsterdam photography firm Ivens & Co in 1897. The beginning of the 20th century saw the founding of two long lasting and important societies Nederlandse Fotografen Kunstkring (NFK) in 1902 as a real trade union and the Nederlandse Club voor Foto-Kunst (NCvFK) in 1907.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN THE UNITED KINGDOM

The material infrastructure of nineteenth-century British photography has received remarkably little attention, yet exhibitions, societies and journals provided the framework for practice and theory. For a period, the social organisation of photography in Britain revolved around gentlemen amateurs. However, the category of the amateur requires scrutiny. Historians of photography have seen amateurs as synonymous with landed aristocrats, engaged in the disinterested pursuit of knowledge: Talbot is the paradigmatic example. An oversimplified distinction is often made between landed gents and middle-class industrialists: in reality, no strong barrier separated these class fractions. However, a drift towards the professionalisation of photography is discernable during the period.

At the outset, photography was organised through bodies associated with the 'men of science': William Henry Fox Talbot exhibited his photogenic drawings at the Royal Society and at a meeting of the British Association for the Advancement of Science. These organisations provided 'men of science' with social networks and models of authority. Typically, early papers appeared in the *Proceedings of the Royal Society* or in the journals of the bourgeois public sphere: *Edinburgh Review*, *North British Review*, *Athenaeum*, *Art Journal*, *Notes & Queries*—even *Household Words* was a generalist magazine. By the 1860s, the *Athenaeum* showed little interest in photography and *Notes & Queries* had been supplanted by the 'Notes and Queries' section of the *Photographic News*. As in everything else, the capitalist division of labour produced increased specialisation in photography.

The earliest recorded organisation dedicated to photography was the Edinburgh Calotype Club, possibly in operation as early as 1841. This amateur organisation had a small membership (mainly legal men) who met over dinner to look at calotypes and socialise. Similar organisations soon sprouted in England: the Photographic Club (sometimes called the Calotype Society), existed by 1847. As a contributor to the *Athenaeum* noted, the Photographic Club consisted of 'a dozen gentlemen amateurs associated together for the purpose of pursuing their experiments in this *art-science*.' The model for these groupings was based on networks of print connoisseurs. Members were to play a prominent role in British photography; among them were artists such as Sir William Newton, and 'men of science' like Robert Hunt. (P. Roberts, 212).

The Great Exhibition of 1851 initiated a transformation in the structure of British photography. An extensive collection of British photographs, and related equipment, were shown; reviews appeared and medals were awarded. However, it was the foreign photographic displays (particularly the French) that drew praise. Many commentators claimed that French photographers outstripped their British counterparts. This argument needs to be treated with caution, because an established discourse suggested that British manufacturers—particularly in the luxury trades—had slipped behind their French competitors. The account of photography circulating around the exhibition meshed with this argument and was, in part, the product of self-serving tastemongers. Nevertheless, combined with the simultaneous foundation of the French *Société héliographique* in 1851 the exhibition provided an impetus to the formation of British photographic societies.

The earliest British photographic society was established in Leeds in 1852. Crucially, in 1853 the London based Photographic Society came into being. The members of the Photographic Club played a significant role in creating this body, with Roger Fenton playing a leading role. The inaugural meeting took place, in 1853, at the Society of Arts—a venue that suggests the Society was modelled on the learned societies. The first Council was made up of twenty-four prominent gentlemen. By June of 1853 Queen Victoria and Prince Albert had agreed to act as patrons (though, it was not until 1894 that it assumed the title of Royal Photographic Society).

During the preparations for the Society, Joseph Cundall proposed an exhibition. Described by Pam Roberts as the first purely photographic exhibition, it opened at the Society of Arts on December 22nd 1852 and ran until January 29th 1853 (Roberts, 215). The first official exhibition of the Society took place in 1854. Thereafter, the Society's exhibition was an important annual event (with the exception of 1862, when it was suspended in favour of participation in the International Exhibition, and 1866). Held at a number of venues over the years, the entrance fee was set at one shilling, though on certain evenings—designated for the 'working classes'—it was reduced to 3d. The pictures were selected by jury and the display mimicked exhibitions of watercolours or prints—photographs in elaborate frames were stacked on the wall; a catalogue was published and extensive reviews appeared in both the national and the photographic press. These reviews provide important sources for judgements on particular images and assumptions about photography.

At least three amateur organisations existed during the

1850s: the 'Photographic Exchange Club' and two groups inside the Photographic Society: the 'Photographic Society Club,' founded in 1856, and the 'Exchange Club of the Photographic Society' (sometimes called the 'Photographic Club'). These organisations existed to facilitate exchanges of images and information between members, but they also provided networks of allegiance and identity. Founded 'to promote friendly feeling amongst members of the Photographic Society,' the Photographic Society Club was restricted to twenty-one members and met five times a year. (Seiberbling, 9–10) In a period when the Society mushroomed, this inner caucus provided the 'amateur' elite with a base for their hegemony. Grace Seiberling has estimated that only forty or so individuals were involved in these clubs. Membership overlapped and those involved were friends and acquaintances; some were relatives. A few of these people were engaged in photography on a professional basis, but these were amateur organisations imitating learned societies and dining clubs (where gentlemen socialised over a meal). According to Seiberling, the rules of the Photographic Exchange Club stipulated two photographic exchanges a year, but only four exchanges took place between 1855 and 1858. (Seiberling, 12) The Exchange Club of the Photographic Society issued two bound albums of members' photographs. The subjects of these pictures—antiquarian images of ancient buildings and monuments, picturesque views, landscapes, and so forth—typify the social vision of the gentleman amateur (Seiberling, 11).

From the outset tensions existed in the Photographic Society between amateurs and professionals. Talbot stressed the organisation should be founded on 'respectable' principles, unsullied by commerce. However, Fenton included professional or 'practical' photography in his vision for the Society. At the first anniversary meeting a motion advocated excluding those who practiced photography for profit. This proposition fell because it would have applied (among others) to Fenton who was Honorary Secretary ('Anniversary Meeting,' 165–66). According to Seiberling this tussle for control continued until 1858 (Seiberling, 73).

Nevertheless, a change was underway. The number of professional photographers in the Society increased substantively as did the range of commercial firms participating in the annual exhibitions. By the middle of the 1860s those involved in the exchange clubs had died or were no longer active in photography. This is not to suggest that there were ever rigid barriers demarcating amateur from commercial work: Talbot patented his inventions and attempted various commercial ventures; in 1853 early amateurs, including Philipe Delamotte and Cundall, instigated the 'Photographic Institution,' which charged for lessons, and sold equipment and prints; in 1856 Fenton, along with others from the Exchange Club, left the Council of the Society to found the commercial 'Photographic Association,' when it flopped he returned to the Society and again played an active role as Vice President. Some early amateurs made the transition to professional photography; others tried to do so but failed.

Shortly after the foundation of the Photographic Society regional groupings appeared. The Liverpool Photographic Society was founded in 1853; the Manchester Society in 1855. Men professionally engaged with photography played a significant role in instigating these organisations in these industrial and commercial cities. But, even in these Northern bastions of capitalism, the key representative roles were filled by local notables. This should come as no surprise: this representative structure mirrors the British state and its colonial extensions. Some societies were short lived (In each case dates are for foundation of the society.): Devon and Cornwall (1854), Norwich (1854), Brighton and Sussex (1855), Birmingham (1856) reformed in 1885, Chorlton (1857), Blackheath (1857), Greenwich (1857) and Macclesfield (1858). The North London Society (1857) and the South London Society (1859) were more stable; as were the Nottingham (1858) and Bradford Societies (1860)**.** With the rise of regionally active groups—the 'parent society'—became known as the Photographic Society of London; then the Photographic Society of Great Britain in 1874.

Special mention must be made of 'British' Societies situated beyond England's borders. Preceded by the Glasgow Photographic Society (1854), the Photographic Society of Scotland was formed in Edinburgh in 1856. Sir David Brewster was elected President; George Moir, previously involved with the Edinburgh Calotype Club was elected a Vice President (though, he stepped down the following year), as was Horatio Ross, a keen amateur and former M.P. for Aberdeen. Prince Albert agreed to act as Patron a month after foundation. The Society held regular meetings at which photographs and items of equipment were displayed and lectures presented; some papers along with the minutes of proceedings appeared in the *Journal of the Photographic Society*. The first annual exhibition was held in December 1856: 1,050 photographs were seen by 8,000 people. The Scottish Society's exhibition was to become a significant annual event. At the second AGM in 1858, membership stood at 151 and was said to include all prominent amateur and professional photographers in Scotland. However, following the establishment of the Edinburgh Photographic Society in 1861, the Photographic Society of Scotland declined, finally folding in 1873. Other Scottish societies included the short-lived Dumfries and Galloway Society (1856) and the Paisley Society (1857). The Glasgow Society became the Glasgow and West of Scotland Photographic Society in 1860.

In Ireland—at this time a part of the British state—

two societies emerged during the 1850s: the Dublin Photographic Society, founded at the premises of the Royal Dublin Society in 1854, and the Belfast Photographic Society, founded 1857, but probably defunct by 1860. The participants in the Dublin Society resemble the figures that made up the London Society: unsurprisingly, many of these people were part of the Anglo-Irish establishment. In a significant move, it changed its name to the Photographic Society of Ireland in 1858. In an empire over which the 'sun never set,' photographic societies were also active in Bombay (1855), Calcutta and Madras (both 1856). Journals were published by the first two societies, but appear not to have survived; the latter published proceedings in the *Madras Journal of Literature and Science* and also held some exhibitions. The social role of these organisations and the images produced by their members were inevitably shaped by this colonial context.

As the South London Society's Honorary Secretary A.H. Wall put it, the range of subjects discussed at meetings:

> are such as, until the introduction of photography, were seldom associated together. The rules of art, the laws of chemistry, the principles of optics, and the secrets of certain mechanical crafts, seem in the non-photographic mind to possess so little in common, that strangers wonder when they hear each, or all, of these dissimilar subjects blending in a discussion following some paper on one or other of the processes of photography. (Wall, 'A Few Thoughts about Photographic Societies,' 487)

Although some of the smaller societies were referred to as 'Gossiping Clubs,' the South London Photographic Society was extremely active and gives an indication of proceedings. Less formal than the London Society, 25 to 30 members gathered to discuss papers or matters of interest. A 'Question Box' allowed issues to be raised 'without writing a paper.' It was suggested that papers should be submitted in advance to the committee in order to prevent presentations that were 'foolish,' 'unsuitable' or in bad taste ('Photographic Societies, Papers, and Discussions,' 147). Evidently, some effort had to be exerted to establish norms of middle-class decorum.

What we know about the societies comes, in large part, from the journals, which carried the minutes of their proceedings and published papers. From the 1850s, numerous photographic journals appeared, often with a short life span. Three stand out: *The Journal of the Photographic Society of London* founded in 1853 (subsequently *The Photographic Journal* from 1859); *The British Journal of Photography* established 1860, but emerged from journals issued in the North West from 1854; and *The Photographic News* (1858–1908). *The Photographic News* was independent (though it was closely allied to the London groupings) and it easily achieved the highest circulation figures. These journals provide indispensable source material, but they need to be read carefully: these are partisan forums for personalities, trends and coteries; all were dedicated to elevating the social status of photographers.

From the outset, photographs were exhibited in a wide range of contexts, including: the British Association for the Advancement of Science, The Society of Arts, The Royal Scottish Academy, The Royal Polytechnic Association, The Photographic Institution, Mechanics Institutes; even the Yeovil Mutual Improvement Society. As we have seen, the Photographic Society and Photographic Society of Scotland mounted annual exhibitions: local photographic societies also held exhibitions on an intermittent basis. Photographs featured in the Great Exhibition of 1851 and in 1857 the Manchester Art Treasures Exhibition included an important collection of photographs selected by Delamotte. Exhibitions of novel subjects began to take place during the 1850s: Fenton's Crimean pictures, for instance, were shown widely around Britain. The 1862 International Exhibition was probably one of the most significant the exhibitions of the period. Following the pattern established in the Great Exhibition of 1851, the commissioners responsible proposed exhibiting photographs and equipment together in the Machinery Court. Photographers were repelled by this suggestion and demanded that their images be exhibited with the Fine Arts. A campaign for reclassification, led by the Photographic Society, was instigated and the national press took note of the argument. As *Punch* observed, the commissioners:

> [h]ave thought fit to pass an insult upon Photographic Art, by classing its productions with railway plant and garden tools, small arms and ship's tackle, big guns, and new omnibuses, donkey carts and corn extractors…. (Silver, 'Fair Play for Photography', 221)

The Society organised a boycott of the exhibition, but eventually accepted the compromise of a 'separate apartment' offered by the commissioners. When the exhibition opened it became apparent that this 'separate room' was a purely notional category in the catalogue; photographs were situated alongside cameras and chemicals amongst an array of educational devices. Despite photographers' evident dismay this exhibition was pivotal, because it pushed photographers to argue on a scale previously unknown that their art was one of the Fine Arts. No doubt, the need to claim invention in copyright law played an important role here, but the existence of networks of professional societies and journals was also significant (in this dispute the *Photographic Journal* received communications from at least nine societies). However, it would be another ten years, before photography was admitted to the category of Fine Art in the International Exhibition of 1872, where it was situated with engraving and lithography.

If the amateur exchange clubs provided one kind of alternative to photographic societies, other organisations also contested for hegemony. Mechanics' Institutes and Literary and Philosophical Societies gave time and attention to photography. During the 1860s James Mudd was a member of both the Manchester Photographic Society and the Manchester Lit and Phil (Photographic Section) were he rubbed shoulders with prominent industrialists and men of science. In 1863 and 1864, responding to the economic crisis in the carte trade, the editor of the *Photographic News*—George Wharton Simpson—advocated the establishment of a 'relief fund' or 'provident society' for photographers ('A Photographers' Relief Fund,' 589). Though little is known of it (probably because historians have been overly preoccupied with the doings of amateur gentlemen) the Solar Club, organised by Simpson, played an important role in the 1860s. Restricted to 25 members, it brought together the '*elite* of the metropolitan photographers' for dinner once a month along with guests from the arts and the press. The model may have been the gentlemanly dining club, but this was no longer an amateur binge. The members of the Solar Club were key figures in professional photography: editors, proprietors of grand studios and writers for the trade journals. At one such meeting the alliance between Alfred Wall and Oscar Rejlander was cemented. There were, of course, also attempts to unionise the industry, though nothing concerted seems to have happened until the early 1890s when Arthur G. Field, Eleanor F. Field and John A. Randall made a determined push for an operatives' organisation.

In his report on the International Exhibition of 1862, published in 1864, Dr Hugh Diamond suggested that there was 'scarce a branch of art, of science, of economics, or indeed of human interest in its widest application, in which the applications of this art have not been made useful.' He offered a list of those who employed photography in their professional pursuits, including: people from medicine, law, architecture and engineering, manufacturers, ethnology, natural history, archeology and antiquarian pursuits. (Diamond, 'Report of Jurors,' 339–46) Lists like this were part of the professional claim to status and shouldn't be taken literally. Nevertheless, photographers increasingly found forms of institutional support by providing the State and private organisations with documents. For example: Fenton, along with the brothers Thurston and Stephen Thompson, worked for the British Museum during the 1850s and 1860s documenting its holdings; penal photography was established during the 1870s and came increasingly to feature as evidence in the law courts; it also came to play an important role in anthropology and colonial administration.

As early as 1859, the need for a permanent collection of photographic portraits was mooted. Lachlan McLaclan took up the idea of a national collection of portraits in 1863. Three years later the Corporation of Manchester adopted his plan and appointed him Honorary Curator. Solicitations for pictures appeared in the photographic press, but, to my knowledge, nothing further happened. In 1882 the South Kensington authorities announced their intention to hold an exhibition surveying the history of photography. The exhibition was to form the basis of a permanent collection at the museum and appeals were again issued in the photographic press soliciting donations of apparatus and pictures. Organised in less than a month and accompanied by a series lectures, this exhibition provided the foundation for the Science Museum collection, and subsequently the nucleus for the National Museum of Photography, Film and Television.

Pictorialism represented both a break and continuity with the established organisations and procedures. The Linked Ring Brotherhood seceded from the Photographic Society in 1892 in order to pursue an untrammelled vision of photographic art. Initially, 28 members were listed on a 'Roll,' rising to 75 at the height of activity. The organisation assembled monthly at a 'Union' for dinner and published *Linked Ring Papers* for circulation amongst the membership. From 1893 it also organised an annual exhibition, or 'Photographic Salon,' which was first held at the Dudley Gallery, Piccadilly, and then at the Pall Mall premises of the Royal Society of Painters in Water Colours. The Linked Ring retained many of the existing organisational forms, but infused them with the imagery and values of the Aesthetic Movement and the Arts and Crafts Guilds. However, Pictorialism was not confined to the elite associated with the Linked Ring: *Amateur Photographer,* a journal peddling a softer version of the Symbolist aesthetic, appeared between 1884 and 1918, and Pictorialism permeated the new amateur hobbyists clubs that developed during the later years of the century. It has been suggested that the number of photographic societies had declined substantially by 1880; in 1885, H. Baden Pritchard listed 17 societies in England and Scotland. (Pritchard, *Photography and Photographers*, 101) By 1900 this figure has risen spectacularly to 256. As Peter James has noted, attention to Pictorialism has largely overshadowed the emergence, around 1890, of the Record and Survey Movement. (James, 'Evolution of the Photographic Record and Survey Movement,' 205). Instigated by Sir Benjamin Stone and W. Jerome Harrison a local survey was initiated to document disappearing monuments, traditions and old buildings in Warwickshire. Other local surveys were undertaken and Harrison attempted to found a national organisation, but he ran foul of the Photographic Society. Stone, by this time Conservative M.P. for Birmingham, established the National Photographic Record Association in 1897, which produced

thousands of images. Despite their divergent aesthetic approaches, Pictorialists and the survey groups pursued a largely anti-urban vision.

SOCIETIES, GROUPS, INSTITUTIONS, AND EXHIBITIONS IN THE UNITED STATES

The development of photography in the United States has often been described as a "pell-mell rush," to quote Albert Sands Southworth's 1871 evocation of the beginnings of American photography: a spontaneous competition, in which academic institutions and formal organizations played little role. Although this characterization is to some extent true, the organizational history of American photography deserves attention, especially since it reveals, throughout the 19th century, a consistent ambition to elevate the status of photography.

During the 1840s, the development of the daguerreotype was largely autonomous and uncontrolled, as trade organizations did not yet exist and academic institutions played only a limited role. In the United States, the first announcement of Daguerre's invention was not carried by a scholarly publication, but rather by dozens of newspaper reprints of a letter by Samuel F.B. Morse, describing from Paris the "results" of the daguerreotype. The decentralized structure of the United States was

mirrored in the way daguerreotype experiments and then businesses popped up in virtually every settled area, the main economic and cultural centers merely leading the way. For most of the 19th century, and despite some important exceptions, federal departments and especially Congress were quite timid in promoting the use of photography, and were even more so in creating conservation and evaluation instruments. Yet the contrast that some historians have drawn between an "academic" Europe and an "entrepreneurial" America must not be overestimated. No existing American institution in 1839 would have had the power, the authority or the design to influence the course of photography in any way comparable to European policies of protection and promotion. An exception may be made for the U.S. Patent Office, which granted between 1842 and 1862 at least fifty patents concerning mostly minor improvements on the daguerreotype, but whose action was of necessity limited to the realm of technology and even then was often contested or disregarded. Beyond this, however, many academic institutions participated in their own way in the development of the daguerreotype. In many parts of the United States, universities and medical schools served as the first centers for information and experimentation, and this was no less true in the major cities. In Philadelphia—America's old capital —, the Franklin Institute was called upon to evaluate Daguerre's process, and shortly published an "explanation" and then an English translation of Daguerre's manual, while in May 1840 the American Philosophical Society was shown portraits of its members, produced through technical improvements on Daguerre's instructions which, based on experiments by chemists from the University of Pennsylvania, came to be known as the "Philadelphia method." In New York, the leading role that Morse and John W. Draper played in the first months reflected their connections to both New York University and Morse's National Academy of Design, the latter a mutual aid society, rather than a formal tribunal of art. Although other groups existed in New York without any such affiliation, and although the Morse-Draper group was short-lived and mostly informal, it was Morse's authority that drew many apprentices to his studio for lessons in daguerreotypy (among whom were Mathew B. Brady and several other future photographic greats). Finally, associations in the larger cities often held fairs where daguerreotypes were exhibited, the most important of these being the American Institute's fair in New York, which awarded medals for daguerreotype from 1840 on, Mathew Brady receiving his first medal there in 1844 and his first gold medal in 1849.

Between 1850 and 1855, increasing competition, signalled by price wars and various attempts at controlling the market through patents, and compounded by the emergence of the new negative processes, caused a great deal of tension in the profession and led to the formation of "protective" or "mutual" organizations. The most famous of several patents that were awarded, with little or no justification, for secondary improvements on the glass processes was the "bromide patent," covering an accelerating formula for collodion on glass, which was one of three granted in 1854 to James A. Cutting, and which virtually enabled him to control the entire sector of glass photography, causing bitter corporative feuds. Along with the anti-patent and price wars, another concern that initially and durably underlay trade organizations was the desire to "elevate" photography, which meant both to expand its uses and to legitimize it as a form of art. These factors merged in the formation in 1851 of the first two American photographic societies: the New York State Daguerrean Association, which aimed primarily at setting floor prices and creating a "fraternal" spirit in the profession; and the American Daguerre Association, whose first secretary was Samuel D. Humphrey, editor of the world's first specialized periodical, *The Daguerrean Journal* (founded 1850). Humphrey's goal was to promote taste in photography and counter its "humbug" reputation. Neither one of these early photographic societies survived for more than a couple of years, and, by 1852, a third one appeared in New York on a similar platform of mutual aid. In these early efforts to organize the profession and more generally to "elevate" photography's dignity one must also include the photographic competition at the New York Crystal Palace Exhibition in 1853, the first World Fair in the United States, where daguerreotypes still dominated in numbers but were outraced for the top award by photographs on paper.

In the decade between 1859 and 1869, as the daguerreotype was definitively supplanted by glass photography, several more attempts at organization betrayed the same protective impulse. In New York in 1859 the American Photographical Society (APS) was founded; it was later renamed the Photographic Section of the American Institute. Among its founders were some of American photography's pioneers, such as Henry Hunt Snelling, Charles A. Seely, John Johnson and Joseph Dixon, but relatively few active photographers. Indeed, this society aimed at placing American photography "in a position equally as elevated as in Europe," as Seely put it, and therefore it called rather on scientists (such as John W. Draper, Lewis M. Rutherford, Robert Ogden Doremus), and, in William Welling's words, "some of the foremost business, professional and social leaders of the day." The APS discussed technical novelties and scientific discoveries, but also various applications of photography and even photography's past, some members tossing around the idea of a photographic museum in New York. In these various aspects, the APS echoed changes in the social and cultural status

of photography in the United States. This was indeed the period in which, thanks to collodion photography, large organizations, especially federal departments and services, but also railroad conglomerates, museums and academic or scientific bodies, started to devise large-scale undertakings of documentation, archiving, map-making and illustration : hence the role of photography in the Civil War, and especially the connection of the Union's Army of the Potomac with Mathew Brady's staff of war photographers, but also Joseph Henry's precocious organization of photo-ethnographic collections at the Smithsonian Institution, and the systematic inclusion of photographers in federal surveys of the West after 1867. Another trend was the emergence of amateur photographers (or amateurs of photography) and local photographic societies. The most important of these was the Photographic Society of Philadelphia, which was founded in 1862, and which drew amateurs and professionals, including major figures such as Coleman Sellers and Edward L. Wilson, editor from 1864 on of the *Philadelphia Photographer*. This periodical continued the goal of "elevating" photography by promoting serious technical innovation and artistically informed discourse and practices. The strength of the Philadelphia connection was reflected in the Centennial Exhibition of 1876, whose large photographic section displayed in Philadelphia what Robert Taft called "the highwater achievement of the American wet plate photographer," as well as the first large-scale confrontation of American and European photographs in the United States before 1895.

Meanwhile, the protective spirit of the earlier daguerrian societies was far from extinct in the profession itself. The ongoing battle against patents was topmost on the agenda of the Photographers' Protective Union, which convened several times in the 1860. The matter finally came to a head in 1868, when in an effort to fight an application to renew the Cutting patent, a National Photographic Convention was held at the Cooper Institute. At this important event virtually all the great names of professional photography and the photographic industry were gathered (including Mathew Brady, John A. Whipple, Henry T. Anthony, Alexander Hesler, James F. Ryder, John Carbutt, etc.), united in a drive to obtain the repeal of the patent renewal. The patent was indeed revoked, and there ensued a new, "fraternal" organization, the National Photographic Association (NPA), which convened for the first time in 1869 in Boston, inaugurating a period of greater stability in the profession. At this convention a large exhibition displayed the state of the photographic art, including photographs made from retouched negatives, and announcing a trend that might be labeled "professional art photography," and which would characterize NPA exhibitions and American professional photography in general until 1900. In 1870, in the same protective spirit, the NPA defended a copyright for photographers, obtaining a provision in the 1870 law that granted copyright to photographs on the condition that two copies be sent to the Library of Congress (the single most important source of that institution's photographic collection). In the 1870s the NPA became the principal photographic organization; its membership exceeded 1,000 and included such prestigious figures as Samuel Morse, Oliver Wendell Holmes, and Hermann Vogel; it held large annual conventions and exhibitions, and pursued a very eclectic agenda, from patent discussions to artistic retouching to the esthetics of landscape to the historiography of early American photography. Although the NPA came to an early death in 1876 as a result of internal dissent, it was more or less revived in 1880 by the Photographers' Association of America (PAA), which essentially continued the former society in its membership, its "fraternal" ambition to elevate taste and quality and to combat price-cutting—a goal that became vital in the face of growing dry-plate companies and nascent popular photography—and in its genteel commitment to art, which as Sarah Greenough has noted, may have been innovative in theory, but was rather conventional in practice. Thus, it could be argued that from the first daguerrian associations to the PAA's continuing fight for "art photography," the mainstream of American professional photography consistently upheld the same agenda of resisting the more brutal forces of business and industry and promoting photography as art.

After 1880 and even more so after 1890 the structure of American photography changed, in response to the advent of popular photography and perhaps more directly to the growing ranks of self-conscious amateurs, whose clubs and societies numbered over 50 in 1890 and over 150 in 1895. This evolution was also reflected in the increasing number of photographic exhibitions and galleries. A Society of Amateur Photographers of New York held its first annual exhibition in 1885, and in 1887, along with its Boston and Philadelphia counterparts, it started holding Annual Joint Exhibitions that gathered vast amounts of photographs, still with a view to raise standards of taste and quality. In 1896 a photographic salon was held in Washington, D.C., at the Smithsonian Institution, and the following year this was enlarged into a "National Photographic Salon," with the Smithsonian Institution pledging to buy the best photographs. Also in 1897 a large salon was held in Pittsburgh. The National Academy of Design housed its first exhibition of photographs in 1898, and the same year a full-fledged European-style photographic salon was staged at the Philadelphia Academy of Fine Arts, which displayed over 200 photographs by 100 photographers. The Eastman Kodak Company itself created clubs and exhibitions for the promotion of artistic ambition within the

ranks of popular photographers. Thus, when Alfred Stieglitz formed the Photo-Secession in 1902, the institutionalization of fine art photography (and pictorialism) in the U.S. was so advanced that the issue was no longer to "elevate" photography, but rather to strip it of both its professional and amateurish connotations, which over half a century had jointly and consistently amounted to a code of photographic correctness.

SOMMER, GIORGIO (1834–1914)

Italian photographer

Giorgio Sommer was born at Frankfurt am Main on the 2nd of September 1834. His parents were Georg and Anna Margaretha Gauff. His father had been the proprietor of a famous hostelry since 1826 and was able to give his growing family a certain measure of comfort. Later, however, he lost everything because of gambling and was forced to put his eldest sons to work to support the family. Thus Giorgio Sommer, the ninth of a very large family, served his apprenticeship in the firm of Andreas and Sons in Frankfurt until 1853. Immediately afterwards he started working professionally as a photographer.

In 1857 he went to Italy, first to Rome and then to Naples, where he chose to take up permanent residence. He went back to Rome in 1859 to keep up his acquaintance with his fellow-countryman Edmondo Behles (1841–921), with whom he had formed an association as soon as he had arrived in Rome. This acquaintance lasted until about 1866. Behles was the most brilliant and most qualified cameraman in Sommer's firm, and even today it is difficult to tell his work from that of Sommer's, since the earliest photographs of both do not indicate copyright.

Behles remained in Rome when Sommer set up in Naples, and worked independently until 1878 in Via Mario dei Fiori 28. Both Sommer and Behles in their new premises sold photographs taken in Rome under their own names while they were working together. This made the attribution of the studio's first photographs very difficult. The years spent in Rome were very fruitful ones for Sommer however and it was there that he put his experience to the test and he made contacts that helped him to consolidate and enlarge his own visual capacity. Rome was the meeting place of artists and intellectuals from all over Europe, the goal of a cultured elite of travellers, and the seat of academies and cultural institutes of different countries. There gathered some of the most eminent photographers, such as James Anderson (1813–1877), Angelo (1793–1858) and Giacomo (1819–1891) Luswergh, Robert MacPherson (1811–1872), the calotypists who gathered around Frédéric Flachéron (1813–1883) of the "Roman school of photography." Of these the most famous were Eugène Constant and Giacomo Caneva, who were often to be found at the famous "Caffè Greco" in Via Condotti. Also in Rome at that time there were many other German photographers, such as Wilhelm Osvald Ufer, Gustav Reiger, Michael Mang and Alfredo Noack. In Rome, Sommer and his fellow-countrymen pursued their interest in archaeology and the ancient world, and often met at the Deutscher Künstlerverein or in Palazzo Caffarelli. They loved the beauties of the Italian countryside and of Italian art, thanks to the return of Classicism and its myths, which were much transformed and "revisited" at a symbolic level. Such a passion for antiquity was nourished at the time by the finds at the excavations around Rome and Naples.

Of Sommer's work at Rome there remain several views and his complete set of photographs of the works of art in the Vatican, especially of the ancient statues of Braccio Nuovo, the Museo Chiaramonti, the Museo Pio Clementino, the cabinet of Pope Pius the VIth, the Rooms of the Muses, the Rotonda and the Candelabra. When he was at Rome, his preferrence was for stereoscopic formats and *carte de visite*, which he abandoned after the 1860s, and for "Medium" (21 by 27 cms) and "Large" (28 by 38 cms) photographic apparatus.

At Naples there were many foreign photographers and artists, such as George Conrad, Roberto Rive, Alphonse Bernoud, and Wilhelm Weintraub. Here Sommer set up

his studio most strategically in the centre, although he changed his address several times. Once his association with Behles had come to an end, between 1873 and 1874 he established himself finally in a palazzo in the piazza della Vittoria, where he stayed until he died on the 7th of August 1914. At the end of the sixties his studio was one of the foremost in Naples, which enabled him to live in considerable ease.

Of the photographs he took while at Naples there remain some extraordinary views of ancient ruins, of the excavations at Pompeii and Herculaneum, of the beauties of nature and of monuments, as well as some pictures of Neapolitan dress. Thus he continued to produce the type of work he had experimented with at Rome. He worked for commission, and free lanced at the same time to increase his own individual collection.

In 1862 he abandoned portraiture and began looking at the everyday life of the people of Naples, took photographs of their costumes and of produced genre scenes. From the numerous photographs of trades at Naples which he produced in his studio from the end of the sixties a fine cultural connection can be seen with the tradition of engraving and the eighteenth century Neapolitan tradition of the crib. However, he did not portray the real miseries of man's existence, but by restoring a degree of humanity gave somewhat picturesque view of life and sold his photographs as souvenirs to middle-class and aristocratic tourists who were looking for traditional scenes of a Neapolitan popular character. Indeed, there is no hint of the social conflicts that were typical of the period. In the nineties Sommer began to specialize in instant photography, using the new gelatine silver bromide process. These photographs, which show ordinary people in an everyday context, have an immediacy that reveals the changed priorities of the photographer, and can be seen as the forerunners of social reportage.

Perhaps at the commission of the great archaeologist John Henry Parker he photographed ancient works of art, in particular those at Pompeii and those in the Museo Nazionale at Naples. His views of landscape, both in Italy and in other European countries, are distinguished by their descriptive clarity and precision of detail. Their extremely high quality is due to the use of gold toning, which gives the prints fine gradations of tone from red and purple to violet. His great skill in composition is shown by the fact that, through a slight deviation from frontal and symmetrical shots, his photographs of monuments and architecture are always dynamic and never static.

His studio became very well-known also abroad, thanks to clever distribution and advertising techniques that gave him sales outlets at Vienna, Genoa, Venice, Florence and Palermo. He also had prestigious commissions in the world of art publishing, such that for the work by Domenico Benedetto Gravina published in 1859 *Il Duomo di Monreale illustrato* [*Illustrations of Monreale Cathedral*]. His remarkable entrepreneurial and organizational skills helped him to set up a strong network of collaborators, and his versatility of character and gifts enabled him to interpret successfully the different roles of photographer, printer, publisher, and distributor. Exploiting the growing taste for antiquities, he also started producing objects of art in bronze, terracotta, and marble, copying in particular originals of Pompeii. He won prizes for this, in addition to prizes for photography, at the international exhibitions at London (1862), Paris (1867), Vienna (1873), and Nuremberg (1885). In 1865, together with Behles, he received a signal honour from Vittorio Emanuele II, and from then on his style and title was that of Photographer of His Majesty the King of Italy.

He made many journeys abroad, especially to Switzerland, where, thanks to his reputation, he gained from 1880 to 1890 a commission from the Swiss government to photograph the mountains in connection with the extension of the railway network. Thus his last years were ones of flourishing activity, affluence, and fame also beyond the Alps. However, the extraordinary quality of his photographs mark him out as the photographer who above all definitively captured the life, the monuments, the natural and artistic beauties of Naples, Pompeii, Herculaneum, Amalfi, and all the region of Campania, rich in history, art, and tradition.

Sommer's firm was officially wound up in 1916, two years after his death. The plates were given by a nephew to Bruno La Barbera and were then destroyed.

Today there are many of Sommer's photographs in public and private collections, both in Italy and elsewhere.

SILVIA PAOLI

Biography

Giorgio Sommer was born at Frankfurt am Main on the 2nd of September 1834. His parents were Georg and Anna Margaretha Gauff. He was the ninth of a large family, and had to earn his own living from an early age because of economic difficulties. He was apprenticed to the photographic studio of Andreas and Sons and at the end of his apprenticeship he decided to work professionally. He began to work in Italy in 1857, at first in partnership with Edmund Behles, and from 1866 on his own. His first studio was in Rome, but almost immediately he decided to settle in Naples, where he changed his address several times (Strada di Chiaia 168, Via Monte di Dio 4 and 8, Piazza della Vittoria). He travelled widely in Italy and abroad, either for his own private work or on commission. His main interests were photographing views of archaeological sites and

of the natural and artistic beauties of Naples and its bay, of Pompeii and Herculaneum, and of the Amalfi coast, and taking photographs of Neapolitan costumes. For a short time he did portraits, but stopped in 1862. In 1861 at Naples he married Antonia Schmid, the daughter of a piano maker; they had two children, Edmund and Carolina. Edmund worked in his father's firm and on the 21 of January 1889 became a partner. The firm won prizes at international exhibitions: London (1862), Paris (1867), Vienna (1873), and Nuremberg (1885). In 1865 Sommer was honoured by Vittorio Emanuele II as Photographer Royal. He died on the 7th of August 1914 after having achieved great affluence and European fame. Nothing remains of his archive of plates. Today there are only some of his photographs in public and private collections.

SOUTH KENSINGTON MUSEUM

The museum was actually located in the London district of Brompton, where it opened its doors in 1857. However, its founding director, Henry Cole, thought that the made-up name of 'South Kensington' possessed more social tone. The museum was based on an earlier one which was originally part of the Government School of Design and went by various names in the early 1850s, such as the Museum of Ornamental Art. These earlier manifestations were much enlarged in physical plant and intellectual ambition in the form of the South Kensington Museum. This was created out of the cultural impetus provided by the Great Exhibition of Works of Industry of All Nations, held in London's Hyde Park in 1851. The Commissioners of the Great Exhibition spent some of its enormous profits buying 86 acres of land south of Hyde Park. Prince Albert saw this as the site of a new cultural quarter. Henry Cole (1808–82), a prime mover in organizing the Great Exhibition, took control of the Schools of Design and the newly formed Department of Practical Art at the Board of Trade in 1852. The South Kensington Museum became a model for many other museums around the world. The new institution embraced the arts of everyday life and developed vigorous teaching programmes to improve design, craftsmanship and taste. Cole did several important things for photography. In 1852 he began a collection of documentary photographs representing works of art and architecture. Among the earliest acquisitions was Maxime Du Camp's *Egypte, Nubie, Palestine et Syrie,* bought by instalments from 1853 onwards. Secondly, from 1853, Cole commissioned photographs of the museum's temporary exhibitions, so that a record would be available for study when objects had been returned to their owners. Francis Bedford (1816–94) and Charles Thurston Thompson (1816–68) photographed An Exhibition of Decorative Furniture in 1853. In 1856 Thompson was appointed Superintendant of Photography and, assisted by soldiers seconded from the Royal Engineers, established the world's first museum photographic service. The purpose of the service was to record works of art with the new authenticity provided by photography and to make these photographs available at modest prices to the designers and others who needed them. Photographs were often used to illustrate the Museum's catalogues in the era before accurate photo-mechanical printing. Cole's third innovation was to begin a collection of the art of photography. He saw

the medium as a tool of education and scholarship, but also as a creative medium in its own right. (His enthusiasm for photography led him practise it as an amateur in 1856.) On 22 January 1856 Cole and Thompson visited An Exhibition of Photographs and Daguerreotypes, the third annual exhibition of the Photographic Society of London. Cole bought 22 photographs from the exhibition, thus founding the earliest collection of the art of photography in the world. His selection included examples of the principal subjects of fine art, such as the nude (an "Academic Study" by John Watson), still life ("Christmas Fare" by V.A. Prout and William Lake Price's "The First of September") and landscape (most notably views taken in the Valley of the Mole by Robert Howlett). Cole's fourth initiative was to host a photographic exhibition—the first in any museum—in 1858. This was a combined show involving the Photographic Society of London and its Parisian counterpart, the Societé Française de Photographie. There were almost 1000 exhibits, including contributions from some of the greatest practitioners of the time, such as—on the British side—C.L. Dodgson (Lewis Carroll), Roger Fenton, J.D. Llewelyn, Oscar Gustave Rejlander and Benjamin Brecknell Turner and—from France—Edouard Baldus, Gustave Le Gray, Nadar and Charles Nègre. Queen Victoria and Prince Albert, both keen collectors of the art of photography, attended the private view of the exhibition held on 12 February 1858. The installation of the exhibition was admired by critics and was recorded in a photograph by Thompson. Unfortunately, none of the exhibits were acquired by the museum. However, Cole was to make a significant acquisition in 1865 when he bought 80 photographs from Julia Margaret Cameron (1815–79). He sat for her at Little Holland House on 19 May 1865. Cameron produced a striking portrait of Cole, resembling a Renaissance grandee (a print is in the Royal Society of Arts), and gave the museum 34 more of her photographs. Cole showed a selection of Cameron's works at the museum in autumn 1865. He also provided her with studio space for her portraiture practice at the museum—this was (his fifth innovation) a precursor of the idea of the artist-in-residence. Her marvellous letters to Cole are in the National Art Library at the South Kensington Museum's successor, the Victoria and Albert Museum (which it was renamed by Queen Victoria in 1899, now popularly called the V&A). Cole's sixth innovation was to send Cameron's photographs to regional centres as part of the museum's circulating exhibitions programme. He was the first, and unfortunately the only, museum director to buy and exhibit Cameron's work in her lifetime. The works she gave Cole and his wife personally were given to the museum by their son, Alan S. Cole, in 1913. Thanks to the various photographic initiatives introduced by Cole at South Kensington, his colleagues were sufficiently sensitized to the art of photography to accept the photographic element when the Chauncy Hare Townshend Bequest was offered in 1869. The photographs were kept alongside other kinds of prints in the Art Library—perhaps the earliest 'museum without walls.' The museum's scientific experts also arranged important exhibitions which presented photography from a technical point of view, notably The S.T. Davenport Collection (1869) and the Special Loans Exhibition (1876). These exhibitions displayed an impressive range of photographic processes, print types and equipment such as lenses. Items from the1876 exhibition became part of the Science Museum collections when the South Kensington Museum was divided and renamed in 1899 and are now in the National Museum of Photography, Film and Television.

SOUTH-EAST ASIA: MALAYA, SINGAPORE, AND PHILIPPINES

Malayasia in 2006 comprises in the west: the southern Malay Peninsula (former Straits Settlements of Penang, Province of Wellesley and Malacca), Singapore and in the east, the states of Sarawak and Sabah on Borneo and the Philippines.

Early photography in the British Straits Settlements was concentrated around Singapore the prosperous port built in 1819 by the English East India Company. Munshi Abdullah in his 1849 narrative *Hikayat Abdullah* reports seeing a daguerreotype view of the city—possibly as early as 1841—made by a doctor aboard a visiting American warship. The first resident photographer in the region was the undistinguished French portrait painter Gaston Dutronquoy (c.1800–c.1857) who set up his 'London Hotel' in Singapore in March 1839, installed a photography studio and in December 1843 advertised his services as 'complete master of the newly invented and late imported Daguerreotype' in the *Singapore Free Press*. His practise may have continued till 1849 but may also have been an occasional activity. French customs expert Jules Itier (1802–1877) did succeed in making daguerreotypes in Asia between 1843–1846 while on a business mission to China. Some plates survive including portraits and views from Singapore, Borneo, and Manila made in 1844–1845. Eliphalet Brown Jr. (1816–1886) official photographer on the U.S .Perry Expedition to Japan, seems also likely to have made plates in Singapore in 1853.

The first generation of photographers in Asia were itinerant and the few established studios lasted only a few years; daguerreotypist H. Husband operated in Singapore in1853 then C. Düben from Batavia who had also visited Hong Kong, Shanghai, Macao and Manila, offered superior improved portraits from 1854 until his return to Batavia in 1857 and in May 1855 daguerreotypist L. Saurman also from Batavia, briefly worked out of the London Hotel. Calotype work popular in British India, is unknown in the Straits and Manila.

In the first decades most photographers in the Asia-Pacific region were European but J. Newman based in Singapore from 1856–57, advertised many refinements and "permanence" for the products of his American Photographic Rooms. He made a side trip to Malacca—the first photographer to work on the Malay mainland.

It seems likely that across the Asia-Pacific hundreds even thousands of daguerreotypes were made even in the 1840s. Englishman J.W. Newland for example, travelled west to east from South America via Australia to India and claimed to have made over 200 daguerreotypes on the way. The number of extant daguerreotypes however, is tiny. This paucity appears to apply equally to the succeeding format of cased ambrotype portraits and views.

By February 1858 Edward A. Edgerton was the first professional to introduce photographs on paper to Singapore but moved on to work as an editor by 1861. He was followed by Thomas Hermitage and O. Regnier offering the new wider range of products; both views and portraits and places. The quest for images to send back to Europe where they would be widely disseminated redrawn as graphic illustrations propelled the growth of the views trade. Stereographs led the way and in 1860 Negretti and Zambra in London pioneered publication of Southeast Asian stereographs. They took the bold step of dispatching Swiss photographer Pierre Rossier to China in 1859 and instructed him to go to Manila where he made images of the Taal volcano. The ease of making multiple prints facilitated the production of albums and panoramas extolling the progress of colonial cities. The earliest panorama in the Straits region was a view of Singapore in ten parts made in 1863 by Sachtler and Co. The firm also made one of the first published albums; *Views and Types of Singapore.* From 1864 the firm was run by August Sachtler and Danish- born Kristen Feilberg (1839–1919) and they built an extensive stock of views from across the region including images from an expedition to Sarawak in 1864. Feilberg, operating alone from 1867, had a feel for picturesque views which he exhibited in the Paris International Exhibition in 1867. J.M. Nauta, operated in Penang and Singapore and had branches in Medan, Achin and Sumatra between 1868–1888. He exhibited Penang scenery at the *Colonial and Indian* exhibition in London in 1886.These shows enabled the public to see large format Asian images first hand.

With improvements in exposure times portraiture continued to grow and Royal courts in Asia were in often enthusiastic and discerning users of photography exchanging images with their foreign counterparts. Views trade work soon merged into reportage and Feilberg also recorded events such as the Penang riots in 1867 and later the visit of the British Duke of Edinburgh in 1869. Other events particularly the increasingly fashionable Royal tours by European and non-European rulers and Vice Regal residents were a stimulus to photography in the Asia-Pacific but more strongly it seems in Hong Kong than in Singapore and Malaya.

The outstanding figure of the period for breadth of coverage in the 1860s and model of the 'travel photographer' was Scot John Thomson who set up a studio in Singapore in 1862 with his brother William but spent most time travelling to Penang as well as Sumatra before departing in 1865 for Thailand and Cambodia. He returned briefly to Singapore in 1867 and published his first book *Cambodian antiquities* before settling in Hong Kong where he illustrated a publication on the Visit of the Duke of Edinburgh in 1869.

John Thomson used Indian assistants on his Straits journeys in 1862 as the Chinese would not go near the processing. Chinese (and a few Japanese) photographers however were among the earliest non-European photographers at work in Southeast Asia mainly, Sun Qua in 1867 and Yuk Lee a portrait painter from Canton, who advertised briefly in Singapore in 1861–1862, and Koon Hin had a studio there in 1880. Hand-colouring

however, a distinctive genre in 19th century India and Japan played only a small role in Southeast Asia.

Photography associated with expeditions and government agents was a factor in the 1870s. Professional photographer and painter Austrian Wilhelm Burger (1844–1920) was part of the Austrian mission in Asia from 1869–1870 and later marketed rather prosaic stereoviews of Borneo, Singapore, Sulu and the Philippines. James W.W. Birch (1826–1875) the first British Resident in Perak in 1873 an amateur photographer, who sent views of his tours in Perak and Selangor to the colonial office in 1874 was murdered in 1875. British Major J.F. A. McNair used illustrations drawn from photographs in his 1878 book on Perak and the Malays. His countryman Civil Servant Leonard Wray (1852–1942) a prolific amateur also documented Perak peoples and places in the 1880s–1890s and was much valued for his efforts. In 1883 J.F. Stiehm in Berlin published their "Marine" series including views of Singapore and the Philippines made by Gustav Riemer the purser on the Austrian S.M.S.*Hertha* expedition of 1880.

Established studios become more common in the late 1870s and expanded their inventory of views and also trained a new generation of professionals. Henry Schuren worked for Woodbury and Page in Batavia before settling in Singapore in 1874 and was soon after appointed official photographer to King of Siam, settling there in 1876. From 1883 August E. Kaulfuss (1861–c.1909) worked for J.M. Nauta studio then became a travelling photographer gathering views from all over and was also official photographer to Sultan of Kedah.

The opening of the Suez Canal in 1869 increased trade and tourism through Asia which benefited firms such as that established by G.R. Lambert 1846–after 1886) a professional from Berlin who advertised his services in Singapore in 1867 but effectively commenced in 1877. During 1879–1880 Lambert was in Bangkok taking over Henry Schuren's stock and his position as official photographer to the King of Siam. Lambert left the business operations by around 1886 and the work was continued under Alexander Koch who recorded such ceremonies as the Kuala Kangsar durbar in 1897 to mark the creation of the Federated States of Malaya.

GR Lambert and Company built the most extensive inventory of views of the Malay Peninsula, Borneo and Sumatra including making the earliest images of Kuala Lumpur and covering all major Malayan ceremonies and events and also kept up with new developments in instantaneous and dry-plate photography. The dominance of such large and mass production studios in Asia as elsewhere was checked by the emergence of the snapshot family photographers including the amateur photographic societies of the 1880s–1890s (Singapore Photographic Society was established in 1887) but compensated for in the new century by the profitable postcard craze.

Images of the Philippines were regularly reproduced in British and French magazines such as *The Illustrated London News* from the 1860s but relatively little is known of the earliest photographers. A Spanish Government agent Sinibaldo de Mas took up portrait work in 1841 to earn extra income. Jules Itier was in the Philippines from December 1844–January 1845 (where he surprisingly records buying 25 new plates in Manila) then in Mindanao, Sulu and Basilan until March. A daguerreotype of the Intramuros is the earliest extant Philippine view. Daguerreotypist C. Düben is known to have been in Manila before 1853.

The GBR museum at Cavite holds a daguerreotype portrait of William W. Wood an American who worked in China as a clerk and newspaper editor from 1827–33 before relocating to Philippines in 1833 where he later operated a photography studio in Manila by the 1870s. His own work in daguerreotypy is unclear. The earliest surviving Philippine images on paper include a cdv of two Indio musicians in La Union by Pedro Picon circa 1860; a group of stereographs from an *Oceanie* series with French captions of the Tinguian people of Northern Luzon made in 1860 and a later group of stereos by an unknown photographer of the 1863 earthquake. Swiss born Pierre Rossier was sent to Manila by Negretti and Zambra to photograph the volcano but would have taken other subjects. T.W Bennett also marketed an early stereograph series of views under the Spanish title *vistas filipinas.*

Studios were established in the 1860s benefiting from the increased commercial activity in the region. From the mid 60s until his death in Manila in 1874 the British photographer Albert Honiss sold a wide range of well-composed views to magazine publishers in Europe; any connection to W.H. Honiss in Singapore in 1862 is unclear. The Dutch photographer Francisco Van Kamp who had exhibited in Amsterdam, took over the Honiss studio in 1874 and later produced a set of views of the 1880 earthquake.

Ethnographic subjects were a staple for resident and visiting photographers. The photographers aboard the British Challenger Expedition of 1872–1876 made or gathered a number of photographs of ethnographic and scenic photographs in Manila and the archipelago in 1875. William Wood made ethnographic cdvs and examples with similar backgrounds appear in Belgian author Jean de Man's 1875 photographically illustrated book *Souvenirs d'un voyage aux Iles Philippines.* In 1881 French ethnologist Alfred Marche (1844–1898) photographed Negritos on his Philippines expedition of 1879–1885 and the photographs were used for illustrations in the journal *Tour du Monde* in 1886. One of the most extensive ethnographic records was

undertaken by German A. B. Meyer (1840–1911) on his own and by use of other photographers work. His *Album von Philippinen-Typen* of 1885 included Luzon and Mindanao people in a mixture of studio set ups and natural settings.

The turbulent revolutionary years at the close of the century also inspired the growth of reportage. Spaniard Manuel Arias y Rodriguez (1850–1924) took up photography in 1892 and ran the Agencia Editorial bookshop at Escolta with his brother Vincente. The firm sold a wide range of photographs of urban and landscape views of the regions but was quietly subversive selling under the counter banned books by nationalist Dr Jose Rizal whose execution in 1896 Manuel photographed. Afterwards Arias took on the role of war correspondent of the Philippine Revolution against Spain 1896–1897 and supplied images to the Barcelona journal *La Ilustración Artística* from 1897–1900. Arias ended up as Spanish ambassador to Tokyo and died there in 1924. Documenting war proved perilous for Francisco Chofré y Olea and Augusto Norris y Olea who were killed in 1896 while photographing during the Philippine Revolution. Their portraits and their photographs were included in two albums on the war *Tristes Recuerdos1896* and *1897* published posthumously by their firm Chofre and Co. in Manila.

The Spanish-American war resulted in American rule in the Philippines from 1898 prompted a flood of illustrated publications including, F. Tennyson Neely's *Fighting in the Philippines: authentic original photographs* 1899, many stereograph series and distinctive solder-portraits wearing their scout-style outfits and striking poses reminiscent of the Old West. James Ricalton (1844–1929) an American teacher who photographed for Underwood and Underwood recorded grisly images of the 1899 casualties (the greater death toll of locals from starvation and disease however, going largely unrecorded).

SOUTH-EAST ASIA: THAILAND, BURMA, AND INDOCHINA (CAMBODIA, VIETNAM, LAOS)

In his memoirs French trade negotiator Jules Itier (1802–1877) describes making two daguerreotypes at the French military fort at Tourane (Da Nang), South Vietnam, in 1845 while on a trade mission to China. Activity by other daguerreotypists in Burma or Indochina is as yet unknown. The response to photography in Thailand (Siam) was however, precocious due to the enthusiasm for the medium in the Royal Court.

In Bangkok in July 1845 French Bishop Jean-Baptiste Pallegoix (1841–1862) received an apparatus he had ordered from France and he and his confreres became adept enough to take Royal portraits and train others. With no tradition of Royal portraiture in the late 1840s and 1850s King Mongkut (Rama IV) had many photographs of himself and court made to mirror European portrait photographs received as gifts and which he returned in-kind. A practise continued even more assiduously by his son Rama V, King Chulalongkorn. Locals and members of the court also acquired photography skills (details are in various Thai histories as yet not available in English). Luang Wisut Yothamat (Mot Amatyakun) the Director of the Siam Mint, made portraits of the Royal couple using a daguerreotype camera sent by Queen Victoria to the King in 1856.

Access to the Thai Royals was granted to foreign photographers including Swiss Pierre Rossier (on assignment in Asia for Negretti and Zambra of London) who was in Bangkok in 1861 and made ethnographic studies and a Royal portrait for Firmin Bocourt a French zoologist and illustrator in Thailand on a naturalist expedition.

Bishop Pallegoix or French priests probably trained the Thai-Christian Khun Sunthonsathitlak (1830–1891) who began photography in the late 1850s, worked for the technologically-minded dual monarch Phra Pinklao, before opening his own studio in 1863 under the name

'Francis Chit & Co' (later *& Sons*). He was skilled in wet-collodion work and made numerous portraits, views and records of events including a large panorama of Bangkok in 1864. In early 1862 Isidore van Kinsbergen (1821–1905) the official photographer accompanying a Dutch delegation visiting from Batavia, made a range of views, portraits and studies of antiquities. Wilhelm Burger (1844–1920) a professional photographer attached to the Austrian diplomatic and trade mission was briefly in Bangkok in May 1869. He later marketed stereoviews of his travels to Vietnam and Japan. Francis Chit & Co photographs were regularly bought by visitors but most ended up uncredited when shown or reproduced in Europe.

A number of ambitious artists also went to Southeast Asia;. John Thompson (1837– 1921) after his first few years as a photographer based in Singapore in 1861–1864, transformed into a freelance 'travel' photographer and set off for Bangkok where in 1865 he photographed King Mongkut and his court as well as other subjects before travelling to his real goal—the fabled Angkor Wat temple complex in Cambodia in early 1866.

Chit and Co outlasted foreign competitors attracted to Bangkok such as Henry Schuren who visited from Singapore in 1874 and gained a Royal 'Appointment' (it was never an exclusive honour) then set up in Bangkok in 1876 but was replaced in 1879 by G.R. Lambert from the flourishing Singapore firm, who made a lengthy visit to Bangkok that year. British photographer William K. Loftus worked in Bangkok from 1887–1891 but his work was rather dull.

Increasingly from the 1860s illustrated magazines used photographs as the basis for illustrations and received images and stories from 'world tours' undertaken by a broader range of travellers facilitated by the improved travel routes and methods, modelled in some cases on the new 'Royal tours' undertaken by European and Asian kings and courtiers. Populist illustrated traveller's tales also flourished. The buoyant young French attaché Ludovic, Comte de Beauvoir for example, collected photographs assiduously in 1865–1867 on a tour with a French Royal, and used these as the basis for illustrations in his best selling books which began in 1869, with *Java, Siam, Canton : voyage autour du monde*.

Burma [Myanmar]

After three Anglo-Burmese Wars beginning in 1824, from 1886 north and south Burma were conquered and administered as part of British India. The last Burmese Kings, Mindon and Thebaw (prior to his exile in 1886) were photographed and later had court photographers but no daguerreotypes are known and the earliest extant photography in Burma is connected to British military expeditions. In 1853 East India Company Surgeon John MacCosh (1805–1885) an experienced amateur photographer, made views and ethnographic portraits while on duty in Burma during the Second Anglo-Burmese War but his work had limited circulation. By contrast, in 1855 Captain Linnaeus Tripe (1822–1902) posted from Madras as the official photographer to the well equipped Indian Government diplomatic mission to King Mindon's remote northern court at Ava. Tripe executed some 200 large paper negatives which concentrating on structures and topography, have an eerie empty stillness and were used as the basis for illustrations in the official *Narrative* of the expedition of 1858. More impressive and influential were the massive 120 image portfolios of original prints published under Tripe's authority in 1858 by the Madras Government. Major Williams an engineer and amateur photographer, accompanied the Edward Bosc Sladen expedition through Burma to China in 1868.

Military training in photography was also the path to a new vocation for J. Jackson (with fellow Private Bentley) who established a long running and prolific studio in Rangoon in 1865. Not all newcomers were British. The German professional photographer Philip Klier (1845–1911) began work in 1871 in Moulmein, lower Burma then at Rangoon where he was in partnership with J. Jackson in 1885–1890. His output was high in quality and extensive and represents the consolidation of the mass-market views trade over the 1880s–1890s—a world wide trend.

Lieutenant-Colonel Willoughby Wallace Hooper (1837–1912) on the British Expeditionary Force during the Third Burmese War produced a set of one hundred images in 1887 which he declared 'were taken entirely for his own amusement and from love of the art' as did Colonel Robert Graham (1838–1918) with his photographically illustrated book on the War released in 1887. Captain-Surgeon Arthur George Newland (1857–1924) published his *The image of war, or Service on the Chin Hills* with fine gravures in 1894.

Perhaps the earlier Burmese War publications scotched the plans of the Italian born Felice Beato (1825–1907) who arrived in Rangoon in 1886. He had made a name in war photography in India in 1858 and China in 1860 and for his prolific Japanese scenes and types over his long years there in the 1860s–1870s. Beato stayed on and set up a studio in Mandalay producing some war related scenes and studio tableaux of Burmese Beauties. He also travelled into the inner region and produced a substantial but now lesser-known body of work. By 1895, Beato had expanded into a quite large photography, furniture and artefacts manufacturing and postcard business. He employed a number of local photographers including in particular H.N. Samuels who wife and daughter apparently modelled local costumes in the Beato studio portraits of local 'types.'

The boom in Burma induced regional studios to set up branches; Frederick Skeen of Skeen and Co in Ceylon (Sri Lanka) arrived in 1887 to set up a branch and worked as Watts and Skeen. The work of the 1880s generation benefited from the introduction of the faster and more convenient dry-plate which allowed for more varied and lively subjects and atmosphere. The firm may have sold Beato material in Ceylon and their inventory seems to have been taken over by Beato after Skeen returned to Ceylon in 1903. Studios based in India also sent representatives including the well-known firm of Bourne and Shepherd.

Anthropology a new science also became codified and politicised in the 1860s and a number of uncredited photographers provided ethnographic images from Burma to the multi-volume *Peoples of India* publication of 1868–1875. Guidelines for scientific anthropometric studies were developed in the late 1860s following strict guidelines but these were rarely implemented. Some ethnographic studies were in fact more like early forms of pin-up girls and the fine-looking Burmese women in their restrained elegant costume proved especially appealing to European taste. A more sympathetic eye and ethnographic interest came from Sir George Scott who took up photography in 1888 and published a set of volumes on the Shan States.

Cambodia

The great abandoned temples of Cambodia, at times under Siamese control, were to become the 'pyramids' of Asia. John Thomson was inspired to visit Cambodia after reading the 1864 English edition of French explorer Henri Mouthot's *Travels in the Central Parts of Indo-China (Siam), Cambodia, and Laos, during the Years 1858, 1859, and 1860* which popularised the ruins. Illustrations after photographs in that (posthumous) book and the *Tour du monde* accounts of Muhout's travels 1868 were not by Mouhot but local photographers including Francis Chit. Thomson was not the first photographer at Angkor; his companion in 1867 British consular officer W.G. Kennedy had visited and taken photographs in 1856, but none are known to survive. Thomson was the first skilled technician and superior camera artist to make images there. His lively accessible prose ensured the success of his own first book of 1867 *Antiquities in Cambodia* illustrated with 16 original prints. His later publications were more widely disseminated as they had photomechanical illustration. The Cambodian work was also Thomson's entrée to the learned societies of his homeland. Thomson returned to Saigon and photographed the Royal family there before returning to Britain.

Soon after Thomson's work at Angkor French military trained photographer Émile Gsell (1838–1879) was at work there in late 1866 with the French Mekong Exploring Expedition initiated and later led by Francis Garnier**.**

Typical of the many French military come civil servants and administrators who became passionate advocates for Asian culture was naval officer Louis Delaporte (1842–1925) on the French Government Mekong expedition which visited Angkor in 1866. He sought help from Thomson and Gsell and perfected his own photography for his later 1873–1874 expedition to Cambodia with F.C. Faraut, seeking constant improvement in architectural work through use of aplanar lenses and gelatin processes. He exhibited at the 1878 Exposition Universelle in Paris His interest came from his passion for archaeology and Khymer culture for which he helped found a Musée Indochinois du Trocadéro .

The French tradition of the centralised grand scale cultural and scientific 'mission' meticulous and methodical was exemplified in the Mission Pavie teams of photographers.Delaporte sent Louis Fourneau on expeditions 1886–88 in which Captain Malgraive and Riviere also where made plates successfully at Angkor. The remarkable Jean Marc Bel and his wife an engineer made many voyages 1893.

International and local exhibitions formed a significant platform in the later 19th century to promote the colonial endeavours and as self promotion for photographers.

Vietnam and Laos

The French had a presence from the 1840s in Vietnam then known as Cochin China in the south and Tonkin in the north, and, as with the British in Burma, their control extended from the mid-1860s through various conflicts until effective control of Tonkin as well as the south came in 1885. Not surprisingly, French photographers were first to appear in Saigon (Ho Chi Minh City): Charles Parant in 1864–1867 and Clément Gillet in 1865–1866. After his Mekon Expedition work, Emile Gsell went private and set up a studio in Saigon in 1866 becoming first long-term commercial photographer in Vietnam. Gsell however, also left Saigon in 1873 to join Louis Delaporte's expedition in Cambodia revisiting Angkor Wat. Gsell Angkor Wat pictures and panoramas earned him a medal at the Vienna International exhibition of 1874 where he also Cambodian and Vietnamese ethnographic studies. In 1876–1877 Gsell was also able to travel in north adding images of Tonkin to his stock which passed to other studios in Saigon after his early death in Saigon in 1879.

John Thomson returned to Asia in 1867 spending some months in Saigon and surrounds even trying to capture clouds without montage suggesting he may have been using a new process. He sent articles to *The China Magazine* but his Saigon work was not included

in his 1875 book covering his *The Straits of Malacca, Indo-China and China, or, Ten years' travels, adventures and residence abroad*.

As elsewhere in Southeast Asia, photographers migrated to new markets opned up by colonisation. M. Martin from Singapore was noted for fine landscape views in the 1880s. The Chinese diaspora reshaped many communities in Southeast Asia; Pun-Ky marketed cdv portraits of Annamite (Vietnam) types probably from the 1870s as did Pun-Lun who had worked in Hong Kong had a studio in Saigon (opposite that of Gsell) from 1869–1872. A rare Vietnamese name appears; Dang Huy Tru, a retired Mandarin who learnt photography while in China, had a studio in Hanoi from 1869 until the French occupation of 1873. He is claimed to have attracted Vietnamese clientele and developed a style of pose based on ancestor portraits but such posing was common to costume portraits and types across Southeast Asia. Other Vietnamese names do not appear although in 1896 Cam Ly was in business in Hanoi. By the 1880s Chinese-born photographers were at work in most regions chiefly in portrait work. Few of their archives are identifiable but some more substantial commissions survive such as the photographs of the French railway constructed from 1889–1897 between Hanoi and Lang Son which executed by Tong Sing. Yu Chong had a studio in Hanoi in 1893–1900.

A number of Europeans in service in Asia became interested in not only the culture of the past but had a feeling for the life of the contemporary peoples. Like so many men attached to the military abroad, Doctor Charles-Édouard Hocquard (1855–1911), who was on service in Tonkin in 1884–1885 in the Franco-Chinese War, published his photographs officially and privately. His field report on the war illustrated with Woodbury types was subtitled '*customs and beliefs of the Vietnamese*, and was, serialised as 'Trente mois au Tonkin,' in *Le tour du monde,* 1889–1891. Aurélian Pestel (1855–1897) took up photography in Saigon in 1892 having arrivied in Vietnam in 1883. He was also noted for showing the customs of the country beyond studio enactments.

The new generation rising in the late 19th century but coming most to the fore after 1900 in the early decades of the 20th century, looked beyond hard objects to lifestyle and customs, including Sub Lieutenant Étienne Francoise Aymonier (1844–1929) in the French Marine infantry in Saigon who learned the Cambodian and Vietnamese languages.

The image of Southeast Asia was shaped and defined by early photographers and the legacy inherited revolved around a nostalgia as well as scholarly pursuit of antiquities. Photomechanical reproduction in photogravure, carbon, and woodburytpe created a new industry at the turn of the century of which a former soldier sent to Hanoi in 1885, Pierre M. Dieufils of Saigon, is one of the best knownt. His distinctive landscape folio publications were typical of the late 19th and early 20th century mass-produced works.

SOUTHWORTH, ALBERT SANDS (1811–1894) AND HAWES, JOSIAH JOHNSON (1808–1901)

In 1840, the daguerreotype exploded onto the American social scene. Thousands took up the business and even more the sitter's chair. Yet with primitive technology, erratic rewards and intense competition, professional survival was difficult. Albert Sands Southworth and Josiah Johnson Hawes epitomized the talents needed to succeed in the chaotic early years of photography. Coupling ingenuity and expertise with great patience and hard work, their partnership was exemplary. Their studio was among the most distinguished and influential in America and their achievement ranks among the most important in nineteenth-century photography. Southworth was a natural promoter and salesman whose restless nature and financial cupidity drove him

to improvement and invention. By contrast, Hawes was a proven artist whose mastery of light, composition, mood and expression was unparalleled. Together, their technological innovations considerably improved the adaptability, application and clarity of the new medium. Likewise, their commitment to art enhanced the standing of the profession and significantly advanced the aesthetics of portraiture and the realism of documentary. Given the daguerreotype's fragile and singular nature, the partnership's legacy is equally remarkable, comprising over 1,500 existent images.

Albert Southworth was born in West Fairlee, Vermont, on 12 March 1811. After attending the Phillips Academy in Andover, Massachusetts, he tried teaching before establishing a drugstore in Cabotville, Massachusetts in 1839. Unhappy with his trade, he attended a lecture early in 1840 on the principles and practice of the daguerreotype. Delivered by François Gourand, a pupil of Louis-Jacques-Mandé Daguerre, the lecture stimulated Southworth and persuaded him to contacted Joseph Pennell, his friend and former roommate at Phillips. Pennell was, at the time, assisting Samuel Morse with his early photographic research and he invited Southworth to New York to participate. Southworth's first-hand experience of Morse's experiments convinced him of the value of the new medium. Displaying the restless enthusiasm and financial ambition that would mark his career, he wrote his sister Nancy late in May:

> You have read of the daguerreotype, an apparatus for taking views of buildings, streets, yards, and so forth. I had an invitation to join Mr. Pennell and in getting one, and partly to gratify my curiosity, and partly with the hope of making it profitable, I met Mr. Pennell and I cannot in a letter describe all the wonders of this apparatus. Suffice it to say, that I can now make a perfect picture in one hour's time, that would take a painter weeks to draw.
>
> (Robert Sobieszek, and Odette M. Appel, *The Daguerreotypes of Southworth and Hawes*, New York: Dover, 1980 (1976): xi)

Barely four months later, Southworth and Pennell opened a daguerreotype studio in Cabotville. Utilizing Alexander Wolcott's patented wooden-box camera, they produced commercial portraits while developing and perfecting the daguerrean process. Although their experiments proved successful—"we have very far surpassed anybody in this country, and probably in the world, in making miniatures"—Southworth and Pennell floundered financially. By the spring of 1841, the partnership was in serious debt and Southworth decided to relocate to Boston. With its prominent families, commercial wealth and large population, Boston seemed to Southworth the solution to the partnership's main financial difficulty: balancing commercial income with the rising costs of invention.

By June 1841, the Southworth and Pennell studio—now operating under the name of A. S. Southworth and Co.—was ensconced atop Scollay's building in Boston. In addition to portrait work, the company sold equipment, provided instruction and contracted for the manufacture of cameras, lenses, plates and cases. They prospered temporarily in their new environment and by 1842 had moved into a more permanent location on Tremont Row, the heart of Boston's artistic community. Yet despite these small gains, the new industry's financial landscape remained fickle. In 1843, Pennell left the company to take up a teaching position at a private school in the South. His place in the partnership was filled shortly afterwards when Southworth made the acquaintance of Josiah Hawes.

Josiah Hawes was born in East Sudbury, Massachusetts on 20 February 1808. After working on his family's farm, he apprenticed as a carpenter. In 1829 took up painting:

> Happening one day to come across an ordinary oil painting which I was admiring, a friend of mine asked me to close one eye and look at the picture through my hand with the other eye. The surpassing change which took place, from its being an ordinary flat canvas to a realistic copy of nature with all its aerial perspective and beauty so affected me, that from that time I was ambitious to become an artist. ("Stray Leaves from the Diary of the Oldest Professional Photographer in the World," *Photo-Era*, 16 (1906): 104–107)

For the next twenty years, he traveled New England as an itinerant portrait painter. Quite by chance, Hawes was in Boston in 1840 and attended the same Gourand lectures as his future partner. Unlike Southworth, Hawes was cautious. Unwilling to give up the steady income he received on his travels, Hawes continued to paint until 1841, when he became an itinerant daguerreotypist. In November 1843, Hawes was invited to join A. S. Southworth and Co. (whose name was changed to Southworth and Hawes in 1845). His financial prudence and artistic bent would perfectly complement Southworth's eye for the main chance.

While failing to shake its precarious financial state, the studio continued to achieve great artistic and social success. They attracted such luminaries as Charles Dickens (who, unfortunately, did not sit for a portrait), Ralph Waldo Emerson, Edward Everett, Charles Goodyear, Oliver Wendell Holmes, Henry Wadsworth Longfellow, Lola Montez, Lemuel Shaw, Harriet Beecher Stowe, Zachary Taylor and Daniel Webster. In addition, they produced important visual documents of such locations as the Boston Athenaeum, Niagara Falls, the operating room of the Massachusetts General Hospital, Mount Auburn Cemetery, the Boston Navy Yard and Docks, the Boston Common and the Emerson School for Girls. Unlike their Boston contemporary John Plumbe Jr., neither Southworth nor Hawes saw their studio as a potential

franchise. They utilized only the best equipment, did not hire outside journeymen and refused to lower their prices in the face of stiff competition. They shunned the conventions of standardized portraiture and sought to communicate a simple yet resonant representation of the sitter's personality:

> What is to be done is obliged to be done quickly. The whole character of the sitter is to be read at first sight; the whole likeness, as it shall appear when finished, is to be seen at first, in each and all its details, and in their unity and combinations and in the result there is to be no departure from truth in the delineation and representation of beauty, and expression, and character. (Albert Sands Southworth, "An Address to the National Photographic Association of the United States," *The Philadelphia Photographer*, 8 (1871): 315–323)

Dissatisfied with the meager income he derived from the studio, Southworth caught the Gold Rush fever and departed for California in 1849. He spent twenty-two months prospecting, yet his returns were minimal and he returned in poor health. The more practical Hawes stayed in Boston, and the studio continued in business. Southworth returned in 1851, and began to focus his attention on the invention and patenting of technical equipment. In 1853, the firm's "Grand Parlor Stereoscope" won a gold medal at the Fair of the Massachusetts Charitable Mechanics Association. Significantly larger and more complex than any previous stereoscope, the device was put on show in the studio and patented in 1854. The first image presented was the Greek statue *Laocoön*: admission was 25¢, a season ticket 50¢ and for those wishing to buy the stereoscope itself, the price was an enormous $1,160. Commenting on the technical marvel, *To-day* magazine found "the illusion and absolute and the effect of the *Laocoön* in this stereoscope is really finer than one often gains in looking at the statue" (Beaumont Newhall, *The Daguerreotype in America*, third revised edition, New York: Dover, 1976 (1961): 46). Further patents followed, most notably for a "plate-holder for cameras" which many thought evidenced no significant technological advance over those currently in use. In 1854, the studio ceased the production of daguerreotypes and took up the collodion glass plate process.

After twenty-one years of financial struggle, Southworth's exasperation reached its limit and he dissolved the partnership in 1862. He returned to the family farm in West Fairlee to settle his late father's estate and stayed to run it with his brother. He continued to practice photography, write for leading journals and address the National Photographic Association of the United States. In later life he became a handwriting expert and died in 1894. Hawes continued to run the Tremont Row studio for a further thirty-nine years and his late nineteenth century images of Boston are regarded as some of the finest documents of life in the city at that time. In the post-Civil War period, Hawes occasionally returned to his earlier itinerant career hawking Stereoscopic views of Boston around the New England countryside in a traveling wagon. Still active in the profession, Hawes died while on vacation in 1901. In tribute, *Photo-Era* magazine praised the achievement of "the oldest living professional photographer in the world": "he was the last link in the long chain connecting the past and the present of photography and he sat at the cradle of photography and helped to rock it into life" ("Stray Leaves from the Diary of the Oldest Professional Photographer in the World," *Photo-Era*, 16 (1906): 104–107).

RICHARD HAW

Biographies

Albert Sands Southworth was born in West Fairlee, Vermont, on 12 March 1811. Attended lecture on daguerreotypy by François Gourand in Boston, 1840; established the A. S. Southworth and Co. daguerreotype studio with Joseph Pennell, 1841; traveled in California prospecting for gold, 1849–1851; developed the Grand Parlor Stereoscope, 1853; left the firm of Southworth and Hawes, 1862. Gave keynote address to the National Photographic Association of the United States, 1871. Died Charlestown, Massachusetts 3 March 1894.

Josiah Johnson Hawes was born in East Sudbury, Massachusetts, on 20 February 1808. Attended lecture on daguerreotypy by François Gourand in Boston, 1840; joined A. S. Southworth and Co., 1843; developed photographic back-lighting and perfected the use of studio skylights, 1843–1845; married Nancy Southworth, 1847; continued to operate out of the Tremont Row studio as an independent photographer, 1862–1901. Died Crawford Notch, New Hampshire 7 August 1901. The Hawes daguerreotype collection distributed to the Metropolitan Museum of Art, New York, the Boston Museum of Fine Art and independent collectors, 1934.

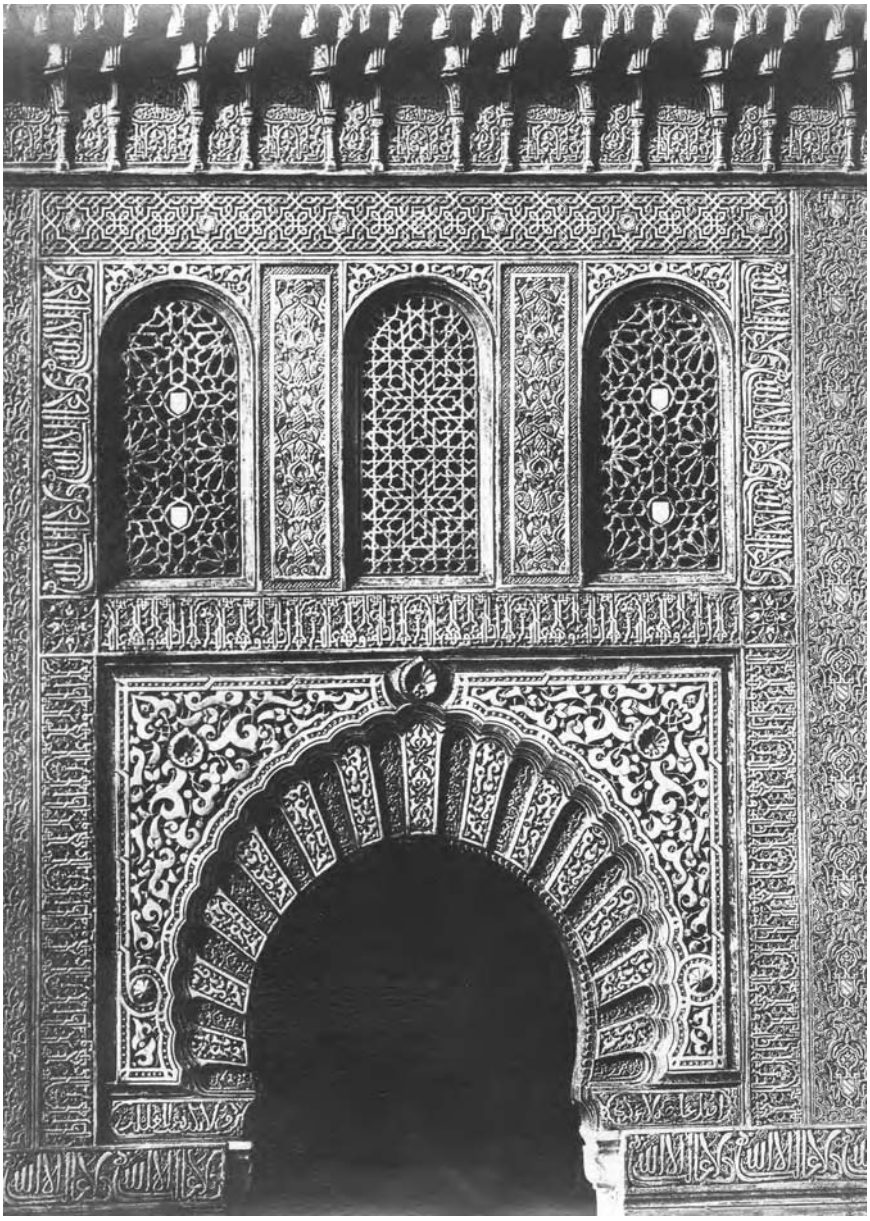
SPAIN

When François Arago publicly announced the invention of the daguerreotype at the Académie des Sciences (Academy of Sciences) in Paris on 7 January 1839, Spain was immersed in a dynastic conflict between Carlists and Liberals that was to determine whether absolutism would continue or give way to allow the consolidation of a constitutional monarchy. In the first third of the 19th century, Spanish society was still primarily agrarian and anchored in the structures of the past. The new photographic technology, however, was to illustrate how the most progressive intellectual and scientific circles committed to modernising Spain immediately learned about and became involved in the initial development of this invention, in spite of their country's economically and socially underdeveloped context. This fact, the lack of government support and the absence of any commercial backing or stimulus characterise the introduction of photography in Spain.

The main figures involved in the earliest introduction of photography into Spain all belonged to the same progressive cultural and scientific elite. Many of them were doctors associated with Barcelona's Academia de Artes y Ciencias (Academy of Arts and Sciences),



Clifford, Charles. The Alhambra, Granad. One of 58 prints in an album entitled: Eighteen architectural studies & city views of Spain by Charles Clifford plus other veiws of Spain and Canada by others.

and several happened to be in Paris during the first weeks of 1839 (Pedro Monlau, Joaquín Hysern, Pedro Mata, Ramón Alabern) and were among the privileged few to see the first daguerreotypes and even Daguerre himself at work. Pedro Monlau was to act as the Paris correspondent for the Barcelona Academy. Shortly after the invention was announced, he issued a very detailed report, which was later published by the magazine *El Museo de Familias*. Once back in Barcelona, an enthusiastic Monlau introduced the daguerreotype process to his fellow academicians at a session held on 6 November 1839 and presented the view of the church of the Madeleine that Alabern had taken in Paris. He suggested that the Academy purchase Alabern's equipment at cost price. This was agreed, and the Academy then decided to convene the citizens of Barcelona so that they could witness a demonstration of the process in what was to be the first known recorded use of the daguerreotype in Spain. This public presentation of the daguerreotype took place on Sunday 10 November, as announced by the *El Constitucional* newspaper and the *Diario de Barcelona* in its entertainment section. The exterior view of the Lonja building was the subject of this first, no longer extant, daguerreotype, again produced by Alabern after a 22-minute exposure.

The origins of photography in Madrid were also linked to Barcelona's Academia de Ciencias (Academy of Sciences) through a group of liberal scientists who worked in the capital and were also members of Madrid's Liceo (Lycée). A few days after the event

in Barcelona, on 18 November 1839, professors Juan María Pou y Camps, Mariano de la Paz Graells and José Camps y Camps, still unaware of the Catalan experiment, made their first daguerreotype—the second made in Spanish territory—which required a longer exposure (60 minutes) due to poor light conditions. This time the subject, a view of the Royal Palace from the right bank of the Manzanares River, was probably related to the interest shown by the Queen-Regent María Cristina [Maria Christina], who agreed to watch the demonstration.

The role played by the aforesaid liberal circles in developing the new invention is also demonstrated by the translation into Spanish and publication, in that very same year, 1839, of up to five different versions, varying in scope, of Daguerre's manual. One interesting example was prepared by Joaquín Hysern and Juan María Pou y Camps and titled *Exposición histórica y descripción de los procedimientos del daguerrotipo y del diorama*. This version includes a preface on photography and its relationships to the arts and sciences, with notes on the authors' own experiences. It offered two innovative theoretical photometry methods, which were surely the first of their kind in the field of photography, but they did not have the recognition they deserved outside Spain. *El daguerrotipo. Manual para aprender por sí solo tan precioso arte y manejar los aparatos necesarios* by E. de L. (Eduardo de León y Rico), published in 1846, stands out amid the second generation of publications on the invention, which appeared from that year onward.

With no apparent contact among cities, this type of non-professional circle continued to practice and disseminate the first advances in this new technology until well into 1841, with no financial backing from any institution and supported only exceptionally by private investors. The press played a very active role in spreading news of the invention and from the outset reported the major international developments in this field.

The year 1842 undoubtedly marks the start of a new era in photography in Spain, characterised by very different objectives and new key players. In a less confrontational political context characterised by greater economic development, the foundations were laid for photography to be launched as a business and for its professionalisation, in much the same way and at about the same time as in the rest of the Western world. Now the protagonists were travelling foreign daguerreotypists who came mainly from France (Mr. Constant, Etienne Martin, Mr. Anatole, Rousson, Jean Gairoard); Great Britain (Charles Clifford); Germany (Taylor and Lowe, Joseph Widen, Madame Fritz); Switzerland (Woelker, Schmidt); and Poland (Count of Lippa). These photographers, most of whom had been unable to cultivate a steady clientele in their own countries, came to Spain to exploit a totally virgin market. Their commercial strategy was to boast artistic or academic credentials, or claim links with Daguerre's circle or dubious aristocratic titles. They usually travelled over wide areas of the peninsula, promoting themselves by placing advertisements in the local press upon arriving at each new town. They often had to combine their trade with other activities such as selling photographic products and teaching the new techniques. Their didactic efforts were indeed crucial to the development and definitive implantation of photography in Spain, because they provided technical knowledge to future Spanish daguerreotypists, who at first were also itinerant and mainly anonymous. From the 1850s onward, some of these itinerants would become fairground photographers, who followed specific routes and worked in standard settings in a profession that survived little changed until the latter part of the 20th century. The majority, however, began to set up professional studios. Mauricio Sagristá opened his establishment in Barcelona in 1842, only a year after the first studios were inaugurated in Philadelphia and London; José Beltrán opened one in 1843 in Madrid, and Francisco de Leygonier started his in Seville in 1845. From 1846 onward, photographic studios were established in numerous urban centres.

Very soon, certain figures began to stand out, including the French photographers Eugenio Lorichon and Franck (François-Alexandre Gobinet de Villecholles) as well as the Spaniards José Albiñana, who successfully took part in the Paris Exposition Universelle of 1855, and Napoleón (Fernando and Anaïs Fernández Napoleón, the latter one of Spain's first professional women photographers). By mid-century hundreds of portrait photographers were already plying this new trade, mainly in the major cities, although they simply recorded their subjects and seem to have had little in the way of aesthetic pretensions, as elsewhere. The most popular daguerreotype formats were 1/4 (10.8 × 6.3 cm.) or 1/6 (8 × 7 cm.) of a plate. Their high prices, although lower than those for paintings, still limited sales to members of the affluent classes. Few daguerreotypes were made of streets or monuments, and those that have survived are usually of major attractions such as Granada, for which there was a ready market among travelleres. In fact daguerreotypes were not used for long. In the 1850s they coexisted with the new photographic techniques that began to appear on the market, such as paper and glass negatives, and in the 1860s they began to be definitively replaced by the new processes.

Long before the invention of photography, southern Spain was a must for foreign travellers, literati and draughtsmen, who were attracted by the exoticism of its Moorish past, still visible in its monuments, and by the local colour of its inhabitants. The late onset of industrial development allowed Spain to continue to provide inspiration for the romantic, orientalist spirit that was a

prevailing characteristic of Western culture at the time. Photography immediately became a tool for this tradition and fulfilled its original goal of obtaining images of the world's most beautiful monuments and places. To cite an early example, in 1840 the writer Théophile Gautier and Eugène Piot travelled with daguerreotype equipment to record mementos of their trip through the Iberian peninsula. But above all, the large European publishers of illustrated publications began to send their own employees to obtain images on which to base engravings. This was true of the series on Spain made by Edmond François Jomard for the famous *Excursions daguerriennes* by Noël-Marie Lerebours, which included two views of Granada (the Patio de los Leones and the Albaicín) and one of Seville (the Alcázar). This series is particularly important as an iconographic reference for the numerous photographs made of the country from then on. Initiatives similar to these foreign publications also began to appear in Spain itself, such as *Recuerdos y Bellezas de España* (1839–1865), published by Francisco Javier Parcerissa y Boada.

The development of calotypes, with their ability to be reproduced, definitively spurred the foundation of the first photographic publishing houses. Starting in 1845 with Nicolaas Henneman's contributions to the *Talbotype Illustrations to the Annals of the Artists of Spain*, many travellers, mainly British and French, arrived in Spain, often on their way to the Middle East, and took photographs that were later marketed in their own countries. These travellers included: Louis-Auguste and Auguste-Rosalie Bisson (c.1848), Claudius Galen Wheelhouse (1849), Louis-Alphonse Davanne (c.1850), the Mayer brothers (c.1850), Vicomte Joseph Vigier (1850, 1851, 1853), Hugo Owen (1851), August F. Oppenheim (1852), Edward King Tenison (c.1853), John C. Grace (c.1854–56), Charles Piazzi-Smyth (1858), aided by his wife Jessie Duncan, Gustave de Beaucorps (1858), Jakob August Lorent (1858), Francis Frith (c.1856–59), Warren de la Rue (1860), Claude-Marie Ferrier (1861), R. P. Napper (c.1863), Louis de Clercq (c.1863), Charles Thurston Thompson (1868), George Washington Wilson (c.1889), and Paul Nadar (c.1895). Likewise, some of the foreigners settled in Spain began to use calotypes, including Clifford, Franck and Leygonier (who opened Seville's first studio and sold calotypes), as did Spaniards such as Pascual Pérez y Rodríguez in Valencia.

Most of these photographers busied themselves producing images—views and popular characters—of typical locales, such as Madrid (El Escorial, the Royal Palace and the Puerta de Alcalá) and Andalusia, the places visited frequently by the romantic travellers who were also devotees of calotype prints.

The presence in Seville of a figure such as Antonio María Felipe Luis d'Orléans, Duke of Montpensier, who was a patron and collector of photography, surely attracted some of these travellers too. In general, there was a certain thematic homogeneity, although some photographers, who were usually anonymous, recorded scenes of everyday life for local sale. Images of Spain's colonies overseas, taken by Mouton y Villar and Juan Buil, among others, also departed from this idealised repertory.

But the true counterpoint to this romantic representation of an idealised Spain came from another series of images: industrial photographs linked to the technical and scientific modernisation process carried out during the liberal monarchy of Isabel II (1843–1868). On another level, however, they could also be understood as an exaltation of what was sublime within the technological landscape and therefore as a continuation of a certain romantic aesthetic. During this period, the Crown used this new form of representation both as a symbol of technological modernity and to legitimise and promote a different view of the country more in line with the development of the industrial revolution. Major public works, such as the bridges and railways that were radically transforming Spanish territory, were documented. Two of the best in this field were Charles Clifford, and the Frenchman Jean Laurent, who were undoubtedly the most important foreign photographers in 19th-century Spain. Clifford was Isabel II's court photographer from 1858 onwards, and accompanied her on royal visits; much of his work was used as a powerful political propaganda tool favouring the monarchy and the progress it promoted. Apart from his more picturesque series, Clifford documented the construction of the Canal de Isabel II (1855–56 and 1858), which has continued to provide water to Madrid ever since. He also documented one of the era's great urban renovations, that performed in Madrid's Puerta del Sol (1856–1862), a square conceived by liberals as a new monumental and central public space. These photographs of the Puerta del Sol recall Marville's work on Paris during Haussman's remodelling. At the time photography in Spain was clearly in the service of government institutions, as was confirmed in Spain's capital city by the Royal Order of 8 May 1869 requiring all public works to be photographed and copies sent to the main institutions.

J. Laurent, who had lived in Spain since 1843 and who began to take photographs in 1857, created the 19th-century's most important commercial enterprise and photographic archive of Spain (Laurent y Cia.), which employed hundreds of professionals. Its Paris branch distributed work throughout Europe for over 50 years. Laurent's company documented all sorts of subjects, ranging from cities, monuments and reproductions of masterpieces of Spanish painting to celebrities and popular characters. His photographs of railways left and invaluable record, like those he made in collaboration

with José Martínez Sánchez of public works in 1866–67, a group of photos that was chosen for the Paris Exposition of 1867, together with Clifford's views of the Canal de Isabel II.

Topographical photography documenting industrial architecture gave way to some of the most interesting pictures from a compositional viewpoint due to their adoption of innovative spatial concepts and a new iconography devoted to modern buildings and the landscapes resulting from human interaction with nature. This was made easier because photography had finally overcome the greatest technical disadvantages limiting outdoor images. Works by José Rodrigo, Pau Audouard, William Atkinson and Pérez y Rodríguez should be added to those mentioned previously. Train images by J. Laurent, José Spreáfico, Auguste Muriel and Martínez Sánchez documented the birth of the many railway lines that, together with new roads, began to cover the peninsula. This increase in transport facilities was spectacular and a boon to photographers because it reduced distances and stimulated the penetration and dissemination of new ideas.

With new advances in photomechanical printing and the spread of the use of collodion and albumen paper, the 1850s also brought the initiation of a Spanish photographic industry. These factors enabled the marketing and mass production of large catalogues, albums and the popular "Photographic Museums," which offered all kinds of images for sale, most of them produced by stereoscopy. In addition to all the Spanish producers of stereoscopic views, at this time large foreign companies, such as the London Stereoscopic Company or Frith & Co., also sent their photographers to capture the country's most typical images.

In the Spanish market it was in the 1860s that the preponderance of foreign photographers was finally reversed in favour of Spaniards. This decade inaugurated the era of large studios and of *carte-de-visite* portraiture, which spread by means of the family album. In Spain, as in the rest of the world, the introduction of *carte-de-visite* meant a certain democratisation of photography, since they were within reach of a much wider public due to their being priced much lower than daguerreotypes. This development created a domestic market and a national photography that was able to fulfil the aspirations of the liberal bourgeoisie, who after the revolution of 1868 needed a way to reflect its growing power and associate itself with a technology that symbolised modernity. Consequently, large galleries of celebrities, consisting of portraits of all sorts of famous people, became the rage and were displayed in the show-windows of studios, usually located in the nerve centres of cities such as Madrid's Puerta del Sol. The most prestigious studios during this period belonged to Pau Audouard, Moliné y Albareda, A. Espulgas and Napoleón in Barcelona; Laurent, José Albiñana, José Martínez Sánchez, Eusebio Juliá, Julián Martínez de Hebert, Alonso Martínez, Edgardo and Fernando Debas, Manuel Compañy, Christian Franzen and Bois-Guillot in Madrid; Antonio Cosmes and Antonio García Peris in Valencia; Xasajús, Leygonier, Lorichon, Enrique Godínez, Julio and Emilio Beauchy, and Barthe-Boyer in Seville; H. Otero and M. Aguirre in San Sebastián; José García Ayola in Granada; Spreáfico in Malaga; and Francisco Zagala in Pontevedra. As elsewhere, many painters and miniaturists decided to adopt the new medium and became photographers, retouchers or lighting technicians, using their artistic skills to win new clients and improve photographic craftsmanship.

If scientists played a vital role in the initial dissemination of photography in Spain, photography, in turn, was to become an indispensable tool for science as technology continued to develop. It was applied in myriad fields, from taxonomy to the analysis of animals, plants and insects, etc. By 1862, Rafael Castro y Ordóñez, a member of the Comisión Científica del Pacífico (Scientific Commission of the Pacific), was already making a photographic record of the Commission's expedition to South America. In astronomy, José Monterrey and Warren de la Rue shot a solar eclipse in 1860, and a decade later in Cadiz, John Spiller and William Crooks recorded the transit of Venus. Photography entered the medical world in 1874, when some doctors in Barcelona were authorised to photograph their patients or use images of patients for teaching purposes. From the mid-1860s onward, photography was also employed as a new tool for social control to document delinquents or condemned prisoners. One extant example of this practice is the series of photographs of bandits that the police commissioned from J. H. de Tejada in 1870.

The relationship between photography and the press in Spain dates from the 1850s, when the first newspapers and illustrated magazines began to use photographic images as the basis for their engravings. From the 1860s onwards, with the improvement of printing techniques, they were able to include photographs directly. The introduction of wet collodion, which enabled shorter exposure times, was a key event in this field, although photography had to wait for the silver bromide gelatine era to achieve real instantaneity. From 1858 noteworthy photographers, including Clifford and Laurent, were asked to contribute regularly to magazines like *El Museo Universal* and *La Crónica* respectively. *La Ilustración Española y Americana*, the most popular illustrated magazine in the 1880s, enlarged its staff with a wide network of regional photographer-correspondents, among whom Juan Comba García, considered one of the founders of Spanish photojournalism, stood out. Nonetheless, the full integration of photography into the press did not occur until the 1890s, when modern illustrated journals

such as *Blanco y Negro* (1891) appeared, and marked the birth of the 20th century. One of the regular contributors to *Blanco y Negro* was the Danish diplomat Christian Franzen, the other great figure in photojournalism and official photographer for Madrid's high society. Franzen also introduced the use of magnesium in Spain, which made it possible to photograph in poorly lit areas. This new market, which provided reporters with an outlet for their work, encouraged photographic testimonies of current events and wars. For instance, Carlist prisoners in Valencia were photographed by Antonio García Peris in 1869, and the bombing of Durango and San Sebastián was recorded by H. Otero and M. Aguirre in 1873. Photographs of the Moroccan War of 1859 taken by painter Mariano Fortuny y Madrazo, among others, and commissioned by General O'Donnell, were clear examples of reportage requested by political authorities for propaganda purposes. The work of Alfonso (Alfonso Sánchez García) should also be mentioned, as he was probably the most important Spanish photojournalist of the generation that started to work at the end of the century documenting a poor and depressed Spain after the crisis of 1898, when the country lost its last colonies overseas.

Apart from the importance of these press reports, Spain also had a series of photographers, often amateurs, whose work constituted a valuable anthropological record, as shown in the Mallorca photographs taken by Tomás Montserrat, those of Holy Week in Lorca by José Rodrigo, the Museo fotográfico (Photographic Museum) and Toledo series by Casiano Alguacil Blázquez, the views of Valladolid taken by Bernardo Maeso, and even the photographic records of Ramón y Cajal's trips to the United States and Antoni Amatller i Costa's journey throughout Northern Africa and the Near East.

At the end of the 1880s, the evolution in photographic reproduction methods and a new demand for print jobs caused the expansion and transformation of many studios into phototype workshops and establishments, and a range of specialised photographic trades appeared. This enabled more flexible ways for professional photographers to market their images and turned the sale of albums, limited editions of scenic views, collectible series, postcards and posters into a lucrative business. These images covered everything, from aerial views of Barcelona to public executions (Isidro Montpart), sports themes (the Debas brothers), to popular views of Madrid (Hauser y Menet). These photographers, and Laurent himself, were just some of many who set up this type of workshop.

As regards photographic products (plates, cameras, paper, etc.), at the end of the century the industry remained almost completely dominated by foreign companies, with the sole exception of Manufactura General Española de Productos Fotográficos S.A., a company founded in Murcia in 1893 to manufacture the *Victoria* bromide gelatine plates and aristotype (citrate) paper. Because of this dependence on foreign sources, important establishments opened in Spain and joined other shops like pharmacies as distribution centres, selling all kinds of photographic materials and systematically advertising their wares in the press. There are very few Spanish contributions to the development of photographic techniques, with exceptions like the leptographic paper patented by Laurent and Martínez Sánchez and research on colour photography, a matter of interest for many amateurs and scientists, including Nobel Prize winner Santiago Ramón y Cajal.

Professional studios reached their height of popularity during the last third of the 19th century, in the era of the Restoration of the Monarchy. This was due to the widespread acceptance of stereoscopy and to the introduction of new portrait formats (*Cabinet, Victoria, Promenade, Boudoir, Imperial*), now added to the already well-established *carte-de-visite*. In terms of photographic processes, the ambrotype was not very successful in Spain, but ferrotypes became quite popular from 1880 onwards; at about the same time both bromide gelatine dry plates and hydroquinone developers first began to be used.

The phenomenon of the expansion of these studios is also marked, however, by an increase in clients that paralleled the epoch's rapid demographic growth, particularly in large cities, which had doubled and tripled their population and had become poles of attraction for the rural exodus. Every urban centre of importance had its photographic studio, and by 1900 there were 439 legally registered establishments concentrated in major cities. Nevertheless, this proliferation took place at the cost of portrait quality, which progressively declined due to the limited technical expertise and low cultural level of photographers who began to work during this period.

The end of the golden age of photographic studios coincided with the turn of the century, marked by the serious economic crisis of 1898, which had repercussions in all financial and industrial sectors and forced a crucial change in the photographic industry. But the seeds of this deep transformation in Spanish photography had been sown previously by the great technical strides represented by bromide gelatine dry plates and the introduction of the first Kodak box cameras in 1888. The number of amateur photographers rapidly grew, reaching more than a thousand in Madrid and almost three thousand in Barcelona. It was now mainly these amateurs, not the studios, who sought and achieved better quality in their photographs. The market soon focused on them, for example with the first specialised magazines, which responded to their interests and technical needs, and organised activities, contests and prizes.

The first photographic societies, clubs and associations also grew up around these magazines. In general, members of such groups still came from the more prosperous social classes. The pioneer magazine was *La Fotografía*, founded in Barcelona in 1886. Figures as vital for the future development of Spanish photography as Luis de Ocharán, Antoni Amatller i Costa and Antonio Cánovas began to stand out among these enthusiasts. Cánovas, known as Kaulak, was one of the instigators of the photographic section in Madrid's Círculo de Bellas Artes (Circle of Fine Arts) (30 December 1899), which a year later became the Sociedad Fotográfica de Madrid (Madrid Photographic Society). This group, as well as other new societies and associations, very soon became the stronghold for the new form of Pictorialism that would develop in Spain after being imported from Europe at a very late date, and which was to continue well into the 20th century.

SPARLING, MARCUS (1826–1860)
Irish photographer

Marcus Fitzell Sparling was born in Ireland, and at age 20, enlisted in the 4th Light Dragoon Guards on March 17th 1846. After five years of service he was awarded a 'Good Conduct Chevron.' He was discharged from the army on September 6, 1853, and left with the honorary rank of corporal.

By then he was already a member of the recently formed Photographic Society of London, participating in the Society's second meeting, where he introduced a variation on Major Halkett's folding field camera. Reports of the meeting by Sir William Newton referred to him as 'Corporal Spalding,' to which he took exception, fearing that the attribution of a rank to which he was not entitled would earn him the disrespect of his regimental colleagues. His protest was published in the Society's Journal as being from M. N. Sparling.

Also present at the meeting was Roger Fenton with whom Sparling developed a lasting professional relationship. Indeed, he was living at Fenton's address by the end of 1853, giving his occupation as 'chemist,' and presumably already employed as his assistant.

He accompanied Fenton on his autumn photographic journey to Yorkshire, and in 1855 he worked as his assistant in the Crimea.

In 1856 he published his manual *Theory and Practice of the Photographic Art*, 'drawn from the author's daily practice,' this time identifying himself as 'W. Sparling, assistant to Mr Fenton in the Crimea.'

He was just 34 years old when he died in Liverpool on August 19, 1860, of hepatitis.

JOHN HANNAVY

SPENCER, WALTER BALDWIN (1860–1929)

British-born Professor of Biology at the University of Melbourne, he is better remembered as an anthropologist. Following formative work amongst the Arrernte people during the 1894 Horn Expedition to central Australia, he made other field trips to remote areas of central and northern Australia. With his collaborator, Frank Gillen (d. 1912), he made many hundreds of photographs and also pioneered the use of film in anthropological fieldwork. Their collaboration was so close that it is not always possible to attribute authorship to individual images. They developed and printed much of their own work and wrote to each other constantly on matters photographic. Spencer was also friendly with the distinguished Australian photographer J.W. Lindt who advised him on occasion. Whilst the photographs were made with scientific intent, many are both culturally engaged and aesthetically aware. The photographs were broadly disseminated. Not only were many of them published in Spencer's ethnographic monographs, such as *The Native Tribes of Central Australia* (1899), but he gave popular lantern lectures on aboriginal culture to packed halls throughout his career. His photographs are now in Museum Victoria, Melbourne, where they are curated with careful attention to the needs of the descendants of the indigenous communities with whom Spencer worked.

ELIZABETH EDWARDS

SPILLER, JOHN (1833–1921)
Chemist

Spiller was born on 20 June 1833, the son of an architect, and attended the City of London School where he showed a particular aptitude for science. He continued his studies at the private Royal College of Chemistry, (RCC), joining in 1849. The RCC had been founded by public subscription in 1845 with the purpose of training chemists to help the economic growth of the country. The training was practical and laboratory based. After two years the best students could become research assistants. Spiller was following this route until the RCC ran into financial difficulties and in 1853 merged with the Royal School of Mines, (RSM), whose Head was Dr Percy, a distinguished metallurgist and a photographer. Spiller transferred to the RSM, where, under Dr Percy's tutelage, he and two colleagues completed an important and comprehensive series of chemical analyses of British iron ores.

The state of photography at the time was such that although many basic principles had been established, there were real problems with the reliability of processes

and the reproducibility of results. This was an ideal and fertile ground for a chemist to delve into. Spiller was one such chemist, and a year ahead of him at the RCC was another, William Crookes, with whom Spiller was to forge a deep friendship. They both appear to have devoted much of the summer of 1852 experimenting at home with the waxed paper process. In 1853 Spiller's emphasis switched to the wet collodion process, and he had his first "Letter to the Editor" published in the *Journal of the Photographic Society* (*JPS*). It concerned the use of the pronitrate of iron for developing collodion images.

In May 1854, Spiller and Crookes published a paper in the *Philosophical Magazine* (*Phil Mag*), which really brought Spiller's name before the photographic community. It was on a method for extending the "life" of wet collodion plates well beyond the normal few hours. This necessitated the retention of a moist surface, which they achieved by putting the sensitised plate into a bath of fused zinc nitrate for about five minutes and then drying. The plate showed no sign of deterioration in sensitivity after a week. They had searched for a deliquescent material that would maintain the plate in its "pappy" state. It seemed a neat chemical solution to the problem. The method attracted much attention but had limited success. A few months later another paper in the *JPS* and the *Phil Mag* proposed using fused nitrate of magnesia. Further experimentation was promised and was revealed, in 1856, in a third paper in the *Phil Mag* (see Further Reading). The possibility of using glycerine was raised in the first article. Now they claimed priority for the suggestion, and developed a workable process. They also looked into other deliquescent materials, but still recommended glycerine. This was fine work by the two young chemists, but it was overtaken by the invention of the dry collodion plate.

During 1856 Dr. Percy invited Spiller on a photographic holiday in Devon. Percy was an active photographer who participated in the Exchange within the Photographic Society of London, (PSL), which produced the Photographic Albums for 1854 and 1857. The latter Album contains the photograph entitled "The New Mill near Lynton North Devon" by Percy and Spiller, taken, (not surprisingly), on collodion, September 1856. It is the only known published photograph by Spiller.

It was in 1856 that Spiller left the RSM and joined Woolwich Arsenal as an assistant chemist. In 1861 Spiller founded the Photographic Department there and lectured on photography at the Royal Artillery Institute and the Royal Military Repository. He continued to produce an impressive stream of articles on the chemistry of photography, and became well known as a knowledgable practitioner, particularly on collodion. He also devised Spiller's Reducer, using copper chloride to thin down negatives. Some of the articles owed their existence to his continuing close friendship with Crookes. Crookes was successively editor of three photographic journals, and at times he was glad to have a friend he could turn to for an article to publish. In 1860 Spiller and Crookes were able to join forces to photograph the partial solar eclipse of the sun, using the telescope at Woolwich. They produced a good set of photographs, of which Spiller was especially proud. Spiller also took pride in being something of a champion of the Woodburytype process. He had been at the first demonstration of the process in London in 1865. At a British Association meeting in Dundee in 1867, he devoted most of a paper about new processes in photography to the Woodburytype.

In 1868, at the invitation of his brother, Spiller left Woolwich and joined the firm of Brooke, Simpson and Spiller as Chief Chemist. They were manufacturers of synthetic dyes, and Spiller was to remain with them for the next twenty years. Spiller's interest in photography remained undiminished, as the flow of articles, mainly on the chemistry of photography, testifies. Of particular significance was a paper, "On the action of chloride of gold upon certain salts of silver" in 1869. This has been regarded as the true invention of the self-toning principle. Spiller himself acknowledged that, although he proposed the idea independently, he was not the first. Surprisingly, he did not join the PSL until 1867, but eventually he occupied, at various times, every office. He was President in 1874–75 at a time of great crisis, when a separate Society might well have been formed. Spiller played a great part in holding the PSL together. Alas, the friendship with Crookes did not hold together. Crookes had become interested in spiritualism and Spiller attended a séance with him. They had different versions of events, which led to a spectacular row in the press in 1871 and the end of their friendship. However, Spiller attended the Golden Wedding celebrations of Sir William and Lady Crookes in 1906, having been their "best man." Spiller remained a member of the, by then, Royal Photographic Society, until his death in 1921, aged 88.

JOHN SAWKILL

Biography

John Spiller was born in London on 20 June 1833, the son of an architect. He attended the City of London School and then moved to the Royal College of Chemistry in 1849. He transferred to the Royal School of Mines in 1853 and analysed British iron ores. He then became an assistant chemist at Woolwich Arsenal in 1856, setting up the Photographic Department there. After twelve years at Woolwich, and at the invitation of his brother, Spiller joined the firm of Brooke, Simpson and Spiller as Chief Chemist. They manufactured colour dyes and Spiller was to stay with them for twenty years. In 1859

Spiller was elected a Fellow of the Chemical Society. He joined the Photographic Society of London in 1867, occupied every office and was President in 1874/75. He married twice, first to Caroline Ada Pritchard and then to Emma Davenport. He died in London on November 8, 1921.

SPIRIT, GHOST, AND PSYCHIC PHOTOGRAPHY

The nineteenth century saw the science and rationalism of the previous century emerge as an even stronger force of change further empowered by the mercantile thinking of a growing middle class. There was an almost frenetic quest for knowledge that rode on the surge of the industrial revolution. The growth of evolutionary and progressive science such as for example Charles Darwin's theory of evolution were perceived to challenge ideas of established belief systems particularly undermining the fundamentalist structure of 19th century Christianity. That the origin of mankind may have been a slow selective development from primates as opposed to a divine creationist intervention was considered both blasphemous and, as the argument developed, increasingly calamitous.

With these changes in perception a battle emerged between the desire or need to continue to believe in the numinous—and as its antithesis an increasingly empirical, materialist vision of creation. The middle ground was indeed growing treacherous underfoot. In his poem *Dover Beach*, the 19th century poet Mathew Arnold described how faith, like the tide, was retreating;

> But now I only hear, Its melancholy, long, withdrawing roar" revealing the, "naked shingles of the world. (Trilling, p.594)

The process of photography is a familiar presence in contemporary life. The photograph has become our ubiquitous shadow and like a shadow is with us in many forms everyday of our lives. Yet when Louis Jacques Mandé Daguerre's process of photography was announced to the world in January 1839 those who examined the new image making process saw the medium not only as a scientific marvel but also as a miraculous aid to drawing that would revolutionise recording and effect an irreversible change in human perception. The photograph has not only altered the way in which we interpret the world around us, it has also affected the manner in which we perceive ourselves (Webster,1).

As a form of representation of external reality the photograph played a powerful role in helping to establish concepts of order and interpretations of a shrinking world. As images were constructed subjectively they were (often it seems unwittingly) used to confirm what was already understood rather than as a cipher of new knowledge.

The apparent veracity of the photographic image lent it an unprecedented (and often unquestioned) credibility. The camera's ability to accurately reproduce the world on a two-dimensional surface stood as proof that the manner in which a subject was recorded was definitive and unquestionable. The photograph was held in a position of unparalleled importance as a piece of factual evidence.

As a device of moralising and comparison the photograph was unsurpassed—for as it was so closely linked to reality belief followed.

When discussing Roland Barthe's posthumously published text *Camera Lucida* John Tagg highlighted these points:

> The camera is an instrument of evidence. Beyond any encoding of the photograph, there is an existential connection between the 'necessarily real thing which has been placed before the lens' and the photographic image': every photograph is somehow co-natural with its referent.' What the photograph asserts is the overwhelming truth that 'the thing has been there': this was a reality which once existed, though it is a reality one can no longer touch. (Tagg, 1)

In the nineteenth century the photograph seemed to affirm that science could transcend the confines of raw nature and that through man's ingenuity science would be the medium that allowed nature to record itself.

One extreme example of this was the case recorded in *The Photographic Times* of 1863 where a murder victim's iris was photographed, the negative enlarged and when viewed under the magnifying glass the

outlines of a human face (the murderer's imprint) could be made out.

> So exaggerated then was the efficacy of the all-seeing mechanical eye and so readily was its recorded image acceptable that those present had no difficulty in seeing the details of the face of the murderer. They saw what they wanted to see: long nose, prominent cheekbones, black moustache and other sinister distinguishing features. (Nickell, 146)

The revolution of photography democratised vision in the same way that the printing press revolutionised the dissemination of learning and knowledge. Although photography did in itself create a window on a smaller shrunken world, its effect was one of enlarging the life experience of the huge mass of avid viewers. And still the perception remained that the camera could not lie—its basis was in optics and chemistry.

It may seem slightly ironic then that the camera and the process of photography—very much a result of a time of innovation and upheaval—should become the tool for those whom wished to prove the existence of an incorporeal afterlife. Yet the belief in the camera's veracity as objective machine of record would ultimately lend credence to the claims of proof when photographic evidence was produced of supernormal phenomena.

When we view a photograph from the early period of portraiture there is an inherently poignant quality about these images. These are the shades of the dead, their actual reflection in silver, recorded as the light was reflected from the skin in darkening silver. Perhaps the irony of these early images of the then living is that they serve to confirm mortality rather than ensuring immortality.

For the Victorians it surely was secure the shadow ere the shadow fade. In industrial centres there were swiftly changing demographics and high mortality rates. The child mortality rate in cities, stable in the smaller decentralised centres, rose alarmingly. Death became a more pronounced cultural aspect of society.

This nineteenth century involvement with mortality, its possible antecedent the afterlife, and new questions of belief, resulted in an intricate relationship with photography, where families celebrated death in albums that included photographs of clocks recording the time of death as well as the post-mortem photographs themselves.

So where rationalism and Darwinian theory challenged belief, the photograph provided at least one place of seeming permanence and an afterlife. Where belief was accentuated the rise of new spiritual movements and spirit photography provided another.

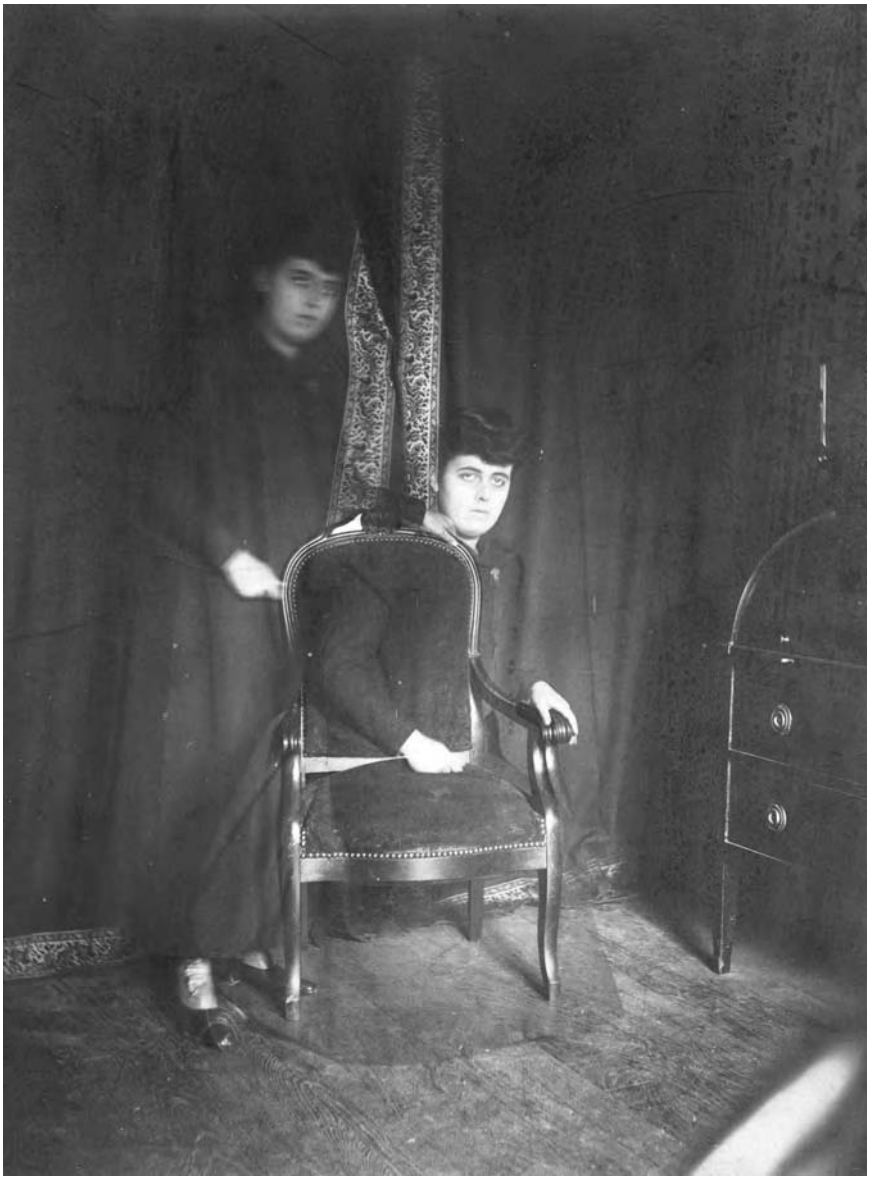
Communication with the dead was not a new phenomenon that arose in the medium's parlour of the nineteenth century. However this occult practice gained new momentum through the growing desire for assurance that there was indeed an afterlife.

Spiritualism itself began as a movement in the United States in 1848 with the séance activity of Margaretta and Katie Fox, sisters from a family in the village of Hydesville, Wayne County, New York. Not only could these sisters apparently communicate through rapping's with the spirit world but also the ability could be passed on. The experiments spread widely from the eastern seaboard of the United States to Britain.

This movement drew its strength in effect from the reactionary beliefs of the 18th century where figures such as the Swedish philosopher Emanuel Swedenborg had begun his counter revolution of belief in a time of scientific rationalism and religious latitudinarianism. Although Swedenborg was influential he had a limited following in the United States. It was another movement, Mesmerism, which, having been far more popular in this country, provided the major basis from which Spiritualism had its origins. Mesmerism was primarily the creation of Franz Anton Mesmer, a German healer who used therapeutic hypnotism and the laying on of hands as part of his healing processes. It was the visions of the so-called spirit world that many of Mesmer's patients or *somnambules* experienced which generated a widespread fascination with Mesmerism. Spiritualism grew from the seeds of such occult attempts at re-enchanting spiritual activity. Within twelve years of the advent of Spiritualism the first photograph claimed to depict a spirit was produced in New Jersey (Guiley, p. 568).

It was the New Jersey commercial photographer W. Campb**ell** who produced the first recorded case of a spirit photograph apparently without his intervention in 1860. He showed his remarkable photograph to the American Photographic Society at their twentieth annual meeting. The image was a test photograph of a chair in which the trace picture of a small boy had mysteriously appeared. Campbell was at a loss to explain the appearance and was never able to reproduce such images again (Permutt,12). This would suggest that the appearance of the boy was not a staged effect. Curiously the rational answer should have been apparent to any practising photographer of the time. This was the period of the wet plate process where glass plates were coated with a photographic emulsion and exposed in the camera whilst still wet. As glass was not inexpensive plates were often cleaned and reused. The result might be the residue of a non-actinic (i.e. yellowish) image that though faint would produce a ghostly image if the plate were re-exposed. But according to Campbell the boy was unknown to him (Nickell, 148).

Far more famous a personality as spirit photographer was the Boston photographer William H. Mumler. Mumler was an engraver by training who worked for the jewellers Bigelow Brothers and Kennard. He appar-



Henry Mathouillot ArchivePartial Dematerialization of Medium M. Buettinger.

ently discovered photographic extras on some amateur photographs he had taken of a fellow workman. This together with the popularity of Spiritualism seemingly provided Mumler with the impetus for exploring the idea of making such spirit photographs as a lucrative business venture. His Psychic self-portrait of 1862 as he accounted:

> was taken by myself, on a Sunday, when there was not a living soul in the room beside me, so to speak. The form on my right I recognise as my cousin who passed away about twelve years hence. (Nickell, 149)

Mumler's business venture thrived and he regularly obtained ghostly extras on the photographs he took of his customers in Boston. At the height of his career he could charge up to $10 per sitting. Nor did his popularity end when a Boston Spiritualist, a doctor Gardner, recognised some of the extras as living Bostonians. Although it damaged business Mumler was able to continue. On one occasion around 1865 Mumler even produced a manifestation of Abraham Lincoln. Mumler maintained that the woman who sat for him retained her veil until the moment of exposure when she removed it for the photograph. He did not he said, realise that she was in fact Lincoln's widow Mary Todd Lincoln (Permutt, 13).

The practice of spirit photography attracted its critics as well as those who were believers. Gradually a realisation that fakery was quite possible in the apparently immutable photographic image crept in. In 1869 Mumler was working in New York where he survived an accusation of fraud through lack of evidence. The accusations however were public notice that belief did not naturally follow the production of a plate. Despite producing a likeness of Beethoven in 1871 Mumler eventually died in obscurity around 1884 (Nickell, 149).

English spirit photographer Frederick Hudson on the other hand convinced his critics with his ability to produce spirit-extras with his own daughter as a medium. Publishing in the British Journal of Photography, July 11, 1873, one investigator John Beattie stated;

> If the figures standing by me in the pictures were not produced as I have suggested [i.e. real spirits appearing through the medium's presence], I do not know how they were there; but I must state a few ways by which they were *not* made. They were not made by double exposure, nor by figures being projected in space in anyway; they were not the result of mirrors; they were not produced by any machinery in the background, behind it, above it, or below it, nor by any contrivance connected with the bath, the camera or the camera inside. (Permut, 17–18)

As convinced as Beattie was, it is interesting to note that Beattie himself had successfully experimented with spirit photography prior to his investigation of Hudson,

Whatever the merits of each individual case what is truly fascinating is not the argument whether or not the works were fakes—most of them almost certainly were, but rather that there was such a huge desire to have this link with the deceased even when the evidence would indicate that the images provided no such thing. The sitters wanted the images to be real and the desire was enough to remove overwhelming doubt. When viewing the images themselves this becomes apparent.

Sometimes fuzzy, of varying scale, technical skill and unconvincingly dressed in shrouds it would seem almost impossible to believe that anyone could accept these images. However it would be wrong to project our own more sophisticated media scrutiny back upon these sitters. The photograph represented the real; there upon the plate where nothing had been before was a trace, a certainty of life beyond life. It was this photographic veracity this machine's verdict, that helped convince his sitters that this was a scientifically recorded truth.

The report of the fraud inquiry into Mumler's work suggested:

> A number of good recognitions were claimed from time to time by sitters, and these can only be accounted for in the light of subsequent events by the long arm of coincidence, and the will to believe that lies in all of us." (Nickell, 149). Especially, it might be added, when the evidence of a machine reinforces the will.

Importantly there was again the encounter between the Victorian understanding of the truth, i.e. the photograph, and the challenge of the unreal, "As visual spectacles and entertainment, such manifestations opened the way for the enjoyment of appearances whose very fascination came from their apparent impossibility, their apparent severance from the laws of nature" (Petro, 68). This type of photograph now offers clues not to the evidence of the afterlife but rather an insight into the Victorian mind and the complex puzzles of representation and implicit belief that the act of making a photograph evokes. As photographic knowledge progressed people were more and more convinced of the ability of the photographic 'medium' to access visual realms the eye could not see. The invention of the X-Ray by Karl Wilhelm Röntgen in 1895, understandings about the visible and invisible spectrum such as infra-red photography and the development of spectroscopy, reinforced such beliefs.

Sir Arthur Conan Doyle, Spiritualist and believer, defended the growth of this belief in paranormal activity. Doyle was himself convinced by the evidence he had seen over the course of his investigations.

> Victorian science would have left the world hard and clean and bare, like a landscape in the moon; but this science is in truth light in the darkness, and outside that limited circle of definite knowledge we see the loom and shadow of gigantic and fantastic possibilities around us, throwing themselves continually across our consciousness in such ways that it is difficult to ignore them. (Doyle, 13)

SQUIER, EPHRAIM GEORGE (1821–1888)

American poet, engineer, archaeologist, and photographer

Born June 17, 1821 in Bethlehem, New York, to Joel Squier, an itinerant Methodist minister, and Katherine Kilmer Squier, Ephraim George gained two half brothers—Charles Wesley and Frank— when his father mar-

ried Maria Kilmer, Squier's own mother's sister after Katherine's death when Ephraim was twelve.

As a young man he wrote poetry and edited several poetry journals. His literary interests switched from poetry to social issues when he became involved with a publication, *The New York State Mechanic*, which supported "...the interests, rights, and social advancement of the laboring classes of America," according to his biographer, Terry Barnhart. Squier went on to obtain an M.A. and a degree in Civil Engineering.

Squier's interest in archaeology began in 1845 with his writings about the Indian mounds in Chillicothe, Ohio, and culminated in one of his most important works *Peru: Incidents of Travel and Exploration in the Land of the Incas,* published in 1877. This extensive record includes 295 engravings based on drawings and photographs—using the wet-plate process—made under Squier's supervision by the Lima based photographer Augustus Le Plongeon, who also probably taught Squier basic photography, a photographer named only as "P," and even Squier himself. His use of photography served him well because the renderings of architectural plans and monuments remain accurate even today.

Some of Squier's other significant works include *Nicaragua: Its People, Scenery, Monuments, and the proposed Inter-Oceanic Canal*, published in 1852, and *Observations on the Uses of the Mounds of the West, With an Attempt at their Classification,* published in 1847.

Ephraim George Squier died April 17, 1888 in Brooklyn, New York. The Library of Congress, the New York Historical Society, the Indiana Histroical Society, and the Latin American Library of Tulane University, are some of the institutions that hold Squire materials and photographs.

MICHELE M. PENHALL

STAHL, THÉOPHILE AUGUSTE (1828–1877)

Born in Bergamo, Italy, on May 23, 1828, Théophile Auguste (Augusto) Stahl came from an Alsatian family. His father was a Lutheran pastor. Stahl arrived in Pernambuco, Brazil in 1853, and in 1862 moved to Rio, where he and Germano Wahnschaffe became Photographers of the Imperial House. A renowned landscape photographer who sold multiple copies of his prints, he portrayed remote parts of Pernambuco, documented the Recife and São Francisco Railway works and recorded Emperor Pedro II's visit to Recife in 1859. The resulting album, "Memorandum Pittoresco de Pernambuco," is considered a pioneering example of photojournalism. Stahl also produced anthropological and anthropometric pictures of "Brazilian types" for the Agassiz expedition (1865–1866), published in *Journey in Brazil,* by Louis and Elizabeth Agassiz (1868). He participated in the First and Second National Exhibitions in Rio (1861 and 1866), the Great London Exposition (1862) and the Exposition Universelle, Paris (1867). He died in Alsace on October 30, 1877.

Collections: Brazilian Historical and Geographic Institute (IHGB), National Library (Brazil); Peabody Museum of Archaeology and Ethnology, Cambridge, Massachusetts (USA). Also published in *Augusto Stahl. Obra completa em Pernambuco e Rio de Janeiro,* by Bia Corrêa do Lago (2001), and *O negro na fotografia brasileira do século* XIX, by George Ermakoff (2004).

STANHOPE

A Stanhope, sometimes called a peep, is a microphotographic image on glass attached to its own small magnifying lens. The construction allows a person to see the image clearly. Stanhopes were produced from the 1860s to the 1970s, primarily in France. They can be found in a variety of decorative, souvenir, and utilitarian objects that were manufactured and distributed around the world.

Microphotography is nearly as old as photography. In 1839 John Benjamin Dancer produced some of the first microphotographs on slides. After collodion came into use in the 1850s, microscope slides became more popular, but people needed an easier way to see the images. Sir David Brewster used the more portable Coddington lens, invented about 1820, but suggested microphotographs could somehow be mounted into jewelry. René Prudent Patrice Dagron was issued a French patent in 1859 involving the use of microfilms and lenses to be placed in novelty items. He produced Stanhopes as we know them today, referring to them as microscopic jewels. He also used the term "Stanhope."

Stanhope is named for Charles, Third Earl of Stanhope (1753–1816), an inventor who lived prior to the era of photography. He did not invent the Stanhope, but he had developed a hand-held lens on which the Stanhope is based. Charles Stanhope's lens had two rounded ends, but Dagron made one end flat so that he could attach the image directly to it. In this way he was able to place the units into holes in novelties so that people could carry them in a fashionable manner.

The images were produced by using a camera with microscope lenses. Although the first cameras had one lens, the later ones had as many as twenty-five. Through these lenses photographic images were made onto a microscope slide by using the collodion on glass process.

By moving the lenses horizontally and vertically it was possible to produce 450 images on one slide. These were then cut into individual square parts with a diamond tool creating images about 1/30 inch square. Onto each image was glued a tiny lens, 1/4 to 1/3 inch in length, and then the corners of the glass unit were ground off making the unit cylindrical. The glue used was Canada balsam which was clear when it dried. The finished piece is usually about 1/10 inch by 1/3 inch, though some Stanhopes were made in larger sizes.

The focal length of the lens equals the length of the lens, so to be in focus, the image must be in direct contact with the flat end of the lens. To view the image, it is necessary to hold the curved end very close to your eye and direct the flat side of the lens toward a light source. Sometimes this is best with direct light, but in other instances diffused light or light reflected off a white surface is best. Since the Stanhope contains its own magnifying lens, most people find it easier to view without the aid of eyeglasses. Often many scenes will appear in a Stanhope, but if there is a single lens it is still only a single Stanhope image. In a real multiple Stanhope item there will be different lenses for each Stanhope.

Today the term refers to both the images and the items containing them. Images can be souvenir sights, religious locations or prayers, political personalities, advertising information or nudes. Certain types of items tend to be from specific geographic regions. Satin spar barrels or similar objects have Niagara Falls images. Items of bog oak come from Ireland. Hoof or horn objects come from Austria or Switzerland and have mountain scenes. The age of many Stanhopes can be determined because the images commemorate datable events. These include celebrations, famous exhibitions and world's fairs. Political Stanhopes also can be dated by establishing election years for the people pictured.

Stanhopes appear in a great variety of articles. Most abundant are crosses, which always have some type of religious image. Common, too, are dip pens and letter openers made of carved wood or bone. The images included are usually locations since these were travel souvenirs. Miniature bone binoculars and telescopes, with nearly every type of image, also are frequently found. Less common are sewing and needlework implements, smoking items, jewelry, writing instruments, bookmarks, grooming tools, knives and assorted other trinkets. Canes, beer steins, and violin bows are among the larger items one can find with Stanhopes. Although some museums have a few Stanhopes, none permits viewing the images. It is possible to do this only in private collections.

The largest and most valuable Stanhopes are dolls. Fewer than twelve are known to exist, all in museums or private doll collections. These dolls are all attributed to Antoine Edmond Rochard, who gained a French patent for them in 1867. They were produced through the 1870s. Most of them have multiple Stanhopes which appear in the bisque bodice. Some of the Stanhope lenses in these dolls are larger than those usually found. The known dolls are all different, varying in looks, height and necklace design. The number of Stanhopes in the dolls ranges from a single one to the thirty in Miss Jewel, owned by the Margaret Woodbury Strong Museum in Rochester, New York.

Several problems can occur in Stanhopes. The lenses sometimes fall out of their housings or the plate with the collodion image separates from the lens. This can be due to the deterioration of the Canada balsam which can dry out. If an item is washed the image will usually be lost because of separation. Sometimes the Canada balsam darkens. At other times bubbles appear in the image, but this probably happened in the production of the unit.

Stanhopes are no longer made, partly because the entire process was labor intensive. The last known Stanhope lens factory, in France, closed in 1972. For awhile they were produced in parts of Eastern Europe. In the twenty-first century people are fabricating images that they call Stanhopes, but they are not traditional Stanhopes.

STEICHEN, EDWARD (1879–1973)

Edward Steichen, born Eduard Jean, Luxembourg, immigrated to the United States in 1881. At 16 he took up photography in 1895 while studying painting at the

Milwaukee Art Students League and on his apprenticeship in lithography, first exhibiting photographs in 1899 at the Second Philadelphia Salon. While few have achieved so many different careers in photography, he seems no longer to be accorded the status he had in his lifetime. The accusation that he kept changing horses for financial reasons may have stuck to his reputation: it is indeed hard to image that his fashion and advertising photography of 1923 onwards for Condé Nast is the same person as the painter and photographer protégé of Alfred Steiglitz, as the man who persuaded Steiglitz to open the 291 gallery in New York; the same photographer (more and more esteemed today) of those Whistler diffused images when he was a member of the Linked Ring (1901) and the Photo-Session (founder member 1902); the exclusive aesthetic interpreter of Rodin, one of the first photographers involved with colour, using autochromes as early as 1904. Pictorialist Steichen, still a painter then, also depicted brooding landscapes. These early Steichen's, essentially developed out of 19th century aesthetics, may well turn out to be his golden period rather than his conversion to 'Straight,' then to 'commercial art,' or that he became curator at the Museum of Modern Art in New York (1947–62), and of the most successful photography exhibition ever held: *The Family of Man* (1955). He was also a successful breeder of delphiniums, an equal art, he would have maintained.

ALISTAIR CRAWFORD

STEINHEIL, RUDOLPH (1865–1930)

Lens craftsman

Rudolph, the son of Adolph Steinheil, was the third and last member of the famous dynasty of lens makers. An accomplished lens designer in his own right, he took over the management of the business in 1893, when he was just twenty-eight, following his father's sudden death.

Rudolph became responsible for the scientific direction of the firm at a time when photographic optics were undergoing enormous changes following the introduction of new optical glasses such as those produced by Schott and Abbe at Jena. He designed a new anastigmat lens and two different types of orthostigmat lens, followed by a number of other lenses, including the Unofocal in 1901. Perhaps his greatest achievement was in the design of lenses for astronomy. He constructed several large telescopes for observatories in Germany and other parts of the world. In 1910, he collaborated with Carl Goerz in setting up the Sendlinger Glassworks in Berlin.

COLIN HARDING

STELZNER, CARL FERDINAND (1805–1894)

Carl Ferdinand Stelzner was born in 1805 in Flensburg and adopted by Carl Gottlob Stelzner in Flensburg. He married this man's daughter Caroline Stelzner in 1834. Both were successfully working in Hamburg since 1830 as miniaturists and portrait painters. In 1842 he opened a photographic studio together with Hermann Biow but the partnership was dissolved in 1843. When the city of Hamburg burnt down in 1842, the studio of Biow & Stelzner produced a series of photographs showing the ruins. Carl Ferdinand Stelzner's fame was for being the first and, for a long time, the best photographic portraitist in Hamburg. A noted miniaturist before taking up photography he knew how to find the moment of expression in his clients' faces, and even today his portraits are a lot more vivid than those of his contemporaries, Hermann Biow included.

His specialities included group pictures which he managed to arrange in very lively settings. For the 15 years Carl Ferdinand Stelzner practised photography he was virtually unsurpassed as a portraitist in the German countries; even as a blind man he remained a well heard spokesman in Hamburg's photography. Due to being blind since 1854, Stelzner's studio was sold in 1858 to Oskar Fielitz from Braunschweig, a year later to Heinrich Gustav Siemsen. Carl Ferdinand Stelzner died on October 23, 1894.

ROLF SACHSSE

STEREOGRAPHIC SOCIETIES

The history of any society or organization is also a history of the people and times within which it exists. Stereographic societies make particularly interesting reading, as their members have proved to be amongst the most active and multi talented of all photographic groups.

The Stereoscopic Club, formed in 1891, was the earliest stereographic group in the world. It was founded by Mr W.I. Chadwick, and it survived until 1905. Its remaining members then moved into The Stereoscopic Society, originally formed in 1893 as The Stereoscopic Postal Exchange Club.

This society offered a wider variety of opportunities and activities, such as meetings and distributing folios of stereo view cards, by post. In 1896, it changed its name to The Stereoscopic Society so as to better represent its members overall interests in Stereoscopic imaging. Its Founder/Secretary was Mr Charles Berti DiVeri. Its first President was Mr W.A. Whiston, followed by the illustrious Dr W.W. Stainforth.

Today, The Stereoscopic Society thus remains as the

oldest extant stereographic society in the world, with a thriving international membership.

In 1894, it became affiliated to The Photographic Society of Great Britain, later called The Royal Photographic Society, and over the next 100 years, they organised many exhibitions and published many articles.

No other independent stereographic societies existed until 1903, when the 'Stereo Club Francais' (SCF) was formed by Monsieur Benjamin Lihou. The club still exists.

Various stereo view card manufacturers, such as Underwood and Underwood, The Keystone View Company- and later ViewMaster- also had enthusiast stereographic groups within their own manufacturing organisations, but were little known outside their own companies.

Meanwhile, The Stereoscopic Society, based in England, encouraged international membership, and so, in 1919, The American branch of The Stereoscopic Society was the first overseas branch to be created, with Mr W.S. Cotton as secretary. Formation of the Australian branch (Secretary H.A. Tregallas), and New Zealand branch followed in 1924/5.

Other overseas branches followed, with autonomous international, national and local and independent societies, growing along the way. Some major national photographic organisations included stereographic groups within their edict. These included The Royal Photographic Society, and the Stereo Division (founded 1951, Chairman Dr Frank Rice) within the Photographic Society of America. Famous local stereographic societies included The Beverly Hills (California) Stereo Club (founded Sept. 1952), which had many Hollywood film star members.

Meanwhile, independent but countrywide stereographic groups formed, often in demand to a local need. These included The Third Dimension Society (founded 1963, Chairman James Milnes), The National Stereoscopic Association (1974). Also, The International Stereoscopic Union (1975) which encompasses many other societies as its members.

The Stereoscopic Society remains typical of the societies, with 15 specialist groups distributing folios of stereo view cards, slides and information to its members. Over a century since its formation, it runs regular meetings, projection sessions, training sessions, conventions, library service and advice.

STEREOSCOPY

A stereoscope is an optical device used for viewing images in three-dimensional depth.

Two photographs are taken of the same scene but from a slightly different angle. This recreates the illusion of depth in the same way as the human eye. Our eyes are set about 2.5 inches (6.5cm) apart. Each eye sees a slightly different field of vision. When these views are combined an affect of binocular vision is created, giving depth height and distance to our view. If the lenses of a camera are set 2.5 inches (6.5cm) apart when taking two photographs, the same illusion can be created when these images are placed 2.5 inches (6.5cm) apart, and viewed simultaneously through a combination of lenses and prisms called a stereoscope.

It may come as a surprise that stereoscopy pre-empted the invention of photography. The concept for the stereoscope was first discovered by Sir Charles Wheatstone (1802–75). Wheatstone was a physicist and professor of experimental philosophy. Among other things, he discovered how to send the electric telegraph and helped create the modern dynamo. He started his career working as a musical instrument maker. It was in 1832 that he first invented the Stereoscope and presented these findings in 1838, a year previous to Daguerre's photographic discovery of the daguerreotype. Describing his instrument he said:

> I propose that it be called a stereoscope, to indicate its property of representing solid figures.

Wheatstones's, *Reflecting Stereoscope* is demonstrated in the diagram. Two pictures were fixed vertically at the end of a bar facing mirrors at right angle to each other. The images were usually of a large size and one could view the images simultaneously with each eye seeing one image. The instrument was successful in showing geometric drawings but not in showing portraits, landscapes and architecture. This original stereoscope remains at the Science museum, London. In c. 1841, Wheatstone approached the early photographers of the time Richard Beard, Henry Collen, Antoine Claudet and H.Fizeau in Paris and requested that they use his apparatus to view daguerreotype photographs. This was unsuccessful as the metal surface created too many reflections. Calyotypes were more successful especially with pictures of large objects. Good large examples were taken by Fox Talbot, Dr Percy, BB Turner, Alfred Rosling and Roger Fenton, some examples of which were on sale in 1846 in the shop of James Newman, Soho Square, London. Wheatstone's process was both expensive and time consuming. In March 1849, Sir David Brewster (1781–1868), presented his invention of the Lenticular Stereoscope to the Royal Society of Edinburgh. This was a modification of the second stereoscope plan by Wheatstone. Two images were viewed in a box

through a pair of prisms, which magnified the binocular image. The height of the images was usually limited to three inches. Brewster exhibited the first model made by Andrew Ross at the British Association Meeting in 1849, and suggested it should be applied to photography. It was slow to catch on at first and he struggled in vain to attract several English opticians to manufacture the instrument. In 1850, Brewster took his stereoscope to Paris where, the author Abbe Moigno was very impressed by the idea and presented it to Jules Dubosq, an optician who suggested producing transparent pictures on glass and replacing the solid bottom with a glass screen. At the Great Exhibition, The Crystal Palace, 1851, a number of stereoscopes made by Dubosq were shown as well as a set of stereo daguerreotype. The effective illusion of the instrument caught the attention of Queen Victoria. This prompted Dubosq to make an elaborate stereoscope for the Queen.

The fascination with this novel instrument soon spread to the general public. Dubosq had many orders and opticians in England started to manufacture stereoscopes. Among the photographers who worked with stereo daguerreotypes were Claudet, Beard, Mayall, Kilburn and Williams. They all took pictures of the Crystal Palace and its exhibits. One of the figures most responsible for the popularity of the stereoscope and for its scientific improvement was A. Claudet (1797–1867. Claudet showed a collection of stereo daguerreotypes at the Great Exhibition, which greatly impressed the Queen. In 1852, Claudet published his first paper on the subject: *On the Stereoscopometer and on a Manifold Binocular Camera* (British Association for the Advancement of Science reports 23 no.1 1852,. 6). The stereoscopometer was an instrument used to measure the position of the two cameras, relative to the subject, in order to achieve a good stereo effect. The *binocular camera* was a special camera for taking stereo daguerreotypes, which had two lenses. Unlike many others photographers Claudet adapted stereo daguerreotypes to portraits and even groups with great success and achieved a very a life like quality. Claudet's portraits were taken with painted backdrops, as this was thought to give the stereoscope a more dramatic three-dimensional affect.

An example of Claudets portrait stereos is *The Geography lesson c 1853* which was referred to in the *Illustrated News* as a charming part of the Gernsheim Collection. The complex composition is made up of a group of figures at differing heights, around a globe in the centre. There is a balance of all elements of the composition. The figures are lower in the foreground and raised in the background. Claudet used this formula for many of his elaborate stereo group portraits, which he called his 'conversationals.' The depth of such a complex portrait can only be fully appreciated when seen through a stereoscope, where the characters are brought to life and given three-dimensional form. Before the invention of the binocular camera, Claudet produced his stereos by setting up two cameras side by side, which accounts for the exaggerated roundness of the figures.

In 1852 J.F. Mascher from Philadelphia invented a miniature case which had on one side the folding stereoscope and on the other a stereo image. In 1853 Claudet gave a lecture at the Society of Arts entitled 'The History of the Sterescope and its photographic Applications.' For the promotion of this area of photography he received the Society medal from the President Prince Albert.

In March 1853 claudet patented a folding pocket stereoscope, in which one stereoscopic daguerreotype was fitted in a case with two lenses. When opened it formed a stereoscope.

A drawback of Brewster's and Dubosq's design was that eye pieces were not adaptable to different eye widths or to different sight. In 1855 Claudet patented an instrument where the lens was set in adjustable tubes. This patent also covered a *large revolving stereoscope*, where one hundred slides could be rotated on a band.

In 1858 Claudet presented his *stereomonoscope* to the *Royal Society*. The instrument combined stereo images on a large glass screen which allowed several viewers to watch at a time, pre-empting cinema.

Before the invention of moving image, at the beginning of the nineteenth century, stereoscopy provided a new and exciting way of seeing the world. This was an ideal medium for travellers to present scenes of places that most people had never seen and to re-create a visual illusion of such scenes. The stereoscope was as common in American homes as the TV is today. People who had never been able to travel could escape to far away places. Stereoscopic pictures were used as travel guides and educators. People could sit in their own homes whilst touring the world with views of the countryside, ancient Egypt, sights from New York or San Francisco. Great events were brought into peoples living rooms. Natural desasters such as the Johnstown flood or the San Franscisco earthquake could be recorded for the first time. Both the Chicago Worlds Fair in 1892, and the St Louis Worlds fair in 1904, could be enjoyed by those who were not even there. A. Claudet described the stereo daguerreotype:

> The general panorama of the world. It introduces to us scenes known only from the imperfect relations of travellers, it leads us to the ruins of antique architecture, illustrating the historical records of former and lost civilisations; the genious, taste and power of past ages with which we have become as familiarised as if we had visited them. ('Photography in its Relation to the Fine Arts,' *The Photographic Journal*, vol. Vi, 15 June 1860)

The invention of the stereoscope marked an important step towards the invention of moving image and for many years Dubosq, Claudet and other pioneers worked

to combine the stereoscope with the zoetrope to create 'moving photographic figures.' Claudet created an instrument where a slide was adapted to the eye piece of the stereoscope. This moved backwards and forwards opening and closing each eye piece. One view shows a man with a cigarette in his hand and the other with the cigarette in his mouth. Moving the slide backwards and forwards across the eye piece, gives the impression that the sitter, A.Claudet, is smoking. Claudet explained this as 'an uninterrupted perception of an object in motion.' This experiment was based on the understanding of how the eye works. Arthur Gill described this as the first photographic device specifically giving an illusion of movement. Arthur Gill 'Antoine Claudet Photographer,' M*odern Camera Magazine,* Nov. 1961 462. Said:

> together with Dubosq his is the honour of having laid an important foundation stone on the edifice of motion pictures.

Claudet knew that the retina retained some of the previous image after viewing. The eyes were able to supply the in between images by the persistence of vision. Claudet elaborated on this idea, showing an arrangement of a series of pictures on blades on a rotating band. This gave an illusion of movement when looked at through the stereoscope. He applied this idea to Plateau's Phenakistoscope in 1865, but failed to achieve a smooth illusion of moving image.

In America daguerreotype photography and stereo daguerreotypes experienced a long duration of success. By the 1850s a town called Dagurreville had appeared in America around a factory which produced three million daguerreotype plates a year. In fact, there were more studios in New York than in the whole of Europe this was due to the more relaxed licensing laws. 'Southworth and Hawes were a successful American studios who produced many stereo daguerreotypes. In an article by the Philadelphian daguerreotypist Marcus A.Root, August 1855 for the *Photographic and Fine Art Journal,* 'A trip to Boston—Boston Artists,' he wrote that:

> Mr Southworth explained the wonders of the stereoscope very clearly, and he takes his pictures of this class without distortion or exaggeration. I think his principle correct, for his specimens were stereoscopically beautiful, and exempt form the many faults witnessed in those of others…They have also invented and patented a beautiful instrument, by which 24 or 48, or even more (stereoscopic) pictures-taken either upon plate, or paper, or glass,- are exhibited stereoscopically; and so perfect is the illusion, as to impress the beholder with the belief, that the picture is nature itself!

Many stereos were sold in sets, and most were of buildings and scenery. The size varies but the most common viewers were 7 × 3.5 inches (18 cm x 9 cm), the images were both about 3inches square (7.6cm square). Stereoscopy became the first in a line of photographic crazes. Within the first three months after Albert and Victoria had taken a shine to the new phenomena, a quarter of a million stereo viewers were bought in London and Paris. The stereoscope experienced its peak of popularity in the 1850s and 1860s. It was estimated that by the mid-1850s over a million homes had one. By 1860 almost every Victorian family of the middle classes had a stereoscope and a collection of photographs to go with it. Many beautiful stereo daguerreotypes were produced in the 1850s but the metal plate was fragile and heavy and not suited to the medium. The plates were expensive to make and the reflections on the surface often interfered with the three-dimensional effect. Once the collodian photographic process was established sterescopic photography received a boost in popularity. Paper prints could be mass produced and were much cheaper than their daguerreotype predecessors.

The most common process for making stereos was the stereocards with the Albumen process. The number of stereo daguerreotypes produced was relatively rare. In 1854 George Swann Nottage set up the London Stereoscopic Company, manufacturing sterescopes and binocular pictures and was one of the largest manufacturers in England. He had 10.000 stereocards on offer in 1854. By 1858 he had increased this to a stock of 100,000 stereos of places of interest in both England and abroad. Within two years they had already sold half a million instruments. His ambition was for there to be no home in England without a stereoscope. With his fortune George Nottage became the mayor of London. Magazines were started up which had stereo images and clubs were formed where people got together and showed swapped and collected stereos. The stereoscope was to Victorians what the television is to us today. Stereo cards were the cheapest type sold at half a crown for three. By the late 1850s there was a trend for dioramas where thin paper could transmit light. Even mundane objects fascinated people by the the apparent reality viewed through the lens. Stereos could be sold of all sorts of subjects, ghost pictures freaks and risque nudes. Paris was one of the biggest exporter of stereos in this genre. Most were taken by photographer who kept their identity anonymous. Due to the strict moral climate in England and America at this time such photographs were considered pornography and were not thought of as acceptable as nude painting.

Soon a variety of viewers became available. The cabinet viewer could store up to 50 positives. Eventually one of the widest used stereoscopes was that invented by American writer Oliver Wendell Holmes designed in 1860. It was cheap to produce and easy to use. The structure which was like a mask, was held in front of the eyes by a handle below, like a lorgnette. There was a piece going across on a runner to support the cards.

This could be moved up and down until the picture was in focus. More elaborate models were mounted on a stand. This type of stereoscope continued to be used into the twentieth century. By the 1920s the stereoscope lost its charm and went out of favour as the most popular form of entertainment. Stereoscopes were eventually eclipsed by the introduction of *carteomania*, the craze for the c*arte de visite*, small portraits on cards 2.25 × 3.5 inches, an invention which had been developed by the French photographer Andre Disderi in 1854. Despite this stereoscopy continued to have revivals in popularity well into the twentieth century. Present day stereo cameras can be bought and modern stereoscopes consist of a plastic box with two viewing holes. *The Sterescopic Society* was formed in 1893 and continues to promote stereo photography today. Stereoscopy is still used for aerial surveys to map out land elevations and for astronomers to view small planets.

STEWART, JOHN (1800–1887)

John Stewart lived and worked for many years in Pau in the Pyrenees from 1847 and for a time in the 1850s, was associated with an informal grouping of photographers who referred to themselves as the 'ecole de Pau.' That group included Stewart's frequent photographic companion Maxwell Lyte.

The group produced impressive and often romantic landscapes, sometimes placing people strategically within the frame to counter the spectacular mountain scenery.

He was one of the exhibitors at the 1852 photographic exhibition at the Royal Society of Arts in London, and an early member of both the Photographic Society of London, and the Societé française de photographie. Stewart was brother-in-law to Sir John Herschel, and Herschel wrote about his work in the 'Atheneum' in 1852, alongside Stewart's own account of his experiences.

He exhibited work at the Photographic Societt of London's 1855 exhibition, but with one exception, he thereafter appears to have exhibited only in France. That date coincides with him joining the Societé Française. The exception was a portrait of his brother-in-law exhibited at the 1857 Manchester Art Treasures Exhibition.

In 1853 and 1854 he published accounts of a 'new photographic process,' and it was examples of his 'wet paper process' which he exhibited in 1855.

JOHN HANNAVY

STIEGLITZ, ALFRED (1864–1946)

American photographer, creator and editor of* Camera Notes*, and founder of the 291 Gallery

Alfred Stieglitz is remembered through his remarkable photographic work, his involvement in the photo secessionist movement, and his pivotal involvement in the fostering of an academicization of photography in America. His work made great strides to promote the symbolic in American art and elevate the position of photographer to that of fine artist, as opposed to a skilled craftsman who is merely technically proficient.

Stieglitz, the first son of four children, including two male twins, was born in Hoboken, New Jersey, on 1 January 1864 to hard-working Jewish parents. Alfred's mother, Ann Werner, who moved to the United States in 1852 and married Edward Stieglitz, Alfred's father, on 21 December 1862, was an educated woman fond of literature and the arts. Alfred's father made it a point

not to mix home life with business life; he preferred to have his home filled discussions of the arts. As a result, Alfred enjoyed a home environment full of discussions of literature and the arts as well as meetings with well-known artistic and literary figures.

Alfred grew up next to the Elysian Fields in Central Park, home to the invention of modern baseball and inspiration for a lifelong love of the game. Stieglitz identified with his subject, a notion that traced back to his childhood experience of bringing food to an organ grinder because Stieglitz identified with the organ grinder. During the 1870s, Alfred saved money and brought a sandwich to an Italian organ-grinder and his monkey, who played outside Stieglitz's house every Saturday. Years later, Stieglitz confessed to his mother that "I was the organ-grinder." Stieglitz often affirmed that whenever he took a photograph he was photographing himself—regardless of its ostensible subject—so that all his photographs were, in effect, self-portraits that conveyed symbolic representations of his and the symbolic representations of his feelings. Alfred would cultivate intense jealousy of the twin boys.

For a good part of the beginning of his career, Stieglitz believed in what is called "straight photography," as opposed to unusual visual effects achieved, among other means, by the manipulation of negatives and chemicals. This later proved seemingly ironic as Stieglitz became one to rely heavily on manipulation of photographic images. However, at the heart of his photographic creations, Stieglitz never wavered from sticking to the fundamental emulsion, lens, and camera qualities. Throughout his career, Stieglitz photographed primarily in the open air.

Lake George, near the Finger Lakes in upstate New York, was a favorite haunt of both Stieglitz and his family, where they often spent their summers, and also the site of many of his photographic images. New York City was an equally important focus of Stieglitz's work. Works such as "Winter on Fifth Avenue" (alternately referred to as "Fifth Avenue, Winter") and "Spring Showers" captured the atmospheric environment of the inner city in a way that previous mediums had been (lacking)/wont to do/capture. Other works, such as "Spiritual America," depicting a gelded or castrated horse captured the spiritual void being created by modern American commercialism and manifested in a crisis in American masculinity. Stieglitz's work, "The Steerage" (1907), on the other hand, dealt alternately with geometric forms constructed in spatial planes within a photographic frame and issues of social class and gender differences.

In 1905, Stieglitz established the famous gallery 291 named for its location at 291 Fifth Avenue in New York City. The gallery was designed to be a location for the exhibition of photography as a fine art in America. Yet, soon after opening, the gallery broadened its scope to include the works of the modern French movement and introduced to the United States the work of Cezanne, Picasso, Braque, Brancusi, and many others. It also made known the work of such American artists as John Marin, Charles Demuth, Max Weber, and Geogia O'Keeffe, whom Stieglitz married in 1924.

Stieglitz moved freely from these works into his photographs of his second wife, painter Georgia O'Keeffe. The nude photographs Stieglitz composed of O'Keeffe's hands, face, chest, and body were the content of a one-man show at his 291 gallery. Ironically, these photographs of O'Keeffe's body, not her body of work, are what brought her attention.

With the demolition of the building 291 occupied, the Photo-Secession ended in 1917. However, the most of its members had already effectively left the group either as a result of personal conflicts with Stieglitz or new ideas about where the movement should be headed.

Never one to tolerate a seeming imperfection in his past, Stieglitz, who maintained a near-obsessive passion for his body of photographic work, attempted to destroy all of the material he produced for Camera Work. However, after Stieglitz happened to communicate with the director of the Metropolitan Museum of Art, the MET decided to collect all of Stieglitz's remaining works from the Camera Work era. This collection would later be incorporated into a separate library within the MET.

Retouching portraits had been common in the collodion era, but after 1917, new art critics were calling for a "straight photography." Straight photography came to refer to art critics desire for an art that relied on the photographer's eye, instinct, knowledge of composition and inherent good taste as opposed to special effects such as retouching. While retouching was necessary procedure for the majority of daguerreotype images as they were fragile, it was not a requisite for modern photography that could now be produced on sturdy papers and could withstand less cautious handling.

Stieglitz sought to produce an art free from the pressures of rampant commercialism. He felt that, unlike in Walt Whitman's era, the then-current day presented a world where advertising and commercials took the place of American imagination. Throughout his life, He tried to spread the idea that art is not property and should be accessible to all.

In 1922, Stieglitz began a series of abstract photographs entitled "Equivalents," or abstract works composed primarily of clouds, atmosphere, and light, in which cloud formations create various moods and textures. He referred to them as his attempt to "put down my philosophy of life—to show that photographs were not due to subject matter" (Newhall, 171). Stieglitz always saw these photographs as a reflection of himself in some way.

Stieglitz's circle, a group of artists who all had exhibited at 291 before the gallery's demolition, combined the Whitmanian notion of nature as health-giving and unifying with an aesthetic philosophy taken from the socialism of William Morris and the Arts and Crafts movement. Stieglitz's determination for high-quality art photography to reach an international audience was proven in his correspondence with Lewis Mumford, the editor of the international art journal with a socialist slant, the *Dial*. Stieglitz desired to have photographs entered into the *Dial* and thereby have well-produced photographs reach an international audience.

From 1917 until approximately 1925, Stiegliz produced some of his best known works including the extraordinary portraits of O'Keeffe, studies of New York, and the "Equivalents," or great cloud series. From 1925 until 1930, he operated the Intimate Gallery (1925–1930) and An American Place (1930–1946), which both sought to further the conceptual advance gained by the exhibitions that occurred with the photo secessionists with 291.

Biography

Alfred Stieglitz was born on 1 January 1864 in New York City. He took up photography in the early 1880s while living in Berlin, Germany. In 1901, he founded a society of American pictorial photographers, the Photo-Secession, based firmly in New York, and he created the journal *Camera Work* in which to display the work of the Photo-Secessionists. Stieglitz was one of the founders of the pictorial movement and an advocate of straight photography, or photography that strove not to alter the photographic image after the image was captured. Stieglitz, who first displayed works of Brancusi, Braque, Rodin, and Matisse in his 291 gallery, is credited with awakening the American public and critics to modern European movements in the visual arts. Often claiming that truth was his obsession, Stieglitz sought not to alter the image after it was captured by the camera. He began a series of photographs of Georgia O'Keeffe, American painter and feminist, who would later become his wife, and launched a one-man show in his 29' gallery entirely of portraits of O'Keeffe. After the closing of 291 and the termination of *Camera Work*, Stieglitz opened the Intimate Gallery, consisting of rooms "at the Anderson Galleries to promote the work of a circle of American modernists in painting and photography that comprised, besides himself, Arthur Dove, Marsden Hartley, John Marin, O'Keeffe, and Strand" and ran the space from 1917 and 1925. Beginning in 1913, he made a series of abstract photographs entitled "Equivalents," the majority of which focused on clouds and atmosphere, to illustrate what he felt were nature's equivalents to his philosophy of life. A number of these "Equivalents" were photographed at Lake George—a site of interest to the Hudson River School painters such as Thomas Cole, Albert Bierstadt, Frederic Edwin Church, and Thomas Moran—where Stieglitz summered. His work in this later period includes portraits, hundreds of studies of Georgia O'Keeffe, photographs of Lake George, clouds, and New York City views. Stieglitz ran *An American Place*, in which he exhibited principally painting, sculpture, and graphic work, and occasionally photography, from 1929 until his death on 13 July 1946.

STILL LIFES

Still life was a popular theme for photographers during the nineteenth century for a number of reasons. Technologically, the long exposure times required to capture an image on a light-sensitive surface meant that moving subjects were impossible to register until at least the 1860s. Still lifes, however, allowed photographers the greatest degree of control over their subject. In the

early years of the medium, the emerging photographer could experiment with lighting, timing, tonal qualities, texture and subject arrangement without interruption or complaint from a live subject.

The natural world was also of great interest to nineteenth-century photographers. One of the principal inventors of photography, William Henry Fox Talbot had a scientific interest in nature and natural phenomena, including botany. For Talbot, photography was a physical manifestation of the wonders of nature, a working tool, a unique recording system and an art. In his first book of photographs, *The Pencil of Nature* (1844), he hoped to show how nature might 'draw' or 'fix' itself on paper. The term 'photography,' literally means 'light drawing' or 'light writing' and in *The Pencil of Nature* Talbot gives an account of photography in relation to painting and its traditions.

Talbot hoped that photography would be an aid to scientists and to artists in their attempts to represent the world. From this time, the extent to which photography continued to be understood in relation to the arts was hotly debated. During the second half of the century, painting exhibitions were often reviewed and discussed in photography publications. Photography's role was frequently a central focus of photographic societies' meetings and discussion centred on what constituted acceptable themes for photographers in order to legitimise their work as Art. In the earliest years after the medium's invention, the acknowledged topics included landscapes, cityscapes, portraiture and still lifes.

Historically, still life is an ancient genre, traditionally associated with the medium of oil painting. By definition, still lifes are an arrangement of inanimate artefacts, often food (especially fruit and dead game), plants and textiles, for example. The composition of still lifes can range from highly elaborate displays to simple arrangements, posed within a domestic setting. While still lifes are most often a subject of painting, throughout history other media have been used, including mosaics, watercolour, collage and, of course, photography. Some of the earliest known images that can be described as still lifes have been found in ancient Egyptian funerary painting.

Despite the existence of still lifes in Greek, Roman and Renaissance art, the form emerged as an independent subject in the West only in the sixteenth century. The genre was highly regarded by artists such as Carravaggio, who elevated still life to a status that was more than merely decorative. Still lifes flourished in seventeenth century Dutch painting where sumptuous arrangements of food, flowers and objects celebrated nature as well as Christian, philosophical and metaphysical ideas. The flora and fauna of exotic places was also a popular still life subject. As historians such as John Berger note, still lifes embody a moment in the history of art where merchandise becomes subject matter in itself.

Frenchman Jean-Baptiste-Siméon Chardin is celebrated as the most notable early still life painter during the peak of the genre's popularity in Europe, in the eighteen century. Still lifes were especially popular in France, Spain and Italy at this time and were often included in *tromp l'oeil* paintings. By the early nineteenth century in Europe there was little demand for still life painting. However, it received a boost in the region through the still lifes of much-famed artists such as Gustave Courbet, Francisco de Goya and the Impressionist Paul Cézanne who pushed the field toward non-representational art. The term 'still life' became accepted in the seventeenth century but there remained a diverse vocabulary for this type of imagery up until then including, *nature morte* in French and *vanitas* in the Netherlands, for example.

Little has changed in style or iconography in still life photography from these prototypes in painting. Nineteenth century photographic still lifes are most often tabletop arrangements of materials traditionally found in still life precursors: fruit, crockery, flowers, shells, statues and dead game. This type of image making attracted a number of photographers, notably the inventors of photography, Louis Jacques Mande Daguerre and Talbot. Other photographers, like Adolphe Braun and Jules Dubosco, also used props such as skulls to make visual connections with painting and its capacity for symbolism, which was also a High Victorian interest and widely understood.

In a letter to his short term partner Daguerre, photography pioneer Nicéphore Niépce refers to two Heliographs, only one of which has been identified. The image, known as *La table servie*, shows a set table, laid with a tablecloth for a meal with bowls, cutlery and a goblet. The date of the image has been disputed, but historians suggest it was taken somewhere between 1823 and 1829, with most dating it around 1827. Produced years before the medium had even been officially invented, Niépce's image is considered the first still life photograph.

Daguerre's first successful daguerreotype was also a still-life, taken in 1837, in a window sill. Entitled *Still life*, it shows a group of plaster casts, a framed print and a wicker wrapped bottle. Daguerre's interests reflect both the technological limitations of the earliest daguerreotypes and the nineteenth-century desire to collate and categorize, as seen in the establishment of museums and their impulse to catalogue the world around us. His famous *Shells and Fossils* of 1839, is also suggestive of this interest in classification and evokes painterly still lifes devoted to meticulously reflecting earthly existence. This tradition continues throughout the history of nineteenth-century still life photography by photographers such as Adolphe Bilordeaux, who created teeming, allegorical compositions that refer-

Bailey, Henry. Trout Roach etc.

ence a cabinet of curiosities. Other key early examples include Hippolyte Bayard's compositions of garden implements, domestic objects and plaster casts, such as *In the Garden* of 1842 and Talbot's image of fruit published in *The Pencil of Nature*.

The best-known photographers to produce still lifes are Roger Fenton and Adolphe Braun. Both created still lifes during the genre's peak in the 1850s and 1860s. Fenton's photographs are some of the most opulent still lifes made in Britain at the time and joined a vogue for this genre already proliferating Paris (Frenchman Henri Le Secq had produced a successful series of still lifes known as *Fantasies* around 1855). Fenton's photographs, such as *Fruit*, 1860, have a great sense of texture and light, drawing on Flemish and French pictorial traditions. Photography historians Helmut and Alison Gernsheim suggested that the painter George Lance used Fenton's photographs as studies for his paintings, even though Fenton was the one accused of plagiarism at the time. Fenton's still lifes are indeed painterly in their formal qualities and reflect the highly privileged lifestyle of those to whom such exotic foods and flowers were available. His compositions regularly include either shot game or exotic fruits and sometimes mirrors and rich fabrics. His subjects are highly symbolic and explore themes such as Christian faith and the transience of earthly life.

Frenchman Adolphe Braun had worked in Paris as a textile designer, and after discovering an interest in photography, set up a large commercial studio, creating images such as *Flower study*, 1854. He later exhibited images of flowers and flower arrangements at the Exposition Universale in Paris in 1855. Braun's work was enthusiastically received and he won a gold medal for the sensuality of texture, softness of tone and the play of reflections in his images. So influential were these photographs and so great was the demand for them, that he and his many assistants produced a collection of studies intended for artists using flowers in decorative motifs. The set consisted of 300 plates of floral arrangements and natural flowers to serve as 'designs' for painters but Braun's principal market were the fabric designers employed by the local mills. In 1864, another French photographer, Charles Aubry, who also worked as a designer, formed a Paris-based company to manufacture plaster casts and photographs of plants and flowers, such as *Leaves*, 1864. Although unsuccessful in his business, he continued to sell the photographs to drawing schools throughout the 1870s.

Braun's still life images that incorporate shot game and hunting equipment, like *Still life with Deer and Wildfowl,* c. 1865, can be seen as modern versions of the work composed by the painters of Northern Europe. Scenes capturing the 'bounty of the hunt' were extremely popular with still life photographers, as they had been during the eighteenth century with painters. Photographers including Fenton, Charles Phillipe Auguste Carey, Dr. Hugh Welch Diamond, Louise Laffon, William Lake Price and Victor Albert Prout all created still lifes on this theme.

Still lifes could sometimes be treated unconventionally, as in Dresden photographer, Hermann Krone's

Still life of the Washerwoman, 1853. Krone's image does not depict a woman at all and instead uses the visual signs of her trade: washing tubs, buckets, pitchers and cloths positioned in a studio setting. Krone was celebrated for his daguerreotype still lifes of scientific instruments and equipment, amongst other subjects, and his stated ambition was 'to make photography useful to all areas of science.' Henri-Victor Régnault also created a number of still lifes with a scientific outlook. His *Laboratory Equipment, Collège de France, Paris*, c. 1852, shows a tabletop arrangement of test-tubes, measuring equipment and other devices, literally reflecting photography's bonds with science.

Similarly, Scottish photographer and writer John Thomson included images of flowers and fruit to an ethnographic end in his *Illustrations of China and its people* (1873–74). Thompson's images draw on the tradition established by European painters who recreated the bounty of the worlds outside England and America in luscious settings. Unlike some still lifes which visually describe such cornucopia as a feast for the senses, Thompson illustrated his subjects in even greater detail by including their botanical classification and descriptions of their texture and taste; intensifying the viewer's experience. He preferred the wet collodion process, a then cumbersome method, and produced large-format negatives and stereographs that are noted for their clarity of detail and richness of tone, securing their 'scientific' status.

The market for still life photography during the nineteenth century was both commercial and domestic. It was a time of art patronage by the fashion-conscious bourgeois when relations between photography and painting were as close as they would ever be and both photographers and painters aimed to service the same picture collectors. Nineteenth century still lifes are now seen in a category of photography that includes genre scenes, allegories and composite images as each attempted to speak the language of 'high art.' One of the first museums to collect photography, the South Kensington Museum (later the Victoria and Albert Museum) included still lifes by Prout and Lake Price in their first purchase of art photographs for the collection in 1857.

Nineteenth century still life photography can be understood through terms of reference drawn from painting, where everyday objects assume a particular monumentality through their meticulous description and often dramatic lighting. The imaging of objects is part of a tradition of probing the external world through its close depiction. Lavish displays of affluence and abundance can also be found at the heart of the still life tradition. It is perhaps photography's ability to radically transform everyday objects, through its peculiar temporal qualities, however, which anticipates the experimental work of the best known still life photographers of the twentieth century, namely Irving Penn and Paul Outerbridge. The tradition of still life scrutinizes everyday existence around the table where simple objects symbolise the decay and mortality associated with life. Still lifes exalt the banality of the subjects they depict through technical virtuosity and they offer a sharp reminder of the materiality of our existence.

STILLMAN, WILLIAM JAMES (1828–1901)

American photographer, painter, journalist

William James Stillman was born in Schenectady, New York in 1828. Despite his strong passion for an artistic career, his family sent young William to the Union College of his birthplace from where he graduated in 1848. His ambition, however, to become a notable painter, dominated his early life. He took lessons and made the acquaintance of well-known artists including William Page and Edward Ruggles. He travelled to England and France where he met J. M. W. Turner, John Ruskin and Dante Gabriel Rossetti. Stillman's career as a landscape painter did not last long despite his recognised work for which he earned the title of the 'American Pre-Raphaelite.' Soon the necessity for a more profitable occupation led him to the practice of journalism. The absence of an American periodical devoted to art prompted him to establish an art journal entitled *The Crayon: A Journal Devoted to the Graphic Arts, and the Literature Related to Them* in 1855. The journal was very successful but the long working hours that the editorial work required soon exhausted him and led to his resignation in 1861.

Stillman, William J.. Relief of Nike from the Temple of Athena Nike, Athens. Figure of Victory, fromt eh Temple of Victory-High Relief. One of 26 prints ina book entitled: "The Acropolis of Athens."
The J. Paul Getty Museum, Los Angeles

During the American Civil War, Stillman volunteered to join the Massachusetts troops. His poor health, however, was an obstacle and he was offered the position of the American Consul in Rome. Three years later, in 1865, he was transferred to Crete which at the time was excluded from the new Greek state and was still part of the Ottoman Empire. During the three years of his stay on the island, Stillman and his family (he had married Laura Mack in 1860 and had two children) experienced the Cretan Insurrection. Their personal safety was at risk, so Stillman was advised to leave Crete for Athens where a few months later his wife committed suicide. His son Russie was suffering from a fatal disease which forced Stillman to return to England where he became engaged in journalistic and literary pursuits for the rest of his life. In 1871 he married the daughter of the Greek consul in England, Marie Spartali, with whom he appeared to have lived happily until his death on the 6th of July 1901.

Stillman was introduced to the medium in 1857. As he mentions in his autobiography '[he had] bought a photographic apparatus, and learned photography as it was practised [at that time], a rude, inefficient, and cumbersome apparatus and process for fieldwork, of which few amateurs nowadays can conceive in inconvenience.' At first Stillman took up photography as 'a means to bring back records of vegetation.' Two years later he published his first photographic album entitled *Photographic Studies by W. J. Stillman, Part 1. The Forest, Adirondack Woods.* The existence of Stillman's late 1850s Italian views testify that he took up photography once again whilst appointed consul in Rome, since his official duties left him plenty of time. However, his serious involvement with the medium came when he was transferred to Crete. During his stay, Stillman photographed even the most remote parts of the island and conducted a number of experiments on the chemical development of images and photographic equipment.

The latter resulted in the construction of an apparatus that he called the 'universal camera' and which was an improvement on his 8 × 10 Kinnear camera.

Stillman's most significant contribution to the history of photography is a body of work of the antiquities of Athens. These photographs were taken in 1869 when he was forced to leave the island of Crete and advised to stay in the capital of the Greek State. The series of images taken that year resulted in the publication of an illustrated album entitled *Acropolis of Athens, Illustrated Picturesquely and Architecturally in photography* published privately by F. S. Ellis, in 1870. This large format album is bound with a red maroon leather cover and contains a total of twenty-six carbon prints. The photographs are mounted separately on individual sheets of card and most of them are numbered, signed and dated. Each image is accompanied by a descriptive text, printed on the opposite page, identifying the site of the precise geographic orientation. Copies of Stillman's Acropolis album can be found at the British Library, the J. Paul Getty Museum and the Gennadius Library of Athens.

Stillman's 1869 photographs of the Grecian antiquities are characterised by sharp detail and extreme depth of field made possible by the sharpness of the Dallmeyer lens used. They demonstrate the choice of an original viewpoint, which reveals the architectural structure of Classical temples with precision and the sculptural details with accuracy. Furthermore, Stillman's originality of visual expression is favoured by his extended knowledge of the technical aspects of photography. The excellent use of his technical skills, in the domains of choosing his photographic equipment and processing techniques, result in a unique clarity within a wide range of focus. Additionally, the realistic representation of ancient ruins reflects Stillman's influence from his artistic background and contemporary aesthetic tendencies.

As the years went by, his involvement with photography became even more diverse. He continuously experimented and improved upon photographic processes. In 1874, he published a handbook entitled *The Amateur's Photographic Guide-Book, Being a Complete Resume of the Most Useful Dry and Wet Collodion Processes* dealing with the problems of working with early processes, especially in difficult terrains and climates. Additionally, Stillman published, in various journals such as *The Nation, The Photographic Times* and *The Photographic News*, a number of articles dealing with technical issues, commenting on the use of particular lenses and giving examples of contemporary photographic works which met his criteria for good practice.

In 1876, during a visit to the United States, Stillman published another photographic album entitled *Poetic Localities of Cambridge*. The album is illustrated with heliotypes depicting the houses of Henry W. Longfellow and Olivier W. Holmes, Harvard College and Washington E.L.M.. The images are accompanied by a text written by Holmes and poems by Longfellow and Lowel. Original copies of this volume can be found at the Union College Library at Schenectady along with Stillman's personal correspondence.

Stillman never considered himself a gifted painter, nor a talented photographer. His introduction to the medium was almost an accident and there is evidence to suggest that his photographic work was a financial necessity. This aspect of his career never seemed to be of importance to him since it went almost unmentioned in his autobiography, which he compiled just before his death. His involvement, however, with photography was not restricted to simple topographical documentation. Stillman's significant contribution to the medium consisted of experiments with chemical processes, improvements to standard photographic equipment and the publication of articles in photographic journals of the period on a variety of subjects from the analysis of technical processes to the theoretical aspects of the medium.

ALIKI TSIRGIALOU

Biography

William James Stillman was born in 1828 in Schenectady, New York. A naturalist, a painter attracted to the Pre-Raphaelite circle, a diplomat and a journalist (he published numerous articles and books covering a wide range of subjects such as archaeology, photography and art criticism), he took up photography in 1857. From 1855 to 1861 he published the art journal *The Crayon: A Journal Devoted to the Graphic Arts, and the Literature Related to them.* During the American Civil War he was offered the position of American Council in Rome and three years later he was transferred to Crete. His involvement with photography was not restricted to simple topographical documentation. Stillman's significant contribution to the medium consisted of experiments with chemical processes, improvements to standard photographic equipment and the publication of articles in photographic journals of the period on a variety of subjects from the analysis of technical processes to the theoretical aspects of the medium. In 1859 Stillman published his first photographic album entitled *Photographic Studies by W. J. Stillman, Part 1. The Forest, Adirondack Woods.* However, Stillman's most significant contribution to the history of photography is the publication of an illustrated album entitled *The Acropolis of Athens, Illustrated Picturesquely and Architecturally in photography (*F. S. Ellis, 1870). Stillman died in England on the 6th of July 1901.

STIRN, RUDOLPH AND CARL (active 1880s–1890s)

The Stirn brothers were manufacturers and retailers of cameras and photographic equipment with their best known camera being the Concealed Vest camera which was patented in the United States, Germany and Britain in 1886.

Stirn's camera was based on a design by the American R. D. Gray which he showed in December 1885 and had refined by May 1886. It was patented in July 1886. C. P. Stirn of the American firm Stirn & Lyons purchased the rights to the camera from Gray and with his brother Rudolph in Germany began manufacturing the camera and selling it in October 1886. The camera made six exposures on a round plate and was hidden behind a vest or waistcoat with the lens peeking through a buttonhole. The camera was an immediate success with 18,000 sold by December 1890. A second model was made larger to hold more exposures and that appeared in 1888. The cameras were sold under several different names.

In 1889 Rudolph Stirn made a 360-degree panoramic camera called the Wonder Panoramic camera designed by an American J. R. Connon, and patented in that year. Rudolph Stirn also patented and sold a range of other camera designs none of which saw the success of the Concealed Vest camera.

MICHAEL PRITCHARD

STODDARD, SENECA RAY (1843–1917)

American photographer, guidebook writer, and lecturer

Stoddard was born 13 May 1843, to Julia Ray Stoddard and Charles Stoddard of Wilton, New York, nine miles north of Saratoga Springs. In the late nineteenth century he was recognized as an outstanding photographer of the Adirondacks in northern New York State, and late 20th century critics have compared him to famous early photographers of the American West.

A job from 1862–1864 with the Eaton and Gilbert Car Works near Troy, New York, taught him landscape painting in decorating rail cars. From there he moved to Glens Falls, strategically located between the fashionable tourist spots of Lake George and Saratoga Springs. He learned *wet plate collodion* photography from a Glens Falls photographer, and soon began photographing the Adirondack scenery and selling *stereographs* and large mounted *albumen prints* to tourists.

Complementing his photography were his various guide books about the Adirondack region. *The Adirondacks: Illustrated* first appeared in 1874, and went through various editions until 1914. Wood engravings based on his photographs were included along with his own maps. Later editions incorporated photo engraving. His first wife. Augusta Potter Stoddard, managed the studio with the help of female relatives, while his brother-in-law Charles Oblinis accompanied Stoddard as an assistant.

Hotels and transportation companies, including the Delaware & Hudson 'Railroad and the New York & Canadian Railroad, used Stoddard's photographs for promotion. In 1878, he headed the Photographic Division of Verplanck Colvin's State Survey of the Adirondacks. Travel involved stage coach, steamboat, railroad, and sailing canoe. He hiked trails and climbed mountains to make thousands of photographs of what became the Adirondack Park in 1892. His slide lecture using oxygen-hydrogen projectors at the New York Assembly in Albany on 25 February 1892, was a lobbying effort to securing legislative backing for the park.

In *Adirondacks Illustrated,* 1874, Stoddard wrote of his own stereographs on sale at Ausable Chasm: "The kind universally acknowledged best are known as the 'Crystal,' and sold at $2.50 per dozen..." There was justification in such a claim, for the E. & H. T. Anthony & Company of New York distributed these images widely.

Stoddard generally used cameras ranging from 5 × 8 inches to 16 × 20 inches, and in the 1880s he turned to the more convenient dry plate process. He was particularly adept at arranging people within a landscape or architectural setting, and his images form a visual history of middle and upper class vacations. With some ability in drawing and painting, expert photographic technique, along with an awareness of art and literature, he revealed the natural setting with careful framing, sensitivity to light, form, and detail.

Historians, including Weston Naef and John Wilmerding, have linked Stoddard's work to the category of

Luminism. The term Luminism was coined to define landscape painting from around 1850 to 1875 or later. The characteristics apply to photography: small scale, depiction of crystalline light, often the inclusion of a small figure, a feeling of silence and the suggestion of a transcendent nature. Many of Stoddard's views of Adirondack lakes and streams fulfill such a 'definition, but it should be noted that the small aperture and long exposures required for overall sharpness tended to render water as a smooth, glassy surface.

Other Stoddard photographs do not fit the luminist category. This would be true of some of his fine architectural photographs of hotels like the Fort William Henry at Lake George or night photographs of tourists around a campfire. The night photographs required magnesium flash powder and with this dangerous substance, Stoddard proved himself a master with a noteworthy photograph of the Statue of Liberty in New York harbor. He used magnesium flash to illuminate the vast spaces of Howe Caverns near Albany, New York, and published an illustrated article, "Photographing Bats" for *The American Annual* of *Photography and Photographic Times Almanac,* 1889.

Photographs for William West Durant, developer of the "Great Camps" in the western Adirondacks provide an impressive record of those rustic estates in the wilderness. Stoddard produced an elephant folio album of silver prints showing Durant's Sagamore and Camp Pine Knot on Raquette Lake.

This Adirondack photographer turned his camera on other aspects of this region which included photographs of lumbering and of large, conical kilns for making charcoal for the tanning industry. Both industries showed little concern for the environment, and this led Stoddard to publish a short-lived periodical, *Stoddard's Northern Monthly,* (1906–1908) in which he took on the lumber interests which were denuding large swaths of forests.

While thought of primarily for his Adirondack photographs, Stoddard photographed in many other areas. In 1892, he traveled to the West Coast via Canadian railroad. He photographed indigenous people as well as scenery and continued his journey to Alaska, where he made photographs that would be used successfully as lantern slide lectures. A mammoth panoramic camera for negatives 20 × 49½ inches, especially made for this excursion, failed to function.

In 1895, he was a ship's photographer covering a Mediterranean cruise. Here, he used a roll film camera to illustrate his text for the self-published *In Mediterranean Lands: The Cruise* of *the Fries/and,* 1896. On June 26,1897, he sailed as ship's photographer for a cruise to northern countries including Russia. Surreptitious snapshots taken with his "kovered kodak"-a Kodak # 4 taking 4 x 5 inch negatives- were a departure from luminist images and glass plate photography. The resulting self-published book for the passengers on the northern European cruise appeared in 1901, as *The Midnight Sun: Being the Story* of *the Cruise* of *the Ohio.*

In the early 1900s, Stoddard experimented with new textured printing papers, cyanotype, and soft focus effects suggestive of the Photo-Secession. Most of his late activity involved writing, revising his guide book, and recycling earlier photographs. He also sold cameras and supplies to a burgeoning amateur photography market.

Stoddard's wife died in 1906, and two years later he married Emily Doty. In 1908, he purchased an qautomobile and was among the first to drive into the Adirondacks. He had early affiliations with the Methodist and Baptist denominations, was an active member of the Temperance movement, and later embraced Spiritualism. Stoddard died on May 3, 1917, in Glens Falls.

JOHN FULLER

Biography

Seneca Ray Stoddard was born 13 May 1843 in Wilton, New York. He acquired art technique as a railroad car decorator in Troy, New York, 1862–1864, and then moved to Glens Falls, New York, where he learned photographic skills from a commercial photographer. The area from Saratoga Springs, New York, northward to the Adirondack mountains was already a tourist attraction, and Stoddard's photography of landscapes and hotels were purchased as stereographs and larger mounted albumin prints. In 1874, he published *Adirondacks Illustrated,* which included his adventures in the wilderness along with his maps and descriptions of accommodations. He was a successful lecturer who showed lantern slides before the State Assembly in 1892, as a lobbying effort for creating the Adirondack Park. He photographed such distant regions as Alaska and part of Russia as well as Mediterranean countries. He published extensively. He exhibited at the Philadelphia Exposition of 1876, and received widespread acclaim .for his multiple magnesium flash photograph of the Statue of Liberty. Since a monograph on Stoddard appeared in 1972, his work has attracted renewed attention, and he is often considered the Eastern counterpart of the noted photographers of the Western United States. Stoddard died in Glens Falls, 3 May 1917.

STONE, SIR JOHN BENJAMIN (1838–1914)

In the seemingly casual context of the life of a Victorian gentleman, John Benjamin Stone was a wonder and perhaps the most prolific photographic recorder of his generation. He dealt with the way things looked and has left us with a huge archive of 25,000 images. The work is simply remarkable. That Stone is not more celebrated should be a national shame for he presented England with its history, perceived from a Victorian standpoint. He also showed the world to England—he was a great traveller.. In short, Sir Benjamin was a man of means and a great character.

The means came from inheritance and his own abilities as an industrialist, the character from a sense of duty. Stone was first a member of Birmingham City Council, later a Tory member of Parliament for East Birmingham, a seat he held for 15 years.. Stone came from a well-to-do Midlands family and was knighted in 1886. In hindsight we can mark his career as one of power and service to the community, but he excelled in his passion—photography.

His interest began through collecting the works of others and later developed into his own practice as an enthusiastic taker of photographs. Stone's zeal can be judged by his output. In the City of Birmingham library sit 19,174 contact prints from his whole plate negatives, 3,045 enlargements, 14,000 negatives and 2,500 lantern slides. They were given in 1921 by the Trustees of Stone's estate. During his lifetime Stone had made a handsome gift of 1200 prints to the British Museum. and various Midland's institutions. Given his combination of wealth and industry, Stone chose three paths. The paths were crucial to his work at and away from Parliament, because he chose to picture the evident, not the incidental. His was a sense of history which he saw vanishing as Britain became increasingly industrialised He could be placed as a late taker of the spirit of William Morris and the 'Art & Craft' movement. He pictured the look of things but avoided what was obvious. One strand lay in compiling a 'National Photographic Record' which documented English customs and traditions, another was a visual account of his time in Parliament and the third was aan extended photographic journal of his travels—he was adventurous and visited North and South America, most of Europe, China, India, Ceylon (as Sri Lanka was then known), the West Indies, South Africa and Japan. And all over Britain. One can only be impressed at how prolific he was. Stone was a visual sociologist, though not in a systematic sense, and tried to gather up an individual analysis of the world. That said, he did not underestimate his worth; he amassed 38 albums of press cuttings, now in the Birmingham library, which give a good view of his abilities as a self-publicist.

The 'National Photographic Record' was originally proposed by Jerome Harrison in 1892. Stone knew Harrison through his involvement with the Warwickshire Photographic Survey; Sir Benjamin was the first President of the Birmingham Photographic Society and the Warwickshire project gave rise to grander ambitions which were nothing less than an audit of 'Life and History' made clear in pictures. It should be said, however, that he took up photography quite simply because no one else was taking pictures of the things he thought to be of value, so he was unable to buy them. Thus he learned how to make them for himself and history. It was to become a work of stature. He stored his glass plates carefully in two specially built out-houses in his back garden because of a personal conviction that the past might inform the future. Sir Benjamin planned three books to cover his work as a photographer. Two were published by Casssell, London. No date appears in the books though 1903 might be close. In typical style they were called 'Sir Benjamin Stone's Pictures." They covered his images of the enactments and ceremonies of British folklore and his documents of the people of Parliament. These two volumes were very handsomely produced. The third, on his travel pictures, was not published, which is a shame as he was an acute observe

of what made the ordinary extraordinary. It has been estimated that Stone spent £30,000 on his photographic exploits—which could be multiplied by 25 to gain a contemporary value.

PETER TURNER

STORY MASKELYNE, NEVIL (1823–1911)

British photographer, chemist, mineralogist and MP

Born on 3 September 1823, in a large Wiltshire country house, Nevil Story, as he was then called, was the eldest son of Anthony Story, a squire and barrister, and had three sisters and a brother. Nevil's mother, Margaret, was daughter of Nevil Maskelyne, an Astronomer Royal of the previous century. Nevil Story became interested in science while still at boarding school, through reading a book by Mary Somerville, which he won as a school prize, later claiming that this book had turned him into 'a man of science.' In the summer holidays of 1840, George Dolland, a family friend, visited the Storys house and showed them how to make photograms, or 'sun pictures,' which awoke Nevil's enthusiasm for photography. Besides trying out photograms, which required perhaps half an hour of exposure to sunlight, he experimented with his grandfather's camera obscura, and constructed himself a second camera from an old cigar box. He became frustrated by the erratic results of his photographic attempts, but this only increased his interest in chemical reactions and the properties of light. In 1842, Nevil went up to Wadham College, Oxford, to read mathematics, but his energies centred on attending lectures on scientific subjects such as chemistry and optics, which were outside the Oxford examination syllabus at that time. To his father's dismay, he also spent substantial sums of money on photographic equipment and chemicals, and evidently passed much time experimenting with them. When Nevil reached his twenty-first birthday, his father changed the family name to Story Maskelyne, ready for the time when Nevil would inherit the estate—a Maskelyne property.

After graduating from Oxford in April 1845, young Maskelyne set up a laboratory in a thatched farmhouse on his father's land and experimented with calotype photographic images. He was particularly concerned at his own failure to record the foliage of trees in sunlight, believing it to be due to 'extreme red,' now known as infra-red, and to their green colour, (ultra-violet radiation from leaves in sunlight was not then understood). He experimented with both chemicals and filters, until he achieved better results with tree photography. In the autumn of 1845, Maskelyne was sent to study for the Bar in London, but the law held no appeal, so he read the latest European scientific articles rather than law-books. As a result of this and of his frequenting Faraday's laboratory, he was thinking deeply about the properties of light and chemicals, and wrote a perceptive manuscript scientific paper concerning light-waves and their relationship to light and electricity. He became a member of the Committee of Visitors at the Royal Institution in London, alongside William Henry Fox Talbot, William Grove, Faraday, and Wheatstone of the electric telegraph. In 1847 he could have applied for a professorship in scientific subjects at St Andrew's University in Scotland, but his father, who felt a professorship was socially beneath the family status, forbade it.

Later the same year, Sir Benjamin Brodie, an eminent chemist, sensing Maskelyne's despair at a lost scientific opportunity, invited him to work in his private laboratory in London. This time, Maskelyne defied his father and turned to chemistry. In 1848 he was experimenting with albumen—egg-white—which had recently been introduced as a medium for attaching photographic chemicals to a glass base, and became involved with the London Christian Socialist movement, a group of young intellectuals aiming to help working men improve their lot. By 1849, Maskelyne was lecturing in mineralogy at Oxford from time to time, to help out Professor William Buckland, whose health was failing. In 1850, he was offered the post of Deputy Professor in Mineralogy, for which he prepared in London, with Faraday's help.

Back in Oxford, Maskelyne lived for the next seven years in rooms in the basement of what was the old Ashmolean Museum in Broad Street. During those years he taught analytical chemistry in his basement laboratory, which was innovative in that chemistry was normally taught as a theoretical, rather than a practical, subject. At this time, Maskelyne was experimenting with mica as a stable base for photographic negatives, and was taking interesting and lively portraits of his own Oxford circle, using chemicals to achieve better contrast than usual for the time. He was successfully using collodion on glass soon after the process was invented and lived a sociable life, entertaining young like-minded Oxford friends in his basement. They were almost all involved in the struggle to improve the status and recognition of science at Oxford. In 1857 Maskelyne met Thereza Llewelyn, herself a keen amateur photographer, whose parents were both photographic enthusiasts, and the couple soon became engaged. While staying with her family in South Wales, whose wealth derived from coal mines and land-ownership, he was invited to a house-party at Charlton Park, Malmesbury, where he took some fine photographic studies of the fashionable assembled company.

Marriage necessitated leaving Oxford for better-paid employment, and he found himself back in London, this time as Keeper of Minerals at the British Museum. Maskelyne tried to establish a small chemical and pho-

tographic laboratory in the museum basement, but fire regulations prevented its use. His career as Keeper of Minerals was successful and lasted for twenty years, during which time he retained his professorship at Oxford, but his photographic contribution was finished now that chemical experiments were impossible. In the British Museum years, Maskelyne wrote numerous scientific papers and counted great numbers of contemporary scientists among his friends. When at last it was time for him to leave the museum in 1879, the year his father died, he returned to Wiltshire to manage the family estate. He became Member of Parliament for Cricklade in Gladstone's Liberal government, and helped to prepare bills on technological matters like electric lighting or the ventilation of London's underground railways. Even though Nevil Story Maskelyne was not among the great artistic photographers of the nineteenth century, he created some interesting and sometimes lively images. His enthusiasm and scientific ability are the attributes which earn him his place in the history of the earliest era of photography.

VANDA MORTON

Biography

Nevil Story Maskelyne was born on 3 September, 1823, at Basset Down in the parish of Lydiard Tregoz, North Wiltshire. An enthusiast for photography and chemistry from his teenage years, he experimented first with photograms and then with calotype negatives and prints. While a student at Worcester College, Oxford, he exploited chemical elements to produce sharper images and to record the growing foliage of trees in sunlight. He experimented with mica as a stable base for negatives, and was an early user of the albumen and collodion processes on glass. He was deeply interested in the properties of light and chemicals, and published numerous scientific papers. Maskelyne later became Professor of Mineralogy at Oxford, Keeper of Minerals at the British Museum and Member of Parliament in Gladstone's government.

STUART-WORTLEY, COLONEL HENRY (1832–1890)

Archibald Henry Plantagenent Stuart-Wortley was born 26 July 1832 at Wortley, Yorkshire. His father Charles James Stuart-Wortley died in 1844. His mother Lady Emmeline née Manners, was a poet and travel writer and his sister Victoria, as Lady Welby, became a pioneer in the field of semantics. Henry joined the army in 1848 as a lieutenant and served as a Captain during the Kaffir Wars 1850–53 in Africa and in the Crimea in1854–55 Deputy-Assistant Quarter Master as a Brevet-Major. It was while in Africa in1853 that Stuart-Wortley took up photography and later observed Roger Fenton in action in the Crimea in 1855. After his mother died while travelling to Beirut in October 1855 Stuart-Wortley escorted his sister back to England where he remained on half-pay during 1856, briefly pursued a career in politics in 1858–59 and retired by sale of his commission in February1862 being granted the honorary rank of Lieutenant-Colonel.

Photography became a vocation for Stuart-Wortley by 1860 and he sought advice from photographic innovators, particularly in the new 'dry 'collodion processes, including Thomas Sutton and George Wharton Simpson, respectively editors of *Photographic Notes* and *Photographic News* who looked to the leisured amateurs to advance photography. Of particular interest in these years was the search for a means to capture motion in photographs, i.e. with exposures under about a second and the development of various "dry" processes to preserve the sensitivity of wet-plates for use outdoors and over the decade the development of dry- collodion plates and developers.

Stuart-Wortley took a trip to India in 1860 where he practiced his craft but it was on his Mediterranean travels in 1861 that he began to apply methods of his own for securing the desired "instantaneous" photography. He must have been familiar with the work of pioneer marine photographer of the 1850s John Dillwyn Lewellyn and the secret of Gustave Le Gray's dramatic "moonlit" effects achieved by photographing directly into a cloud-covered sun at mid-afternoon. Stuart-Wortley however, used a fast wide aperture and learned to whip his cap over his Dallmeyer triplet achromatic lens in under a second. He used a version of a dry collodion process in the field, a light-tight carrying box of his own design, fixed the negatives at night and then intensified the thin plates on his return. On his return to England his atmospheric Italian pictures showing the belching Mt Vesuvius, waves and rich cloud effects gained him membership in 1862 of the Photographic Society of London and an honourable mention as at the Society's International Salon. As referenced from "9th Annual Exhibition of the Photographic Society London," *British Journal of Photography,* January 15 1863 p.31, his

cloud studies were described as "gems" of the 1863 salon and these and his portraits up to10 × 12 inches were noted for their size.

By 1863 Stuart-Wortley was on the Council [of the Photographic Society] and later served as Vice President at various periods over the next twenty years. From 1863 he exhibited regularly at the Photographic Society of London and received medals there, at the Royal Polytechnic Society of Cornwall, and the Manchester Photographic Society as well as at the Société française de photographie in Paris where his "A Wave Rolling in" was praised. He also began lecturing and contributing papers to the *Photographic News* and the *Photographic Journal* of the Photographic Society of London where his long article "On Photography in Connection with Art" appeared in October 1863. In it he describes how the beauty of a sunset serves as a respite from the vexations of life and an inspiration. He thus recommended amateurs get "life" in their pictures with some form of rapid process and told of his own success with adding bromide to collodion and liberal nitric acid in the bath. This was Stuart-Wortley's only manifesto; his succeeding articles were mostly concerned with plate sensitivity. His quest to capture the ephemeral beauty of seascapes was not mere rising to a technical challenge but embodied deeply felt belief that spiritual comfort and values could be expressed in photographs of fleeting natural phenomena.

In 1864 Stuart-Wortley settled in Rosslyn House, St John's Wood, London where he built a studio, and in 1865 married Augusta Vershoyle—the couple divorced in 1878. He also turned professional in 1864 forming the United Association of Photographers, an ambitious multifaceted commercial franchise company; His brother-in-law Sir William Welby, was a shareholder and Director. The Association aimed to specialize in upper class and royal portraiture and over the next few years registered 82 portraits in the Copyright Office. They promoted new products in various formats—chiefly the German Jacob Wothly's 1864 uranium and silver process; an early but ultimately unsuccessful form of collodio-chloride printing-out paper—and released art reproductions in the new carbon process. The venture and was not as successful as hoped and in 1866 Stuart-Wortley took on a position as Secretary to his uncle, Lord John Manners, at the Department of Works. The United Association of Photographers company was liquidated in1867.

Through the late 1860s Stuart-Wortley continued exhibiting and publishing unusually large portraits and art reproductions in carbon including a series old master drawings in the collection of his relative the Duke of Rutland at Belvoir Castle In 1869 James Sheldon Wholesale Publishers of London released a series of card mounted albumen prints "Photographed from Nature by Colonel Stuart-Wortley." His "moonlit" seascapes also developed new scale and drama in the late 1860s and came with poetic titles.

In 1872 Stuart-Wortley again tried business when he founded the Uranium Dry Plate Co. to market his own urano-bromide dry-plate negatives. Despite energetic promotion, further demonstration in 1873 that a strong alkaline developer considerably increased the sensitivity of his plates and endorsement of the plates by Captain William Abney, the business was sold in 1875. A year before the Lord Chancellor appointed Stuart-Wortley as Head of the Patents Museum at South Kensington. This position evolved into that of Keeper of Machinery and Inventions, which he held until retirement in 1889.

Wortley turned his enthusiasm in the late 1870s to further the cause of carbon printing and then later gelatine dry-plate processes. He exhibited widely, winning a medal for large figure studies in 1875 at the Royal Cornwall Polytechnic and medals at Philadelphia Centennial in 1876 for large portraits and his new almost abstract large seascapes. He returned as a Vice President at the Photographic Society from 1875–1888 and served as a Trustee of Photographer's Benevolent Society formed in 1874 with Lord Hawarden, whose late wife the amateur photographer Clementina Hawarden, had also won medals for "instantaneous" prints at the Photographic Society of London exhibition in 1863. In 1879 he discovered that gelatine emulsions kept at a high temperature could be made sensitive over a few hours rather than days.

Stuart-Wortley travelled during and after his military service to Africa, Turkey, Ceylon, India, Greece, Turkey, Europe and the Mediterranean. In 1880 he undertook a world tour with his new wife Lavinia, neé Gibbons. The couple travelled via Australia and New Zealand to Tahiti and on to New York. He carried his own gelatine dry-plates especially modified to withstand the heat of the tropics and a mechanical shutter of his own invention to cater for the shorter exposures needed for the bright light of the Pacific. In 1882 he published a book illustrated with collotypes titled *Tahiti: a series of photographs taken by Colonel Wortley with letterpress by Lady Anne Brassey*. In addition to his photography Stuart-Wortley was an expert in marine fauna and maintained a large collection of British specimens in aquaria. He called on ethnographic collector William Macleay in Sydney in February 1880 and a photograph of the latter's collection of native artefacts appears in the Tahiti book ascribed to that of Mr Flockton.

Stuart-Wortley continued to exhibit until the mid-1880s and resigned from his position at the South Kensington Museum in 1889 due to ill health. He died 30 April1890 in London. In 1898 a group of fifty prints were exhibited for sale at the International Exhibition of the Royal Photographic Society. The fate of the bulk

of his personal archive is not known; the Huntington Library and Art Gallery, California holds 27 seascapes that were found within Lady Annie Brassey's travel albums and were acquired in 1923, and the J.Paul Getty Museum holds 35 seascapes—31 of which were collected by Sam Wagstaff in the late 1970s.

GAEL NEWTON

Biography

Archibald Henry Plantagenet Stuart-Wortley was born on 26 July 1832 in Wortley, Yorkshire. He first took up photography in Africa in 1853 while in the army and began exhibiting portraits and dramatic 'instantaneous' seascapes in 1862 the same year he was elected as a member Photographic Society of London later serving on the council and as Vice-President on and off until 1884. He contributed papers to the *Photographic News* and *The Photographic Journal*. In 1864 Stuart-Wortley formed the United Photographers Association, a commercial franchise liquidated in 1867and from 1871–74 marketed his own plates through his Uranium Dry Plate Company. He is recognised as the author of one of a number of "dry" collodion processes in the 1860s and 70s. Simultaneously with his photographic work, he held several paid positions. He died in London 30 April 1890. Stuart-Wortley is best known aesthetically for his large "moonlit" seascapes with poetic titles. A series of his nature studies published by James Sheldon, London in 1869 and proved popular with artists. His 1882 book *Tahiti: A Series of Photographs…with letterpress by Lady Brassey* was illustrated with collotypes from images made in 1880.

STUDIO DESIGN AND CONSTRUCTION (1840–1900)

George Cruikshank's 1842 cartoon showing Richard Beard making a daguerreotype at the Royal Polytechnic Institution in London is believed to be the earliest illustration of a photographic studio. The cartoon was created as an illustration to accompany S. L. Blanchard's poem "The New School of Portrait-painting." In that woodcut we see a surprisingly sophisticated studio design, considering that portrait photography had only recently been introduced, and that Beard's studio was the world's first.

Daylight was the exposing light source, supplied through a glass ceiling. A system of calico blinds could be drawn or opened to control the direction and intensity of the light. The subject sat on a raised dais, with a moveable screen overhead—to reduce glare on the top of the head. The dais could be moved at will around the circular walls of the studio, to ensure that the subject was lit as well as prevailing daylight conditions permitted.

Cameras were fixed on a platform suspended from rails around the walls of the studio, ensuring that the camera to subject distance remained fixed, eliminating the need for the camera to be focussed before each exposure. In the Cruikshank cartoon, two cameras—presumably offering two different plate sizes—can be seen on the platform while the photographer, standing on a set of steps, times the exposure.

With exposures running into minutes on dull days, and still very long even in the brightest of light, the subject was held in place with a head clamp.

Top lighting on its own was found to result in deep shadowed eyes unless reflectors were used to direct more light directly into the subject's face. A more satisfactory answer was a studio where side lighting light could also be introduced—the top floor of a building with large windows as well as skylights being one of the options. The alternative was a large greenhouse-like glasshouse structure, fitted with screens and blinds.

That basic idea of a glasshouse studio where light could be controlled by blinds remained the guiding principle of studio design for several years. In today's studio, the photographer starts off in a black room with

no light, and introduces light where required. The early practice of starting off with diffuse even lighting and removing light where it was not needed arguably yielded a much more natural effect.

It had its drawbacks, however. The more the photographers used baffles and shutters to create special visual effects, the longer the exposure times became. Julia Margaret Cameron**'s** sitters frequently complained about exposures running into several minutes as the great portraitist sought to create dramatic effect.

Many early studios were built on the roofs of tall buildings, ensuring even and consistent lighting. According to a newspaper report in the *Glasgow Herald* in 1843, the location of the studio was to ensure that 'the light of day which acts to him [the photographer] the part of a pencil, may have free and uninterrupted access.' But, of course, in cities, that high position surrounded by chimneys brought with it soot and smog from coal-burning fires.

Before the end of the 1840s, converting the upper floor of a building to give good window space—facing north if possible—and a large skylight, offered the ideal combination of top and side or front light. Those walls not replaced with glass were painted white or light blue, to ensure the highest actinic value of the reflected light.

In 1849, Henry Hunt Snelling writing in his book *The History and Practice of the Art of Photography* (New York: G. P. Putnam) noted

> In choosing your operating room, obtain one with a northwestern aspect, if possible; and either with, or capable of having attached, a large sky-light. Good pictures may be taken without the sky-light, but not the most pleasing or effective.

That advice was echoed in manuals throughout the 1850s. Keeping the glass clean, however, posed a considerable challenge. Dirty glass, polluted by smoke not only increased exposure times by acting as a filter, but also radically altered the actinic value of the light. The blue content of the daylight to which the daguerreotype and wet collodion processes were sensitive was considerably reduced by having to penetrate the yellow tar stain which smoke and rain overlaid on to the roof glass. Writing in his 1868 *Manual of Photographic Manipulation,* William Lake Price observed that

> Thus the light cast on the sitter traverses a villanous compound of concentrated coal smoke and the victim, impaled on the head rest, is made to suffer double the requisite amount of "exposure."

To alleviate this suffering, he outlined an ingenious and semi-automatic system of pipes and pumps for washing and cleaning the skylight. An added bonus of this system, he noted, was the cooling effect on the studio itself by the periodic flushing of the roof with cold water during hot days.

The head clamp remained a part of studio portraiture into the 1870s, with a wide variety of devices being invented and marketed. Some were free-standing on heavy cast-iron bases, whilst others were built into chairs. All were designed to reduce the instances of a portrait being ruined by the subject inadvertently moving his or her head during exposure.

The idea of painted studio backgrounds was first mentioned in Antoine Claudet**'s** 1841 British patent No. 9193 'Daguerreotypes' although there is no evidence that his rights to such an 'invention' were ever upheld in any court of law. In his patent he stated that

> When the daguerreotype process was originally applied to portrait taking it was necessary to place behind the sitter some plain background or neutral tints in order that the outlines of the figures should be delineated and brought out. I have now improved this by applying behind the sitter some backgrounds of painted scenery representing landscapes, interiors of apartments, and other representations adapted to the taste and habits of the sitter or to his profession.

The studio portrait was further embellished by the balustrades, potted plants and other ephemera which continued to be used throughout the *carte-de-visite* and cabinet portrait eras. The earliest known daguerreotype of a photographer at work (in the collection of the National Museum of Photography Film and Television, Bradford, UK)—showing Jabez Hogg making a daguerreotype portrait of William Johnson in 1843—depicts a curtained window-frame with trees beyond, ornate trellis work, a classical sculpture, stools and chairs, and a caged bird above the camera (watch the birdie).

With pitched glass roofs, the photographic studio was much prone to leakage, and manuals and journals offered wide ranging advice on how to render the 'operating room' watertight. Ingenious seals were suggested—the most elaborate being the 'Philadelphia Sash' which, it was claimed, guaranteed that any leakage would be carried away by internal drainage ducts. The dual problems of waterproofing, and of minimising the impact of framing bars which might cast soft uneven shadows, brought suggestions that the thick plate glass be cut in such a way that each sheet slotted into a groove on the next.

As photographers became more concerned with the creative exploitation of light, a number of major figures started to break away from the tradition of using north light. Significant amongst these were O. J Rejlander, and Valentine Blanchard whose south-facing studio in London's Camden Town (1866) used a series of movable opaque screens to diffuse and reflect the lighting. This approach permitted much greater variety of contrast

and direction, permitting the photographer more control over visual effect.

As late as 1911, in the *Encyclopaedia of Photography* (Bernard Jones, Editor), and despite the fact that various forms of artificial light had been readily available for more than two decades, the daylight studio is still given prominence.

The daylight studio, while allowing photographers considerable control over lighting effects, limited the hours they could work. On dull winter days, low light levels resulted in over-long exposures. Several portrait photographers in the 1860s and 1870s advertised their studio opening times as 'weather permitting.'

With the widespread availability of gelatin dry plates from about 1880, with their considerably increased sensitivity, exposure times in daylight studios were reduced to only a few seconds, allowing photographers to refine the lighting techniques they had used for three decades without unnecessarily inconveniencing their sitters.

Thus the introduction of artificial lighting in the 1850s was, at first, not widely taken up by portraitists. For those who did embrace the new technology, it considerably extended working hours. John Moule's patented 'Photogen' light source—burning a powdery mixture of antimony, sulphur and potassium nitrate—was advertised in 1857 as a "rival to the sun," but was not adopted by many portraitists. Perhaps the noxious smoke it generated had a significant impact on its popularity.

Credited with the first successful use of flash was Manchester photographer Alfred Brothers in May 1864, although initially on location rather than in the studio. By the end of that year, however, he was using magnesium ribbon to create a sustained high-intensity light for studio portraiture.

Amongst those to embrace the possibilities of artificial lighting were itinerant photographers, who took their caravan studios to villages, towns and fairgrounds throughout the country.

A writer for the journal *Photographic News* (Vol. 30, no.1434, February 26 1886), described such a photographer's caravan. Attracted by a notice offering photographic portraits in five minutes by electric light, the writer entered the caravan just before the studio's closing time of 11pm remarking that "The desire to witness this astonishing advance in photographic science could not be resisted."

> So I ascended the wooden steps to the caravan…The studio was certainly no more than five feet by three. It was painted a light blue, and in the left-hand corner, fronting the sitter, was a sort of glass cupboard placed diagonally. The glass was blue, and its use I was presently to see. The studio was wholly devoid of "properties; its solitary article of furniture was a common Windsor chair, behind which was a well-worn head-rest…The head-rest was applied in half-a-second, and in a second more the artist had his head beneath the focussing cloth, and a camera with four lenses was protruded towards my face…… ……he was profoundly indifferent as to my expression…All he said was: "Now don't be afraid, it won't hurt you," and up blazed an intense light in the blue-glass cupboard. I must confess that the sensation of the blinding blaze was not pleasant. The exposure was probably five or six seconds.

The lighting was generated by a device known as the Luxorgraph, patented in Britain in 1878 by Alder and Clark, and described in E. J Wall's 1897 *Dictionary of Photography* (London: Hazell, Watson and Viney) as 'A large lantern-like device with tissue paper front in which pyrotechnic or other compounds can be burned to give artificial light for portraiture.'

The photographer stressed that this was not a magnesium wire or ribbon light source (which was covered by patents), but "Luxorygraph powder." As to the exact composition of the powder, he did not elaborate. The combustible powder was flared by a gas jet which was in turn ignited by an electric spark. The device produced a very flat lighting effect especially when used in such confined spaces.

Credited with being the first studio in the United Kingdom to offer portraits by electric light was that of Henry Van der Weyde, an American photographer who had opened premises in London's Regent Street as early as 1877. To power what he advertised as "The Van der Weyde Light" he generated his own electricity using a gas engine—another first. It was not until the late 1880s, that portraiture studios generally started to embrace the new lighting technology, and several changed their names to incorporate 'Electric' or 'Electric studio' into their names. Thus, for example, Thomas Charles Turner, who had been in business since c.1875, started to advertise his "electric and daylight" studios in 1891, and celebrated that fact on the backs of his cartes-de-visite. Electric lighting came in a variety of forms—gas lamps as well as acetylene and arc lamps.

Once artificial light became commonplace, photographers were able move their studios from the top floors of buildings to ground floor locations, offering easier access to their customers. Many, however, used electric light to augment or partly replace daylight, simply extending their ability to work independently of weather conditions. Many daylight studios continued in use well into the twentieth century.

STURMEY, JOHN JAMES HENRY (1857–1930)

Henry Sturmey, born in the Somerset village of Norton-sub-Hamden February 28, 1857, started a career in the burgeoning late Victorian leisure industry through a passion for cycling. An early promoter of the Bicycle Touring Club (later Cyclists' Touring Club), Sturmey teamed up with the publisher William Iliffe to edit the "Cyclist," after his compilation of the "Indispensable Bicyclist's Handbook in 1877. In the early 1880s, Sturmey moved into photography, joining forces with the journalist Walter Welford to produce *Photography* (1888), later absorbed into *Amateur Photographer* (founded 1884).

Sturmey's collaboration with Welford led to the publication of their two major encyclopaedias, *The Photographer's Indispensable Handbook* (1887), on photographic apparatus, and the *Indispensable Handbook to the Optical Lantern* (1888). Sturmey also edited the *Photographic Reference Book* (1897; 2nd ed. 1904), as well as the first volumes in the series *Photography Annual*, from 1891.

By the mid 1890s, however, Sturmey's main area of interest had passed to the automobile. He founded and edited Autocar (1895), and invested heavily in the Great Horseless Carriage Company; in 1900 he became one of the early victims of an automobile accident. Sturmey's later career is entirely linked to the car industry, founding Sturmey Motors and launching the Lotis car range, which went into liquidation in 1911.

In later life, Sturmey concentrated on the design and patent of a five—hub cycle gear, but this never reached the manufacturing stage. He became something of a recluse in his final years, dying in Coventry January 8 1930.

SUN ARTISTS JOURNAL

The *Sun Artists Journal* is a significant example of photogravure in the history of the photographically illustrated book. *Sun Artists* was published in eight parts by Keegan Paul, Trench and Trübner, London between October 1889 and July 1891. Each Issue was devoted to the work of a single British photographer, illustrated by four hand-pulled photogravures, together with an introductory descriptive essay. Laurence Housman was commissioned to provide the cover design for the series, the letterpress being by the Chiswick Press.

Particular care was taken by the publisher of *Sun Artists* to identify the individuals who prepared the gravures for publication, all leading exponents of photogravure at the time. Mr Dawson of the Typographic Etching Company, himself an acclaimed photographer, made the etchings for Issue 1. Mr Cameron Swan of Messrs Annan and Swan made those for Issues 2, 3, and 4 while the etchings for Issues 5–8 were made by Mr W.L. Coll.

Issue number 1 featured the work of Colonel Joseph Gale (d. 1906) (essay by George Davison): *Sleepy Hollow, A foggy day on the Thames, Brixham trawlers, Homewards from the plough.*

Issue 2, Henry Peach Robinson (1830–1901) (essay by Andrew Pringle): *Carolling*

A merry tale, Dawn and Sunset, When the day's work is done.

Issue 3, James Booker Blakemore Wellington (1858–1939) (essay by Graham Balfour): *Eventide, A tidal river, East Coast, The broken saucer, A study of sheep.*

Issue 4, Lyddell Sawyer (1856–1900) (essay by Rev. F.C. Lambert): *Waiting for the boats, The castle garth, In the twilight, The boat builders.*

Issue 5, Julia Margaret Cameron (1815–1879) (essay by P.H. Emerson): *The kiss of peace, Sir John Herschel, Lord Tennyson, The day dream.*

Issue 6, Benjamin Gay Wilkinson (1857–1927) (essay by Rev. F.C.Lambert):

Sand dunes, Prawning, A pastoral, A windy corner.

Issue 7, Mrs F.W.H. Meyers (1856—1937) (essay by John Addington Symonds):

Robert Browning, Right Honourable W.E. Gladstone, M.P., Rebekah at the well, The summer garden. Myers, née Eveleen Tennant, was a highly regarded portrait photographer.

Issue 8, Frank Meadow Sutcliffe (1853–1941) (essay by Charles N. Armfield):

Water rats, Dinner time, Excitement, Sunshine and shower. The six man editorial board for *Sun Artists*, headed by W. Arthur Boord, announced in the introduction to the first issue that they sought to "emphasize the artistic claims of photography by reproducing the best work of the best photographers in the best possible manner"

and noted that previous efforts in this direction "have almost invariably had a basis personal to the artist reproduced." The board made clear that the members were themselves amateurs,"corporately unassociated with any particular phase of photographic endeavour" and expressed the hope that the whole series would form a true representation of modern photographic photography. They provided no indication that the series would be restricted to British photographers nor any criteria for the selection of artists or of individual images.

They were, however, were at pains to state that they would provide no prediction on the nature or extent of future issues, especially the single artist single issue format. Perhaps more importantly in view of their objective, they gave a clear undertaking that all hand work on the plates "would be scrupulously avoided."

Significant changes occurred during the life of the series. Issue 7 was advertised as featuring the work of J. E. Austin but he was replaced, without comment, by Mrs Meyers. Similarly Mr Seymour Conway was advertised for Issue 8 but replaced by Frank Sutcliffe, again without comment.

The editorial board closed the series at Issue 8. Responding to criticism that younger photographers had not been represented, they stated that the series was "a monument to great British photographers who had brought honour to the Art.," a significant change in direction and emphasis from their originally stated aim. One can infer that the series was initially a commercial success with the first Issue going to reprint and the publishers offering a premium on behalf of a subscriber for an undamaged copy of that issue. Similarly, the published excerpts of reviews might indicate some critical success both for the series and the original concept. Using either the citerion of "best photographer" or that of "great British photographers," it is difficult to understand the selection of some of the artists represented and the omission of others. While Emerson was a noted author on the aesthetics and practice of photography, the omission of his photographic work is highlighted by his appearance as critic for the Cameron images. Similarly the inclusion of Meyers appears to say more about the social context of the editorial board than its commitment to the best in photography. While John Addington Symonds is laudatory in his comments on Meyers portraiture, other critics found the figure "amateurish" and as Fletcher noted in the *RPS Journal*, December 2004, "the art does not hide the art." On the other hand it must be noted that Symonds essay represents one of the first attempts to address photography in critical language with a vocabulary other than that of painting or drawing. *Sun Artists* appeared at a critical time in the history of photography. George Davison (1854—1930), the author of the essay in Issue 1 was to launch the Pictorialist movement with the exhibition of his image *The Onion Field* at the annual exhibition of the Royal Photographic Society in 1890. Davison later became one of the founding members of The Brotherhood of the Linked Ring. During this time Peter Emerson recanted his original view that photography should seek to reflect human vision, stating in 1890 that photography lacked the capability to render a natural subject accurately. It is more likely that the fundamental change that was occurring in photography at that time, already represented by Davison's *Onion Field* and anticipated by Sawyer's *The Castle Garth* had rendered both the style and substance of *Sun Artists* no longer representative of the cutting edge of contemporary art photography. At a different level, *Sun Artists,* appears to be the first attempt to showcase the work of individual artists using the best available technologies to faithfully represent the work to a wider audience. As such it might be seen to anticipate Alfred Steiglitz' *Camera Work.* Photogravure represented the fourth and most significant development in nineteenth century efforts to develop an efficient method of faithfully reproducing the photographic image on the printed page in continuous tone. Karl V. Klič, a Czechoslovakian residing in Vienna, utilised the Swan/Poitevin gelatinised carbon tissue technique to produce an intermediate image on a copper plate coated with an asphalt resin. Following exposure, the plate was etched in acids of varying strengths to capture the tonal range of the original. The plate was then inked, wiped and then printed. The resultant print was a faithful copy of the original image with the fine particles of ink providing a grainless, continuous image. Klič subsequently licensed the Thomas and Craig Annan of Glasgow to use his process in England and Scotland.

While dust grain photogravure had replaced collotype as the preferred method of reproducing photographic images on the printed page, it was replaced in the early 1890's by a further Klič development, half-tone. By 1890 the introduction of the halftone process had made photogravure virtually redundant for all but the highest quality reproductions of photography. Peter Henry Emerson's *Wild life on a tidal water*, (1890) used the new half-tone process for the reproduction of his images, although his later *Marsh leaves* (1895) is regarded as the finest example of photogravure in a printed book. Perhaps the best and final examples of dust grain photogravure for the reproduction of the work of the artist photographer are found in Alfred Steiglitz' *Camera Work* (1903 –1917).

A facsimile edition of *Sun Artists* was published by Arno Press, NY, in 1973.

SURVEY PHOTOGRAPHY

As a means of gathering visual evidence of the world, photography became useful in the 19th century to a number of activities associated with the idea of the survey. To survey generally means to ascertain and delineate the physical scope and specific characteristics of an entity or related entities, usually places or areas relative to their position on the earth's surface and often including people and objects. Though the activity of surveying can be traced back to antiquity, its significance with respect to developments in the modern world including the adoption of photography in its practice can be understood in light of scientific inquiry and exploration and the formation of national identities in the previous century; the geographical and geological survey and civil engineering were both practical outgrowths of eighteenth-century scientific advancement and political ideology. Surveying as a form of engineering and geographical demarcation emerged in order to articulate boundaries, topographical contours, and to establish zones of operation and the structures necessary for resource development, transportation, and commerce. It would then seem reasonable for photography to have joined preexisting representational and symbolic strategies ideal for conceiving geographical space: drawing and map and model-making procedures.

By the middle of the eighteenth century Britain and France had become absorbed with the lands and major features within their own borders, including distinctive monuments that were thought significant in the construction of a national patrimony. The Ordnance Survey of Great Britain began in 1747 as a military defensive measure to map the borders of England, but soon became an official government department to map the entirety of the United Kingdom. In the same year, France started a school in Paris for specialized training in public engineering projects, the *École des Ponts et Chaussées* (School of Bridges and Roads). That photography had come of age in this enterprise is witnessed by its having become part of the training of engineers in both of these rival countries almost concurrently: in 1856 at the school for Royal Engineers at Chatham, England, and the following year at the École. This civilian effort thus served to give momentum to the systematic use of photographs as a form of documentation of expanding industrial infrastructures and resource development in Europe and regions subject to colonialist expansion. Further, as national institutions took on more responsibility for the improvement of urban conditions, pictures of older streets or areas in decline became central to the demonstration that governments were attending to social need through new construction and civil engineering projects.

In France, sentiments toward educating the public in the past glories of its medieval history had been signaled early in the nineteenth century. *Voyage pittoresques et romantiques dans l'ancienne France* (1820–1878), a multi-volume work illustrated with lithographic plates, set a precedent for a growing "preservationist" movement that fed the collective imagination of the people. The *Mission Héliographique* was commissioned in 1851 by the Commission des Monuments Historiques, a group of authorities on the culture of France, to survey the country's architectural heritage with the camera. Photographic documentation for the purposes of preservation and restoration of selected monuments was the main thrust of the program, but the effort was not systematic nor did it appear to have the full authority of government behind it. Several of the photographers who were affiliated with the Mission Héliographique,

Watkins, Carleton E.. Cape Horn near Celilo. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 (2005.100.109) Image © The Metropolitan Museum of Art.*

including Gustave Le Gray and Henri Le Seq, had been formally trained in the studio of the painter Paul Delaroche; many of the several hundred images produced for the mission were thus endowed with a pictorial artistry and a marked skill with the variant paper processes of the period. Though the photographs were not utilized in any official capacity, this tentative embrace of the medium was soon to change. From the late 1850s to the end of the century the engineering school had amassed an enormous collection of pictures of public works, railways, bridges, and other constructions taken within France as well as other countries. Some of the photographers who had been affiliated with the earlier *Mission* and contributed to this and other archives, including Édouard Baldus, who produced views in the early 1860s of railway bridges for civil engineers who had worked on these projects. Charles Marville, who had also engaged in earlier documentary projects published by Louis Désiré Blanquart-Evrard's printing establishment *Imprimerie Photographique*, was commissioned by Georges Haussmann's *Travaux historiques* in 1865 to photograph the city streets while undergoing modernization under the latter's supervision.

As the major industrial powers extended their reach into other parts of the world, photography was employed to extract visual evidence from lands of scientific, archeological, architectural, and ethnological significance, economic promise, and political importance to probing western nations. In this respect, the medium was found useful by officers in the British army and the Government Civil Service. India especially was the site of an emergent economy of British intelligence and imperialism in which the camera was adopted readily enough for specific activities that may fall under the broad rubric of surveying: of reconnaissance, surveillance, and exploration of places and their inhabitants. One Philip Henry Egerton, for instance, was Deputy Commissioner of Kangra in the western Himalaya when he made a photographic excursion through the rugged mountain environment near the Tibetan border in 1863. His *Journal of a Tour through Spiti, to the Frontier of Chinese Thibet*, illustrated with thirty-six of his views of particular ethnographic and geological interest, was published by Cundall, Downes and Company the following year. Egerton's intentions to stimulate further exploration and encourage trade in the region were clear. British enterprise "would bring manufactures into the heart of Central Asia, extending civilisation to the barbarous hordes which people those vast tracks, and enriching the manufactures, exporters, and carriers of European produce, as well as Tartar Shepherds." (Egerton, 1864, pp. iv–v) More systematic efforts were to come almost immediately thereafter, with increased use of the camera for surveying the antiquities of the subcontinent in conjunction with the establishment of the Archaeological Survey of India. Photographs by various military and civilian operators would also be selectively acquired by professional and government agencies. Such collections as formed in the 19th century at the South Kensington Museum (which became the

Victoria and Albert Museum), the India Office Library and Records (acquired by the British Library), and the Royal Geographical Society (acquired by Cambridge University), testify to the robust application of the medium to the knowledge base of empire.

Having already achieved recognition for his explorations in charting the little known recesses of Africa, David Livingstone's Zambezi Expedition of 1858–64 sought to incorporate photography into the quest for knowledge of the principal features and natural resources of the eastern and central regions of the continent. The expedition was launched by Sir Roderick Murchison, geologist and President of the Royal Geographical Society, who aside from scientific interests also aimed to encourage agriculture and commercial activity among the inhabitants, thus remaining true to the colonialist project. The navigation of the Zambezi River was essential to the enterprise, and was consequently photographed in an effort to record the terrain along the water body. The expedition's botanist Dr John Kirk realized some success with the camera; his work provided images of the land that were useful in the study of disease and plant life. Such wilderness views could seem neutral enough on the surface as empirical data for scientific argument, yet they also literally and symbolically enacted a form of dominance over the native environment (consider the naming of indigenous places after British explorers or individuals of political distinction). Close ties existed between the British War Department's Topographical Department and the Royal Geographical Society, whose maps were employed for gathering information about foreign regions, including Africa. In 1867 Sir Robert Napier led a political rescue operation into Ethiopia, generally known as the Abyssinian Campaign of 1867–68, which is purported to have yielded 1500 photographs taken by a corps of Royal Engineers. The fact-finding, scientific contingent of the expedition was directed by Murchison once again, thus bearing further witness to the importance of the medium with regard to the survey in the double sense of the term: a coordinated effort to articulate of boundaries and landmarks and to ascertain features of scientific and political significance in the overall geophysical and ethnological comprehension of an environment.

The Abyssinian expedition was one of several geographical campaigns in which the Royal Engineers participated and included the camera as a survey instrument. Already in 1857, they had begun to work with photographs to assist in North American Boundary Survey. This was a joint enterprise between the United States and Canada to mark the boundary along the forty-ninth parallel to avoid possible contention over gold. Though the Americans had tried their hand at the medium, only the British engineers trained in photography seemed to have success. Their work, mostly produced in the Pacific northwest, comprised an official photographic record that made its way to the Secretary of State for Foreign Affairs in 1863. A corps of Royal Engineers was also hired to undertake extensive mapping and documentation of the Holy Land—Jerusalem, Palestine, and the Sinai Peninsula. Ordnance Surveys were conducted of Jerusalem in 1864, and of the Peninsula in 1868. These were chiefly geographical and scientific in nature, in part privately funded, and especially significant for strengthening the religious ties of Britain with the Judaic and Christian past of the region through the pictorial and cartographic identification of biblical sites. Thus, in the linking of picture with site, and the coordination of pictures with the procedures and symbolic meanings of mapmaking and the topographical survey, the survey became a process that was clearly more than a mere exercise in measurement and pictorial documentation.

While one could cite further cases related to expeditionary enterprise and ideology beyond the few examples discussed thus far, the survey as a projection of a larger vision of expansion is especially well evinced by the grand surveys of the American west between 1867 and 1879. These were geologist Clarence King's US Geological Exploration of the Fortieth Parallel, launched under the auspices of the US Geological Survey; Lieutenant George Montague Wheeler's US Geographic Surveys West of the One Hundredth Meridian; the US Geological and Geographical Survey of the Territories, led by the geologist Ferdinand Vandiveer Hayden; and John Wesley Powell's US Geographical and Geological Survey of the Rocky Mountain Region. The civilian and military men who were the leaders of the surveys recruited photographers to augment the communication of their findings to the scientific community, and to persuade government that additional expenditures for further campaigns were worthwhile. Among the best known of the operators were William Henry Jackson (with the Hayden survey), Timothy H. O'Sullivan (King and Wheeler), Carleton Watkins (King), E.O. Beaman (Powell), and John K. Hillers (Powell). Their works were distributed in stereographic form, single prints, and albums, and reproduced in print media both in the reports of the expeditions and in popular illustrated journals.

Survey activity during the nineteenth century was aligned with the growth and spread of modern institutions. In this period of positivist reliance on observable phenomena for knowledge of the world, photographic images were increasingly accepted as visual evidence of domestic and foreign places and public works important to cultural legacy and national determination. Photographs also began to meet the requirements for pictorial accompaniment in geophysical and anthropo-

logical study. The findings of scholarly, scientific, and government sponsored enterprises as well fostered a demand from the mid-century on for illustrated accounts of these activities in the popular journals. Overall, the quest for new knowledge verifiable through the agency of photography, among other systems of recording, has been characterized as a "compulsive visibility" (Marien, 2002, 79)—a double quest for knowledge, one related to an ideology of power, the other to a democratic idealism that attempted to bring cultural enlightenment to those accorded a place within the domains of western economies.

SUTCLIFFE, FRANK MEADOW (1853–1941)

British photographer

Frank Meadow Sutcliffe was born at Headingly on October 6, 1853, the son of Thomas and Sarah Lorentia Sutcliffe. He was the oldest of eight children. As a child Frank slept in his father's studio surrounded by painting equipment, plaster busts of classical sculpture, and a printing press. Thomas Sutcliffe was an artist working in oils and watercolors. He was also an etcher, lithographer and amateur photographer although none of his images appear to have survived. To encourage his children Thomas painted a diorama in one end of his studio complete with lighting and sound effects.

One of Frank's first creative works was achieved on the printing press. It was an etching of two ships used to create a letterhead for himself. The design survives in a letter Frank wrote to his brother Horace in 1869. He also worked as printer of his father's small books of stories written under the pseudonym of Jossy Hullarts. He was also the occasional illustrator of these stories. He had this to say about his childhood:

> I spent much of my childhood running up and down narrow lanes only wide enough for one carriage…The boy who has lived the country life and whose eyes and ears are open to every movement in hedge or bank or tree, is much more likely to have his eyes and ears around him than one who has lived among tram cars and smoke.
>
> When not out of doors my childhood was spent with tiles and bricks. This I believe was a capital education, give a child a heap of squares and triangles, and let him puzzle with them till he makes a picture or at least an ornamental design. He will not be at a loss to know how to place a group of figures afterward. (Frank Meadow Sutcliffe. "Factors in My Success." *The Photogram*, April 1902, 107)

In 1865, at age 14, Frank was apprenticed as a clerk at the offices of Tetley Brewery on Hunslett Lane in Leeds. He lasted eighteen months as an apprentice. This apprenticeship was during a period of his father's illness. While recuperating from his own experience with the city Sutcliffe discovered Lake Price's *A Manual of Photographic Manipulation* published in 1858 on the family bookshelf. His first camera was a 24x18 that he modified to an 8.5x6.5 with a 24" lens. It was John William Ramsden, a portrait photographer and founder of the Leeds Photographic Society who introduced him to the learned photographic journals whose articles covered the latest in scientific and technical matters relating to photography. His early work included portraits and still life studies. He also attempted an image of birds in flight before the use of stop motion photography was common knowledge.

In 1870 Thomas Sutcliffe moved his family to Ewe Cote approximately a mile from Whitby. Thomas died in December of 1871 and by the summer of 1872 Frank is photographing for a client in the Lake District. In 1872–1873 he photographed for Francis Frith a series of views of Yorkshire's abbeys and castles. It was from Frith that he learned to use tracing paper masks to achieve the proper tonal range in prints. He was also advised not to include people in the views since the customer was only interested in the view. During his work for Frith he makes an image called *Sunset after Rain* shot above Rievaulx Abbey. A family friend sent a copy to John Ruskin who invited Sutcliffe to visit him at Brantwood in September 1873 where he photographed Ruskin and the surrounding countryside.

He married Eliza Duck in 1874 and they moved to Tunbridge Wells in 1875 to establish a photographic studio. It was a financial failure and he returned to Whitby in 1876 to establish a studio in Waterloo Yard. It was a one man operation specializing in portraiture. On the verso of a carte mount c 1883 he advertised himself as photographer to Mr. Ruskin, a member of the Photographic Society of Great Britain and prize medals in photographic show in 1881 and 1882. In 1894 he moved the studio to 25 Skinner Street, Whitby where he was able to pursue his portrait work in a state of the art studio. He became a familiar sight in Whitby and developed a rapport with the fishing community. It was the rather rambunctious children of the fishermen who became his water rats. The "Water Rats" is the most famous of his photographs winning a medal at the 1886 Photographic Society Show in London. From his return in 1876 until he sold his business in 1922 Sutcliffe photographed in and around Whitby. His photographs show an understanding of the people and the community of Whitby that is unsurpassed. He began with the collodion wet plate switched to dry plates and then to cameras and roll film provided by Kodak.

In 1892 he joined the Linked Ring whose purpose was to promote photography as an art. He exhibited at the annual Photographic Salon of the Linked Ring from 1893–1904. In 1888 he had a one man show at the Camera Club in London and in 1891 he has a one man show at the Royal Photographic Society. However, it is not until 1935 that he is made an Honorary Fellow of the Royal Photographic Society.

He began writing journal articles in 1875 and went on to become an editorial contributor to *Photography* and between 1895–1913 he regularly wrote for *Amateur Photographer* and contributed to *The Practical Photographer, The Photogram* and *Camera Notes*. He also wrote a weekly column "Photography Notes" for the *Yorkshire Weekly Post* from 1908–1930. In 1922 he became curator of the museum of the Whitby Literary and Philosophical Society and continued in that position until March 1941. He died at his home in Sleights on 31 May 1941.

SUTTON, THOMAS (1819–1875)

English technical writer and photographer

Thomas Sutton was born in London's Kensington district on 22 September 1819. Very little is known about his early life. In 1846, he received a Bachelor of Arts degree from Caius College, Cambridge.

Sutton's first experience with photography was in 1841, when he posed for a portrait in Antoine Claudet's daguerrian portrait studio. At the time he was planning to continue his education in the direction of art, and some advice from Claudet made him consider becoming a photographer. A few weeks later, on a holiday in Jersey, he met an amateur daguerreotypist and started to pursue photography as a hobby; however, his first attempts were unsuccessful.

From 1842–50, study at Cambridge and the demands of married life seem to have prevented him from continuing with photography.

In 1850, he and his wife settled in Jersey, buying some land and building a cottage at St. Brelade's Bay. There he received some lessons from a calotype photographer known only as Mr. Laverty.

From 1851–53, during an extended voyage to Italy and Switzerland with his wife and son, Sutton made the acquaintance of two photographers based in Rome, Frédéric Flachéron and Robert MacPherson. Flachéron gave him further lessons in the calotype process, showing him the wet-paper technique he was using. MacPherson initiated him in the albumen-on-glass negative process. After trying both methods, Sutton settled upon the paper negative process.

Following his return to England in 1853, Sutton was commissioned by the London publisher Joseph Cundall to make twelve prints each of one hundred of his best negatives from Italy. Dismayed by the task, Sutton attempted to arrive at a developing-out printing process similar to the one used by Louis Désiré Blanquart-Évrard—whose photographic printing facility in Lille, France had published several impressive photographic albums. Failing at this, he sent Blanquart-Évrard some negatives he had made since returning to Jersey, asking him to print them. These were published by Blanquart-Évrard in 1854, under the title *Souvenirs de Jersey* [Souvenirs of Jersey]. Sutton also offered to pay Blanquart-Évrard one hundred pounds for the details of his developing-out printing process, but was politely refused.

In 1855, Sutton published a technical treatise titled *The Calotype Process: A Hand Book to Photography on Paper*, which attempted to cover all facets of the photographic process on paper known at the time. This was immediately followed by treatise titled *A New Method of Printing Positive Photographs, By Which Permanent and Artistic Results May be Uniformily Obtained*, in which Sutton outlined the steps for a developing-out printing process using whey, or milk-serum. The success of this procedure induced Prince Albert to suggest that Sutton set up a photographic printing facility.

Aware that he lacked experience with full-scale industrial printing, Sutton again contacted Blanquart-Évrard, asking for his assistance in establishing the printing facility. Blanquart-Évrard—at this point suffering from financial difficulties and realizing that Sutton's published procedure was a serious rival to his own—accepted the offer, and invited Sutton to tour his printing facility in Lille. There he showed Sutton his industrial printing methods without reservation, which Sutton later described in an 1862 article. Blanquart-Évrard's printing facility was then shut down; and in September 1855, the two men launched a new printing facility at Jersey, the Establishment for Permanent Positive Printing.

Sutton's business partnership with Blanquart-Évrard lasted about two years. During this time they published, at irregular intervals, a series of installments to a larger work titled *The Amateur's Photographic Album*. Each installment contained three to four photographs and sold for the price of six shillings. In January 1856, they also launched a photographic journal titled *Photographic Notes*, which ran as a monthly journal at first, then becoming fortnightly from September 1856. Blanquart-Évrard's contribution to either of these undertakings has yet to be fully determined.

As the editor of *Photographic Notes*, Sutton proved himself to be a venomous and opinionated writer. The journal was used for launching personal attacks and new photographic innovations were often treated with derision and scorn—only to be accepted in a contradictory, face-saving manner once Sutton's initial reactions had been proven wrong.

Largely overlooked, but nevertheless important, are a number of articles Sutton wrote and published in *Photographic Notes* during the years 1856-61, in which he expanded upon his earlier, 1855 developing-out treatise. Here he outlined a method of developed-out salt printing that yielded results virtually indistinguishable from ordinary, printed-out salted paper, while at the same time requiring much less exposure to light.

In 1858, Sutton published *A Dictionary of Photography*, which featured encyclopedic articles on every aspect of the photographic process, mostly written by himself.

By the late 1850s, Sutton's interests appear to have moved away from the chemical operations of photography and more towards optics. In 1859, he wrote that a triplet lens he had made from two opposing, achromatic plano-convex elements, with a small, bi-concave quartz element in between, corrected curvilinear distortion and curvature of field. But the lens was never manufactured. This was followed in 1860, by the introduction of a ball-shaped water lens, capable of a 100 angle of view. The lens was formed by two opposing positive meniscus elements, with water in between also acting as an optical component. The lens reached a limited scale of production and was capable of producing fine images, but was never widely used—in part because it required a curved ground glass, curved negative plates, and a curved contact printing frame.

In 1861, Sutton was appointed lecturer on photography at King's College, London, where he succeeded T. Frederick Hardwich; but within a few months he had resigned from the position, citing domestic problems caused by repeated travelling between Jersey and London.

In 1867, Sutton terminated his involvement with *Photographic Notes*, it then being absorbed by *The Illustrated Photographer*. Sutton and his family moved to Redon, in Brittany. There he lived in semi-retirement, contributing articles to the *British Journal of*

Photography, most notably his "Reminiscences of an Old Photographer," which was published under a pseudonym.

In 1874, Sutton moved to Pwllheli, in North Wales. He died very suddenly, allegedly from stomach cramps, on 19 March 1875.

ALAN GREENE

Biography

Thomas Sutton was born on 22 September 1819 in London. After studying at Caius College, Cambridge, he and his family moved to the island of Jersey. In the early 1850s, he made a number of calotype views of Rome, aided by lessons obtained from Frédéric Flachéron. Wanting to print his negatives from Rome, he became interested in the industrial, developing-out printing process of Louis-Désiré Blanquart-Évrard. This led him to devise a developing-out process of his own, the details of which he published in 1855. In 1855–1857, Sutton and Blanquart-Évrard founded an industrial titled photographic printing facility at Jersey. During this time they also started a journal *Photographic Notes*, which Sutton continued to edit until 1867. A prolific writer, Sutton wrote a number of technical manuals, contributed articles to different photographic journals, and compiled a photographic dictionary. He also was interested in optics, designing a triplet lens and a wide-angle duplet lens filled with water. He died on 19 March 1875 in Pwllheli, North Wales.

SUZUKI SHINICHI STUDIOS

The Japanese photographers Suzuki Shinichi I (1835–1919) and Suzuki Shinichi II (1855–1912) were simultaneously apprenticed to Shimooka Renjo. The connection was that Suzuki II married Suzuki I's daughter. Suzuki I was born Takahashi Yujiro in Izukuni. In 1854 he married into a Suzuki family, adopted the family name, and moved to Shimoda. That year he lost everything in a tidal wave and moved to Yokohama. In 1866 he became apprenticed to Shimooka and then left in October 1873 to set up his own Yokohama portrait studio which also sold souvenir albums to foreigners. That year he also changed his given name to Shinichi and saw his daughter married to Okamoto Keizo, also apprenticed to Shimooka. Okamoto changed his name to Suzuki Shinichi II. Suzuki I pioneered a technique for printing photographs onto porcelain and authored the *shajo* series which realistically documented the life and customs of rural communities. Retiring in 1892, his son Izaburo changed the studio name to I.S. Suzuki.

Suzuki II was born in Izu. Originally intending to be an artist, he switched to photography and in 1870 apprenticed to Shimooka for seven years. In 1876 he opened his own studio in Nagoya. Although successful, in 1879 he decided to improve his technical knowledge by studying for one year with the famous Isaiah West Taber in San Francisco, becoming the first Japanese photographer to study abroad. Returning to Japan he built an extensive studio complex in Tokyo which was known as the 'branch studio' to Suzuki I's Yokohama premises. Suzuki II won prizes at Japanese and European exhibitions, and he photographed many famous statesmen and members of the Japanese royal family. His success peaked in around 1896 and shortly afterwards he lost everything after speculating in the shipping business. He died in relative poverty and obscurity in 1912. Examples of work from the Suzuki studios can be found in the Tokyo Metropolitan Museum of Photography, Tokyo.

SWAN, JOSEPH WILSON (1824–1914)

British scientist and inventor

Born in Sunderland on October 31,t 1824, the physicist and electrical visionary Joseph Wilson Swan originally

trained as a chemist. Earlier in his career he was appointment as an assistant, and later partner, to the Newcastle chemist John Mawson. The company later became Mawson & Swan.

Swan is most widely remembered as the inventor of the incandescent filament electric light bulb in 1860. Due to the poor quality of vacuum pumps at the time, it took a further twenty years before he was able to demonstrate a lamp with sufficient luminance to be practical. By 1880 he had set up the Swan Electric Light Company.

In photography, Swan is credited with the introduction of the first practical carbon printing process in 1862—based on Alphonse Louis Poitevin's 1855 patent. He is also credited, in the 1870s, with the introduction of the gelatine bromide dry plate which evolved into the mainstay of the photographic industry and, a few years later, with the introduction of bromide printing papers.

With the chance discovery—while investigating materials to make electric light bulb filaments—of how to make fibres out of nitro-cellulose, he is credited with the creation of one of the first man-made fibres, later used widely in textile manufacture.

Swan was knighted in 1904, and died in Surrey on May 27, 1914.

JOHN HANNAVY

SWEDEN

News of the invention of photography reached Sweden with the speed of the stage-coach. Three weeks after Daguerre's invention had been briefly announced in Paris, a newspaper in Stockholm was able, on 28 January 1839, to report "one of the most important inventions of the century." More details became available during the autumn, after Arago's big introduction, and at Christmas that year, the bookseller Adolf Bonnier published a Swedish translation of Daguerre's manual.

Among those who bought the book were, naturally enough, the scientist Jacob Berzelius and his circle. He, as well as Carl Wilhelm Scheele before him, had been responsible for some of the chemical findings which made photography possible. The Swedish Academy of Science published continuous reports on the advances made in photography.

The pioneers, however, were to be found elsewhere. *G. A. Müller*, stage designer at the Royal Opera, acquired photographic equipment together with *U. E. Mannerhjerta*, once a pioneer in lithography and at this time a translator of French plays. Müller had learned his craft as an assistant of Gropius in Berlin, the stage decorator who had built his own Dioramas as direct copies of Daguerre's stage designs.

This was early in 1840, when another lithographer, the young Liutenant *L. J. Benzelstierna*, received an apparatus from the Swedish ambassador in Paris. In September 1840, these three men exhibited their views of Stockholm at the Royal Museum.

At the same time the visting French merchant Neubourg exhibited his Daguerreotypes in the Old Town, a few blocks away from the castle. One year had passed since the official announcement of the new invention, and four photographers were already exhibiting.

Müller and Mannerhjerta soon abandoned the daguerreotype. Müller followed Daguerre and built a Diorama in Stockholm. Benzelstierna became our first professional photographer, although not by selling his images: He choose instead to demonstrate, for an admission charge, the entire complicated process involved with the slivered copper plates. For almost two years he travelled Sweden, photographing and exhibiting.

While Benzelstierna toured the countryside with his rapidly ageing technique, new daguerreotypists were appearing in larger towns and cities. Many of the itinerant photographers during the first decades were Danish and German. Some of them took their time to train assistants and apprentices.

The greatest portraitist of this era was *J. W. Bergström*, whose life began in poverty and ended in riches: After ten years as a daguerreotypist he turned his interest to industry and made a fortune as a manufacturer. He left behind him a large work of masterly portraits, but it is his pictures from the sphere of his private life that attract our greatest interest.

Gradually, the itinerant daguerreotypists introduced new methods as the ambrotype. The style remained however the same. From the glass plates were also made positives on salt or albumen paper. Paper was also tried as negatives. The pioneers appear to have been *David Gibson* in Gothenburg 1851 and the painter *C G Carleman*, who was later to be one of the inventors of the halftone block. His first halftone blocks were printed in Swedish magazines in 1871.

The introduction of better negative-positive processes and the *carte-de-visite* format created a boom. The number of professional photographers increased from 12 in 1860 to 65 in 1865. Among them, an elite of about 20 organised themselves in a professional association.

The most legendary studio of the era was established by *Johannes Jaeger*, a German who after a few iterant years settled in Stockholm in 1863. In Gothenburg his equivalent was *Aron Jonason* The artistically inspired photographers included *Frans Klemming*, closely related to the school of national romanticism.

While studio photography developed technically, the first amateurs appeared with a freedom to choose their motifs. *Carl Curman* was a doctor, and the pioneer of the Swedish bathing resort. As a photographer he emphasised the greatness of nature in a romantic style. Painter

Severin Nilson was his opposite, using his camera to document the poor and urban slum areas.

August Strindberg tried photography during a few intensive periods. A journey through the French countryside aimed to create a social documentation in a new way, but his disregard for established techniques made the material unusable. Another project to photograph clouds failed for similar reasons. But the existing body of around 60 pictures consists mainly of strong portraits and auto portraits.

Several of Sweden's best photographers have been immigrants. To a greater extent, a number of Swedish photographers have produced their most important work in other countries. The most famous was *Oscar Gustav Rejlander*, who studied painting in Rome before moving to England. His "art photography" attracted a wide audience in the 1850s.

Otto Wegener, from the south of Sweden, opened in 1883 an elegant studio in Place de la Madeleine in Paris, competing with Nadar the Younger and Reutlinger. He signed his works simply by using his Christian name Otto. His period of fame lasted until the end of the century but the body of his work seems lost. Hence, he is overlooked by photo historians, except for a few footnotes in connection with his apprentice Edward Steichen.

John A. Anderson photographed lumberjacks and railroad workers in California, *Eric Hägg* documented the Gold Rush in the Klondike and *Gustaf Nordenskiöld* explored the ancient rock dwellings in Meza Verde, Colorado.

The Swedish tourist Association was formed in 1885 as a part of a nationalist movement. To help Swedes discover their own country, photographers were invited to portray landscape, wildlife an people in their home regions. A generation of versatile professionals found a reason to get out of the studios and deliver coherent portfolios of cities and countryside.

The signals of pictorialism were rapidly registered in the 1890s. Amateur *Gunnar Malmberg* and the professional *Herman Hamnqvist* were the first to introduce the gum bichromate process. The pictorialist era was dominated by photographers as *Ferdinand Flodin*, *John Hetzberg* and *Henry B. Goodwin*, but their main oeuvre was created after the turn of the century.

SWITZERLAND

The first announcement of Daguerre's discovery appeared in the Schweizerischer Beobachter on the 19th January 1839 and the first specimens of the new process were shown in St-Gallen and Zurich as early as October of the same year. In 1840, the French itinerant photographer named Compar was touring the country, followed by many others introducing the daguerreotype to an interested public and teaching its technique.

Even though the physicist and professor of veterinary surgery at the University of Bern Andreas Gerber (1797–1872) claimed in February 1839 to have been able to fix microscopic prints on silver chloride paper as early as 1836, one of the most important pioneers of early Swiss photography remains Johann Baptist Isenring (1796–1860), a landscape painter and engraver from St-Gallen. He succeeded in obtaining excellent portrait daguerreotypes already in November 1839. And in August 1840 he showed in his first photographic art exhibition ever examples of his art in St-Gallen, and later in Zurich. As an itinerant photographer, he worked and traveled with a "sun-wagon" in Switzerland, Southern Germany, and Austria.

During the 1840s, daguerreotype studios appeared in many cities. Beginning in 1841 the sculptor Antonio Rossi (1823–1898) ran a Kabinett in Locarno.

The optician and precision mechanic Friedrich Gysi (1796–1861) in Aarau added another branch to his business by producing daguerreotypes from 1843 onward, while in 1847 another optician, Emil Wick (1816–1894), decided to change profession and became the first daguerreotypist in Basle. Franziska Möllinger (1817–1880) began taking daguerreotypes views of main cities and landscapes around 1844. She published 15 of them as an edition of lithographs but only one original daguerreotype by this first Swiss woman photographer has come down to us. The lithographer Carl Durheim (1810–1890) in Bern produces daguerreotypes since 1845.

In the French-speaking part of Switzerland the diffusion of the new medium happened differently. Sev-

Durheim, Carl. Postmortem of a Child.

eral aristocratic families enjoyed close relationships to France and its scientific milieu and it is rather through this network that photography was introduced. A banker in Geneva, Jean-Gabriel Eynard Lullin (1775–1863) produced as an amateur daguerreotypist a remarkable photographic oeuvre depicting his relatives, his friends and his mansions. The mathematician and astronomy professor in Lausanne, Marc Secretan (1804–1867) published his ³Traité de photographie² in Paris in 1842. At the same time Les Excursions daguerriennes were issued by Lerebours, for which the painter, engraver and collaborator of Secretan, Frederik von Martens (1806?–1885?), engraved a few plates. In the early 1840s, the tinsmith Samuel Heer-Tschudi (1811–1889) provided them both with metal plates for their daguerreotypes, before he himself turned daguerreotypist in the mid 1840s. Despite the several mentions in the newspapers of views of cities, buildings and landscapes, the daguerreotypes which have survived are almost exclusively portraits.

Adrien Constant Delessert (1806–1876) who entertained close links with international photographic circles and was recognized as a photographer as well as a scientist, was instrumental in transmitting the technique of the Calotypes. Paul Vionnet (1830–1914), Secretan's nephew, learnt it from him in 1845 and was to use it as a means of documenting old buildings, monuments and landscapes. The tradesman Jean Walther (1806–1866) in Vevey, also taught by Constant Delessert in 1850, worked locally but took a series of remarkable views of Athens. Around 1855–60, Charles de Bouell produced a series of salt prints representing Basle and the archeologist, historian and politician Auguste Quiquerez (1801–1882, perhaps together with his son Edouard) documented the Canton of Jura with more than a hundred pictures of monuments, ruins and landscapes. In 1852/53, Carl Durheim created one of the most interesting group of Calotypes, the first large body of police photographs: about 220 portraits of itinerants without citizenship, vagabonds and criminals, commissioned by the new Federal Government. The use of photography for police purposes was introduced on cantonal levels soon after that. Many daguerreotypists began offering salted prints in the early 1850s, like Durheim in Bern, Christian Müller in Zurich or Wick in Basle.

Around 1860 large family businesses began emerging, most of them devoted to portrait photography and the production of local views. The Taeschler studio, founded by the watchmaker, painter, and later itinerant photographer Johann Baptist Täschler (1805–1866) was established in St. Fiden (near St. Gallen) in 1850 and forced to close after WWI. The German Jakob Höflinger (1819–1892) settled down in Basle in 1857. His firm did not flourish however, until the introduction of the *carte-de-visite*. His son, Karl Albert (1855–1936), and his nephew, August (1867–1939), took up the business in 1885 and managed it until the 1910s. The inventor of the Pinacoscope (a projector for colored slides), Johannes Ganz (1821–1886) opened a store in Zurich in 1859. His son Rudolf (1848–1927), a great portraitist, sold the company to Camille Ruf (1872–1939) in 1902. Another German, Johann Linck (1831–1900) arrived in Winterthur in 1863 and opend his own studio a year later. Apart from portraits, Linck specialized in exterior and interior views of the plants and factories in town documenting the booming industrial growth beginning in the 1870s.

Henri-Antoine Boissonnas (1833–1889) active in Geneva in the clock-making industry started a new business in 1864–65, succeeding the photographer Auguste Garcin (1816–?). First taking landscape and city views, he specialized in children portraiture. After his death his sons took over, Edmond-Victor (1862–1890) inventing ³Orthochromatic² plates, for which he received a silver medal in the Vienna photographic exhibition of 1882. Fred (1858–1946), the most famous of the family, was a successful businessman and a great artist at the same time, creating refined studio portraits and impressive tableaux vivants. He experienced with a large variety of printing techniques and became one of the only internationally recognized Swiss Pictorialists. Since the 1860s, the most important portrait atelier for the Lausanne bourgeois society was run by the De Jongh family. After working with Niepce de St-Victor in France, Alphonse Dériaz (1827–1889) established himself in Morges in the 1870s taking studio portraits and occasional industrial views. His son Armand (1873–1932) opened a business for postcards and alpine panoramas.

Early examples of Swiss landscape photography are scarce: Durheim took a few pictures of the Bernese Oberland as early as 1849, Samuel Heer even earlier, but no trace of the latter's pictures survive. However, Swiss landscapes became well known through the work of foreign photographers, artists, scientists, alpinists and travelers like Adolphe Braun, Francis Frith, William England, Giorgio Sommer, who produced large corpuses covering the whole country, or like Aimé Civiale, F. Donkin, G. Roman, the Bisson brothers. who focused on the Alps. Around 1860, it was Garcin from Geneva who provided Swiss views for tourists. Johann Adam Gabler (1833–1888) in Interlaken did the same in alpine areas beginning in the 1860s just as Romedo Guler (1836–1909) in Davos would do in the Grisons a decade later.

Carl August Koch's (1845–1897) alpine photographs attracted attention in the National Exhibition of 1896 in Geneva.

Even if the Charnaux brothers took pictures in the Alps, they are better known for the very broad selection of views of Switzerland they offered in the 1870s and 1880s, thus anticipating the industrial ventures of the firms Schroeder & Cie, Photochrom (later Photoglob after the fusion with Schroeder in 1895) and Gebrüder Wehrli, which merged into Photoglob in 1924. These tree companies flooded the market with commercial images of all areas of the country. Whereas the brothers Wehrli produced only black and white pictures, Photochrom specialized in polychrome photolithographs taken by its anonymous operators all over the world and sold to an increasingly picture-hungry international audience.

SZATHMARI, CAROL POPP DE (1812–1887)

Romanian portrait photographer

The Romanian photographer Carol Popp de Szathmari was born in Transylvania and moved to Bucharest by the age of eighteen. He trained in art, and embarked

on a career as a court painter before taking up the daguerreotype c.1844 and establishing himself as a portrait photographer. By 1848 he was using albumen-on-glass. By the early 1850s, he was working with collodion.

Szathmari took his camera to war a full year before Fenton, photographing the early months of the Crimean conflict along the River Danube. He also reportedly had a horse-drawn darkroom van with him, and, like Fenton, found himself under fire.

Unlike Fenton and others, whose photography was unashamedly partisan, Szathmari's political contacts enabled him to photograph the war from both sides. Thus his images showed the Russian troops and their fortified positions as well as Turkish units, field hospitals and military leaders. It was while working at a Russian field hospital that he came under fire from the Turkish artillery.

After the war, Szathmari compiled albums containing 200 images from the campaign which were widely acclaimed throughout Europe. Amongst the reported recipients of copies of the album were Napoleon, Queen Victoria, the Emperor of Austria, and the pianist Franz Joseph Liszt. The images were exhibited at the Exposition Universelle in Paris in 1855.

He also photographed the Turkish-Russian-Romanian War of 1877 at age 65.

JOHN HANNAVY

T

TABER, ISAAC WEST (1830–1912)

Isaac West Taber was born in New Bedford, Massachusetts on August 17, 1830. In 1854, Taber opened a daguerrotype studio in the town, and with his brother Freeman Augustus Taber, subsequently ran a studio in Syracuse, New York, 1857–1864. Taber then moved to San Francisco, operating on behalf of Bradley & Rulofson until opening his own gallery in 1871. He took over Carleton Watkins Gallery in 1876.

Taber exhibited prominently in the 1877 San Francisco Art Association show, and the Mechanics' Institute Exhibition in 1880. In 1880, he published *Photographic Album of Principal Business Houses, Residences and Persons*, as a promotional venture, and photographed Kalakaua, King of Hawaii during a Pacific cruise. In 1885 Taber developed a method for enlarging and printing fingerprints, and opened a factory for dryplates. In 1894 Taber obtained exclusive rights to photograph within the grounds of the San Francisco Midwinter Fair, and in 1897 opened a branch of the Taber Bas Relief Photographic Syndicate in London.

Taber's studio was totally destroyed in the San Francisco earthquake of 1906, including 80 tons of portrait negatives. He died at his home in San Francisco on February 22, 1912.

TABLEAUX

The tableau is a combination of visual and theatrical arts, consisting of costumed figures arranged in static poses so as to create the effect of a picture. In the nineteenth century, the tableau vivant, or living picture, imitating a well-known work of art or literary passage, was tremendously popular both as a private amusement and as public entertainment. In their most elaborate form, carefully posed and lit tableaux were staged behind large gilt frames, covered with a layer of gauze that imitated the effect of varnish on an old painting (Stevenson, 45). Tableaux flourished during photography's first half-century, especially in Britain, where the two phenomena, tableaux and photography, often coincided. Not only did figures holding still in a tableau lend themselves to being photographed, but to make an artistic or pictorial photograph with figures, one in effect had first to construct a tableau.

Carroll, Lewis. Tableau with Xie Kitchin as the Damsel in distress with St. George and the Dragon.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

With roots in medieval and Renaissance pageants, the modern tableau emerged in the eighteenth century. In his writings on the theater of the 1750s and 1760s, Denis Diderot argued that stage productions should create emotional and moral effect like the best painting of the day by presenting deliberate tableaux at critical moments in the drama. In Naples in the late eighteenth century, Lady Emma Hamilton famously assumed frozen "attitudes" after figures on Greek vases and ancient statues. This activity would soon be echoed in a music hall entertainment, the *pose plastique*, where partially dressed figures assumed positions suggesting classical statuary (Stevenson, 57). In 1809, Goethe prominently featured the practice of staging tableaux vivants in his novel *Elective Affinities*. Tableaux vivants became especially popular in Great Britain when the Scottish painter Sir David Wilkie, having witnessed in a German theater a tableau after a painting by David Teniers, began arranging figures after famous paintings and literary works. In his most well known examples, based on the stories of Sir Walter Scott, Wilkie constructed elaborate scenes requiring weeks' preparation, all for brief performance (Stevenson, 46). The amusement of staging tableaux was enjoyed among the highest classes of British society, including the royal family.

In 1845 David Octavius Hill and Robert Adamson photographed a number of tableaux after Scott featuring medieval costumes, using as models friends who were practiced in the art of assuming characters and holding poses from having enacted tableaux. These works related both to literary painting of the day and to the contemporary craze for tableaux vivants. They also helped to initiate a trend of fictional photographs in which groups of two or more figures enact a scene for the photographer. As with tableaux, such images might refer to historical or allegorical themes, or to recognizable moments from everyday life.

William Lake Price, who created elaborate costume photographs after literary sources such as *Don Quixote* and *Robinson Crusoe* in the mid-1850s, noted the difficulty of photographing figure groups, attempts at which marked much ambitious art photography in the Victorian era. When O.G. Rejlander produced his intricate composition photograph *The Two Ways of Life* in 1857, he was trying to exceed the limitations of photography in rendering complex figural arrangements, by combining a number of discrete tableaux into a larger scene that itself resembled an elaborate tableau vivant. It has often been noted that Rejlander employed professional models from a troupe of *pose plastique* actors, accustomed to partial nudity and long poses, for *The Two Ways of Life*, and it has been suggested that some of the negative criticism directed toward the work may have derived from the picture's associations with the "debased art form" of commercial tableaux vivants and *poses plastiques* (Daniel, 15).

Rejlander more directly copied specific paintings in a number of studies, made after the old masters, in which, wrote the critic A.H. Wall in *The Photographic News* of 31 December 1886, "he selected models, illuminated,

and posed them in imitation of some of the grandest masterpieces in the public galleries, and then photographed them" (Wall, n.p.). Wall recommended this practice as the best training for an aspiring art photographer, who, like Wilkie with his tableaux, needs to know how to make pictures out of living models. The problem of the imperfect model as opposed to the idealized figures of painting was often noted in mid-century photographic criticism, suggesting that photographs of pictorial or literary subjects were tainted by the intermediate step of needing to construct a tableau with real people as actors. At the same time, however, there was quite a vogue in British photography for just such images among professionals and amateurs alike.

Both Henry Peach Robinson and Lewis Carroll frequently staged scenes that were meant to conjure up paintings or that made literary reference. Whereas Robinson's efforts are professional in the extreme, using hired models and carefully constructed scenarios, Carroll's tableaux involving children, such as *St. George and the Dragon*, ca. 1874, are notable for their playful, amateurish quality. For her *Studies* of the 1860s, Viscountess Clementina Hawarden, while spurning period costumes and props, posed her figures in attitudes reminiscent of paintings as well.

A new dimension was added to the photographic tableau with the advent of stereoscopic photography. From the 1850s through the 1880s and beyond, narrative tableaux became a staple of commercially published stereographic cards internationally. This hugely popular form came to involve extensive story-telling sequences of photographic tableaux, common at the turn of the century (Henisch and Henisch, 70–77).

Among art photographers, perhaps the work of Julia Margaret Cameron most consistently and ambitiously incorporates the tableau. Her Madonnas and saints, allegorical figures, and subjects from poetry involve servants, family, or friends costumed and arranged in sometimes quite elaborate mises en scène. These works, enacted wholly for the camera, often allude to the amateur theatrical, with spare, makeshift stages and distinctly non-professional actors. For one of her last and most involved projects, Cameron in 1874 spent several months, and enlisted dozens of models, to produce twelve large-scale photographic images of Arthurian subjects to illustrate a volume of her friend Alfred Lord Tennyson's *Idylls of the King* (Bajac, 5). Critics and historians in the mid-twentieth century would condemn such works of the Victorian art photographers as misguided attempts to produce "imitation paintings," preferring, in the case of Cameron, her simple and direct portraits to her fanciful literary scenes. With the shift to a postmodern aesthetic in the late twentieth century, however, the practice of staging fictional scenes again came into prominence in photography, and with it a renewed appreciation for the role of the tableau in nineteenth-century photography.

TAFT, ROBERT (1894–1955)

Born of missionary parents in Japan in 1894, Robert Taft grew up in the U.S. After receiving a B.A. in history in 1916 and a Master's in 1919, he joined the University of Kansas where he obtained a Ph.D. in chemistry (1925) and taught chemistry until his death in 1955. An amateur of art and history, Taft was drawn to photographic history upon realizing, around 1932, that no existing book would satisfy his curiosity about early photography in the American West. He started amassing information by exploring the 19th-century press and writing old-timers and local historical societies. Out of this enormous personal effort came a series of articles in Kansas and other Western magazines, followed by his masterful Photography and the American Scene: A Social History 1839–1889 (1938), the first comprehensive history of American photography, which has become a classic of the socio-cultural history of the medium. Along with many lesser publications on photographic history he also

made a major contribution to Western American cultural history with his Artists and Illustrators of the Old West (1955). The extensive collection of Taft's papers at the Kansas State Historical Society is a major resource for further understanding of this often underestimated photo-historian.

François Brunet

TALBOT, WILLIAM HENRY FOX (1800–1877)

William Henry Fox Talbot, photographic inventor, mathematician, etymologist, Assyriologist, and botanist, was born 11th February 1800 at Melbury in Dorset, the home of his maternal grandfather, Henry Thomas Fox-Strangways, the 2nd Earl of Ilchester. His father, William Davenport Talbot (1764–1800), was a Captain in the 88th Foot Regiment. His mother, Lady Elisabeth Theresa (née Fox Strangways) (1773–1846) was the daughter of the 2nd Earl of Ilchester and his first wife Mary Theresa.

When Talbot was five months old his father died leaving him the Lacock Abbey estate and over £30,000 in debt. In order to pay back these debts, Lacock Abbey had been let out to the Countess of Shrewsbury starting in 1795, and after her death in 1810 to John Rock Grosset, the local Member of Parliament. Talbot spent his youth living in a variety of relative's homes or away at boarding school. It wasn't until Talbot reached the age of 27 that he finally took possession of the Abbey and began to make it his home. In 1804, Talbot's mother married Captain Charles Feilding (later Rear Admiral). His attention both to the Lacock estate and to his stepson brought stability to both. Talbot's mother and Feilding had two daughters, Caroline Augusta (1808–1881, later Lady Mt Edgcumbe), and Henrietta Horatia Maria (1810–1851, later Henrietta Gaisford), who both showered affection on Talbot and influenced him with their artistic interests and talents.

Education

Talbot's earliest educational experiences were, certainly, at his mother's knee. Her knowledge of languages and the essentials of the classics, frequently presented in the form of games, was the foundation of Talbot's tutelage. Long periods during his childhood spent at Penrice, his aunt's home in the Welsh countryside, collecting shells, stones and plants initiated Talbot's life-long interest in the natural sciences, especially botany. His mother and stepfather's frequent trips on the continent also gave the young Talbot a broader view of life and put him in contact with important people.

From the age of eight, Talbot was a boarding student of the Reverend Thomas Hooker's school at Rottingdean in Sussex. Here he expanded his knowledge of Latin and French while reading and translating literary works, also continuing his interest in botany.

From age 11, Talbot attended Harrow, living in the Head Master's House under the watchful eye of the Reverend George Butler, a man he highly respected. This seemed a most satisfactory time for Talbot who made many friends, took part in sports and, with his friend Walter Calverley Trevelyan, went in search of botanical specimens culminating in a handwritten book on the 'Flora of Harrow.'

After leaving Harrow at the top of his class, but still too young to enter university, Talbot was tutored first by the Reverend Theophilus Barnes at Castleford, Yorkshire, and second by the Reverend Thomas Kaye Bonney at Normanton in Rutlandshire.

Talbot's years at Trinity College Cambridge (1817–1821) were centred on a passionate interest in mathematics, which, at that time, was seen as one of the consuming interests of Cambridge itself. In order to get a first class BA, a student had to sit for the 'Tripos,' then the most demanding and prestigious examinations in the country. Talbot received his first class BA and was named 12th Wrangler, disappointing his mother who had hoped he would be named Senior Wrangler. Talbot proceeded MA in 1825.

> Far from excelling only in mathematics, Talbot also received the Porson prize for his Greek Iambic translation of Macbeth, and the second Chancellor's Classical Medal.

Family Life

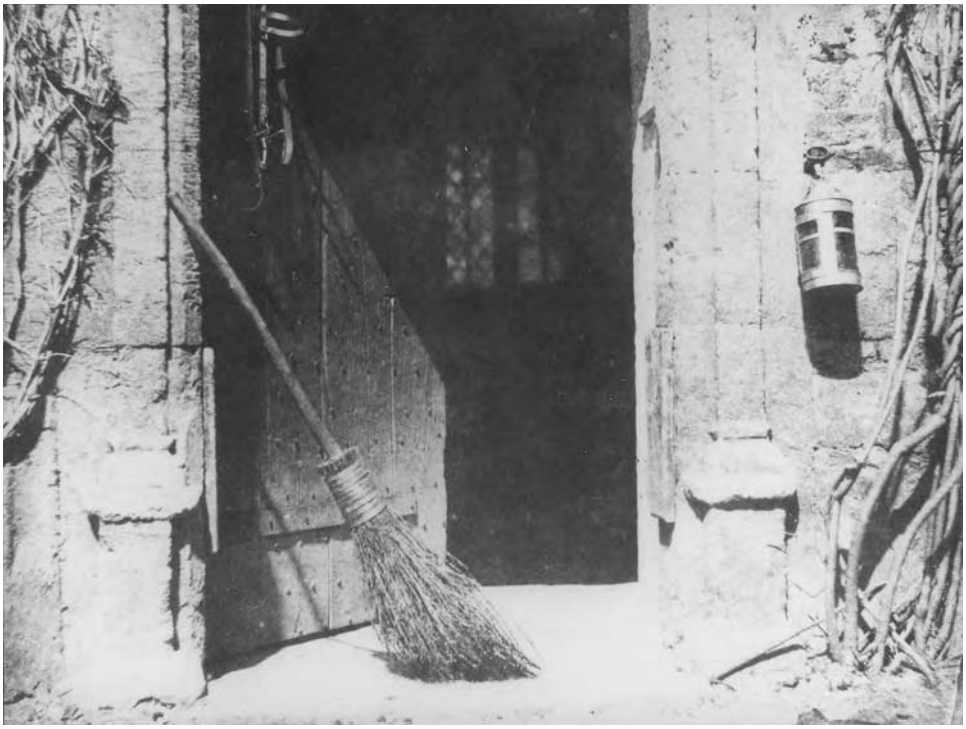
In December 1832, Talbot married Constance Mundy of Markeaton Hall in Derby. Their marriage took place at All Souls Church in Langham Place, London. They had four children: Ela Theresa (dsp), Rosamond Constance (dsp), Charles Henry (dsp) and Matilda Caroline who married John Gilchrist Clark of Scotland.

First Experiments

In the first fascicle of Talbot's Pencil of Nature published in 1844, he writes of the epiphany that led him to the discovery of photography. In the opening pages he relates:

> One of the first days of the month of October 1833, I was amusing myself on the lovely shores of the Lake of Como, in Italy, taking sketches with Wollaston's Camera Lucida, or rather I should say, attempting to take them: but with the smallest possible amount of success. For when the eye was removed from the prism—in which all looked beautiful—I found that the faithless pencil had only left traces on the paper melancholy to behold.

He considered using the camera obscura for drawing, as he had on earlier trips to the continent, but this too



Talbot, William Henry Fox. The Open Door. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Joseph M. Cohen and Robert Rosenkranz Gift, 2005 (2005.100.498) Image © The Metropolitan Museum of Art.*

required some previous drawing skill on the part of the amateur artist.

> It was during these thoughts that the idea occurred to me... how charming it would be if it were possible to cause these natural images to imprint themselves durably, and remain fixed on the paper!

Talbot's first experiments, beginning in the spring of 1834, involved coating common writing paper with silver nitrate both alone and in combination with sodium chloride. Too slow for use in a camera obscura, his first images were sunprints created by placing botanical specimens onto the sensitive paper and exposing it to the sun. The greater challenge he faced was that once the paper had been made sensitive to light and an image was formed, it was necessary to somehow halt this sensitivity so that the image would remain. Although creating paper sensitive to light was straightforward, and was known to have been achieved as early as 1800 by Thomas Wedgwood, the inability to halt the sensitivity meant that images would continue to print out until the paper was black.

In examining early prints, Talbot noticed that some areas appeared morelight sensitive than others. He attributed this to varying proportions of sodium chloride to silver nitrate. Further experiments showed that less sodium chloride made the paper more sensitive to light. He reasoned from this that if a light coating of sodium chloride made sensitive paper, it could then be desensitised or stabilised by soaking the finished print in a bath of saturated sodium chloride.

Sciagraphs or Photogenic Drawings

To make the paper sensitive enough to be used in the camera obscura, he found that multiple coatings of silver nitrate and sodium chloride would increase the sensitivity to an extent that exposures could be made in one of several small, crude box cameras fitted with microscope eyepiece lenses that were made for Talbot and his experiments. Exposures were long as he was still relying on the action of light alone to bring out the image. He had not yet discovered the latent image.

He began writing up his results in late 1838 for presentation to the Royal Society. However, in January 1839 word came from Paris that a Frenchman named Louis Daguerre had also created a photographic process, although no details were published on the actual process itself. Fearing that his labour in developing this process might be in vain should Daguerre's process turn out to be identical to his, Talbot pulled together the samples that he had made previously and on 24th January, Michael Faraday exhibited them at the Royal Institution. On the 31st of January, Talbot's paper 'On the Art of Photogenic Drawing' was read to the Royal Society in London. He then revealed the full working method of the process in a letter read to the Royal Society on the 21st of February. When Daguerre's process was disclosed in August of 1839, it revealed that there was no overlap between the two processes. The strong support for Daguerre by the government of France and the French scientific community, combined with the fact that the daguerreotype was made to be used in a camera, meant that Talbot's process was obscured in the press and public discourse.

Calotype Process

Talbot continued with his experiments attempting to make the paper sensitive enough to be easily used in a camera and trying different methods for fixing the image after exposure. His friend, Sir John Herschel, recommended the use of 'hyposulphite of soda' as the best fixing agent and after some months of experiments, Talbot began to use that for the vast majority of his work. The photogenic drawing process was successful as far as it went, but Talbot took a large leap forward in his work when he discovered in September 1840 that a short exposure to light was enough to create a latent image on the paper which could then be brought out by chemical development. This single change brought exposure times down from minutes or hours to seconds.

More than an improvement on Photogenic Drawing, the Calotype was virtually a new process. Although he had given his Photogenic Drawing process free to the world, through the urging of his mother and his friend Sir David Brewster, Talbot took out a patent on the calotype. The restriction of this patent, along with the widespread public delight about the daguerreotype, was blamed for slowing further development of photography on paper during the 1840s. Frederick Scott Archer's introduction of photography on glass in 1851 was the first serious commercial challenge to the daguerreotype and was quickly taken up by photographers in England. Talbot believed that the basic concept of Archer's process differed little from his calotype process. In 1852, at the urging of the Royal Society and the Royal Society of Arts, Talbot relinquished his patent rights for all amateurs, scientists and artists with the exception of commercial portraiture, which he felt he had to retain to protect the business of those who had already taken out a license from him.

In 1854, Talbot brought suit against a photographer named Martin Laroche (real name William Henry Sylvester) claiming that Laroche's use of the collodion process violated his patent rights. Although Talbot had the support of Sir John Herschel and Sir David Brewster, the judgment assigned Talbot credit as the inventor of the photographic process on paper, but ruled that Archer's process was outside his patent and was therefore available for public use.

Photoengraving

Talbot's desire to create images that were both reproducible and permanent was not to be found in silver printing processes. Talbot made his last photograph in 1846. His mother's death in 1846 and his prolonged illness throughout the late 1840s brought an end to his experiments using the calotype process. Although Talbot's experiments with photography ended in 1845, in the early 1850s he picked up his earlier researches on printing photographs by way of a printing plate and ink. By 1852 he had created his first successful photoengraving process, which he patented. Later changes brought about a greatly improved process, which he called Photoglyphic engraving, taking out a patent on it in 1858. These two photographic engraving processes were the foundation for photogravure printing.

Talbot's Later Years

From the mid 1850s until his death in 1877, Talbot turned much of his intellectual energy to deciphering Assyrian cuneiform tablets held by the British Museum. Along with Sir Henry Rawlinson and George Smith of the British Museum, Talbot was one of the major translators of this previously unintelligible script.

In 1863, Talbot was awarded an honourary Doctor of Laws degree from Edinburgh University for his "pre-eminence in literature and science, and the benefits that his discoveries have conferred on society.

Talbot died in his study at Lacock Abbey on the 17th September 1877 and was buried in the cemetery at Lacock. His entire estate, including all of his photographs and scientific notebooks, were left to his son Charles Henry. When Charles died in 1916 he left everything to his niece Matilda Gilchrist Clark who then changed her name to Talbot. She was a great promoter of her grandfather's work and it was through her that large collections of his work were lodged with the Science Museum (now at the National Museum of Photography, Film and Television) and the Royal Photographic Society with smaller collections given to the Smithsonian. In 1944, Matilda donated Lacock Abbey and its estates to the National Trust. The contents of the house, including his photographs and papers remained with the family and are now in the William Henry Fox Talbot Trust collection.

Although usually referred to as Fox Talbot in both contemporary and modern texts, he preferred Talbot and usually signed himself Henry F Talbot or HF Talbot. The use of H Fox Talbot Esq. on the title page of *Pencil of Nature* is probably the origin of this use of the family name.

In addition to a number of published articles and pamphlets on mathematics and other subjects, Talbot also published seven books: *Legendary Tales in Verse and Prose* (1830); *Hermes or Classical and Antiquarian Researches* (vol. 1 1838, vol. 2 1839); *The Antiquity of the Book of Genesis—Illustrated by Some New Arguments* (1839); *The Pencil of Nature* (published in fascicles from June 1844 to April 1846); *Sun Pictures in Scotland* (1845); *English Etymologies* (1847).

TAUNT, HENRY WILLIAM (1842–1922)

Henry Taunt was born in Oxford, and at the age of 14 was apprenticed to portrait photographer Edward Bracher. When Bracher sold the business in 1863, the new owners retained Taunt as manager, but four years later he left to establish his own studio.

One of his first publishing ventures in the late 1860s was the first photographically illustrated guide to the River Thames—later to be followed by over fifty other publications. The second edition of his *New Map of the River Thames*, published in 1873, was illustrated with eighty original photographs and hand tipped onto the pages. Talented at self-promotion, he generated demand for his work by giving lantern-slide lectures throughout the area.

Using wet collodion during the early years of his career, he is reputed to have carried all his equipment, materials, and darktent on a small boat as he explored the river.

In addition to illustrated books, Taunt & Co. published many albums of views of the Thames and the surrounding areas.

Taunt was politically active throughout much of his career, and in 1880 became involved in a campaign to improve Oxford's water supply, at a time when it was reportedly possible for live shrimp to be delivered through the cold water tap. He participated in this cause by threatening to photograph the shrimp and publish the images.

JOHN HANNAVY

TAUPENOT, JEAN MARIE (1822–1856)

Originally from Givry, in Burgundy, Jean Marie Taupenot was born the 15th August 1822. He studied physics and biology. His work about Montpellier and the Cevennes's geology (south of France) gave him the doctor graduate in natural science in 1850.

He became professor of physics, first in Romans (in the south of France), then in Chaumont (in the Champagne area).

Eventually, he was named professor of physics and chemistry in the military high school of La Flèche, the Prytanée Impérial Militaire in 1853. There began his interest in photography: he setted up in this school the laboratory where he worked the next three years.

He invented and revealed to the Société française de photographie a dry collodion process in 1855, to which he gave his name. At this time, he became involved in this society.

The same year he presented to the French Academy of Sciences a little photographic device called "chercheur photographique" or a photographic view finder.

After his wedding in 1856, he carried on his researches in geology and natural sciences, inventing a wind gauge.

Jean Marie Taupenot died the same year, at the age of thirty-two, the 15th October, in La Flèche.

Jean Marie Taupenot was not a professional photographer, he was a scientist involved in photography by passion.

The photographic process invented by Taupenot gave to the unknown professor a world-wide acknowledgement. At this time, the best photographic technique was the Wet-plate or collodion process, an invention of several persons, especially Frederick Scott Archer, an English photographer, and Gustave Le Gray, in 1851. The negative was on a glass plate coated with collogion, a mixture of guncotton and ether. It was quite fast (only a few seconds to pose), but all the process had to be fulfilled before the complete drying of the glass plate. Practical for photographic studios, it was very complex to take photographs outside.

For this kind of photographs, another useful process was the negative albumen process proposed by Niepce de Saint-Victor in 1847. The glass plate was coated with iodide and bromide of potassium.

Jean Marie Taupenot used to employ both processes, wet collodion and albumen, but "he was impatient of the slowness of the albumin and perhaps more of the defect of solidity of collodion" ("il était impatienté des

lenteurs de l'albumine et plus encore peut-être du défaut de solidité du collodion," extract from the *Bulletin de la Société française de photographie,* 1855, 234). The unique solution the photographer had found, was to put varnish on the negative plate poured with wet collodion to give them stability. However, this result was expensive and not easy for people who were living in the countryside as was Taupenot (la Flèche is about 300 km far from Paris).

That is the reason that he had the idea to combine both techniques. As the main principle, he substituted the varnish with albumen, a nitrogenous substance found in egg white, making it less costly and easier to obtain.

As an amateur photographer, Taupenot's research was a great help to other photographers. He did not patent his process, making it freely available to all, but he was aware of its importance. He created an album of photographs that he presented and offered to the emperor Napoleon the Third, who decided to add his pictures to the Exposition Universelle in Paris the same year. The scientist even won a bronze medal for his work.

In this album, the photographs presented the procession of the Fête-Dieu (in June), in the Prytanée: the students in the gymnasium, the chapel of the School, the Library, the Laboratory, the garden and the park. As a matter of fact, he had to prove that his process could be used inside as well as outdoor.

A professional chemist and physician, he was looking for the acknowledgement of his colleagues: that is the reason he presented his discovery to the French Academy of Sciences. One of the most important scientists of this time, Michel Eugène Chevreul (1786–1889), made the report about it.

At the same time, he described his process before the members of the Société française de photographie, in September 1855. He brought with him several samples of photographs made with his technique in order to show the good quality of images he obtained. A commission constituted of MM. Bayle-Mouillard, Bayard, Humbert de Molard, Fortier and Fierlants, was gathered to test the invention.

The Taupenot process consisted of a classical collodion preparation sensitized with iodide of ammonium, to which he added a mix of fermented albumen, honey, iodide of potassium, and water with brewer's yeast.

Taupenot coated the glass with the collodion, as the photographer used to do, and he washed it with water. Then he poured the collodion glass with the albumen and drained it off until the albumin was dry. To sensitize the plates and use them, the photographers had to put them in a bath of aceto-nitrate as used for the classical albumen process. The scientist used the gallic acid, a classic modus operandi in the 1850s, to reveal his negatives.

With this process, the glasses could be exposed more than one month after their preparation.

The most important problem with the collodio-albumen technique was the exposure. It required a longer time exposure than the collodion-based one (sometimes eight times more). The photographs he showed at the French Photographic Society were obtained with an exposure time between six seconds and one minute, making this technique perfectly suitable for representing still life, landscapes and architectures, but not fast enough to be used for portraits. The quality of the photographs was as subtle and delicate as with the albumen process.

The notice of this discovery was spread all over the world, relayed by the newspapers specialized in photography and the photographic societies. This process has been used by many photographers particularly from Austria, the French Louis Alphonse Davanne and Alphonse François Jeanrenaud, among others. Several names were given to the Taupenot's technique: collodio-albumen process, dry plate process, Taupenot process, albumenised collodion.

The apex of the Taupenot process was between the middle of the 1850s and the 1870s. By these times, different people were looking for a better technique than the wet collodion process and tried to dry the coated mix. Such attempts include Fothergill's process invented in 1856, the tannin process of Major Russel in 1861, and Bolton & Sayce's process, which added silver-bromide to collodion. However, Taupenot's walked away the support of the amateur photographers.

In the same spirit of this first invention, the simplification of the photographic technique, Jean Marie Taupenot also presented to the French photographic society, in January 1856, a little device everyone could realize, that he named "chercheur" (researcher). It looked like a small cork tube pierced with a round hole at one extremity and a square hole at the other extremity. This last hole should have the same ratio as the negative glass. In fact, it had the same purpose that the "iconometer": finding the best position to give to the camera.

Taupenot's photographs were not particularly worthy for their aesthetics: he was an amateur and his practice was mostly a validation of his chemistry research on photography. Unlike other chemists, he never advertised his work by publishing books, and these pictures are the sole testimony of his studies. They are conserved in the Bibliothèque Nationale de France and the French Photographic Society.

TAYLOR, A. & G.
Company

Andrew and George Taylor founded a highly successful string of photographic studios which capitalized upon the 1860s craze for collecting and commissioning portrait photographs. They were previously engaged in the production of miniatures and like many others in this trade they made the transition to photography. Their first photographic studio was opened in London around 1864 with an address at 11 Cannon Street West. They were soon to establish branches outside London and numbered the following locations among their outlets: Birmingham, Carnarvon, Glasgow, Leeds, Liverpool, Manchester, Newcastle and Dublin. They also opened further studios in America including New York, Boston, Pittsburgh, Philadelphia, Chicago, and Newark. A Paris studio was opened some time after 1879. In adevertisements and upon the reverse of photographs they regularly claimed to be the 'Largest Photographers in the World.'

In 1882, a detailed account of their central operations at Forest Hill, London was given by H. Baden Pritchard in his publication entitled *The Photographic Studios of Europe*. Here a large number of staff, many of them female, were engaged in processing and printing the images which were sent to London from the firm's branches throughout England. The account took the form of a guided tour given by the works manager, Mr Smith. This factory demonstrated a strict division of labour with entire floors of the immense building being designated to particular tasks, for example, the Enlarging Room. Daily targets were set for the employees who worked on assembly lines. Taylor's success may have stemmed from their centralized approach to production which utilized high quality equipment such as lenses by Dallmeyer. In Dublin they were the first photographic studio to establish an instalment method of paying for photographic portraits. It is probably through the introduction of such shrewd business methods that they were able to sustain successful studios in a multitude of locations.

It is also thought that the basis of the company's success was the sale of many copies of a carte-de-visite of Queen Victoria and Princess Alexandra. The publication in 1860 of a set of royal portraits started a fashion in Britain for collecting carte-de-visite portraits of famous people. Though the validity of Taylor's claim to royal patronage may be in question as the company lost a court case in 1884 for illegally representing themselves as photographers to the Queen, which was a matter widely reported in the photographic press of the time. Like other portrait studios they utilized the verso of carte-de-visites and cabinet portraits to name royal customers and to boast of medals awarded at the many international exhibitions which took place during this period. Taylor's exhibited at numerous exhibitions including the Edinburgh Photographic Society's show of 1890.

The firm was also engaged in the production of photographic furniture. This consisted of the many studios props that appeared in the background of carte-de-visites and cabinet cards. Their advertisements offered items such as posing chairs, ornate cabinets and head rests. The need for such a service was indicative of the increased popularity of the studio portrait. It also explains the sameness that was found in studio portraits of the era, where every sitter appeared in a refined middle-class setting. There was also evidence that they were involved in the production of postcards from 1901. Their premises at Hastings was used for this purpose from 1914 onwards where processes such as the Collotype, Albertype and the 'Lichtdruck' which was a variation on the Woodburytype**,** were employed.

During the period between July and October 1869 Andrew left the firm. However he is listed as the manager of the Head Office in Regent Street, London, in the 1880s. Throughout this period they employed a network of managers and the whole business seems to have been run somewhat on a franchise basis. Although George Taylor died in 1911, branches were to continue in business for many years afterwards.

TAYLOR, JOHN TRAILL (c. 1827–1895)

John Traill Taylor, born in Scotland's Orkney Islands, and the son of a watchmaker, went on to become one of the most influential figures in the emerging photographic press in Great Britain.

Moving to Edinburgh c.1845, initially working as an optician and watchmaker, he is believed to have written for several daily newspapers, and to have contributed to a number of scientific and optical journals.

In 1856 he founded a manuscript journal entitled *The Photographer* and three years later began his long association with *The Photographic Journal*, formerly the *Liverpool & Manchester Photographic Journal*. This became *The British Journal of Photography* (*BJP*) in 1860 and which he edited from 1864 until 1879, and again from 1886 until his death in 1895, also editing *The British Journal of Photography Almanac* during that latter period.

Taylor's interest in the practice of photography had started with the daguerreotype in the 1840s and continued throughout his life. He regularly communicated with William Henry Fox Talbot in the 1860s both on scientific issues, and in preparing an account of Talbot's life and work for the *BJP*. He resigned his editorship in 1879 intending to take up photography professionally, but by 1880 he had moved to the United States where he spent five years as Editor of *The Photographic Times*.

His influential writings on photography were reprinted in several journals in both Britain and America. Having purchased land in Florida planning to live there in his retirement, he died there suddenly in November 1895.

John Hannavy

TENISON, CAPTAIN EDWARD KING (1805–1878)

Irish

Tenison was a wealthy Irish landowner who was an early pioneer of the calotype and waxed-paper negative. He married the eldest daughter of the 1st Earl of Lichfield, Lady Louisa Anson, in 1838 and lived at Kilronan Castle, Roscommon. Tenison and his wife travelled to France and Spain in the early 1850s and in her 1853 journal *In Castile and Andalucia* Lady Louisa gives a humorous account of the interest her husband's suspicious 'Talbotype Apparatus' aroused amongst the locals.

Tenison exhibited various studies at the 1853 Dublin exhibition and joined the newly formed Dublin Photographic Society the following year. He showed four Spanish architectural studies from waxed-paper negatives in the 1854 Photographic Society's London exhibition and in 1855 ten views of chateaux, priories and churches in Normandy. His large Spanish pictures were generally well received at the Dublin exhibition, the Photography Section Report jurors remarking on the prints' unusual warm-yellow and violet tints (from gold-toning), however it was suggested that they had too much contrast and could perhaps be improved by printing with the Blanquart-Evrard process. Tenison seems to have taken this advice on board and many of his later French views were produced by the French process.

Ian Sumner

TERRIS, ADOLPHE (1820–1900)

French photographer

Adolphe Terris is best known for his photographs of the large-scale public construction projects that occurred in and around Marseilles, France in the early 1860s. Terris was born in 1820 in Aix-en-Provence to a family of craftsmen. Terris' first known commercial venture was a book store, which he opened in Marseilles in 1845. His interest soon turned to photography, however, and by 1856 he was working in a local photography studio in the port city. Terris was a founding member of the Société Marseillaise de Photographie in 1860, and in 1861 he had organized a photographic exhibition in his studio. In 1861 Terris also received his first commission to photograph the large civil engineering projects underway in and around Marseilles, on this occasion his subject was the extensive renovation of the Rue l'Imperiale. Between 1861 and 1875 the city commissioned Terris to document other aspects of their construction and modernization program, including the rehabilitation of the public roads and buildings, the harbor and waterfront. Terris' photographs serve as an important historical record of the transformation of the city of Marseilles. Several of his photographs were included in *Les Travaux Publics de la France*, which was published through the French Ministry of Public Works. Terris died in 1900.

Maxim Weintraub

TEYNARD, FÉLIX (1817–1892)

French, active in Egypt 1851–1852, photographer, civil engineer

Félix Teynard, a provincial civil engineer, completed an extensive photographic survey of Egypt during the course of a Nile voyage beginning in late 1851 and concluding in 1852. Working with the calotype process, Teynard made more than 160 paper negatives along the Nile from Cairo to the level of the Second Cataract. He completed what to date was the most thorough documentation of the recently cleared site of Abu Simbel, as well as extensive and systematic records of Karnak, Luxor, and Philae. Publication of Teynard's work began in 1853

Terris, Adolphe. Rues des Grands Carmes, Marselles.

and culminated in 1858 with the two volume *Egypte et Nubie* containing 160 photographs. It is considered one of the masterworks of early travel photography. However, Teynard's project was not the first sustained photographic record of Egypt, nor was it the first lavish photographic publication based on the ruins along the Nile. Maxime DuCamp, traveling with Gustave Flaubert, had photographed along the same route in 1849–51. It was DuCamp's photographs, brought out by Gide et Baudry in 1852, that received attention and accolades as the first and extensive photographic record of the sites of ancient Egypt and the first photographically illustrated travel book. In January 1853, before Goupil began printing Teynard's photographs for distribution, DuCamp received the Legion of Honor in recognition of his photographic work.

Teynard's photographs epitomize the tensions inherent in early expeditionary photography: on the one hand, the acceptance of photography as the newest tool in the long effort to create accurate visual records of the world, the latest technological innovation in the long tradition of drawn and printed topographic views; and, on the other, a growing appreciation of the photograph's unique ability to capture and convey the sense of a place as experienced at the moment the photograph was made. In short, the tension between neutral record and the evocation of experience. Teynard's project must be seen as part of the drive to apply the new technology of photography to record the physical world, in this case the sites of ancient Egypt. From this perspective, photography, rather than a radical break with the past, was part of the continuum of strategies in the ongoing project to replicate and reproduce for publication views of the world, a project which began with the printing revolution of early modern Europe. Teynard embraced this view of photography as a complimentary technique to earlier modes of recording when identified his project in the subtitle of *Egypte et Nubie*, as a "photographic atlas complementing the great *Description de l' Egypte*"—the massive multi-volume publication of

Napoleon's scholars. Yet he recognized the inherent difference in mediums—the engraved illustration as an idealized summation of multiple sketches and measurements versus the photograph as carrying the impress of the physicality of a place at a specific moment. He offered his photographs to his readers as the "records of his sensations" as he experienced the ancient sites of Egypt.

Both formally and intellectually, Teynard's work is connected to pre-photographic projects to order and record ancient Egypt. His work rests squarely on French scholarship begun by the cadre of scholars who accompanied Napoleon's Army of the Nile in 1798. The *Description de l'Egypte,* which included ten volumes of highly detailed engravings based on sketches and measurements made by the over 100 scholars and engineers, was the summation of the work of Napoleon's scholars. It offered an encyclopedic treatment of Egypt and became the foundational text in the developing discipline of Egyptology. Teynard's engagement with the *Description* was not perfunctory. His approach to complex sites such as Karnak and Philae was modeled on that in the *Description*. He provided site plans upon which he indicated camera positions and angles. Captions of photographs related the images to the site plan. Where possible, he photographed structures from vantage points that replicated the illustration in *Description*. Napoleon's teams of scholars had not ascended the Nile into Nubia; there he turned to Gau's *Antiquités de la Nubie*, published in 1822 and conceived by the author as the continuation of the work of the earlier scholars. Again, Teynard photographed, almost exclusively, the structures and sites illustrated by Gau, choosing vantage points which yielded views which corresponded to Gau's illustrations. While Teynard's debt to earlier models can be seen in choice of subjects and viewpoints, the startling immediacy of photographs made in the shadowed recesses of colonnades and across the desolate sweep of desert reinforce his description of the photographs as the record of sensations. The tension between positivist record and romantic experience distinguishes his work from that of others practicing in Egypt at the time.

After his return, Teynard's photographic activity was confined to scientific and technical experimentation. In 1862, he submitted the winning solution to the problem posed by the Academie des Sciences for the Prix Bordin, a problem on optical focus. He continued to investigate the focusing properties of lens and submitted work to the Academy. In 1869 he was among the invited guests of the Khedive at the opening of the Suez Canal. He died outside of Grenoble in 1892.

The publication history of Teynard's photographs is complicated. His work was first issued as *Voyage en Egypte et en Nubie: Sites, Monuments, Bords du Nil* in thirty-two livraisons of five prints beginning in 1853 by Maison Goupil et Compaigne, Paris. It was only in 1858 that the complete book was published by Goupil et Cie in two volumes under the title *Egypte et Nubie: Sites et Monuments les plus interessants pour l'etude de l'art et de l'histoire*. The 160 prints were accompanied by his short descriptive texts. The two volume set commanded a very steep price, 1000 Francs. The size of the edition is unknown but fewer than 15 complete copies of the two volume work are known to exist.

THOMAS, JOHN (1838–1905)

Born Glan-Rhyd, Cellan, West Wales, John Thomas left his draper's assistant post in Lampeter in 1853 and walked to Liverpool to start a similar post. Ill health prompted an outside job and he became a 'Town Agent on Commission' for a firm trading in stationary and photographs of famous personalities along the North Wales route, from Liverpool to Holyhead. It was the absence of any Welsh personalities that prompted him to take up photography in 1863. He became the manager for Harry Emmens Studio in Liverpool, photographing mainly non-conformist ministers. In 1867 he launched his own business, producing *carte-de-visites*, also *-in memoriam*, under such titles as bards, poets, musicians, singers, missionaries, church dignitaries and ministers. While he spent most of his time tramping round North Wales his wife ran the mail-order business from the Cambrian Gallery, Liverpool, which lasted for around 40 years. Before his death, he selected 3113 plate negatives which were bought by Sir O. M. Edwards who used them to illustrate articles in his *Cymru* magazine. This collection is now in the National Library of Wales. Along with his depictions of tradesmen, working women, town characters, the almshouses, farm yard and market streets, the coming of the railways, building the reservoirs, he accomplished the most important depiction of life in 19th century Wales, and one of the earliest sustained documentary projects in the history of photography.

ALISTAIR CRAWFORD

THOMPSON, CHARLES THURSTON (1816–1868)

British photographer, official photographer to the South Kensington Museum and Department of Science and Art

Charles Thurston Thompson was born in 1816, the son of a wood engraver, John Thompson. Charles took up his father's profession under his tuition. With his father he drew and engraved many of the illustrations for William Yarrell's *A History of British Birds* (1843). In his early thirties he turned to photography and began practising the wet collodion technique around the time it was introduced in 1851. The same year, Thompson assisted Henry Cole, civil servant and Chairman of the Fine Arts Committee of the Society of Arts, with the arrangements for photography at the Great Exhibition in London. Thompson worked with the photographer Robert Bingham on the production of the photographic prints for the *Reports by the Juries of the Great Exhibition* (1851) and in 1852 worked with him in his studio in Paris.

Out of the proceeds of the Great Exhibition and with government help, land was purchased in the area south of Hyde Park, for the establishment of the new South Kensington Museum (later renamed the Victoria and Albert Museum). Henry Cole, later to become Thompson's brother-in law, was appointed first director. The Museum officers were keenly aware of the possibilities that photography could play in the development and promotion of museum activities and collections. Thompson was called upon by the Museum as a freelancer to produce photographs of objects on loan to an exhibition of decorative furniture held at the Museum's temporary accommodation at Gore House in 1853. In the gardens he photographed the *Venetian Mirror c.1700 from the Collection of John Webb* (1853, V&A collection), along with other studies of mirrors, showing himself reflected in the glass. Usually, such photographs had the mirror glass obscured during exposure or blacked out in the printing to remove the reflection. Thompson's images of mirrors reveal the processes of early object photography and suggest that he was consciously showing himself at work in the new-founded profession of Museum photographer.

In 1855 Thompson was appointed superintendent of the British photographic contributions to the Paris Exposition Universelle and travelled there to work with Bingham on photographing the exhibition and its buildings. While there he was granted special permission by the French government to photograph art objects in the Louvre. On his return to London in 1856 Thompson submitted works for the exhibition of the Photographic Society of London. That same year he was appointed official photographer to the South Kensington Museum and the Department of Science and Art thus establishing the earliest Museum photographic service in the world. Thompson photographed not only Museum objects but also made pictures of the construction of the new museum. Non-commissioned military officers of the Royal Engineers, or 'sappers,' contributed to many aspects of the Museum's operations and were enlisted to assist Thompson in photography as they had done previously during the Great Exhibition. Thompson was formally appointed by the War Department to teach photography to the Royal Engineers in 1856 for which he was paid ten guineas when each soldier was granted a certificate of proficiency. Their photographic skills were subsequently of great use to the military in documenting terrain in many corners of the world and in reproducing Ordnance Survey maps.

On the completion of its main buildings the Museum re-opened at South Kensington in 1857 and Thompson's studio was set up at the site. In July he returned to Paris to purchase a lens suitable for photographing the sizeable Raphael Cartoons then housed at Hampton Court Palace prior to their removal and display at the Museum. A special camera was constructed to accommodate large glass negatives measuring 30 × 48 inches (76 × 122 cm). Only full daylight was sufficient to obtain the correct exposure so a method of photographing the fragile works on paper in the outdoors was devised: they would be hung out of the windows at the Palace on fine days. This work continued throughout 1858. The prints were offered for sale to the public but they also proved useful to the Museum staff who marked the prints with diagrams to identify areas of the original cartoons requiring treatment—possibly the first use of photography for conservation purposes. The negatives and marked prints remain in the V&A collection.

The same year Thompson photographed the Exhibition of the Photographic Society of London and the Société française de photographie held at the South Kensington Museum (V&A collection). This image is an important record of the appearance of early photographic exhibitions with stereoscopes on tables and pictures hung floor to ceiling, frame to frame. A figure seated is likely to be Thompson himself. Three of his works, tree studies made in Surrey probably taken in 1857 or 1858, are visible in the exhibition. His systematic representation of trees was intended to be of use to the Museum in its capacity as a source of inspiration for artists and designers. They served as studies from which students could copy, much like Edward Fox's *Anatomy of Foliage* acquired by the Museum for the same purpose in 1865. Thompson's tree studies survive, along with many of his other works, pasted into the Museum's 'guard books'—bound volumes containing one print from every negative made for the Museum photographic service (V&A Archive).

In April 1859 Thompson became a full employee of the Museum on a retainer of an annual fee of one hundred pounds. Although obliged to be at the call of the Museum, he was not prohibited from engaging in private work. Partly in order to keep up with demand, he concentrated on making negatives only at the Museum. In addition to his retainer he received 3d for every square inch of negative. A further reason for Thompson's concentration on making negatives only was as a reaction to a debate brewing between the Museum and the private trade. Objections were raised that the Museum was undercutting the general trader by selling exclusive reproductions of works of art that were financed by public funds. Furthermore, because of Thompson's official employment, private photographers were discouraged from working in the Museum. The issue of safety to Museum objects complicated the issue. At the British Museum, where Roger Fenton had worked as a freelancer, an accidental fire caused by another photographer had led the trustees to prohibit anyone but the photographer approved by them to work on the premises. This, and the fact of the existence of an established negative store and printing establishment at South Kensington, led to the British Museum's arrangement with Fenton being discontinued and all photography for both Museums being transferred to South Kensington.

A Select Committee of the House of Commons was set up to enquire on the issues. The minutes of evidence published with the Committee's report in 1860 give a fascinating insight through photographers' testimonies. It was decided that the appointment of an individual or firm to the Museum was necessary for the smooth running of a Museum photographic department. However, A Committee on Education passed a minute on 10 January 1862 stating that photographs from negatives produced from objects of art being public property should be sold through channels of trade.

Thompson was industrious photographing a huge variety of objects at the Museum. It is estimated that he produced in the region of 10,000 negatives. A *Price List of Mounted Photographs printed from negatives taken for the Science and Art Department by the Official Photographer C. Thurston Thompson* (London: Chapman and Hall) dated 1864, lists nearly one thousand different photographs. These include categories such as Italian sculpture, arms and armour, engraved ornament, cartoons and drawings of Raphael, portraits by Holbein in the Royal Collection at Windsor Castle, Limoge enamels, ivory carvings, objects in crystal in the Louvre, Turner's *Liber Studiorum*, and trees studies. Prints could be obtained through the photographic firms of Chapman & Hall, P. & D. Colnaghi, Scott and Co. and Cundall, Downes & Co. The public could also request images to be made of objects in the Museum not already photographed.

In 1866, Thompson left on a tour of Spain and Portugal to photograph works of art and architecture. John Charles Robinson, curator of the South Kensington Museum, had visited the Cathedral of Santiago de Compostella in Spain the year before. He singled out the cathedral's Romanesque doorway, the Portico de la Gloria, for special treatment commissioning a gigantic plaster cast of the whole structure to be shipped to the Museum. He also asked for Thompson to photograph the site, so that the photographs could be shown alongside the plaster cast, showing the context of the doorway. Robinson left precise instructions for Thompson down to placing the camera 'betwixt the 9th and 10th trees at the roadside.' However, Thompson went beyond his brief, photographing the crypt, and the tribune above the Portico de la Gloria and views of the Puerta de las Platerias. In 1868 the Arundel Society published a volume of the photographs that brought the hitherto largely unknown cathedral to the attention of scholars and played a central role in raising interest in Spanish antiquities in the later 19th century. His photographs of Portugal were exhibited in the Portuguese section of the Universal Exhibition of Paris, 1867 and the Arundel Society published, *The Sculpted Ornament of the Monastery of Batalha*, 1868.

Thompson was described as "a man of extensive and varied art culture, possessing a most discriminate taste and judgement; but, withal, modest and unassuming. As a private friend he was a rarely amiable man, possessing and unusually winning and conciliatory deportment" (*The Photographic News*, Vol. XII, no.490, 24 January 1868, 38.). Late in 1867 he stayed in Paris to assist with the photographic section of the British portion of the exhibition. While there he suffered severe attacks of jaundice and died on 20 January 1868 aged fifty-two.

MARTIN BARNES

Biography

Charles Thurston Thompson was born in 1816 and trained with his father as a wood engraver. In his early thirties he turned to photography and began practising the wet collodion technique around 1851. The same year, Thompson assisted with the arrangements for photography at the Great Exhibition in London. He worked with the photographer Robert Bingham on the production of the photographic prints for the *Reports by the Juries of the Great Exhibition* (1851) and in 1852 worked with him in his studio in Paris. On returning to London in 1853 Thompson was employed by the newly founded South Kensington Museum (later renamed the Victoria and Albert Museum) first as a freelancer and from 1859 as official photographer, the first post of its kind. He made thousands of negatives of objects in the Museum and of artworks in other public and private col-

lections including the Royal Collection and the Louvre. Thompson was an active organiser and exhibitor of the Photographic Society throughout the 1850s and early 1860s. In 1866, at the direction of the Museum, Thompson left on a tour of Portugal and Spain and produced fine architectural photographs, among them views of the Cathedral of Santiago de Compostella, Spain. Late in 1867 he stayed in Paris to assist with the photographic section of the international exhibition. While there he suffered severe attacks of jaundice and died on 20 January 1868 aged fifty-two.

THOMS, WILLIAM JOHN (1803–1885)

The writer William John Thoms was born in Westminster, London, and initially trained as a clerk, working for over twenty years at Chelsea Hospital before moving to the House of Lords as Clerk around 1845. He eventually held the post of Deputy Librarian there from 1863 until his retirement.

In addition to his clerical posts, Thoms was a prolific writer, and in 1849, founded the subsequently influential journal *Notes & Queries*. The journal first carried an essay on photography in September 1852, and in the following issue, Thoms explained his decision to include the new art:

> The shadow of a doubt that we once felt as to the propriety of introducing the subject of Photography into our columns, has been entirely removed by the many expressions of satisfaction at our having done so which have reached us.

and thus embarked on an engagement with the medium which continued for many years. Amongst his early contributors were Dr Hugh Diamond, who would later edit the *Journal; of the Photographic Society* and George Shadbolt, later editor of *The Liverpool & Manchester Photographic Journal.* Thoms, himself a keen amateur photographer, continued to edit *Notes & Queries* until 1872.

In the wider world of literature he is remembered for his 1879 book *The Longevity of Man: Its facts and Its Fictions* (London: F Northgate) and for the invention of the word 'folklore' in 1846.

JOHN HANNAVY

THOMSON, JOHN (1837–1921)

John Thomson was born in Edinburgh in 1837. While little is known of his early years, the intellectual breadth of his writings suggests that Thomson was well educated. He was a versatile photographer whose work ranged from portraiture, landscape and architecture to studies of urban life. Thomson was a keen observer of his various subjects, a skill that led him well beyond the conventions of travel photography.

Thomson traveled to Asia in 1862, at the age of twenty-five, settling first on the island of Penang in Malaysia. With brief interruptions, Thomson lived in Asia for the next decade, photographing in Siam, Viet Nam, Cambodia, Formosa, and vast stretches of China. It is difficult to overstate the challenges that Thomson confronted during his travels in Asia. Traveling with the paraphernalia involved in the wet collodion process was arduous, what with the weight and fragility of the cameras, lenses, glass plates, chemicals, trays, and material sufficient to make portable darkrooms. He transported himself and his equipment to high mountain ranges, jungles, swamps, and the upper reaches of the Yangtze River. But just as formidable were the challenges of negotiating different languages and cultures. Thomson must have been a man of considerable charm and persuasion, since he repetitively connected with powerful, well-placed people in these countries who sat for his portraits and then enabled him to gain access to other people and remote areas. The King of Siam, for example, provided support for Thomson to photograph, for the first time, the extraordinary ruins at Angkor Wat.

Thomson was not immune from ethnocentrism and cultural bias in his images and writing, but in the main he expressed a genuine respect for native customs, and he took evident pleasure in explaining these differences to his European readers. When traveling, Thomson took extensive notes which he later used for the essays he published along side his photographs, in which he explained in considerable detail a wide range of local customs. On occasion he made pointed comments about how Europeans could learn could learn from the comparisons. When writing about Cantonese merchants, for

Thomson, John. A Young Prince. *The Metropolitan Museum of Art, Gilman Collection, Purchase, Cynthia Hazen Polsky Gift, 2005 [2005.100.583 (33b)] Image © The Metropolitan Museum of Art.*

example, Thomson suggested that, "Here we find none of the display, none of those desperate efforts to secure the lion's share of custom, which competition has fostered in European towns." Thomson photographed and wrote about the full spectrum of society from Kings, politicians, and traders to peasants, street people, beggars, and even criminals. To appreciate the achievement of Thomson's Asian work, we should bear in mind that most of the people who posed for him had never seen any picture of themselves, much less a European who brought with him this odd collection of equipment that somehow produced miraculous images. Thomson clearly had the ability to put people at ease and gain their trust, which in turn allowed him to convey a sense of unforced naturalness in his portraits.

Thomson also made outstanding photographs of the various terrains that he traveled in Southeast Asia and China. His photographs of mountains, for example, compare favorably to the Bisson Frere's studies of the Alps and Samuel Bourne's images of the Himalayas, and he was no less successful in photographing jungles, farmlands, rivers, and seacoasts. He also made accomplished architectural photographs of pagodas, houses, temples, and other structures. Like many great photographers, Thomson's visual versatility allowed him to find unique solutions to challenging subject matter.

When Thomson married his wife, Isobel, in 1868, they settled in Hong Kong. When she returned to England after the birth of their son, Thomson continued photographing in Asia, but he finally returned to England for good in 1872. He published four volumes on his travels in China entitled *Illustrations of China and its People* (1872–74). These ambitious books contained over two hundred photographs, which were published along side his detailed and entertaining commentaries. In 1875 he published a lengthy memoir of his travels in Asia, *The Straits of Malacca, Indo-China and China,* which were illustrated with engravings based on his photographs. Taken together, these books comprise the most complete photographic and ethnographic record of China and Southeast Asia made during the 19th century.

Thomson applied the skills he had honed in Asia to his native culture when he began photographing street people of London. The resulting book, *Street Life of*

London (1877), combined his Woodburytypes with detailed essays on the images. His collaborator, Adolphe Smith, wrote most of the texts, although Thomson wrote some of them, and in all likelihood they collaborated on many of the rest. The authors stated their intentions in the Preface:

> we have sought to portray [the] harder phases of life of bringing to bear the precision of photograph in illustration of our subject. The unquestionable accuracy of this testimony will enable us to present true types of the London Poor and shield us from the accusation of either underrating or exaggerating individual peculiarities of appearance.

Street Life of London represents a major breakthrough in street photography, which until that time had been a minor sub-genre of photography. While photographers like Charles Marvill, Charles Negre, and Henry Mayhew had occasionally ventured into the streets, the bulkiness of the cameras and slow exposure speeds were obstacles. But the obstacles extended considerably beyond technical limitations: with few exceptions, art and literature before the mid-nineteenth century seldom dealt with the common man, much less the impoverished or the homeless. However, a combination of political, intellectual, and cultural factors had developed since the late eighteenth century that led writers and artists to begin to pay attention to the under classes. Thomson's extensive experience in Asia made him uniquely suited to take on the poverty in his own back yard. Thomson's London photographs are beautifully rendered, but they also function as moving documents of people who were living on the edge of society.

Unfortunately, this was not the kind of work that could sustain Thomson's stillgrowing family. Accordingly, in 1879 Thomson set up a studio in London where he specialized in portraits and took on various commercial assignments. He continued his studio work until around 1910, when he finally retired.

Thomson's legacy lies in his extraordinary versatility as a photographer and his ability to capture in his photographs and writing the salient features of a broad range of subject matter. He photographed and wrote about individuals from all walks of life with remarkable equanimity. His work can be seen as a precursor to much ethnographic and anthropological work that developed in the twentieth century. Thomson brought to his photography a rare combination of visual virtuosity and keen intellectual curiosity.

THORNTON, JOHN EDWARD (c. 1865–1940)

John Edward Thornton was born around 1865 and started his photographic career in 1885 when he was twenty. By the end of 1886 he was trading under his own name in Manchester selling photographic equipment. By then he had also been granted several photographic patents.

He started the Thornton Manufacturing Company and introduced several cameras and his patent roller-blind shutter which proved popular. A need for capital to expand the business seems to have been required and by 1887 Thornton was working with Edgar Pickard and a formal partnership, under the name The Thornton-Pickard Manufacturing Company commenced in January 1888. The success of Thornton's roller-blind shutter which had sold 12,000 units within three years allowed the firm to build a new factory in Altrincham. The factory, which was mechanised, produced shutters and an extensive range of cameras starting with the Ruby field camera. Thornton-Pickard became a significant British volume manufacturer of cameras in the period 1890–1914.

Edgar Pickard died in 1897 and his brother George Arthur Pickard joined Thornton as joint managing director. The same year Thornton reported that shutter sales had shown an increase of 11 percent and camera sales 264 per cent with profits of £7255. The company began to concentrate on producing cameras where greater profits were to be had. In 1898 after an Extraordinary General Meeting Thornton was forced out of the company the result of him trying to respond to increased competition by developing new products, notably sensitised film, in the face of the opposition of Pickard who wanted to maintain the company's existing product range. Over the long term Thornton's strategy was shown to have been the correct one.

Under Pickard the Thornton-Pickard company initially continued to expand. The factory was increased

to 20,000 sq ft and employed 250 employees in the pre-1914 period. The company mass-produced a range of cameras from traditional mahogany field cameras to amateur hand, box and folding cameras and, from 1908, reflex cameras. During the war it developed aerial cameras for the government but after 1918 it failed to innovate its consumer and professional products and despite attempting diversification into toys in the 1920s with Picabrix it gradually declined as a photographic manufacturer. TP ceased trading in 1959 by which time it was only undertaking photographic repairs.

After 1898 Thornton continued to patent a range of devices relating to photography and other subjects and he tried, unsuccessfully to expand into film production and undertook other business ventures before he moved to the United States. He seems to have had some success with cinematography and was earning royalties from Kodak during the 1920s.

Thornton returned to Britain and died on 5 October 1940 forgotten by the photographic industry that he had been part of fifty years previously.

TILBROOK, HENRY HAMMOND (1848–1937)

Tilbrook was born in Llandudno, Wales, and arrived in Adelaide, South Australia, with his family aboard the *Albermarle* in 1854. He worked as a compositor for the *Register* newspaper and after other work including a stint in New Zealand looking for gold he established the *Northern Argus* newspaper in Clare in 1870. He became a keen amateur photographer in the dry plate era, making numerous trips into the surrounding countryside and beyond. After retiring in 1891 he moved to East Adelaide and he made a number of lengthy photographic (and hunting) excursions including visits to the Flinders Ranges in 1894, Mount Gambier in 1898, Mount Bryan in 1899, Mount Gambier to Robe in 1900 and Mount Gambier and Portland, Victoria in 1905. He created albums of prints, stereoviews and enlargements but did not make a commercial venture of this although some of his enlargements were supplied to the Railways Dept to decorate train carriages in 1901. Tilbrook made detailed notes of his travels in diaries and a collection of his photographs and glass negatives was acquired by photographic historian R. J. (Bob) Noye and is now in the State Gallery of South Australia. An exhibition of his work was held there in 2001.

MARCEL SAFIER

TINTYPE (FERROTYPE, MELAINOTYPE)

A process first introduced in the mid-1850s, the collodion and later gelatin-based images on thin metal sheets were customarily sent through the mail to sweethearts and family. Though popularly called "tintypes," they were never made of tin. Tintypes have been produced in the studio, by itinerant photographers and by the general amateur. Tintypes became the vacationers' keepsake, the Sunday strollers' memento. Ironically, the tintype, which so permeated the lower working class of society, rarely outlined its social problems and other struggles. Rather the tintype image, largely through the use of studio props, created an ersatz lifestyle and does little to further our understanding of the working-class life. This suggests that it is wise to remember that photographs cannot stand alone as interpretative statements about the past, any more than can other primary sources.

The tintype was immensely popular in North America from late-1850s onward and, to a much lesser degree in Europe and elsewhere. The use of collodion chemistry eventually gave way to gelatin emulsion manufacture by the early-1890s. This genre survives even today and noticeably practised by street photographers in Central and South America and India.

Ferrotypy is the proper technical name for the process. The words "ferrotype" and "tintype" are often used interchangeably to describe the light-sensitive plates, and "tintypist" to describe the photographer. These and other terms proliferated throughout the popular language and in commercial and technical publications (see Appendix).

The tintype was the particular application of Frederick Scott Archer's wet-collodion process. A japanned (i.e., blackened) sheet of thin iron was substituted for the ambrotype's glass support. The plates were coated with collodion, quickly sensitized and immediately exposed in the conventiona "wet plate" manner. The "tintypist" would develop and fix the plate, and cut it apart with tin shears. Formats ranged from postage-stamp size "gem" tintypes (approximately 1.5 × 2 cm) to the large "double whole" plates (21.5 × 33 cm). (Though technically inaccurate to classify a tintype by "plate" dimensions, popular nomenclature prevails.) Tintypists enhanced the image by applying assorted water- or oil-based colours and protective shellacs to its surface.

Collodion Ferrotypy

By 1853 Parisian college professor Adolphe Alexandre Martin presented to the Société d'Encouragement and to

the French Academie des Sciences two *Compte Rendus* which outlined processes to make direct positives on glass and on tinned plate or galvanized iron. His reports had little impact on a nation still enamoured with the daguerreotype and certainly with the new albumenized paper processes. Apparently unaware of Martin's work, Hamilton L. Smith, professor of natural science from Rambier, Ohio, carried out similar work with a seminary student, Peter Neff Jr. during 1853–54 and then independently in 1855. In 1856, on the advice of Neff, Smith obtained U.S. Patent 14,300 (February 19, 1856), to make "ferrotypes." The patent suggested that black japan needed to coat the metal plate (before one can make it light-sensitive) could also be applied to "leather, fibrous materials and rubber." William Kloen and Daniel Jones Enlgand also patented the "ferrotype" that same year. Europe, with its predilection for social classes, showed no interest in the "lowly" process. Peter and William Neff eventually purchased the patent rights for the manufacture of the plates.

In spring 1856 Peter Neff promoted the new process through a pamphlet entitled *The Melaintotype Process, Complete*. By October, American innovator Victor Moreau Griswold applied for two patents to improve the process. Soon-to-be-competitor Griswold criticized the name "tintype," calling it "senseless and meaningless." He sarcastically pointed out that "not a particle of tin, in any shape is used in making or preparing the plates, or in making the pictures …, unless it be, the *tin* which goes into the happy operator's pocket after..." In 1863, tintypes were purchased for as little as two cents each and still proved profitable! Oliver Wendell Holmes pushed to have 'the 'tin-types' "properly" renamed 'stannotypes.' (Ironically, Holmes' "stannotype" might refer to iron-black colour but its root *stannous* refers to any compound containing tin.)

By early 1857, continued experimentation resulted in improved resistance and assorted hues (blue, green, red and chocolate) to the japanned surfaces. The japan or varnish was made with linseed oil, asphaltum and sufficient umber or lampblack to give the desired shade, boiled, then tested for consistency—thinned with turpentine if necessary—and eventually brushed onto the metal, and oven-dried. Other possible ingredients included mastic, lac or copal varnishes and other shades of colouring matter. The reported manufacture of white enamalled plate susceptible to produce a negative image never materialized.

From mid-1850s to early-1860s, Neff and Griswold were the sole manufacturers of tintype plates in North America. Through pettiness or excessive competitiveness, each threatened the other with lawsuits. Griswold cut his prices as he improved production of his plates. Neff countered by freely making available the necessary licenses to practise ferrotypey, since patents forced the photographic fraternity not only to buy the plates at monopoly prices, but also to buy the right to use them. Fees ranged from $25 to $300 for a "room-right license." Both failed to recognize early the weakness of their geographical location that eventually saw the manufacture of japanned collodion plates switch from their Ohio bases to the increasingly industrialized cities of Newark, New Jersey, and New York. By 1868 several companies had joined the fray: Holmes, Both & Hayden; Willard & Co.; and Anthony & Co. acting as distributing agents to several manufacturers. The Chadwick Leather Manufacturing Company of Newark, New Jersey, manufactured tintypes, but no evidence exists of its pannotype, i.e., the manufacture of photo-sensitized leather.

Horace Hedden or his son H. M. Hedden, of the Ph[o]enix Plate Company, Newark, New Jersey, created the "Chocolate" plate after obtaining a patent on March 1, 1870. This plate would temporarily renew the interest in ferrotypy. By August 1871, an English patent had been obtained.

The More Rapid Gelatin Dry Processes

While producing astounding results, collodion photography, by its shortfalls (i.e., the need to immediately prepare, sensitize and photograph), encouraged the search for a more convenient means of capturing an image. The new, consistent and reliable, gelatine dry plate of the 1870s would some twenty years later give rise to commercially manufactured gelatin-silver tintypes.

In 1871 Richard Leach Maddox invented and published the first practical formula for gelatin-silver halide emulsion. By 1873 prepared *gelatine dry* plates were being marketed in England. The following year Richard Kennett introduced the "high speed" pelllicle and subsequently offered prepared dry plates. The manufacture of the gelatin tintype however only came into existence in 1890. Basic emulsion manufacture ("ripened" emulsion) was cooled to a jelly; cut into noodles, washed of excessive chemicals and by-products; reheated (altering the chemistry) and finally coated onto a continuously moving roll of sheet metal support (i.e., the plates) and cut into standard sizes and packaged. In England's post-industrialized social climate, ferrotypy gained popularity, especially with the introduction of dry "ferrotype" plates by Ladislas Nievsky in 1891. Dependable development time varied from eight in hot climates to sixty seconds in polar temperatures. After fixing (1:5 ratio hyposulfite/water) for ten to thirty seconds, the plate was quickly rinsed, dried and then varnished.

The advent of the "street" camera, with built-in processing facilities removed the need for a portable darktent and contributed to the third and final resurgence of the tintype, especially in North America. By 1894 The Bosco Automatic (booth) Camera manufactured by

Bernitt, Hamburg, Germany, produced a small tintype shaped like a shallow tray. The recessed shape sequentially held developin /processing and fixing chemistry. Patrons entered the booth, paid their fee, and exited with a tintype self portrait within three to five minutes.

TISSANDIER, GASTON (1843–1899)

It was as a scientific scholar, a public educator and writer, and an enthusiast for new inventions that Gaston Tissandier's major contribution to photography in the nineteenth century was made. His formative influences were in science, journalism and ballooning. Having completed studies at the Lycée Bonaparte, Tissandier studied in the chemistry laboratory of P.P. Dehérain at the Conservatoire des Arts et Metiers, Paris, before taking courses at the Sorbonne and the Collège de France. By the time he was only twenty-one (1864), he became Director of the Laboratoire d'essais et d'analyses chimique de l'Union nationale. Within three years he co-authored, with Dehérain, the 4-volumed *Elements of Chemistry* (Hachette, 1867–70) and was commissioned by Hachette to write four books for the series Bibliothèque des Merveilles (Library of Marvels), beginning in 1867 with *l'Eau* (*Water*) and progressing through to 1874 with monographs on Coal, Fossils and Photography. The first of these was certainly indebted to Dehérain, but the fourth in the series, *Les Merveilles de la photographie* (*Handbook and History of Photography* (1878)), reflected the young scholar's own interests. Tissandier continued to write many books on science, including those on dust particles in the upper atmosphere and on the construction of electrostatic dirigible balloons.

If science was his first love, writing was a close second. Aged twenty-three he began contributing to Edouard Charton's illustrated weekly on the arts, literature, history and sciences, *Magasin Pittoresque* (established 1833 to "instruct and moralise the new generations"), awakening in the young man a lifelong belief in education through the popular press. In 1873 Tissandier established his own illustrated scientific journal, *La Nature*, attracting the publishing support of Hachette after the first year. Tissandier wrote innumerable articles on all branches of the sciences for this journal, and as editor was able to attract the support of leading scientists. Much of the material that first came to light in *La Nature* was collated and expanded into one of his most influential tomes, *Les Récréations scientifiques* (1880), which presented science as knowledge attained through wonder and fun-filled experiments, most of them amenable to the home enthusiast. As a fluent writer and eloquent public lecturer, many of his books went into multiple, revised editions, and were translated into many languages.

A third formative influence was ballooning. Having made his début ascension on 16 August 1868, Tissandier went on to make many aerial voyages. Most of his ascensions were to further meteorological knowledge (e.g. analysing dust particles in the upper atmosphere) and the science of aeronautics (leading he and his architect brother and lifelong companion, Albert, to devise electric and propeller-driven balloons). Indeed, it is as a balloonist that Tissandier is now best known.

To these formative influences should be added patriotism, for Tissandier's ballooning expeditions over enemy lines during the Siege of Paris by Germany (1870–71) was not only rewarded with his being made a chevalier of the Legion d'honneur on 15 November 1872, but predisposed him to embrace the philosophy of the newly-formed French Association for the Advancement of Science which stood 'for country and for science.' According to his biographer, Le Cholleux, *La Nature* and his many other publications were driven by a desire to enhance the quality of science in France.

Tissandier's interest in photography is best revealed in three texts, *Les Merveilles de la Photographie* (1874); segments in *Récréations* (1880); and *La Photographie en ballon* (1886).His photography has its roots as much in popular entertainments of illusionism, as in painstaking scientific experimentation. 'Admirable photographs,' he argued in *Photographie*, reflect the 'skill of the physician and the taste of the artist,' and have 'colour, relief, delicacy and truth,' their 'rigorous precision' making them invaluable to the artist, architect, archaeologist, geographer, explorer, and those maintaining criminal and juridical archives. For Tissandier, aerial panoramas could assist surveying as much as military reconnaissance. Indeed, *Photographie en ballon* includes an albumen print frontispiece of the port of the Hôtel de Ville, Paris, 'taken at 600m. altitude by messieurs Gaston Tissandier and Jacques Ducom,' where the strongly intersecting diagonals of streets and bridges, remarkably modernist in composition, are delineated on a transparent overlay, to demonstrate its value as a map. This and other crisp aerial images, in fact taken by Ducom, were indebted to successful efforts to minimise shudder in the basket, and the use of M. Bacard's plates enabling exposures at 1/50 sec. He also collaborated with Paul Nadar, who photographed Versailles and Sevres from 800m. Tissandier wrote lucidly of the history, chemical processes and applications of photography. His enthusiasm for 'that sublime and beneficent art' rested on the camera's ability to accurately reproduce the human face, distant lands, and all the sciences from laboratory-based micrography to astronomy. Writing in a clear and accessible narrative style, often complemented by the inclusion of abundant images, his books and articles were written to inform and enthral young and old.

Tissandier was an amateur photographer, serving at various times as president and vice-president of the Société d'excursions des amateurs de photographie (founded 1887). He was a member of the Société française photographie, as well as societies of aerial navigation, meteorology, chemistry, and served on government commissions of military aerostations and civil aeronautics.

His prodigious publishing activity ensured that Tissandier was well known to his contemporaries in France and abroad. During his life he was included in national dictionaries of biography. Few authors in the twentieth century have referred to his work, and most only in passing and by reference to aeronautics.

CATHERINE DE LORENZO

Biographical

Gaston Tissandier was born in Paris on 20 November 1843, the second son of Paul Emmanuel Tissandier and Caroline Agathe Decan de Chatouville. Interestingly enough, all contemporary accounts give Tissandier's birth date as 21 November 1843, but the copy birth certificate at the Service des Archives départementales, Paris, clearly states his birth as 20 November 1843. The original birth certificate was destroyed during the Siege of Paris in 1871 when the Hôtel de Ville was set alight. Following his studies at the Lycée Bonaparte, he worked as a chemist at the laboratory of the Conservatoire des Arts et Métiers, before being named director of the Laboratory of Tests and Chemical Analysis of the Union Nationale in 1864. He published more than two dozen books, jointly authored nine more, presented more than ten major papers to learned societies, and wrote innumerable articles, especially on hot-air ballooning and popular science. He was the founding editor of the illustrated popular science journal, *La Nature*, His death certificate notes he was predeceased by his wife, Louise Anne Arbouin, and his brother noted that he had two children. Tissandier died 30 August 1899 in Paris.

TONING

Armand-Hippolyte-Louis Fizeau—the French physicist best known for being the first to develop a reliable method of calculating the speed of light—was responsible, in August 1840, for proposing some significant advances in the daguerreotype process. The most enduring of these was the use of gold chloride as a final chemical treatment after fixing—most recipes employed dilute solutions of both 'hyposulphite of soda' and 'chloride of gold' mixed just before use. This had several effects, marginally raising the contrast of a daguerreotype, slightly intensifying the image, and most significantly, increasing the stability and permanence of the delicate image. It also slightly changed its color, imparting a warm tinge to the darker areas of the image.

Despite the fact that this process changed the color of the daguerreotype image, it was invariably described in contemporary journals not as 'toning' but as 'fixing' or 'gilding.' The term 'toning' would not come into general use until well into the ascendancy of the paper albumen print. Gold chloride remained the basic building-block of the majority of toners throughout the remainder of the 19th century.

Writing on the subject in *The Dictionary of Photography* in 1897, Edward John Wall noted that "If a silver print is placed directly into the fixing bath, an

unpleasant brick-red color is the result." That brick-red color, and the wide range of other reds and sepias which could be produced when making both salt prints and albumen prints had long been considered unpleasant.

It was probably Louis-Desiré Blanquart-Evrard, the originator of albumen printing paper, who first proposed the application of the gold chloride toner to the paper print. Fortuitously it had the same preservative and stability effects which had been experienced with the daguerreotype, but also brought about a dramatic color change. The albumen image was, in its un-toned state, both reddish-brown, and unstable—neither of them desirable qualities. Relatively quickly the image deteriorated and the highlights—always a pale cream and less brilliant than had been previously experienced with the salt print—darkened and yellowed. The gold toner not only produced a rich purple/brown hue to the shadows, but also acted as an effective barrier to the yellowing of the highlights, as well as reducing image fading. The richness of many of the Victorian images preserved today attests to the effectiveness of the gold toner to an otherwise correctly processed print.

As understanding of the chemical processes deepened, it became clear that the acidity or alkalinity of the gold chloride bath had a significant impact on its effect. By the closing years of the nineteenth century, over twenty recipes for gold chloride toning baths were available in contemporary manuals—each offering a slightly different effect dependent upon its pH. An acidic solution was found to produce a reddish hue in the print, a neutral solution created the purple/brown colors so fashionable from the 1850s, and an alkaline solution tended towards the blue/black shadows, creating a much colder image.

With the introduction of the bromide print, and a broader understanding of chemical effect, a much wider range of print colors could be achieved by the end of the century—platinum toners produced a rich sepia, copper a bright red, vanadium a deep muted green, and iron toners offered a range of blues.

TOPLEY, WILLIAM JAMES (1845–1930)

Photographer and businessman

William James Topley, was born 13 February 1845 at Saint John, near Montreal, Canada East, now Quebec and died 16 November 1930 in Vancouver, British Columbia.

Topley began his career as an independent tintypist but from 1864 apprenticed with William Notman, Montreal. At age 22, Topley took charge of the new Notman studio in Ottawa, the first established outside Montreal; by 1872 Topley was "proprietor" of the Notman studio, and in 1875 set up independently as The Topley Studio with a staff of fourteen. By 1880 he had vice-regal patronage, being appointed photographer to Governor General the Marquis of Lorne; this confirmed his reputation but did not appear to increase his income. The Topley Scientific Instruments Company, established in the 1890s, specialized in the repair and sale of optical and survey instruments and photostat machines; at the same time the Topley Studio started selling cameras and film and provided developing and printing services for amateurs.

While the studio specialized in portraits, including those of most of the leading politicians, it also did scenic work for the tourist trade and a great deal of commercial, industrial and government work, in Ottawa and Quebec, Ontario and the west. Some of Topley's work has been used on Canadian currency and postage stamps. Approximately 150,000 negatives are located at Library and Archives Canada.

Topley and his son William de Courcy managed the Studio from 1868 to 1923, successfully negotiating major changes in photographic methods and materials, accommodating business cycles and the advent of the snapshooter, but finally closing it because there was no family successor.

ANDREW RODGER

TOPOGRAPHICAL PHOTOGRAPHY

Dependence on a long history of pictorial and landscape conventions means that topographical photography inherited ways of seeing which precluded the sort of objectivity and inclusiveness which the medium was capable of delivering—much that was feasible from 1839 is absent but the reasons for these absences are complex. Processes were unwieldy, image permanence problematic, but, above all, demand hardly existed. The depiction of buildings, townscape and the human environment does of course occur—but the earliest evidence is frequently visible at one remove: daguerreotypes were employed as the source for line illustrations. This indirect application of photography is most evident in N.

P. Lerebour's *Excursions Daguerriennes* [1842]. In the United States the advanced development of daguerreotype technology meant that the depiction of topography is a little more common.

Only in France was there any form of official attempt to record the cultural landscape but even the Mission Heliographique proved to be a premature model for the systematic use of photography in a topographical or architectural manner. Depiction of isolated cultural treasures and picturesque landscape precluded many representations of personal and public spaces. A recent pioneering photographic survey of Antwerp acknowledges these visual absences but also noting that the smells, sounds and urban historical context necessary to allow proper interpretation. Apart from the work of a few photographers such as Charles Marville in Paris and Thomas Annan in Glasgow who were commissioned to record redevelopment or slum clearances there is only weak or indirect visual evidence for the reality of Victorian culture: the objective eye of the camera was simply not pointed in directions we now want to explore.

The daguerreotype quickly became ubiquitous—much is known of work in Egypt, Palestine, Jordan, India and North Africa and South America but it is significant that in Canada the earliest known topographical views are recorded as late as the mid-1850s. Unlike the sophisticated application in the United States, topographical daguerreotypes in many other countries were never taken or do not survive. This absence is directly related to absent markets—especially in tourism. Viable marketing and distribution conditions are necessary for photographic production but even when both the technology and the incentive existed, prevailing fashion dictated specific 'polite' forms of coverage avoiding whole sectors of the society in question: all topographical 'records' and 'views' are clearly limited by both social and market forces.

It is only very recently that some of the earliest topographical collections have surfaced at auction (Gilbert de Prangey) and the extent of knowledge and image survival is still fragmented. Much of what we know has only developed since the 1970s and is dependent on haphazard factors—in the market, in academia and in the variable criteria applied to digitisation. The archaeology of photography and the genealogy of image generators remain undeveloped discipline but an emerging global outline of topographical collections means that key figure like Russell Sedgefield (born in Devizes, Wiltshire) is best known through family sources in New Zealand and Australia, Gustave le Gray's later Egyptian life can now be linked with his earlier fame in France, and the surviving archives of key Scotish topographical companies (James Valentine, George Washington Wilson) are being made available online (in Scotland) It can also mean that more is known about the North American work of a mobile photographer like William England than any of the rest of his English or international work he mostly executed for the London Stereoscopic Company, whose remit was by no means restricted to London or even England.

Sophisticated marketing and distribution systems and the dispersal or amalgamation of collections means that interpretation of apparently national concerns may require international context. 'Local' views may indeed be generated by local photographers but many similar views were produced by major commercial companies so that an understanding of business history starts to become necessary. In particular the huge market for stereoscopic views confirms the need for a global overview. Negretti and Zambra consciously sought the views created by Francis Frith in Egypt which they knew they could sell in key locations where there was domestic demand for tourist views such as the Crystal Palace at Sydenham. Later Underwood and Underwood operated on an international basis and competed with European companies for the lucrative stereo market. However, the massive educational and tourist output of such companies was still constrained by the landscape and fashion conventions. The reach of individual photographers like Felice Beato could extend beyond the Mediterranean basin as far as Japan—indeed his complex nationality and extended travels illustrate the sheer breadth that one photographer could encompass. In a cultural sense, however, barriers still existed: for much of the century topographical views signally avoided social realities allowing images to be culturally integrated in historical terms.

In France, Britain and the United States the combination of industry, commerce, empire and antiquarianism succeeded in producing a global photographic era. John Thomson is famous for work in the Far East yet his extensive operations in his home country (apart from his famous publication on London street life) are little known: as the chosen photographer for the English branch of the Rothschild dynasty he may have been better remunerated for his opulent English architectural commissions than for his views of Japan. Based in Alsace Adolph Braun dominated European tourist views as well as creating a monopoly for tourists intent on acquiring or appropriating gallery images associated with the Grand Tour. Braun and Frith represent the new industrial application of photography which before the advent of wet collodion was pioneered by Blanquart-Evrard in Lille: the first mass production of topographic views occurs in limited form in the early 1850s but was succeeded within a decade by the massive printing operations by Francis Frith in Reigate, Surrey and by Adolph Braun in Dornach. By the 1860s the beginnings of huge national branch empires are evident such as A & G Taylor of London who combined chains of portrait

studios with topographical work using the full industrial printing techniques. Such mass production (often mixed with portraits) means that the study of such photographic concerns has be merged with knowledge of printing or lithograph companies if we are to understand the first generation of mechanical processes driven by the increasing audience for topographical images for the burgeoning tourist market. So all images from the 1860s need to be assessed in such a light: Fratelli Alinari in Florence dominated the Italian tourist market, William Lawrence of Dublin dominated Ireland, Notman becomes a major producer in North America based in Montreal, and Matthew Brady signals the advent of the photographic combine in the United States. Careful distinction needs to be made between these 'super-companies' who with others must be seen as a distinct category quite separate from individual photographers or small firms such as F M Sutcliffe of Whitby who also undertook more mundane commissions like recording the Whitby branch of the Woolworths chain store. The same photographer could equally embrace both the picturesque and romantic as well as the more practical or commercial aspects of the same region.

It is only later in the century with the availability of cheaper equipment and processing that a demand appears for nostalgic delineations of the lost national cultures now dominated by industry. Yet the very industrial and urban environments which had helped to create and popularise photography are often the very elements least evident in topographical views.

TOURIST PHOTOGRAPHY

Travel and travel reports have been associated with each other since ancient times. The Greek Odyssey is no more than a travel report; the same for Gulliver's Travels and many other more or less fantasy tales and 19th Century photography was able to provide more reliable information about far away places.

Nineteenth century travel was marked by an earlier 18th century idea that travelling was a "grand tour" in which any well born, young, rich gentleman should take, seeing historical places, like Italy, in order to see ancient sites, architecture and art. Travelling and enlightenment

were typically closely linked. With the advent of photography, tourists, with the help of the *Camera Lucida,* or from other optical devices commonly photographed monuments and anything of interest, including William Henry Fox Talbot as he did during his 1830s travels.

By the mid 19th century this kind of travel was well established, however, difficulties with using cameras prevented most travellers and novice photographers to have to purchase images from independent professional travelling photographers. At the same time large commercial photographers started to see an important market in photographing distant or exotic places. Not surprisingly, the locations appearing in early travel photography were similar or the same places considered worthwhile to "grand tour" travellers such as Italy and Greece for the classical travellers and the Holy land and the Middle East for the biblical and exotic travellers.

During the19th, century new means of transportation allowed travelling large distances to be made with greater speed and comfort. Photography, since the mid 19th century was an important travel companion. Coincidentally, the train and camera were invented almost at the same time, and technological progress in photography paralleled the growth of railway lines in most developed countries, suggesting perhaps a symbiotic relationship. Both however answered the needs of industrial society and middle class aspirations. In the late 19th century, lighter cameras and dry plates, made travel photography more widely available to the well-heeled traveller and to middle classes. From the 1890s onward, travel was to be one of the most important genres for photography.

Mid-19th century travel photographs were mainly produced by professionals such as Francis Firth, Antonio Beato, Felix Bonfils and the Zangaki brothers in the Middle East; the Bisson brothers for the alpine mountains; the Alinary brothers in Italy; Charles Clifford or J. Laurent in Spain, John Bourke in India, Felice Beato in China and Japan, Carleton Watkins and Eadweard Muibridge in the North-American west or Cunha Moraes in Portuguese Western Africa. These professional photographers travelled on photographic expeditions using whatever transportation they could to take pictures. Then, they produced their images and sold them in both small and large formats, as well as in stereograms. Generally the images taken on these trips were for those who could not travel, often serving as a substitute for travelling.

Often travellers would carry their photographic souvenirs with them when they returned home. These were typically studio portraits that had been taken abroad and served as proof of travel. Also, these images were representative of affluent classes and linked the owners to high society as represented by the fashionable photographer. This idea of having one's likeness taken at a major travel destinations came early in History of Photography. Daguerreotypists had been active at Niagara Falls since the late 1840s where they targeted the tourists who travelled to this important destination in American. Many 19th Century people had their picture taken for the first time at other vacation or tourist destinations as well like beach or other tourist spots.

Even though there were great difficulties involved in travelling and photographing with mid 19th cntury cameras and processed, there were quite a few amateurs among the travelling photographers such as George Moir (1800–1870), a founding member of the Edinburgh Callotype Club, college professor and latter Sheriff of Ross-shire, and photographer of Ghent; Sir James Dunlop (1830–1858), photographed Malta and Italy in the course of a "Grand tour" in the late 1840s; another Scot, Robert McPherson (1811–1872) photographed Rome and its surroundings, as did Giacomo Caneva (1813?–1865) from Padua. Since the 1850s every major European country had its gallery of amateur travelling photographers, including the Germans even if they seemed to be less active than others.

Later, local photographers understood the potential of the tourist market selling views and images of local or indigenous people to travellers. Even if this was a worldwide practice, Samuel Bourne took a good part these types of images especially in India, the most striking example of tourist photography however came from photographer Christiano Júnior, who produced and sold studio pictures of slaves as a souvenir to those visiting Brazil. Even ambulant photographers understood the new market potential, placing themselves close to main tourist attractions in order to make visitors "instant" photographs.

With late 19th century technical progresses in photography there was a bigger place for one of the most popular photo motivations, travel. Newer cameras that were smaller in size and easier to operate were created as were dry plates, which did not needed to be sensitised before exposure, making travelling with a camera painless. Travelling itself also became much easier as trains were able to go farther distances in smaller amounts of time, and because of this the travel industry was developing, catering not only to the upper classes, but to a middle class as well, which began to take part in tourism.

It the late 19th century, the photographic industry saw the emergence of cameras that were smaller and lighter which made hand held exposures possible. This innovation created a new market potential for tourist photography. This practice was compatible with not only simpler and cheaper Kodaks, but also for the more expensive hand cameras like Ernemman; Voigtlander; Contessa and Goerz. Furthermore, some inventors even developed a special type of camera for the tourist mar-

Beato, Antonio. Group at Abydos.
The J. Paul Getty Museum, Los Angeles
© The J. Paul Getty Museum.

kets like tropical cameras which were made to deal with warm, humid climates and a special bike cameras was invented to allow people to carry a very light camera while cycling.

To further develop people's interest, photographic societies were started allowing people to pursue both photography and travel, or even sometimes, photography and cycling. The train and the bicycle were the two main travel companions for the 1890s photographers, replacing the mule cart used by photographers of the daguerreotype and wet plate decades.

Besides travelling to new places an increasingly large group of society was enjoying parts of the summer at seaside resorts. Even though these resorts were mostly class segregated, photography played an equal part in the summer for all classes, starting from the small trade of ambulant photographers to the high-class studios from the large cities migrating with his well-heeled clients.

This usually local summertime tourism meant that a good amount of tourist photography from the later 19th century was made in the photographer's own country. Some spots with a special aura would evoke that country's history and meaning. Some figures, like Shakespeare in Great Britain, and others that were seen as particularly important would have their lives as imagined by photographers explored and photographed, not only by a large number of amateur and professional photographers, but images of their houses would appear in photographically illustrated books and tourist guide books. Each country created its own photographic stereotypes, one for instance was that England was magic and small, and another was one where Spain exotic and grand.

With mass travel and mass tourism came the distinction between the tourist and the traveller, the former being unable to grasp below the surface of things, being

the second able to enjoy aesthetically the pleasures of the landscape. This means that there was a complete social set of what deserved to be photographed and what did not, the landscape, coming from 18th century painting was a socially constructed one. Some of these conventions are still important in today's tourist photography.

This need for tourism to the most significant parts of a country came, also, from the idea that the countryside was soon to disappear under the huge wheels of the industrial society. To photograph what was about to disappear, creating a link between past, present and future, was a duty to photographers. Sir Benjamin Stone even proposed this to be done systematically, being the resulting photographs deposited at the British Museum; some other such attempts were made locally, or in other countries.

Nationalism, the need for History and the 19th century obsession with classification, is all associated with tourist photography. Tourist photography can be loosely defined as a class experience and one that is dictated by convention. The socially constructed landscape of 19th century tourist photography came from 18th century painting and picturesque notions which continued through into 20th century tourist photography. Photography became an important part of travel and, for some, the only way of seeing far away places. Perhaps though, the success of tourist photography came instead from the need of creating memories of special moments and the proof of status it gave.

TOURNACHON, ADRIEN (1825–1860)

French photographer

Alban-Adrien Tournachon was born in Paris in 1825 to Victor Tournachon and Thérèse Maillet. He was the younger brother of Gaspard-Félix Tournachon, better known as Nadar, a name he adopted in 1838 as his *nom de plume*. By the 1840s, Nadar was famous for his caricatures and his incendiary writings for leftist Parisian journals. Nadar let Adrien work at his studio, where he learned caricature. He soon decided that Adrien should learn photography and opened a studio that he would partially own and Adrien would run as the principle operator. For training, Nadar placed Adrien with Gustave Le Grey, a photographer known for his landscapes and his technical skills. Nadar's friend Louis Le Prévost funded the studio, which opened in early 1854 at 11 boulevard des Capucines, a fashionable area filled with photography studios. Adrien soon claimed exclusive credit for the studio, which he decided to run alone.

Like Nadar, Adrien photographed artists, although he never achieved his brother's level of success. He is best known for the physiognomic studies made for Dr. Guillaume-Benjamin-Armand Duchenne (also known as Duchenne de Boulogne), a French physiologist and psychiatrist credited as the founder of electrotherapy, between 1853 and 1854. The photographs represented the 19th century obsession with mental illness, a subject of great scientific and artistic study. Adrien photographed patients at the Parisian hospital, Salpêtrière, where Duchenne worked and Géricault created his studies of psychological problems. Featured in Duchenne's 1862 book, *Mécanisme de la physionomie humaine, ou analyse élector-physiologique de l'expression des passions applicable à la pratique des arts plastiques* (*Mechanism of Human Physiognomy, or Electro-physiological Analysis of the Expression of the Passions Applicable to the Practice of the Figural Arts*), the photographs illustrated various emotional states that Duchenne achieved through electric shocks that stimulated muscles. Adrien mainly photographed an elderly male patient, who expressed reactions including terror, fear, amazement and displeasure. The photographs reflected the influence of Positivism, a philosophy based on the Enlightenment principles of scientific analysis and classification that sought truth through observation and study. Visually

Tournachon, Adrien. Self-Portrait. *The Metropolitan Museum of Art, Gilman Collection, Purchase, The Horace W. Goldsmith Foundation Gift, 2005 (2005.100.44) Image © The Metropolitan Museum of Art.*

interesting, the works show chiaroscuro and a baroque use of space. Attribution is generally given exclusively to Adrien, who signed the works "Nadar jeune," as historians are unable to find evidence that Nadar worked on these images. Two works signed "Nadar jeune" were found in Duchenne's own collection and in his text, Duchenne wrote "Monsieur Adrien Tournachon, whose skill as a photographer is known to all the world, kindly contributed his talent by shooting a few of the pictures in this scientific portion."

Yet despite this commission, Adrien's studio was not successful. By mid-September 1854, Nadar returned to the studio and the brothers worked together. By this time, Nadar was trained in photography and had access to supplies, chemicals and studio equipment, in addition to celebrated and wealthy clients. During the period of 1854–1855, the brothers collaborated on portraits of Ernesta Grisi (the wife of Théophile Gautier), Alfred de Vigny, Edmond and Jules de Goncourt, and Gérard de Nerval. Although the subjects were photographed in Adrien's studio, the photographs have a psychological dimension more associated with Nadar.

The most famous images the brothers made were the series featuring the character Pierrot, as played by Nadar's friend, the mime Charles Deburau fils. It is unclear what each brother contributed to the photographs. In one image, Pierrot is shown holding pieces of paper that said "ad. Tournachon" and "nadar j," both in reference to Adrien, as was the stamp "TOURNACHON 11 Boule. des Capucines," Adrien's first signature and the studio where he and Nadar worked. The photographs also reflected Adrien's physiognomic studies, printing technique and his larger, 12 × 9½ inch plates. However, their expressive, theatrical quality connects the works

to Nadar, who was more familiar with the work of Charles Deburau and his father, Baptiste. Nadar used his influence to have the series, submitted under the name "Nadar jeune," exhibited at the 1855 Exposition universelle where it won a first-class medal. In a review published in 1856 in *Photographic Sketches* (*Esquisses photographiques),* Ernest Lacan praised the works for the emotional quality of the mime's body and face. Like most critics and historians, he saw the works as a collaboration and attributed the works to "Messrs. Tournachon and Co."

Yet this collaboration was not to last. Nadar left the studio by mid-January 1855 and in October, Adrien, with two new backers, opened a studio, Tournachone Nadar et Companie, at 17 Boulevard des Italiens. Because Adrien was working as *Nadar jeune*, often minimizing the *jeune* to "*jne*" written in small type and in Nadar's celebrated script, Nadar was forced to exhibit under the name *Nadar aîné*. Despite Nadar's repeated requests and financial incentives, Adrien refused to stop using *Nadar jeune* until Nadar sued him to claim the name exclusively for himself and his family. Nadar also claimed authorship of their photographs and attempted to recoup money invested in their studio. By January 1856, Nadar opened a studio and signed works *Nadar et Cie/Nadar Société de Photographie Artistique* 113 R. St. Lazare" and "Nadar/113, rue St. Lazare, *pas de succursale*" (Nadar/113 rue St. Lazre, no branches) in reference to Adrien. Although Adrien won the first suit in 1856, he lost the December 12, 1857, appeal, with the court declaring Félix "the only, the true Nadar."

Adrien's new studio was initially successful and in 1855, he became a member of the *Société française de photographie.* However, by 1858 his studio was bankrupt. He tried to appeal the court's ruling, but was denied in June 1859. Later that year, the estranged brothers were reunited due to their mother's illness. She died in February 1860 and, as a last wish, asked Nadar to help Adrien with his floundering career. Nadar settled some of his debts and purchased Adrien's photographic equipment, even though he had paid for most of it six years earlier.

Between 1862 and 1864, Adrien ran a new studio with J.P. Johannes at 124, avenue des Champs-Elysées, where he created portraits of animals, such as angora goats and horses. In April 1867, Adrien opened a firm dedicated to photographic enamels, which failed and was closed by 1872. He continued to produce work and exhibited with the Société des Artistes Françaises at the Salon of 1884. In 1893 Adrien entered the retirement home at Sainte-Perrine, then the pension Galignani at Neuilly, where he was treated for mental illness. He spent his last decade in mental institutions before dying on January 24th, 1903.

Since the late 1970s, historians have reevaluated Adrien's photographic legacy. Comparing photographs made by the two brothers reveals both their differences and the extent of their collaboration. While Nadar's role has been acknowledged in works signed exclusively by Adrien, it is also clear that Adrien significantly contributed to works made by the two.

JENNIFER FARRELL

Biography

Alban-Adrien Tournachon born 1825 to Victor Tournachon and Thérèse Maillet in Paris. Younger brother of Gaspard-Félix Tournachon, known as Nadar. Adrien studied photography with Gustave Le Grey. Between 1853 and 1854, Adrien created physiognomic studies for Dr. Guillaume-Benjamin-Armand Duchenne, known as the founder of electrotherapy. In early 1854, Adrien opened a studio at 11 Boulevard des Capucines, partially funded by his brother, Nadar. They worked together for four months between until December and produced portraits of artists, friends, and clients. Their celebrated photographs were of the mime Charles Deburau as Pierrot, which were exhibited at the Exposition universelle in 1855. The brothers acrimoniously split and Nadar left the studio in January of 1855. In 1856, the brothers went to court over Adrien's use of the name "Nadar jeune" and financial issues. Adrien won the initial trial, Nadar eventually gained exclusive rights to the name. Adrien received acclaim for his animal portraits, yet his subsequent studios failed. In 1893, Adrien entered a retirement home for mental illness. He died on January 24, 1903.

TOWLER, JOHN (1811–1889)

Born in Yorkshire, England, on 20th June 1811, Towler was educated in Yorkshire, Germany and Cambridge. He migrated to the United States in 1850.

The Silver Sunbeam: A Practical and Theoretical Text-Book on Sun Drawing and Photographic Printing: Comprehending all the Wet and Dry Processes at present Known, with Collodion, Albumen, Gelatine, Wax, Resin, and Silver; first appeared in 1864, from the New York publishing house of Joseph H Ladd. It became one of

early photography's 'best sellers' with sales exceeding nine thousand copies over a fifteen-year period in America alone. Several thousand more copies were sold in Britain, and yet more in three Spanish-language editions. It was the comprehensive nature of the book, and the accessibility of Towler's text, which attracted such significant sales. In nine editions, new discoveries and inventions were appended as they were introduced, and by the 1879 edition, the 351 pages of the first edition had swelled to 599. He went on to write several other important books and manuals on photography, but none captured the imagination, or achieved the sales enjoyed by *The Silver Sunbeam*. Towler edited *Humphreys Journal of Photography* from 1864 until 1867.

Other publications included essays on dry plate processes (1865), photography on porcelain (1865), and the production of high quality prints (1866, 1870), and several translations of works from the original German.

From 1882 until 1886 he served as US Consul in Trinidad.

JOHN HANNAVY

TOWNSHEND, CHAUNCY HARE (1798–1868)

British art collector, writer, and poet

Townshend was born on 20 April 1978 at Busbridge Hall, Godalming, England, the only son of a landed gentleman, Henry Hare Townsend and his wife, Charlotte. (Chauncy Hare Townshend added the letter 'h' to the family surname in 1827 when he succeeded to the family estates.) From an early age Townshend was encouraged to take an interest in the arts. He was educated at Eton College and Trinity Hall, Cambridge where he won the Chancellor's medal for his poem *Jerusalem*. In 1826 he married Eliza Frances Norcott.

Townshend took holy orders but felt unable to pursue this vocation due to a nervous complaint –a combination of melancholia and hypochondria to which he succumbed during the 1820s or 30s—that was to plague him for the rest of his life. However, his passion for travel and collecting, his contacts with distinguished friends, and his enormous personal wealth allowed him to lead an active and fascinating life. The experience of Townshend's journeys in Britain fed into his first published prose work, *A Descriptive Tour in Scotland* (1840). He was an accomplished amateur painter and draughtsman, musician and composer and an ardent advocate of mesmerism, aspects of which are now known as hypnotism. He published *Facts in Mesmerism* (1840) and *Mesmerism Proved True* (1854) and also practised the technique on others. He moved in the highest social and literary circles in London hosting musical evenings at his house at 21 Norfolk Street, (now Dunraven Street) looking on to Hyde Park. Among the many guests were the poet Laureate Robert Southey and the novelist Wilkie Collins, much of whose description of "Mr. Fairlie" in *The Woman in White* is modelled on Townshend. Charles Dickens is said to have taken Townshend as his inspiration for the character of 'Cousin Feenix' in *Dombey and Son* and became a close friend, dedicating *Great Expectations* to him. He acted as literary executor after Townshend's death and edited his posthumous *Religious Opinions* (1869). After separating legally from his wife in 1843, Townshend spent his winters in Switzerland at his villa near Lausanne on the Lake of Geneva.

Townshend's wide-ranging interests in the 1840s and 50s informed his taste in his large, eclectic collection of pictures including oil paintings, watercolours, prints and photographs. Many of his acquisitions adorned the walls of his houses or would have been kept in portfolios and presses for viewing. He remains one of the few identifiable British private collectors of early photographs, on any significant scale, apart from Albert, the Prince Consort. After his death in London on 25 February 1868, *The Times* described Townshend as "a collector of rare judgement and exquisite taste." A bequest of porcelain, glass, watches, geological specimens, curios and the bulk of his library was made to the Museum at Wisbech, Cambridgeshire, near his country estates. The bequest to the South Kensington Museum (later renamed the Victoria and Albert Museum) was instigated at the suggestion of one of the curators, G.F. Duncombe, who put the idea to Townshend while accompanying him on a tour of the Museum. This bequest contained some of the finest treasures in his remarkable collection including photographs, paintings, prints, drawings, books, gemstones, coins, cameos and intaglios. This bequest ensured the rare survival of a key group of art photographs from a 19th century private collection.

An inventory of his collection made at his London home shortly after his death (V&A Archive) reveals how Townshend grouped and housed his collection. It also gives a valuable insight into his taste in photography that encompassed many of the major French and British names of the 1850s. He had visited the Exposition Universelle, Paris, 1855 and may have noticed works by Gustave Le Gray and André Giroux there but could have purchased fine photographs such as these at London dealers such as Murray and Heath. Townshend's photographs fall into three groups: those he kept carefully housed in presses also containing his watercolours and print collection old master etchings and engravings, (including Rembrandt) topographical and architectural views, drawings, zoological plates and leaves of dried plants; books illustrated by photographs which were shelved with the other books of his library; and stereoscopic photographs and daguerreotypes kept in cases in the "Front Room" or study. The stereographs and

daguerreotypes remain untraced, as does one photograph of a waterfall by an un-named photographer which is listed as being framed and hung among the paintings.

Of the holdings of Townshend's photographs still extant in the Victoria and Albert Museum the greatest group are twenty by Le Gray, comprising mainly his Fontainebleau forest pictures and celebrated seascapes, considered today to be among the finest selections of his surviving prints in the world. Among the other important photographs are a number by Camille Silvy, including his masterpiece *River Scene, France*, (1858), André Giroux's landscape *The Ponds at Obtevoz (Rhône)* (c.1855) and architectural studies by Édouard Baldus and the Bisson Frères. Among Townshend's photographically illustrated books is *The Sunbeam*, (1859)—edited by Philip H. Delamotte, including photographs by him and others such as Joseph Cundall, Francis Bedford, George Washington Wilson and John Dillwyn Llewelyn—William and Mary Howitt's *Ruined Abbeys and Castles of Great Britain* (1862) and photographic reproductions of J.M.W. Turner's compilation of drawings, the *Liber Studiorum*, photographed by Cundall, Downes & Co. (1862). Like many of his Victorian contemporaries, Townshend was also fascinated by popular and eccentric figures. The collection contains portraits of such people Mr. Rarey the famous American horse trainer with the stallion "Cruiser" by Caldesi and Montecchi (1858) and the champion boxers, John C. Heenan, "The Benicia Boy," and Tom Sayers, by George Newbold (1860). Townshend's interest also extended to pictures of topical interest at the time shown in Roger Fenton's Crimean war images and some remarkable scenes of ruined houses in the aftermath of the "Clerkenwell Explosion" taken by Henry Hering. On December 13th, 1867, a hole was blown in the prison wall at Clerkenwell House by Fenians attempting to release one of their group. The photographs record the extent of the resulting damage to buildings. These were some of the last objects collected by Townshend before his death.

TRAVEL PHOTOGRAPHY

The link between photographic practice and the activity and experience of travel was forged before Louis Jacques Mandé Daguerre's process was announced to the Parisian public in 1839. The symbolic meeting of activities occurred at the meeting in 1838 of two principals when the eminent geographer and explorer Alexander von Humboldt visited Daguerre in his studio. Humboldt met with Daguerre in the geographer's role as member of the committee appointed by the Academie des Sciences to evaluate Daguerre's claim that he had perfected a process to record and fix through chemical means the images produced in the *camera obscura*. As Schwartz argues: "at a time when travel was embraced as a way of seeing and knowing the world, photographs offered a new means of acquiring, ordering, and disseminating geographical information" (Schwartz, 1996, 16). Travel was the primary means of gathering the empirical knowledge of the world; travelers' accounts supported by printed illustrations based on sketches, topographic views, and maps produced during the course of travel disseminated that knowledge. The emphasis on travel as a mode to acquire knowledge is part of the nineteenth-century emphasis on collecting, categorizing, and possessing the world associated with the sciences of geography, anthropology, and archaeology. After the introduction of photographic processes, whether as permanent image on metal plate or paper print, photography became the preferred and trusted mode of creating and presenting the visual records of travel because it was derived from the "neutral" operations of chemistry and optics. Later, travel as a method of empirical knowledge pursued by a relatively small cadre of explorers gave way to travel as part of the burgeoning activity and industry of tourism—the organized consumption of place as leisure activity. Photography participated in the change to touristic consumption as a record and validation of leisure travel and by creating and amplifying the desire to participate in leisure travel activities.

The first practitioners of travel photography were amateur enthusiasts who pursued their interests in the new technology of image making as they undertook travels for official, commercial, or personal interests. Joly de Lotbinière and Frederic Goupil-Fesquet sepa-

rately came to be photographing the Sphinx on the same day in November 1839, scant weeks after Daguerre's public demonstration. Lotbinière went on to make an extensive daguerreotype record of his travels over the next year. Jules Itier (1802–1877), a government functionary in the French trade ministry, was an early adopter of Daguerre's technique and made daguerreotypes on trade missions to Senegal (1842) and China, Singapore, the Philippines, Borneo, and India (1843–1846). Baron Louis Gros, a French diplomat, made and exhibited daguerreotypes of the monuments and landscapes he encountered on extensive travels in the Americas, Greece, and England. While yachting in the Mediterranean in 1845, Christopher Talbot, William Henry Fox Talbot's cousin, and Reverend Calvert Jones made a number of calotype views, including early two part panoramas of Naples. The Reverend George Bridges (active 1846–1852) photographed extensively during a tour of the Mediterranean and North Africa. Ernest Benecke (active 1851–1853), the son of an Anglo-German banking family, also compiled an extensive calotype record of travels perhaps undertaken to familiarize himself with family business interests in the region. In most of these cases, the work was shared privately or had limited exposure in exhibitions organized by the newly formed photographic societies. Lotbinière is the exception in that his work was reproduced in some of the first books to feature illustrations derived from photographs—those by Lerebours and Horeau, for example.

Excursions daguerrienes, representant les vues et les monuments les plus remarquables du globe (1840–44), published by the Parisian optician Nicholas Lerebours, was the first book of travel images derived from daguerreotype images. *Excursions* eventually comprised 100 plates of views of Egypt, Italy, Greece, Russia, France, and other countries provided by a number of early daguerreotypists. In this first use of the photographic image as document of travel, images were reproduced as engravings derived by tracing the outlines of the daguerreotype image and then laboriously adding by hand the exquisite detail which the daguerreotype was capable of rendering. Although a very few plates were printed directly from the daguerreotype plate using Fizeau's process, the plates were engraved copies after daguerreotypes. While *Excursions* was the largest and earliest photographic entry into the travel book market, it was rapidly followed by others that reproduced either daguerreotypes or calotypes through engraving, aquatint, or lithography—see for example, Hector Horeau's *Panorama d'Egypte et de Nubie* (1841) and Pierre Tremaux's *Voyage au Soudan oriental et dans l'Afrique septentrionale exécutés de 1847 a 1854* (1852–1854). The first travel book with direct photographic illustrations was Maxime Du Camp's *Egypte, Palestine et Syrie* (1852). Du Camp's book comprised 125 calotype prints derived from paper negatives nade during a lengthy journey in 1849 to 1851, printed by Blanquart Evrard, and accompanied by short texts supplied by Du Camp. Although the work was judged extraordinarily successful—Du Camp was awarded the Legion of Honor in recognition of his achievement—probably no more than 350 copies were printed.

These initial productions defined an elite market for deluxe photographically illustrated travel accounts for the scholar or arm-chair traveler. While amateurs continued to make photographs on their travels, entrepreneurial photographers realized that market demand could be better and more economically met by superior printing technology utilizing wet collodion glass plate negatives from which a large number of albumin prints could be made. Frances Frith should be credited with developing and refining marketing strategies for travel photographs by recognizing the existence of distinct market segments. Beginning in 1856 with his views of Egypt and the Holy Land, Frith produced photographs in a range of formats, including stereo-views, which were affordable to a growing middle class while appealing to Victorian ideals of self-improvement by offering direct visual knowledge of the world. After first working with established publishers, Frith formed his own photographic publishing firm—Frith & Co.—which continued to offer, throughout the nineteenth century, views of local and foreign destinations from a network of operators, as individual prints, collected in volumes, and in sets of stereo cards.

The photographically illustrated travel account, which paired text that reported incidents encountered en route and offered instruction in the history and culture of the region with photographs, functioned as both the document of a completed journey and the stimulus for journeys of the imagination. Frances Bedford accompanied the Prince of Wales' 1862 tour of Egypt and the Holy Land as the official photographer. On his return, prints were offered for sale through his Bond Street gallery and later compiled in *The Holy Land, Egypt, Constantinople, Athens, etc*. (1867). Both offered the British public vicarious participation in the royal journey and a record of the tour. The production of images of foreign or distant locales, ala Frith, Bedford, and innumerable other operators, was accomplished within a distinct set of practices associated with view photography, defined by expectations shared by maker and consumer. View or topographic photographs did not suggest or allude to a place, they delineated it precisely. Dramatic effects of light and shade that might confuse the presentation of a complete, spatially coherent, record of site were avoided. A well-executed view was as much a map as it was a picture, offering a clear understanding of the disposition of structures, access into and within the space, and relative scale and distance. Indeed, the fine detail

of glass plate negative/albumin print could provide an almost tactile registration of the materiality of physical space—the grit of masonry and sand, the smoothness of plastered walls, or subtle texture of wood.

As the industry of leisure travel grew, a development which can be dated to the first package tours to the Crystal Palace exposition in 1851, photography and the activity of travel became ever more intimately entwined. Travel views at once satisfied a demand for views of the world to those who would never visit the places shown, as they encouraged the consumption of places which were becoming more broadly accessible through organized tourism. Thomas Cook was one of the earliest, but by no means the only operator, offering package tours; Cook's Tours brought a growing number of middle class travelers to the Universal Exposition in Paris in 1855, to holiday destinations in Great Britain and Continental Europe by 1860, and to Egypt and the Holy Land in 1869. Expanded access to leisure travel altered the point of purchase of travel photographs but not the standards for the way in which place was inscribed as view. Travelers could purchase photographs of the sites they visited along their route. Commonly loose prints were purchased and arranged in elaborate photographic albums which served as the recapitulation of the journey, although local photographers did offer commercially printed albums dedicated to the particular area. While these albums operated as souvenir and proof of status for a traveler, they also retained the earlier connections between travel, photographic record, and nineteenth-century knowledge making. A number of photographic Tour de Monde albums were placed in public reading rooms or libraries, as a source of instruction for those who could not travel (Mickelwright, 2003. Local photographic studios were common at major sites after the late 1850s and nineteenth-century travel guides listed the best local sources for photographs. Commercial photographers offered photographs specifically for the visitor wishing to preserve the sights he or she encountered in the course of travel, including a variety of staged photographs of local life which had more apparent than real connection to his or her experience as tourist. Native "types" photographed in cafes, dimly lit courtyards, or "domestic" surroundings offered the illusion of connection with the foreign other that was seldom provided by the protected experience of the package tour arranged and managed to cause the least discomfort to western travelers. Maison Bonfils and Abdullah Freres in the Middle East, Bourne and Shepherd, and John Burke in India; Georgio Sommer, Fratelli Alinari, Tommaso Cuccionni, and Robert Macpherson in Italy; Muybridge, Watkins, and Jackson in the American West; Jakob Laurent and Charles Clifford in Spain; Felice Beato and his successors in the Far East; Baldus in France; and George Washington Wilson, Francis Frith, and Roger Fenton in the United Kingdom, to name just a few—were photographers with large commercial offerings of travel views available both on-site and through publication and distribution networks in European and American cities. Views of the Alps by the Bisson brothers (1860) and Charles Soulier (1869) recorded mountaineering, another form of leisure activity that developed as tourism expanded. Rail journeys were recapitulated by photographers in France (Baldus) and the United States (Rau and Jackson), as rail travel accelerated access to distant places. Increasingly railroad companies, who understood that leisure travel passengers offered a significant potential market, enticed those travelers by photographs which celebrated the engineering accomplishment embodied by the railroad and offered the inducement of miles of unfamiliar landscape to delight a passenger's eye. In the United States, the Santa Fe Railroad Company commissioned both painters and photographers to provide images calculated to whet the public appetite for the visual attractions of the American Southwest. Commercial photographers—initially subsidized by the railroad company—set up shop at rail stations and tourist destination hotels, also subsidized by the railroads.

Stereo photography was particularly well suited to travel images, offering as it did an immersive experience of place through the combination of the three-dimensionality of the image and the restricted field enforced by the viewer (Schwartz 1996). The effect of "knowing" the place seen through the stereoscopic viewer was reinforced by the inclusion of didactic text on the reverse of the card. A number of major publishers of stereo images—Underwood and Underwood, Kilburn Brothers, Frith and Co.—dispatched photographers to locations, events, and the aftermath of disasters around the world to feed the extensive market for entertainment and instruction. Realistic Travels Publishers offered stereo views of the far reaches of the British Empire from offices in London, Delhi, and Cape Town; views that reinforced imperial possession while providing instruction to future colonial officers. Stereo series of foreign and exotic locales continued to be widely marketed through the 1930s. Touted as an entertaining form of armchair travel and an educational tool, they could be found in parlor as well as classroom.

Perhaps the last manifestation of commercial photographic practice associated with travel in the nineteenth century was the development and rapid proliferation of the picture postcard industry at the end of the nineteenth century. By the 1890s, travel views sized to meet new postal codes and reproduced in collotype (also known under a number of proprietary names such as Phototype, Heliotype, Albertype, and Lichtdruck) or photolithography became a standard accompaniment to travel. By 1888, the halftone process and later a chromo-halftone

process, which provided rudimentary colored images, made picture post cards ever more available and less expensive. The picture postcard—mailed to friends and family or collected as souvenir—reigned as the commercially produced photographic marker of travel for the next century (Geary and Webb). After 1885 and the introduction of the Kodak, a unitary system of camera, film and processing that reduced the complexity of the photographic act to "You push the button and we'll do the rest," the commercial image was paralleled by the personal, informal, traveler's snapshot. Kodak advertising connected "Kodaking" to the modern pursuit of leisure—outdoor activities such as biking and automobile touring, and, of course, travel—and ads featured prominently the Kodak woman as tourist with camera in hand (West, 40). The personal snapshot and the commercial picture postcard dominated travel views throughout the twentieth century, only to be supplanted at the end of the century by digital images posted on users' spaces and accessed electronically from any computer.

Photography and travel, including the transformation of individual travel through the burgeoning tourism industry, are central and distinct elements of modern life from the nineteenth century forward. The centrality of these linked phenomena has been the focus of critical analysis from a variety of theoretical positions. Analysis of the cultural formations of travel and its associated imagery have addressed the economic and social implications of consuming the world as image and mediated experience (Osborne, Gregory, Taylor)The experience of travel, the visual record of distant locations, and the dissemination of that visual record were recognized as important elements of the social and political structures that reinforced imperial and/or colonial control of distant lands. Thus travel photography has been viewed through the lens of post-colonial critiques of power and resistance (Ryan, Nordstrom, Micklewright, Gregory). Ryan argues that photographic practice was an essential tool in the formation and maintenance of British imperial rule. Taylor focuses on the use of photographs of the British Isles to construct national identity through a shared tourist experience. Gregory defines the production of personal travel photographs by the amateur as one of the central acts in the performance of touristic explorations of the world.

In all of the critical discourse surrounding travel and photography are cores assumptions relating to the value of knowledge production in the nineteenth century and the power of the photograph, by virtue of its perceived transparency and veracity, to transmit knowledge of the world. Prior to the advent of photography, extensive travel was considered the ultimate source of knowledge of the world. Travel books might offer the traveler's journals expanded with observations and field notes, buttressed by research and citations from other authorities, perhaps accompanied by reproductions of sketches and plans, but these were partial and mediated experiences of direct knowledge—valuable but inherently flawed. As Schwartz (2003) argues, the photograph became the surrogate for the direct experience of the world, acting as a neutral, impassive eye in distant places. Not a pale substitute for direct experiential knowledge but a form of knowing that offered advantages over physical travel because it permitted careful and repetitive examination of place, and facilitated comparison between distant places. The assumption that photography functioned as a technologically based system which mechanically produced direct observations of the natural world ensured that photography wielded the intellectual power that allowed it to operate as a tool of imperial and colonial control, a means of structuring national identity through shared place, the underpinning of commercial tourism, and ensures that it continues to provide proof of experience to modern day travelers, despite our understanding of the suspect nature of photography's claim to truth.

TRÉMAUX, PIERRE (ACTIVE 1853–1868)

French, photographer, architect, architectural historian

The architect Trémaux was a member of the Académie des Beaux-Arts and Société de Géographie, and winner of a second place Prix de Rome in 1845. He was born in 1818, and is known for a extensive, profusely illustrated, three-part publication on the architecture of Africa and Asia Minor: *Voyage au Soudan oriental et dans l'Afrique septentrionale exécutés de 1847 a 1854* (1852–1854); *Une parallèle des édifices anciens et modernes du continent africain* (1861); *Exploration archéologique en Asia mineur* (1862–1868). Trémaux explored the use of photography for illustration, initially using photographs, as well as drawings, as source documents for lithographic plates. In 1853–54, he made calotypes in Egypt which were bound into volumes in addition to lithographs. The photographic prints deteriorated rapidly and he replaced them with lithographs. For the third part of the series, he turned to Poitevin's photolithographic process. Despite the technical shortcomings of his photographic work, Trémaux's calotypes are recognized as some of the earliest photographs of the people of Egypt.

KATHLEEN HOWE

TRIPE, LINNAEUS (1822–1902)

Working in India and the East in the mid 1850s the photographs of Linnaeus Tripe, along with those of his contemporaries John Murray and Samuel Bourne, rank amongst the finest of the period. Tripe, an accomplished amateur, was amongst several army officers seconded from military duties to record antiquities, architecture and ethnography of the continent and created a body of work which, though highly regarded by his contemporaries, has until recently been sadly overlooked.

Born in 1822 in Devonport, England, Linnaeus Tripe was the ninth of Cornelius and Mary Tripe's twelve children, his siblings including Theophilus, Octavius, Lorenzo, Septimus and Algernon. Tripe studied mathematics and the classics and at seventeen he joined the East India Company as an ensign. By the early nineteenth century, the East India Company itself had evolved from a small trading company to control much of India, employing both political and military rule to protect its commercial interests. The 'Government' was organised into three Presidencies of Bombay, Madras and Bengal respectively. Tripe was stationed with the Madras Establishment, rising from humble ensign in 1839 to honourary Major General by his retirement in 1875.

Tripe's first known photographs were taken between 1853 and 54 around his hometown of Devonport towards the end of a three and a half-year furlough. On his return to India he continued with his new hobby and while on leave in December 1854 took a series of photographs around Halebid and Belur. These prints were greatly admired when shown at the Madras Exhibition of 1855 and Tripe was awarded the first class medal. At this time the Government of India was already showing interest in photography as a more cost and time efficient method to document and record antiquities than commissioning traditional artists. In 1855 they sent a mission to Ava to persuade the King of Burma to recognise the British annexation of Lower Burma following the Second Anglo-Burmese War of 1852. Captain Tripe, probably as a result of his success in the Madras Exhibition, was appointed official photographer and during the three and a half-month trip he produced nearly 220 calotype negatives. In truth, due to sickness and bad weather, Tripe had only 36 working days in which to photograph the region. This was indicative of the problems of the 19th century photographer in India: heat, dust, and flies in summer, damp humid conditions and sickness during the monsoon months, the rapid deterioration of chemicals, and difficulties procuring and transporting the bulky equipment were regular complaints. For many of these reasons Tripe preferred the calotype, modifying Le Gray's waxed paper process to suit his needs. However even this method was not without its difficulties and Tripe complained that the wax often melted in the heat leaving spots on the first prints "so as to spoil them."

On his return to the photographic department in Bangalore Tripe began the labourious task of printing 50 boxed sets from 120 negatives selected from the trip for The Government of India—a total of over 6,000 prints. The skies of these Burmese views have a pronounced granular texture and lack of definition, a fault typical of early negatives since different exposures were needed to record sky and solid objects. Tripe blacked out the sky on his negatives completely so it printed white,

Tripe, Linnaeus. Basement fo a Monolith in the Raya Gopuram, Madura.

dubbed artificial clouds or settled for the grainy 'salt and pepper' effect. Tripe had begun printing when the Madras Establishment again requested his services as Government Photographer but printing the Ava views prevented him from taking up the post until the beginning of the following year. The aims of his new post were to photograph the southern states of the province, recording important items of interest to historians, antiquaries, and architects, to document different races, and to initiate other photographic projects.

The post also required Tripe pass on his knowledge and he taught the calotype process to employees of the public works department of Madras and the collodian process to pupils of the Madras school of Industrial Arts that spring. While teaching in Madras Tripe photographed the exhibits of the 1857 Madras Exhibition (and a number of prominent Madras civil servants) using the collodion negative process. On his return to Bangalore he printed around 1,800 prints for the government and a further 1,000 for public sale. Printing again delayed the start of his next project: a photographic tour of the Southern States of the Presidency. He finally set out in December 1857 taking four bullock carts to transport his equipment on a trip that lasted seven months—much of it during the troublesome hot season. Tripe produced 275 paper negatives, 16 collodian glass negatives and 160 stereographs on glass. His subjects included the temples of Madura, Seringham and Tanjore, the palaces of Madura, Tanjore and Poodoocottah, the forts at Trichinopoly and Trimium, landscapes around the beautiful Salem district, and the Elliott Marbles in Madras. This body of work is considered to be his best and once more the Government ordered many sets of the prints. Back in Bangalore, Tripe and his assistants began printing once again, however a new problem faced the department. As a result of the Indian Mutiny the British government had taken over the rule of India from the East India Company in late 1858. The new Governor of the Madras Presidency viewed that in such difficult times the Photographic Department was "an article of high luxury" and soon ordered its closure on grounds of excessive costs. Tripe was to be allowed to finish work in hand, but there would be no new commissions. Tripe argued strongly against the decision, but to no avail and

on completion of printing and finalising the accounts in 1860 he left for England on a two-year furlough disappointed and in poor health.

Tripe returned to military duties in 1863 and his last known photographs were taken in 1870 while stationed in Burma. In 1873 he returned to Devonport, England, retiring from the army in 1875. During the 1880s he was active in local charities, and indulged a passion for collecting shells and corals, some of which were acquired by British Museum after his death in 1902. His photographic record shows not only diligence and determination to carry out his commission well, a technical mastery of his medium, especially the calotype process, but also a great visual awareness and sympathy for his subject, producing some of the finest architectural studies of the period.

SARAH MCDONALD

Biography

Born in Devon, England on 14 April 1822. Educated in classical and mathematical studies at Devonport Classical School. 1839 joined the Madras Establishment of the Army of the East India Company as a Cadet of Infantry. First documented photographs taken around hometown of Devonport 1853—54. Photographs taken on leave around Bangalore 1854 received the first class medal in the Madras Exhibition of 1855.

Appointed Official Photographer to the Government of India Mission to Ava (Burma) in 1844 and following year appointed as government photographer to the Madras Presidency taking up post in 1857. Photographed exhibits in the Madras Exhibition and Madras residents followed by a photographic tour of the Southern Districts of the Presidency. Published various volumes in 1858: *Photographic Views in Madura; Photographic Views of Poodoocottah; Photographic Views of Ryakotta and other places in the Salem District; Photographic Views of Seringham; Photographic Views in Tanjore and Trivady; Stereographs of Madura; Stereographs of Trichinopoly.* 1860 Photographic Department of Madras Presidency closed. Last known photographs taken in 1870. In 1873 returned to England, retiring from the army in 1875 with honourary rank of major general. Died 2 March 1902.

Exhibitions

1855 Madras Exhibition of Raw Products, Arts and Manufactures of Southern India. Awarded First Class Medal.
1857 Madras Exhibition of Raw Products, Arts and Manufactures of Southern India.
1857 Photographic Society of Bengal Exhibition (Calcutta)
1859 Madras Photographic Society Exhibition

TUMINELLO, LUDOVICO (1824–1907)

Italian photographer

Along with the painter Giacomo Caneva (1813–1865) from Padua, Tuminello represents outstanding, aesthetic Italian photography at the beginning of the introduction of the process to Italy. Although not always consistent in quality, at his best in landscape topography and architecture, he conveys, by control of tone, especially the use of strong contrasts, of dark shadow and bright light, and an expert selection of composition and viewpoint, the grandeur and emotional experience, the melancholy that is Rome. In this he mirrors the monumentality caught by both Caneva and Robert McPherson, the foremost photographer of the period. Born Rome, Tuminello started photography around 1842 but moved to Turin in 1849 for political reasons during the revolutionary upheavals in Rome. He returned in 1869 and commemorated in a panorama (three photographs) the siege of Rome by the Italian troops in 1870, including the breach of the walls. He also visited Sardinia, Egypt, Sudan and Tunisia on expeditions led by the Marchese Orazio Antinori. Tuminello persisted in using the calotype (along with glass negatives) after the sweeping success of the new wet plate process post 1851 when the market then became flooded with often nondescript images made exclusively for those on the Grand Tour: their success was to deny the photographer's personality. Tuminello bought and distributed Canova's picture library produced for the artists of the French Academy at the Villa Medici (and may have used some of his negatives as his own, not uncommon). In 1903 his archive was auctioned but some paper negatives are preserved in the Gabinetto Fotografico Nazionale in Rome. We still await a serious study of this remarkable photographer.

ALISTAIR CRAWFORD

TURNER, BENJAMIN BRECKNELL (1815–1894)

British photographer

Benjamin Brecknell Turner was born on 12 May 1815 at 31–32 Haymarket, London, the eldest son of Samuel Turner and Lucy Jane Fownes. He attended Queen Elizabeth's Old Palace School, Enfield, London, until 1831. At sixteen he was apprenticed to his father as a tallow chandler in the family firm Brecknell, Turner Ltd., which made and sold candles and soap from their premises at Haymarket. In 1836, the family moved to live in Balham, South London. In 1840, Turner travelled to Belgium, Switzerland, and Paris. At his father's death the following year he took over the family business. He continued his continental tour in 1845 with visits to Switzerland, Munich, Salzburg, Vienna, Prague, Dresden, Berlin, and Hamburg. In 1847 he married Agnes Chamberlain with whom he had eight children. The family lived above their shop at Haymarket. In 1849, at the age of thirty-four, Turner took out a licence for one guinea from Talbot to practice calotype photography as an amateur.

Turner's earliest surviving photographs were taken in and around the location where the family spent holidays at Bredicot, a farm four miles outside Worcester bought by Turner's father-in-law, Henry Chamberlain, in 1840. These pictures were made with a modestly sized camera, taking negatives of about 7½ × 5½ inches (19 × 14 cm). By 1852 he had acquired a larger camera taking impressive negatives of about 12 × 15 inches (30 × 40 cm). In this format in March that year he photographed the interior of the Crystal Palace in Hyde Park, London. It was probably the display of photographs held there at the Great Exhibition of 1851 that spurred him to greater ambition. His photographs, taken after the Exhibition had closed, capture the scale and elegance of engineering of the light-filled structure.

Two views of the Crystal Palace open his sequence from a unique album of sixty photographs—his major extant body of prints—entitled *Photographic Views from Nature. By Benjamin Brecknell Turner. Taken in 1852, 1853 and 1854, on paper, by Mr. Fox Talbot's Process*, now in the Victoria and Albert Museum. Unlike nearly all other British photographers, Turner remained faithful to Talbot's calotype paper negative process for most of his career. The collection of some 250 negatives made by Turner between about 1852 and 1860, preserved by the Royal Photographic Society, demonstrate that he occasionally doctored them by adding pencilled foliage details or blacking out skies with Indian ink. However, he chose mostly to use the newer albumen (rather than salted paper) print process. This results in an image that successfully combines the grainy quality of the negative with the depth and clarity characteristic of the print.

Apart from its opening images, *Photographic Views from Nature* contains examples of the kind of subjects which Turner would favour and excel at throughout the 1850s: English churches, abbeys, castles, cottages and farms—rural scenes and ancient architecture—especially in the counties of Worcestershire, Surrey, Sussex, Kent and Yorkshire. His choice of canonical Picturesque subjects—rustic scenes, ivy-clad ruins and trees—was drawn from the English water colourist tradition of the pre-photographic generation. Updating his subjects for the photographic art, Turner understood the power of the medium to capture both broad handling of light and shade and to render minute, textural detail. Typical examples include, *At Compton, Surrey* (c.1852–4 showing an ancient barn and farmyard with thatched hayricks, *Whitby Abbey, Yorkshire, from the North East*, (c.1852–54) capturing the brooding ruins and *Hawkhurst Church, Kent* (1852) remarkable for its almost perfectly symmetrical reflection in the village pond. *Scotch Firs, Hawkhurst* (1852) was his most frequently exhibited photograph. The 1850s was one of the last decades before mechanised farming and the expansion of the rail network changed the landscape irrevocably. Turner's works contain a reverence for the disappearing older order. Because of their long exposure times (documented as up to half an hour) his photographs are largely unpopulated. This lends his work a timeless, meditative quality.

Turner's work was highly regarded in its day and constantly praised by reviewers. He exhibited regularly, beginning at the world's first ever purely photographic exhibition at the Society of Arts in London, 1852 and participated in photographic society shows throughout the 1850s in London, Norwich, Manchester and Glasgow. He exhibited at the Exposition Universelle held in Paris in 1855—the French follow up to the Great Exhibition—and was awarded a bronze medal. In 1862 he contributed nine photographs at the London International Exhibition.

Turner was a founder member and later a Vice President of the Photographic Society of London (founded 1853). He was also an honorary secretary and treasurer of the Photographic Club, within the society, which produced albums of photographs in 1855 and 1857. Members used the albums as a means of exchanging their works. Turner contributed a print of his own for both volumes and organised the 1857 album. At a glass-house studio, which he constructed above his London business, he took portraits in collodion of fellow photographers, friends and family. He also experimented with collodion negatives for landscape subjects in 1856 but the results lacked the charm of his works

from paper, to which he immediately returned. In May 1857 he travelled to Amsterdam to make some of the earliest photographs of the city. His sixteen surviving images from this journey concentrate exclusively on the canals. In 1860 he volunteered as an ensign in the Queen's Westminster's regiment but resigned in 1862. He moved from Haymarket to Tulse Hill, London in 1864. From 1873 he became concerned about the decline of his tallow chandling business and moved to a smaller house in the area but continued photographing until the 1880s, keeping pace with technology by making large carbon prints but showing much the same picturesque subjects he had explored in the 1850s. Agnes Turner died in 1887; her husband who passed away at Tulse Hill on 29 April 1894.

Martin Barnes

Biography

Benjamin Brecknell Turner was born on 12 May 1815 at 31–32 Haymarket, London, the eldest son of Samuel Turner and Lucy Jane Fownes. He attended school at Enfield, London until 1831. At sixteen he was apprenticed to his father as a tallow chandler in the family firm Brecknell, Turner Ltd., which made and sold candles and soap from their premises at Haymarket. In 1836, the family moved to live in Balham, South London. In 1840, Turner travelled to Belgium, Switzerland, and Paris. At his father's death the following year he took over the family business. He continued his continental tour in 1845 with visits to Switzerland, Munich, Salzburg, Vienna, Prague, Dresden, Berlin, and Hamburg. TURNER, SAMUEL N. (active 1880s–1890s)

Camera manufacturer

Samuel N. Turner owned the Boston Camera Company which he started in 1884 and by the late 1880s the Blair Camera Company was acting as both his purchasing and sales agent.

In 1888 Turner designed and introduced a roll film camera called the Hawk-Eye which incorporated a roll film holder. This attracted the attention of George Eastman as it appeared to infringe the Eastman-Walker patent. In June 1889 Eastman and Thomas Blair agreed that the Eastman Company would supply the roll holders for the Hawk-Eye camera taking a royalty on each one sold.

In 1894 Eastman sought an injunction against the Boston Camera Manufacturing Company and their Bulls-Eye camera which had been designed by Turner and incorporated a daylight-loading film system. Turner's patent described using a flanged spool with sensitized film protected by opaque paper at each end to form a light-tight roll. He had developed a new system of roll film photography which did not infringe Eastman's patents.

The injunction was denied and Eastman began to develop a camera to compete called the Bullet which he introduced in March 1895. By June, after Eastman had been advised he was infringing Turner's patents, he negotiated a sole and exclusive license except for the Boston Camera Manufacturing Company to use Turner's system. Eastman introduced the Pocket Kodak in July and in August he bought the Boston firm outright and Turner's agreement not to manufacture cameras for five years. Turner was put on a $100 per month retainer in return for his ideas.

Eastman's activities with roll film opened a flood of litigation with Thomas Blair, Anthony & Scovill and Hannibal Goodwin which was to drag on into the early twentieth century.

Michael Pritchard

TYTLER, HARRIET CHRISTINA (1827–1907) AND ROBERT CHRISTOPHER (1818–1872)

The son of an officer in the Bengal Medical Service, Robert Tytler was born in Allahabad on 25 September

1818 and entered the Bengal Army in 1834. During the Indian Mutiny of 1857 he played a conspicuous part in the re-taking of Delhi, his wife Harriet (born in Sikora on 3 October 1827) being one of the few European women present throughout the siege. After the Mutiny, having received tuition from both John Murray and Felice Beato, the couple undertook an extensive photographic documentation of sites associated with the recent events. In the space of some six months in 1858, the couple produced nearly 500 large-format calotype negatives of Delhi, Cawnpore (Kanpur), Lucknow, Benares, Agra and other locations, which, when shown to the Bengal Photographic Society in 1859, were considered 'perhaps the finest series that has ever been exhibited to the Society.' While many of their photographs bear the clear compositional influence of both Murray and Beato, these images remain one of the most remarkable of the various photographic records of the mutiny, additionally impressive in the light of the couple's photographic inexperience. The Tytlers subsequently settled in Simla, Robert establishing a museum, with which he was involved until his death on 10 September 1872. His wife set up an orphanage in the hill station in 1869, where she also lived for the remainder of her life, dying there on 24 November 1907.

JOHN FALCONER

U

UCHIDA KUICHI (1844–1875)
Japanese photographer

Uchida Kuichi was born in 1844 in Nagasaki, Japan. He may have first encountered photography through contact with the Dutch physician Johannes Pompe van Meerdervoort at the naval training school there. Uchida studied photography with Ueno Hikoma in the early 1860s. In 1865 Uchida and Morita Raizø opened the first photography studio in Osaka. Uchida moved his business to Yokohama in 1866, and then to Tokyo in 1869. Over the next several years he established a reputation as the finest portrait photographer in Tokyo. His fame resulted in a commission from the Department of the Imperial Household in 1872 to make the first official photograph of the Emperor Meiji. Uchida photographed the young emperor wearing traditional court dress. State authorities believed the image fed negative stereotypes of Japan as a regressive country, and commissioned another photograph in 1873 to show a more updated look. The later image, depicting the emperor in a Western military-style uniform and with a new short haircut, was widely distributed as the official imperial portrait. Uchida also traveled with the emperor throughout Japan in 1872, where he photographed the various locations visited as well as the public's response to the imperial entourage. Uchida's successful career was cut short when he died of tuberculosis in Tokyo in 1875.

KAREN FRASER

UENO HIKOMA (1838–1904)

Ueno Hikoma was born in Nagasaki, Japan in 1838. His merchant father, Ueno Toshinojø, imported Japan's first camera in 1848. Ueno's interest in photography did not stem from this event, however, but from studying chemistry at the naval training school in Nagasaki under Johannes Pompe van Meerdervoort, a Dutch naval doctor. Ueno was an intrepid student, constructing his own cameras from old telescope lenses and experimenting with various ways to make photographic chemicals, which were not yet readily available. In 1859 Ueno learned collodion wet-plate photography from the Swiss photographer Pierre Rossier, sent to Nagasaki by the London firm Negretti and Zambra. In 1862 Ueno published *Seimikyoku hikkei* (Chemist's Handbook), co-authored with Horie Kuwajirø. It included an appendix describing collodion wet-plate photography, Japan's first manual on the process. Later that year, Ueno opened a studio in Nagasaki, one of Japan's first, and he also began importing cameras and photographic supplies. Ueno became well known for both landscape and portrait photography. He photographed a number of important nineteenth-century figures, including former U.S. president Ulysses S. Grant. Other highlights of his career included assisting a team of Americans who came to Nagasaki in 1874 to photograph the transit of Venus across the sun, and photographing the battlefield during the Satsuma Rebellion in 1877. Ueno was one of Japan's most successful early photographers, later opening branch studios in Vladistock, Shanghai, and Hong Kong in 1890 and 1891. He died in Nagasaki in 1904.

KAREN FRASER

UKAI GYOKUSEN (1807–1887)
Japanese photographer

Ukai Gyokusen was the first Japan-born professional photographer, operating a studio in Edo (Tokyo) from 1860 or 1861 until 1867. Until recently his reputation has been overshadowed by Shimooka Renjo and Ueno Hikoma**'s** who nevertheless did not open their studios until 1862. It is strange that Ukai's significance was

forgotten since biographical details are carved on his gravestone in Yanaka Cemetery, Tokyo. Born into a wealthy samurai family, in Ishioka-shi, Ibaraki Prefecture, Ukai worked as a merchant in the sake business until 1831 when he decided to become a full-time artist. Nothing is then known until he decides to move to Yokohama in 1859 or 1860 with the intention of studying photography. His gravestone inscription confirms he consulted the American, Orrin Freeman, who had opened an ambrotype studio and was giving lessons. It then seems that he purchased, for a considerable sum, Freeman's camera, equipment, and a series of lessons before opening a portrait studio in Edo. At his studio, named Eishin-do, he photographed over 200 members of the aristocracy. In 1879 he was employed by the Government to photograph antiquities in western Japan. In 1883, Ukai unaccountably buried several hundred glass negatives adjacent to his final resting place in Yanaka Cemetery. (One of his ambrotypes is held by the *Yokohama Archives of History*, Yokohama.)

TERRY BENNETT

UNDERWATER PHOTOGRAPHY

Nineteenth century interest in utilizing the power of photography in all forms of scientific endeavour led the Englishman, William Thompson (1822–1879), to speculate on the use of photography as an inexpensive method of assessing the damage to bridge piers in time of flood. In February 1856 Thompson succeeded in making a weak collodion negative of the sea floor of Weymouth Bay at a depth by lowering a box containing a 5 × 4 inch plate camera on a rope some eighteen feet to the bottom. Thompson described his methodology in a paper "On Taking Photographic Images Under Water," published in the *Journal of The Society Of Arts*, May 9th, 1856, which is reproduced in *Historical Diving Times*, 19 (Summer 1997).

In 1866, the Frenchman, Ernest Bazin claimed to have made underwater photographs at his marine observatory. Bazin used a form of diving cylinder to enable him to descend below water with electric lights to illuminate his subject. However none of these images have survived and it appears that none were ever made public. While there are reports of photographs taken from a submarine by the German Wilhelm Bauer and various experiments by the Swiss F. A. Forel to determine the penetration of daylight through water by photographic means, the first major publication to utilise photography for the illustration of marine specimens was William Saville-Kent's *The Great Barrier Reef of Australia, its products and potentialities* published in 1893. However Saville-Kent's specimens were not photographed with an underwater apparatus.

The first systematic approaches to underwater photography were commenced in 1886 the Frenchman Louis Boutan (1859–1934) and his assistant Joseph David (1869–1922). Born in 1859, Boutan obtained his doctorate of science from the University of Paris in 1879. In 1880, at the time of the Melbourne Exposition, he was sent by the French Government to Australia to study the embryology of marsupials. He was appointed maître de conference at the University of Lille in 1886 before undertaking a mission to the Red Sea in 1890. In 1893 Boutan was appointed professor at the Arago Laboratories at Banyuls-sur-Mer, part of the University of Paris. By the end of that year Boutan had established the fundamentals of underwater photography.

Writing in *The Century Illustrated Monthly Magazine* in 1898, Boutan recalled that he was fascinated by the underwater landscape he found at Banyuls-sur-Mer when invited to use the Laboratory's diving suit. He wrote "why, I asked myself, could I not succeed in making a photograph at the bottom of the sea?" In a note in *Archives de Zoologie expérimentale et générale*, Boutan described the principal features of his underwater photographic apparatus, the plans for which had been devised by his brother Auguste, an engineer and manufactured by the firm of Alvergniat in Paris with anastigmat lenses by Darlot. These had the form of a rectangular metal box fixed to a metal tripod having adjustable legs, external controls for adjusting the shutter and diaphragm and changing the specially varnished Lumiere plates and a rubber balloon with which to adjust the buoyancy to the whole. One of these cameras was illustrated in the Century Magazine article together with several of Boutan's underwater images.

Initially Boutan found that back-scattering of light and the lower contrast gave unsatisfactory images on his "isochromatic" plates. After considerable experimentation he was able to obtain more satisfactory images by interposing a blue filter in front of the camera lens.

Several ingenious methods were employed by Boutan to illuminate his underwater scenes. In 1893 he collaborated with a French electrical engineer, M. Chaffour, to make the first flash bulb. Chaffour used a thick glass bottle, some 10cm in diameter, mounted with the neck down. He placed a coil of magnesium ribbon inside the jar before replacing the air with pure oxygen. An electric current was used to ignite the magnesium ribbon, producing a very intense flash of light. This system was not without its disadvantages. When ignited, the magnesium produced a dense cloud of magnesium oxide vapour which not only reduced the light output but also coated the inner surface of the bottle. Moreover the high temperature produced at ignition frequently caused the bottles to explode, even underwater. Although only an experimental model, the Chaffour flash established the principles for all future flash bulbs while Boutan had produced the first underwater image made with flash.

A more reliable, if cumbersome, system of illumination

was built by David for Boutan. An alcohol lamp was placed in a glass bell-jar secured to the top of a wooden barrel. An external reservoir of magnesium powder was connected to a metal tube placed just in front of the lens flame. Using a rubber bulb, Boutan was able to blow the magnesium powder into the flame to produce his flash illumination. A scale model of Boutan's camera and the "barrel" flash is on permanent display at the Musée de la Plongée, Sanary-Sur-Mer, France. A later system utilised carbon-arc lamps power by banks of batteries.

Boutan described in some detail his methodology for making underwater images. Descending to the bottom in a diving suit, he selected the area to be photographed, then signalled to the dive boat for the apparatus to be sent down, stand first then on signal the camera box and illumination source. Once set up, Boutan then signalled that he had commenced the exposure and waited for a signal from the boat to tell him when the required time had elapsed.

In 1898 he published the first book on underwater photography: *Photographie sous-marine et les progrès de la photographie*, Schücher Frères, Paris. The following year Boutan obtained sharp images of underwater vegetation at night and, using battery-powered arc lamps, images of a plaque at a depth of 50 metres. The exhibition of slides of his underwater photographs at the Expositions Universelle, Paris in 1900 and publication by Charles Mendel of more images in *La Photographie sous-marine*, with text by Pierre Guichard, served to further Boutan's reputation as the foremost underwater photographer of the time.

UNDERWOOD, BERT (1862–1947) AND ELMER (1858–1943)

Manufacturer of ten million stereo cards and 300,000 stereo viewers a year (1901)

The Underwood brothers built a Stereoscopic production and sales organization that surpassed all that had preceded them. By learning the door to door selling techniques of B. W. Kilburn of Littleton, New Hampshire, the Underwoods took the lead in the creation of the world's largest stereo view business. Even The Stereoscopic Company in Great Britain could not match their success.

Elmer and Bert Underwood, sons of the Reverend E. Underwood, were born in northern Illinois Elmer in 1859 and Bert in 1862.

Elmer started a publishing business there in 1879 whilst Bert worked in a grocery and then for the White Sewing Machine Company in Kansas City before becoming a sales agent for a medical book which he peddled from door-to-door throughout his assigned area on the edge of Indian Territory. A natural salesman, Bert became known among the farmers as "that boy who sells a book to everyone:' During his book selling trips in 1881, he met an agent for stereoscopic views and became convinced that if the merits of the then "out-of-date" stereoscopic views could be properly presented to the public they would prove to be fast sellers. Ordering a stock of views and a stereoscope he began to formulate a system for selling them that proved immediately successful.

Bert's sales grew so fast that within a few months he persuaded his brother to sell his publishing business and join him in expanding the stereo view business into other areas. At that time, the Underwoods were selling the stereo views published by Charles Bierstadt (Niagara Falls), J. F. Jarvis (Washington, D.C.) and the Littleton

View Company (one of B. W. Kilburn's competitors) in the sparsely settled areas west of the Mississippi. (Some of these early views have been found inscribed on the back "Sold by Underwood and Underwood, Ottawa, Kansas:') In a year's time the brothers had established their own group of sales agents (all trained in the Underwood method) working in Missouri and Kansas.

The Underwoods directed this sales force from a small office in Ottawa, Kansas. Many of these agents were recruited from colleges and universities. Some earned enough during the summer months to pay their entire college expenses for the year.

As their business grew, they documented the system in a manual that taught their agents how to successfully sell stereo views. To learn just how these agents plied their craft, a copy of their Sales Manual for 1890 was examined at the Oliver Wendell Holmes Stereoscopic Research Library.

The Underwoods divided their sales effort into two parts—the canvassing and the delivery. Canvassing included gaining a hearing, creating a desire to buy and obtaining a small order for a stereoscope or views. Upon delivering the original order a week or two later, they made their major pitch to sell more views.

The manual took the new agent, step by step, through a typical sales call, telling them what to say and how to handle all objections. The agent was instructed to greet the person answering the door with: "I have something very beautiful I want to show you. It will take just a minute:'

No mention was made of the product they were selling. If the prospect hesitated, they added: "It is something new in this line, and I can show you much better and easier than I can tell you:' If told there was no interest in buying anything they countered with: "Oh, I am only showing now and I have something so interesting I do like to show it. You can spare just a minute:' After gaining entrance, the agent laid his case down and removed the stereoscope saying: "Of course you have a stereoscope:' If the customer did not, the agent stated that they have never seen views through this type of glass. "Everyone says it is the finest lens they ever looked through:' The important thing was to get the customer seated and to hold the scope. The manual advised the agents to insert each view into the scope before taking the preceding one out so the customer was always looking at something, the better to hold their attention.

They made each view as interesting as possible by pointing out the objects of value, beauty or novelty in each. For example, "Phoebe's Arch, Palmer Lake, Colorado. Notice how far through that arch, across the landscape you can see. That farthest mountain is thirty miles from the arch. Isn't it something wonderful to cover such distance in a view" Remember, the manual advised the agent, "your customer will often see, in the views you show him, only what your words have the power to make him see. They credited the glass for the beautiful details and distances brought out in perfect relief. They dwelt on the power of the glass as a sale of the scope obviously produced a demand for views.

They attempted to close the sale by saying: "If I will bring you just as good a lens as this is in about two weeks, you will want one of them won't you? This scope is only ninety cents and if the one I bring is not as good as this, don't take it." Price was only mentioned after they had shown a number of sample views.

The agent then advanced numerous reasons the customer should have a stereoscope in their home—they cost very little and yet are so interesting; if company comes they can help entertain themselves with a stereoscope and a collection of views; children read, hear people talk then study about places in the views; they can never visit all these places as it would cost hundreds of dollars to visit only a few and the stereoscopic views, as seen through a good glass, will give them a better idea than they can get in any other way.

The agent concluded with: "Well, I shall put you down for the glass, shall I not, as it's only ninety cents:' The order was written up for "Scope and Views" and the customer was told: "You see, 1 have put you down for a scope and left the views indefinite. When I bring around your scope I will have a fine collection of views and our $2.00 per dozen views are the finest in the country."

If the customer already had a stereoscope, the agent switched the emphasis away from the lens, crediting all the fine effects to the superior quality of the clear sharp views, all from original negatives taken by the best view artists in the country. The agent worked prominent names into the sales pitch to influence the customer: "Dr. Jones liked that view very much. I have his order for a collection. The agents were told that local personal influences of this kind are impossible for anyone to resist entirely.

The experienced agents carried a small folder containing a list of prominent local people and their avocation who had purchased views. These were shown to the prospect with the comment: "Here is the Mayor you see, the Minister, the Postmaster, and of course, these Doctors, who have all purchased views for their collection:' The great secret of moneymaking with views, it was emphasized, was to canvass their territory thoroughly—exhaustively. It was easier to build up the order if many of the customer's neighbors were taking views. They were advised not to be easily put off as "NO, is not always an answer in canvassing any more than in courting. Persistence wins the day.

The manual also offered advice on how the agent should conduct himself while on the road. They 'were admonished to find a good boarding place, keep the

best of company and not talk politics and if a Christian, to go to church Sunday and make themselves at home in prayer-meetings or the Y.M.C.A. rooms. To be neat and clean in attire, to dress well and never boast of his business, only talking about his views when actually canvassing. (No mention of female agents has been found.)

When delivering the scope, it was important to once again get the customer seated to try it out. Views were shown in the same manner as when canvassing, having the customer decide on each view separately, laying aside those they wanted to keep. If the customer protested: "Oh, I have more than I can take now;' the agent replied: "Why this is only a start—you have an opportunity to obtain the finest views that have ever been made and it will pay you to take advantage of it and get a good collection. Your scope is not so interesting without a nice collection. The more you get the better:' The agent was reminded not to lower prices as that lowered the value of the goods in the minds of the patron. However, to clinch a large sale, the agent would offer a free stereoscope with an order for six dozen or more views!

In addition to their first class views, the agents carried a small number of copied views that they sold for three cents each. The purpose was to counter the customer's objections that they could buy views cheaper elsewhere and to prove the superiority of their more expensive views. By downgrading these views with the comment: "These are copies. We carry them only for a cheap class of trade;' they seldom had to show them. They also carried hand painted views and French transparencies with them that sold for 25 cents each.

Using these successful methods, Bert expanded their sales force into western Iowa, Nebraska, Dakota and Minnesota throughout 1884. At the same time, Elmer built the business in eastern Iowa, Illinois and Wisconsin. By the end of the year, they covered Kentucky Tennessee, Arkansas and Louisiana with their agents.

The following year, Elmer worked his way east into Pennsylvania and in a year and a half built the foundation of an immense business through the populous eastern and southeastern section of the country. Meanwhile, Bert crossed the Rockies, covering the Pacific Coast, from San Diego to Puget Sound, with agents.

The Underwoods claimed to have sent out 3,000 college students in one summer. Agents traveled by bicycle, or horse and buggy in farm country, and were sometimes invited, to spend the night with their last customer, paying for their room and board with stereo views. A few agents used their experiences with the Underwoods to go on to bigger and better things. One was James M. Davis, who became the exclusive Sales Agent for Kilburn stereo views. Another was B. L. Singley, founder of the Keystone View Company of Meadville, Pennsylvania. Keystone, in time became a strong competitor to the Underwoods.

Outgrowing their single supply house in Ottawa, Kansas by 1887, they opened an office in Baltimore to supply all the territory east of the Mississippi. That same year they also secured control of the stereo views produced by Strohmeyer & Wyman. The combined capacity of their four suppliers, Bierstadt, Jarvis, Littleton Views, and Strohmeyer & Wyman was ten million stereo views per year. A Canadian office was opened in 1888 to handle the large sales there.

Underwood and Underwood expanded into Europe in 1890 when Bert opened a branch in Liverpool, England. He personally ran the office for three years, creating a renewed interest in stereo views there. They moved their Baltimore office in 1891 to New York to better serve their growing sales overseas.

By 1894, they were selling their views wholesale or through agents in all European countries, Australia, New Zealand, South Africa, India, Japan, Cuba, Mexico and nearly every country in South America. In that year, the Underwoods shipped three million views to England retailing them for $2.00 a dozen. 160,000 stereoscopes were also sold there for $1.00 each.

Gradually the Underwood firm began to publish their own original views to supplement already established trade lists of their four suppliers. In 1891 Bert took lessons in photography from M. Abel in Mentona, France. The excellent travel views of Italy Greece, the Holy Lands and Egypt, published under the U&U label, all were produced from Bert's negatives.

While in Rome, Bert arranged to photograph Pope Pius X in stereo, producing a 12 card set on "The Pilgrimage to St. Peter s and the Vatican:' After presenting a set to His Holiness, the firm received the following note from a Cardinal at the Vatican:

> His Holiness Pope Pius X., wishes me to tell you how much He had admired the stereoscopic views which Messrs. Underwood & Underwood have kindly presented to Him. As a token of His special appreciation of these very interesting photographs, His Holiness bids me send you in His name a silver medal together with His thanks.

It was not until 1897 that the company supplemented Bert's work by employing their own full-time photographers and using free-lance operators for specific assignments.

By 1901, the firm had finalized the design of the U&U logo on their stereo views and were publishing over 25,000 views a day of their own. They also sold 300,000 stereoscopes a year—a prodigious output that made the firm the largest of its kind in the world. Their stereoscope supplier was Henry E. Richmond, a native of Bennington, Vermont, who had established a

stereoscope factory for the trade around 1890, in the small town of Westwood, New Jersey, population 838. The factory was just fifteen miles from mid-town Manhattan and employed about thirty people. His factory ground the lenses, cut out the wooden parts, stamped and shaped the aluminum hoods, binding the edges with velvet. Those he made for the Underwoods were stamped on the hood with the words "Sun-Sculpture" surrounded by their rising sun trademark. The factory was a two-story building with a water tower that supplied water to the town of Westwood. U&U apparently bought the factory around 1901 and retained Richmond as their Manager through at least 1914.

They also purchased a factory from Strohmeyer & Wyman in Arlington, New Jersey, eight miles from Manhattan, that produced both stereoscopes and views. Seventy persons were employed there in 1906. One of the Underwoods' more famous staff photographers, James Ricalton, was from Maplewood, New Jersey, just a few miles from their factory in Arlington. Their Westwood factory produced stereoscopes exclusively, employing 10 men and 20 women the same year.

At the turn of the century the Underwoods introduced their unique boxed set of views—a sequence of views that simulated a tour of the country depicted. Some views had captions in six languages printed on the back. A descriptive guidebook accompanied the views which included a map showing the exact location and boundaries of the views in the set.

U&U Guide Books were edited by some of the most eminent scholars of the day. The popularity of these travel sets and guidebooks made it difficult for smaller companies to compete and was responsible for some of them closing up shop and selling their negatives to the Underwoods, which grew even bigger as a result. Their boxed sets and books became immensely popular, forming the bulk of their output for the next 15 years. Their sales literature pointed out—"The Underwood Travel System is largely mental. It provides Travel not for the body, but for the mind- but travel that is none the less real on that account. It makes it possible for one to see as if one were present there in body—in fact to feel oneself present—and to know accurately famous scenes and places thousands of miles away without moving his body from his armchair in his comfortable corner; indeed, it enables him to take up one standpoint and then another with reference to them and so see them as a whole, and to study them minutely just as one would on a visit to the places in the ordinary expensive way."

By 1910 they had 300 different stereo view sets for sale and had diversified into the new field of News photography. As stereo views declined in popularity their News Division grew. They ceased production of all stereo views in 1920, selling their stereo negatives to the Keystone View Company which continued to produce Underwood inspired travel sets, primarily to schools. Shortly after the Underwoods retired, the company was reorganized as Underwood & Underwood News Photos, Inc. In 1943 Bert Underwood died in Arizona. Four years later, Elmer died in St. Petersburg, Florida.

Since 1978, much of the Underwood and Underwood archives have been housed within the University of California Riverside (UCR). This is as part of a 30 ton collection of 350,000 original stereoscopic negatives, 140,000 cards, record books, and salesman cataloques, primarily from Underwood and Underwood, The Keystone View company, B.W. Kilburn, H.C. White, and The American Stereoscopic company.

Underwood & Underwood images are a vast and invaluable resource showing the modernization of the world, brought to life by the power of Stereoscopic viewing.

UNION CASES

Union cases are plastic photographic cases made during the 1850s and 1860s primarily in the New England section of the United States and used to house daguerreotypes and later, ambrotypes. Made from the earliest form of plastic, or composition, the case material consisted of shellac and pulverized wood fibers (sawdust) which, when thoroughly mixed and sufficiently heated, resulted in a thick-flowing malleable substance. This substance

was pressed into molds which had die-engraved designs. The lid and bottom of each case were held together with metal hinges. "Union" cases were so named because of the combining of materials to produce a new substance, the earliest plastic.

From its inception daguerreotype was immediately popular in the United States and the demand for these portraits was overwhelming. In order to protect their delicate surfaces, daguerreotypes were, at first, placed under glass and fitted into wooden frames. A much more popular and portable method of protecting daguerreotypes was the use of the jewelry case, following the fashion established for portrait miniatures. As the production of daguerreotype images dramatically increased, so did the demand for cases to house them. Throughout the 1840s and early 1850s photographic cases were generally designed as shallow wooden boxes covered with thin sheets of leather or pressed paper to simulate leather.

The plastic photographic case industry began with the Scovill Manufacturing Company of Waterbury, Connecticut, and the daguerreotypist, Samuel Peck. The Scovill Company, a partnership between brothers James M.L. Scovill and William H. Scovill, was one of the earliest brass manufacturing companies in America. They had experience in making rolled plate metal, including silver plated copper sheets. One early supplier for cases to the Scovills was Samuel Peck of New Haven, Connecticut who began his career as a daguerreotype artist in 1844. By 1850 he was manufacturing cases and soon began a co-partnership with the Scovills that was named Peck and Company. In addition to leather and paper cases, Peck began creating "fine cases" including those made from papier-mâché. Perhaps it was the technique used in making these cases which inspired Peck to his greatest innovation. By May of 1852 Samuel Peck and his brother-in-law, Halvor Halvorson began producing daguerreotype cases molded from plastic.

Another important early plastic case manufacturer was Alfred P. Critchlow, a button maker from Haydenville, Massachusetts. Critchlow moved to Florence, Massachusetts and soon began experimenting with steam presses to mold shellac and gutta-percha compounds. He was producing plastic daguerreotype cases as early as 1852, soon after Peck began his work. Critchlow entered into partnership with Samuel L. Hill and Isaac Parsons in 1853; this new company issued a line of standard size cases, from which dozens of different designs have been identified. Beginning about 1857 the photographic supply firm of Holmes, Booth and Hayden in New York City were also actively engaged in plastic case manufacturing.

Great Britain was an early market for American made union cases, especially those with a distinctly British appeal such as "Sir Henry Havelock," "The Calmady Children," "Sir Roger de Coverly," and "The Highland Chief." Peck cases were being used there soon after their introduction in America. John Atkinson and Elisha Mander were two importers of these cases based in Liverpool and Birmingham. Some union case examples found in Great Britain have labels which read, "Patent American Union Cases." These were sold by Mander and were probably re-labelled for his market in cases made by Littlefield, Parsons & Co. or Critchlow. At least one firm manufactured union cases in Britain in the early 1860s—John Smith of Birmingham. The rare ninth-plate case, "Amazon on Horseback Being Attacked by a Tigress," was probably created by his firm, although none of the known examples carries a trade label. The dramatic design was based on the sculpture of the same name by Auguste Kiss which was a major attraction at the Great Exhibition at the Crystal Palace, Hyde Park, in 1851. Brookes and Adams were two die engravers who created case designs for the British market. Of major significance are two British patents made by John Smith for a thermoplastic mixture "...capable of being used for jewel cases, photographic cases, and 'horn' buttons in a variety of colours." The influences of this relatively small group of British dealers and manufacturers were important to a market which had been exclusively American.

Union case designs range from traditional subjects, such as patriotism and religious sentiment, to scenes from romantic literature, children's stories, mythology, and classical allusions, as well as vignettes of Victorian domestic life. Patriotic designs include "Shield with Flags, Cannons, and Liberty Cap," "Union and Constitution," "The Eagle at Bay," and "Constitution and the Laws." Religious motifs decorate "The Lord's Prayer," "Daniel in the Lions' Den," "The Holy Family," "Rebekah at the Well," and "The Church Window." Children's stories and Victorian sentiment were especially popular design themes with titles such as "Bobby Shafto," "See Saw, Margarey Daw," and "The Faithful Hound." American history theme cases include "The Landing of Columbus," "The Sweet Potato Dinner," "The Capture of Major André," "The Warning at the Green Spring," and "The Washington Monument, Richmond, Virginia." Many of these designs were based on prints, paintings, sculptures, and other works of art. Some die engravers were completely faithful in their translations for case designs, such as Smith and Hartmann, who copied Emanuel Leutze's epic painting "Washington Crossing the Delaware" in almost precise detail. Geometric, scroll, and floral designs were also used extensively on union cases—about 70 percent of all case designs. Plastic, or union, cases were manufactured in several standard sizes from the largest whole plate size (7 3/8" x 9 3/8"), half plate (5" × 6 3/8"), quarter plate (4" × 4 7/8"), sixth plate (3 ½" × 3 ¾"),

ninth plate (2 ½" × 3"), sixteenth plate (2" × 2 1/8"), and "sweetheart" (1 ¾" diameter) and came in several shapes, rectangular, octagonal, oval, and circular. Colors were at first limited to black and brown, ranging from a very light, almost tan shade to a dark, lustrous chocolate brown. Not until the late 1850s did union cases appear in colors other than these standard two. Small cases, usually ninth, sixteenth, small ovals, and the circular "sweetheart" cases were produced in a variety of colors including orange, red, and green.

Between 1853 and the mid-1860s, hundreds of thousands of union cases were produced to meet the demands of the rapidly growing photographic market. By 1857, with the advent of paper photographs which did not need to be protected in cases, the union case industry suffered its decline. The 1870s witnessed the disappearance of the cased image—both the daguerreotype and ambrotype processes were obsolete. Case manufacturers found new uses for thermoplastic and manufactured buttons, belt buckles, jewelry, combs, knife handles, chessmen, mirrors, gun cases, brush handles, picture frames, and lids for men's collar boxes, some using union case designs.

Union cases were America's first plastic products—the very beginning of a significant industry. Used as a protective device for the popular daguerreotype, union cases became artful objects in their own right and are collected today for their wonderful and intricate designs.

UNIONS, PHOTOGRAPHIC

The need for a 'photographic union'—an association designed specifically to offer support to professional photographers—manifested itself in some regions of the world much earlier than others. Despite early photographic societies and groups declaring themselves to be open to all who had the interests of photography at heart, it very quickly became apparent in some countries that the needs, motivations and intentions of the amateur and the professional were distinctly different.

Though the initial spread of the daguerreotype in the United States was largely spontaneous and unorganized, after 1850 various factors such as increased competition, questionable patenting of minor improvements (such as a bromide coating of glass plates) and the rise of the negative processes led to several attempts at uniting professional photographers on a "protective" or "fraternal" basis. In 1851 were formed the first two American photographic societies, which were closer to being unions than their French and British counterparts: the New York State Daguerrean Association thus aimed at setting floor prices, while the American Daguerre Association sought to vindicate the profession from its "humbug" reputation. These short-lived organizations, and their immediate followers, also resembled earlier artistic unions in providing for "mutual aid." This professional concern was less prominent in the formation of the American Photographic Society in 1859, which emphasized larger, social and cultural goals. Hence the creation of a Photographers' Protective Union in 1860 and the ongoing battle, in the 1860s, to repeal the infamous "bromide patent," a goal that was finally achieved in 1868. In 1869 was formed the National Photographic Association, the first "fraternal" organization of professional photographers to remain stable and to combine mutual aid and a concern for the elevation of pictorial standards, as shown in its annual exhibitions until 1900. The 1870s and early 1880s were thus a period of relative stability, though early photographic giants such as the Anthony and Scovill companies had come to control large sectors of the photographic market, bypassing professional organizations. After 1890, the rise of popular photography, embodied in the phenomenal growth of the Eastman Kodak Co., threatened to relegate the old professional and fraternal pattern to marginal status, while a new industrial framework emerged that had little tolerance for workers' unions.

In Europe, Julius Schnauss founded the *Allgemeiner Deutscher Photographen-Verein* in 1858, and went on to edit its journal, *Photographisches Archive*, while Ernest Mayer of Mayer Freres et Pierson in Paris, founded the

Union photographique in 1859 as a mutual aid society for the protection of workers engaged in all aspects of professional photography.

Very little is known about the situation of the majority of photographic workers in 19th century Europe. Most photographers were artists or craftsmen, and their studios employed just a few assistants in setting up chemicals, carrying equipment, or retouching the results. Larger studios began to employ women for greeting the clients when entering the rooms. Social problems arose with the establishment of larger companies and studios after the introduction of the carte-de-visite and stereo cards.

Workers at lithographic establishments such as Hanfstaengl in Munich or Roemmler & Jonas in Dresden organized themselves in printers' unions but because of the nature of their operations, photographic workers had little or no access to such organisations. Membership of many of the early mutual aid societies was restricted to studio principals—the photographers themselves—with little or no protection available to their workers.

About 1865, twenty Danish professional photographers formed themselves into a professional association—the first such organisation in that country—but like so many early attempts at the formation of trade associations, it was relatively short lived.

In 1870, there was an "Association of Photographic Operators" (Photographischer Gesellenverein) founded in Berlin, and in 1885 there was a branch set up in Dresden, in 1887 as well in Chemnitz and Munich. In 1891, authors of a meeting's report hastened to tell the public that they had 'eliminated all socialist elements' from their organisation, and in 1898 a Viennese association of operators had similar problems in distinguishing themselves from workers' unions.

As many photographic assistants worked in large printing offices they found themselves organized as printers by the late 1860s in Italy, France, Switzerland, and Austria, to be followed by Germany in the late 1870s. Lithographers became well organized after the invention of the autotype process both in Germany and Austria, and it is likely that numbers of practitioners went under the shelter of their union by this time.

Britain was very slow to adopt the idea of a trade association or union for photographers and photographic workers. From the 1850s, organisations such as the Photographic Society and the Architectural Photographers Association (later the Architectural Photographic Society) were open to amateurs and professionals alike—the criteria for membership focusing on the 'gentleman photographer' rather than the staff who worked behind the scenes. So the negotiations with Talbot over the restrictions imposed by the calotype patents were conducted through the Photographic Society rather than by any professional grouping.

It was the 1880s before an exclusively professional association was first mooted in Britain, and 1890 before a trade union for photographic assistants came into being—the same year that the Photographic Manufacturers Association was formed. A busy year for the formation of specialised groupings, 1890 also saw the establishment of the Society of Professional Photographers (quickly renamed the National Association of Professional Photographers) towards the year-end. None of these groupings endured—the NAPP folding by 1898—and a Master Photographers Association enjoyed only a very brief existence during the 1890s. It was 1901 before the Professional Photographers Association (now the British Institute of Professional Photography) came into being. That association continues today.

In the southern hemisphere, the distances which separated areas of photographic activity dictated that local rather than national associations were established.

The earliest professional photographic group in Australia was the Photographic Society of Victoria, formed in 1860, which held meetings at the studio of Batchelder & O'Neil at 57 Collins St. Melbourne. The secretary was Charles Hewitt. In 1894, the Professional Photographers Association of Sydney formed, meeting in the Sydney School of Arts with J. Hubert Newman as Chairman, and a state-wide group, the New South Wales Professional Photographers Association formed in the same year, holding meetings at the Baker & Rouse Warehouse in George St, Sydney.

The Photographic Association of South Australia was formed late in December 1882 and the first meeting was held at George Freeman's studio in King William Street, Adelaide where it was reported that twenty-four persons had sent in their names for enrolment, but the group was short lived.

The South Australian Photographic Society first met 14 August 1885 at Chairman Aaron Flegeltaub's office in Freeman Street, Adelaide, catering for both professional and amateur photographers, while in Queensland the Professional Photographers Association formed in Brisbane in 1893 with Gustave A. Collins, operator at the studio of Albert Lomer & Co, as president.

UNITED STATES OF AMERICA

In view of photography's extraordinary development and deep assimilation in the United States, it has been suggested that although it originated in Europe, it should really have been invented in the U.S. Such a claim could hardly be justified on mere technological grounds, since by all accounts there were few, if any, serious precursors in the U.S., and since the American contribution to photographic technologies was minor, at least until the emergence of dry plates and popular photography after 1880. Similarly, the artistic achievement of 19th-century American photographers, at least until the 1890s, has often been regarded as secondary in comparison to that of leading European countries, although since 1975 or so a few American "masters," such as Edward S. Curtis or Carleton E. Watkins, have received increasing attention. If one is to uphold the idea of a special success of photography in the U.S., then it must be understood less in the traditional categories of science and art, and more in terms of social, economic, and cultural development, as was already made clear in Robert Taft's pioneering history of American photography, published in 1938 under the significant title *Photography and the American Scene: A Social History, 1839–1889*.

Social history, in a broad sense, has been a continuing trend in the ever-increasing historiography of 19th-century American photography since Taft, and it has been important not only in unveiling previously unknown or underestimated American photographers and pictures, but more generally in stressing social patterns of practice, use, and appreciation. These patterns were doubtless more pronounced or more noticeable in the U.S. than elsewhere, but they were by no means unique to the U.S. In that sense, the social bend of much of American historiography has served in recent years as a model for other areas, especially Europe, where the social dimension of photography had often been eclipsed by a more narrowly academic historiography. The following presentation, while arranged in broad chronological fashion, will focus on the connections between photography and society, which in the case of the U.S. determined the course of photography as a medium of culture and memory, rather than a mere form of art.

Most accounts of the beginnings of photography in the U.S. have emphasized the sweeping enthusiasm of Americans for what Oliver Wendell Holmes called "the mirror with a memory," i.e., the daguerreotype, which was the sole process being practiced in the 1840s and which was dominant until 1855 at least. This enthusiasm was reflected in countless press articles and other records, starting with Samuel F.B. Morse's famous description of Daguerre's "results" in a letter he sent his brothers from Paris in March 1839, and which was subsequently published in dozens of American newspapers. According to the American painter-inventor, Daguerre's plates were "Rembrandt perfected," and "their exquisite perfection almost transcend[ed] the bounds of sober belief." A few months later, Edgar A. Poe hailed the daguerreotype as "the most important, and perhaps the most extraordinary triumph of modern science," while Ralph W. Emerson, noting the sobering effect of a daguerreotype sitting, wrote in his journal that "a Daguerreotype Institute is worth a National Fast." Many more examples of this enthusiasm could be adduced, especially from the scientific, literary and artistic milieus, which almost unanimously embraced the daguerreotype and in many cases kept abreast of improvements. What was perhaps most distinctive about the American response, however, was not its superlative and sometimes fantastic character, but its primarily social and technical dimension, which quickly transformed the foreign invention, its use and its practice, into a booming profession and something of a national pastime. It would be exaggerated to claim that the beginnings of photography in the U.S. amounted to a rush of entrepreneurs and fortune-seekers, as opposed to the genteel world of *savants* and *artistes* supposedly typical of European countries. Many of the early practitioners and promoters of the daguerreotype in the U.S., notably in New York, Philadelphia and many other cities, were artists, such as Morse, whose studio served in 1840 as a school for many a future great of American photography, including Mathew B. Brady, Edward Anthony, and Albert S. Southworth. Most American painters of the mid-century would experiment in one way or another with the daguerreotype and then with other processes. One must not overlook either the initial role of professional scientists, such as the leading chemist and colleague of Morse at New York University John W. Draper, the University of Pennsylvania chemist Paul Beck Goddard, and the future president of Columbia University

Frederick A. P. Barnard; in addition, the development of the daguerreotype in smaller cities, such as in the South, was often led by local academics or physicians. It is clear, however, that these beginnings were less academic and more professional than in Europe, and that they took place mostly outside established institutions, or rather that those academic institutions that did play a role (such as the American Institute, the Franklin Institute, or even the American Philosophical Society) were at the time too insignificant or too weak to exercise any kind of control or even any major influence over the course of events. Thus, what is striking about Morse's letter of March 1839 is not just its fantastic style, but rather the fact that this private letter, full of emotional marvelling, and necessarily devoid of any proof or illustration, was reproduced in hundreds of newspapers and served as the nearest equivalent of an official annoucement of the daguerreotype in the U.S. In contrast to the ceremonious and centralist rituals that surrounded the invention in France, the spontaneous and diverse beginnings of photography in the U.S. were auspicious for an invention that was to become a "mirror image," in Richard Rudisill's phrase, of political and cultural democracy—so much so that by the 1850s many an American journalist would claim that "photography was born in the U.S."

The fact that Daguerre did not take out a patent in the U.S. was a major factor in the daguerreotype's long domination; its development, however, took almost immediately a decisively technical and professional turn. Virtually every effort of the pioneers centered on the drive to make portraits and to make a business out of them, and this soon led to the registration of many patents for technical improvements. Whatever the answer may be to the much-debated question of the "first photographic portrait," and while European experimenters were also involved in 1839–40 in research aimed at reducing exposure time and increasing light input and chemical sensitivity, such research mobilized more energy and ingenuity, and yielded quicker positive results, in the U.S. than anywhere else. A classic example of this American specialization is the short career of the Wolcott-Johnson partnership, which in October 1839 created and soon patented, for the purpose of making portraits, a simple design of a camera without a lens, and used its superior luminosity to open in New York, in May 1840, the world's first studio for photographic portraiture. While Wolcott also designed many recipes for "accelerating" silver salts and more generally reducing exposures, many more examples could be adduced of early and continuing American experiments that almost always touched upon the technique of making portraits, including its more artistic aspects such as lighting, background, and the expression of the sitter. Between 1839 and 1845 at least, portrait-making was virtually the sole photographic activity practiced in the U.S., and after that it remained both the most important and the most prestigious branch of daguerreotypy, as illustrated by many an enterprising "daguerreotype institute" (such as the network of studios owned by the Bostonian John Plumbe), and, most famously, by Mathew Brady's Broadway studio. Brady's "Gallery of Illustrious Americans," which became something of a household word in the 1850s, especially exemplified the link between photography and the building of a national identity, as well as the connection that the portrait always suggested between one's image and the public image of celebrities functioning as models. Well beyond the daguerreotype era, indeed for the entire 19th century, portrait-making would remain the dominant use of photography, feeding a profession which, as early as the 1840s, emerged as unrivalled in size, dynamism, and business.

The unique success and durability of the daguerreotype process in the U.S. can be measured by the fact that both in quantitative and qualitative terms it reached its climax after 1850, rather than before, and that it remained dominant until 1855 and widely practiced until the early 1860s, thereby departing radically from the general course of development observed in Europe. Thus in 1851 at the London Crystal Palace Exhibition, Americans showed nothing but daguerreotypes and indeed won several prizes for them: a first prize to Martin M. Lawrence for stylish and allegorical portraits, a second prize to Mathew Brady for his portraits of celebrities, and another second prize to John A. Whipple for his daguerreotypes of the moon. At the 1853 New York Crystal Palace Exhibition, daguerreotypes were still largely dominant, although for the first time the top award went to paper photographs. The years 1850–1853 were the peak of a kind of Daguerrian cult in the U.S., with the publication of the world's first specialized journal under the title *The Daguerreian Journal* (founded in November 1850 by Samuel D. Humphrey); the creation of the first two professional associations, namely, the New York State Daguerrean Association and the American Daguerre Association; and, in the same year, 1851, which saw the death of Daguerre and an emotional homage from the American profession to the "French master," the building of a huge photographic manufacturing complex on the Hudson under the name Daguerreville. According to sources quoted by Taft and other historians, in 1853 the number of daguerrian establishments in New York exceeded one hundred, which is twice as many as the figure known for Paris in 1848, and the annual production of daguerreotypes in the U.S. was estimated at three million; between 1850 and 1860, the national census recorded an increase from 938 to 2650 daguerreotypists, while the 1860 census also registered a new category of "photographists" with a population of 504, probably an underestimation since by this date

many daguerreotypists were also practicing photography on glass. By 1855–1860, every town of any significance and many a tourist spot or place of passage had at least one resident photographer, and the itinerant "dag'typist" with his wagon and chemicals had become a familiar feature of the countryside.

The daguerreotype boom of the 1840s and early 1850s was sustained by a climate of "near-perfect competition" (Reese V. Jenkins) that was facilitated by the quasi-absence of commercial restrictions on the practice. This situation changed with the advent of negative-positive processes, which made it possible for some individuals, notably one James A. Cutting, to take out patents on minor improvements with a view to controlling the entire market of glass-plate photography. The "Cutting patent" or "bromide patent," awarded in 1854 for the use of potassium bromide in combination with collodion on glass, enabled its holder to exert durable financial pressure on many practitioners, until it was repealed in 1868 upon an application to renew it. More generally, the 1850s and 1860s witnessed a greater diversity of processes, as well as the emergence of cheaper variants (such as the "ambrotype" and its more popular version, the tintype, which as a pseudo-positive process on a dark metal base continued the daguerreotype model in the U.S. and remained hugely popular throughout the 19th century) and mass-market picture products (such as the carte-de-visite and then stereophotographic views). These cheaper, more common types of pictures gradually transformed an activity that had been largely a craft into a more industrial and more aggressively commercial business. Thus, this period was marked on the one hand by the rise of larger suppliers or brokers and a few dominant picture-making firms (the most important being the Anthony brothers' company in New York), and on the other by a spirit of suspicion and bitter rivalry among the more isolated individual photographers, leading to countless efforts, between 1850 and 1870, to organize the profession (see entry "Societies, groups, institutions, and exhibitions in the United States"). The atmosphere of defiance and the absence of a strong organizational framework was illustrated by the famous affair of the "hillotype," an alleged process for color daguerreotypes which the Reverend Levi Hill claimed to have invented, but which could never be either proved or disproved, despite a protracted investigation and major turmoil in the photographic profession in the 1850s.

Meanwhile, by 1860, it can be said that photography had become part of American culture at large. Even though the prices of full-plate daguerreotypes had remained too high for most people to afford them, the carte-de-visite, the tintype and the stereoview gradually turned the experience of photography into a common one, and allowed large segments of the population to own at least a few pictures. These would of course be portraits for the most part, and the more privileged individuals and families who had started accumulating daguerreotypes in the early 1840s were already, by 1860, enjoying the later popular ritual of viewing the growth of children, family resemblances and more generally family history through the photo-album. This photographic construction of family memories was already commented on by Oliver W. Holmes in his famous articles on stereoscopic photography, which appeared between 1859 and 1863 in the *Atlantic Monthly*, and which also indicated the emergence of a cultural consumption of images of the world in the upper, educated classes. For indeed, besides portraits, an increasing share of photographic production in the 1850s illustrated aspects of public life and national culture, from portraits of statesmen and artists that were reproduced as engravings to views of prominent buildings, city scenes, and some already well-established tourist sites (such as Niagara Falls), which would be made popular mostly by stereo-views. Many burgeoning American cities of the antebellum period were illustrated by photography, sometimes in a very self-conscious way, as in the case of Cincinnati (a stunning multi-plate daguerreotype panorama of which, by Charles Fontayne and William Porter, had won a prize at the Franklin Institute in 1849) or especially San Francisco, which almost from its very inception as a city cultivated a kind of photographic narcissism (with views by George Fardon, Charles L. Weed, and then Carleton E. Watkins and others) that would only expand in the 1860s and 1870s; in later years, the rise of Chicago as a metropolis was similarly documented almost day to day by photography. The 1850s and early 1860s also saw the first significant examples of landscape and survey photography, in California especially, but also in the Philadelphia area, although this trend really picked up force only after 1868 or so. Although still timidly, some Federal and state institutions, such as the Department of Treasury for instance, started to use photographers, as did also some large-scale expeditions such as Colonel John C. Fremont's fifth expedition across the Rocky Mountains in 1853 (daguerreotypist Solomon N. Carvalho) and Commodore Mathew Perry's inaugural voyage to Japan in 1852–53 (daguerreotypist Eliphalet Brown). The idea that photographs carried a memorial and documentary value, and therefore could produce a new kind of archive, was making its way into many corners of society. Although American scientific institutions were typically slow and reserved in this process, the 1850s and 1860s saw some attempts at building up collections of ethnographic photographs, in a few cases of African-American slaves and, through the practice of some Washington, D.C., photographers (such as Zeno Shindler), of Indian representatives on delegation visits. Thus, the earliest significant bodies of images of minority groups in the U.S. came into being

as a function of archival projects. The political world itself began during the 1850s to realize the impact of photography as a means of publicity and emotional effect; this is how, during the 1860 Presidential campaign, Mathew Brady became "Mr. Lincoln's camera man." Finally, the new cultural role of photography in American society was recorded in much writing of the time, from Nathaniel Hawthorne's *The House of the Seven Gables* (1851), the first major piece of fiction probably anywhere in the world to stage a photographer (in this case a daguerreotypist) as a protagonist, to dozens of more popular novels, tales and stories exploiting the supposed "mysteries of the darkrooms" and the magic powers of the camera, and to the more philosophical reflections of Emerson, Holmes, and others; around 1860, Walt Whitman had become the first major public image of a writer through photography.

These various trends truly gained full force during and immediately after the Civil War, as the glass-plate, negative-positive processes finally superseded the daguerreotype, now making the multiplication of prints a defining aspect of photographic practice and business. The Civil War itself provided direct and decisive impetus for the suddenly accelerating spread of photography in American society and institutions. What is most obvious and most often mentioned in this connection is the outstanding and unprecedented body of thousands of photographs of the war that were produced by the hundreds of photographers associated with the Union army, many of them in the employ of Mathew Brady (such as

Alexander Gardner, Timothy H. O'Sullivan, George N. Barnard): camp scenes, army group portraits, but also the first "straight" photographs ever of war casualties and destruction, among which the most famous one is probably O'Sullivan's "A Harvest of Death," a view of Union soldier corpses left lying at the battlefield of Gettysburg. Here were, to quote Gardner's words in his *Photographic Sketch Book of the Civil War* (1865), the "dreadful details" and the "blank horror" of war: these pictures indeed clashed with the traditionally staid pictorial representation of war, and inaugurated a tradition of war reportage, and of reportage in general, that would be durable and especially strong in American photography. The unique photographic documentation of the war that was thus collected—mostly, once again, from the Union side—has become a major document of American history. Along with various technical uses of photography for map-making, reproduction and filing that the military itself promoted, it has often been cited as one of the illustrations of the Civil War's "modern" dimension. But there were other aspects as well, although often overlooked. First, the war affected virtually every American family, and it tragically strengthened the desire of relatives to remain linked to their boys by getting their pictures, and of soldiers to keep a remembrance of home, peace and family ties through the carte-de-visite portraits of loved ones they kept in their wallets. The production of photographic portraits during the war was enormous, and it was one of the immediate reasons why the armies—especially on the Union side—decided to allow and then to invite photographers among their ranks. Although from its inception photography had been especially linked with the keeping of family portraits and especially the commemoration of the dead, the Civil War more than any other single event made photographic portraits a part of American life. And it was after the Civil War that increasing numbers of ordinary American citizens, including a large number of women (who have more recently been brought to our attention), took up photography either as a business or as a hobby. Second, the Union Army's involvement with photography and photographers precipitated, in the wake of the war, its inclusion in virtually every sector of scientific, museal, documentary and more generally institutional activity in the U.S. It was after the war, and often as a direct result of Army staff connections with photographers, that many new or preexisting institutions started to use photography and to hire photographers on a more or less permanent basis. This was true with a number of medical, police, and other public institutions. But the most striking example of this phenomenon was the widespread use of photography and photographers in Federal surveys of the West between 1867 and 1880, which involved several veterans of war photography, such as O'Sullivan—who remained in Federal hire from 1867 to his death in 1881, and who is now the most valued and scrutinized of the survey photographers—and Andrew J. Russell, who after serving with the Quartermaster Corps went on to document the building of the Union Pacific Railroad line. Along with the spirit of conquest and colonization that characterized the post-war years, the Army's involvement with photographers thus paved the way, somewhat paradoxically perhaps, for the exceptional flourishing of documentary and landscape photography that took place in the West, under Federal direction mostly, around 1870. Beyond O'Sullivan, the survey photographers included, among others, William H. Jackson, another "grand old man" of American photography who recorded the first views of Yellowstone, the Mountain of the Holy Cross, Mesa Verde and many another of the "wonders of the West," and Jack Hillers, the photographer on Major John Wesley Powell's survey of the Colorado who almost singlehandedly created the photographic archive of Indians in the Bureau of American Ethnology. When looking at the sublime landscapes of California, Colorado, Wyoming, Idaho, etc., which were taken by these photographers in large, sometimes gigantic, collodion-coated glass-plates, one cannot but be struck at their magnitude as well as technical and artistic excellence. At the same time, however, one cannot either avoid the supposition that the Federal Government, by 1870, had found in the photography of the West's grand landscapes a perfect visual and even artistic expression for its policy of "reconstruction," i.e., a means of replacing the wounds of the war with visions of both a pristine Nature and a grandiose future in the imagination of Americans.

Many of these photographs, including especially hundreds of landscape pictures that basically defined the contours of the American imagination of the West and its great sites, were exhibited and rewarded in several important exhibitions, including the World Fairs of Paris in 1867 and Vienna in 1873, as well as the Centennial Exhibition in Philadelphia in 1876. They were also distributed, along with many other similar pictures of private or corporate origin, in the form of stereoviews, which by 1870 had become the most important popular medium of visual information and entertainment. The railroad companies were especially active in promoting and selling landscape photography. The business of landscape views was between 1865 and 1890—aside from portraits—the primary channel of popularization of photography and photographs in American society, and it continually reemphasized the connection between the new medium—for photography was still considered such by the general public—and the new perspectives of American society. But it also served, although somewhat paradoxically, the recognition of photography as an art form. Because these views obsessively staged

the spectacular landscape forms of the West, and because their authors in general tended to underplay or perhaps to hide their stylistic input in them, they were generally regarded as anonymous "views of the West," notwithstanding the specialized interest of a small "photographically literate" community in their makers' idiosyncrasies. For that reason especially, as well as because of increasing acts of piracy and underselling, the more culturally conscious segment of American photography fought after 1865 for a legal recognition of their authorship, which resulted in 1868 in a modification of the copyright laws that provided some protection for authors. Thus, the same moment that witnessed the true popularization of photographic images in American society was also the time when the idea of photographic authorship gained a measure of recognition. This dual pattern was to maintain itself for several decades, as the social distribution of views expanded into the business of chromolithographs and then (after 1890) postcards on the one hand, and as more demanding artist photographers on the other hand devised stylistic and publishing means of distancing themselves from the mainstream. William H. Jackson, who after his survey years went into partnership with the railroads and then with the Detroit Publishing Company, was an example of the "commercial" model, as were also, in the last years of the century, Frank Jay Haynes and Adam Clark Vroman (although all three of these photographers at the same time practiced more advanced or formally innovative photography). Conversely, more sophisticated or more artistically ambitious individuals, such as Peter Henry Emerson, the founder of "naturalistic photography" in the 1880s, and his followers illustrated a more formally and intellectually demanding perspective, although they learned immensely, if not always admittedly, from the "view" or "business" photographers.

This latter trend, which led to the differentiation of "professionals" and "artists," was also a reflection of broader patterns after 1880, among which the most significant was the emergence of amateur photography and the ensuing transformation of the older forms of practice. Until 1880 or so, there were few amateurs in the U.S., and those who existed were for the most part the learned, high-profile type, engaging primarily in documentary endeavours. While the French law of 1839 on the daguerreotype had implausibly announced that with the daguerreotype, every one could make a picture, the democratic promise of universal access to picture-making had remained until around 1880 a fairly abstract notion, even though the possession of pictures had already been democratized. In fact, in the U.S. even more markedly than in Europe, the business of picture-making had been, almost immediately and durably, the exclusive privilege of a professional class, which prided itself on its technical achievement, and which because of its lack of reputation was especially prone to bar outsiders from entering the field. Photography until 1880 or 1885 remained, in Daniel J. Boorstin's phrase, "esoterical." But then after that things changed rather quickly, as dry plates, smaller formats, and the first attempts at providing photographic customers with technical services started to catch the fancy of the urban upper-middle class. By 1885 there were amateur photographic clubs in most leading American cities, and photography was becoming a fad along the same lines as bicycling or going to the beach. Then a new and decisive threshold was crossed with the introduction, by the Eastman Company of Rochester, of the first Kodak (1888–89), an easy-to-handle hand camera loaded with film (first mounted on paper, then on celluloid) for a hundred views, which after exposure the firm would take in and process for a relatively low cost : "you press the button, we do the rest," the slogan went, as if to materialize the promise of 1839. This slogan was successful enough to become a catchphrase of the 1890s, as thousands of Americans discovered the pleasures of snapshot-taking and thus constructing their own private memories, and as the Eastman Kodak Company kept introducing newer, simpler and cheaper models (such as the famous Brownie in 1900). The Kodak organization reflected the new potential of American industry for technological innovation, which around the same time was also embodied in the development of moving pictures. But the Kodak was primarily a concept, and although it had been preceded, and was largely imitated, by many competitors (such as Ansco, Carbutt, Cramer, etc.), it was a revolutionary one, just like its author George Eastman had intended it to be: for George Eastman had been perfectly explicit about his ambition to make "a Kodaker" of every American man, woman, and child, be it at the cost of displacing the former corporative privileges and organization of the professionals. Professional photography did not simply disappear around 1900, but it was progressively stripped of its basic functions and relegated to more specialized ones, such as ceremonial portraits on family occasions and the like. Meanwhile, much of the former public and commercial character of photographic practice was replaced by a new interrelation of industrial and domestic concerns, out of which, in addition, the amateur photographer now also started to evolve, at least in some cases, as a new type of artist. To be sure, serious amateurs and artist amateurs had been around, and had even formed clubs, for several decades before 1900, an early and important example being the Philadelphia Society, which starting in 1860 gathered around Edward L. Wilson and published a high-class periodical, *The Philadelphia Photographer*. But the boom of popular photography in the 1890s transformed the very concept of amateur, in the sense that being a popular photographer meant taking the kind of pictures

that a professional might have made before, although not necessarily with strong artistic consciousness. Finally, this process of popularization also coincided with, and in several ways underlay, the much more self-conscious efforts at distinguishing art photography from run-of-the-mill professional photography—as well as from "button-pressing"—by some advanced individuals, who since about 1885 had been advocating and practicing "pictorial photography," under the influence of P.H. Emerson, and British and other European artists and critics. The most notable example of the partition between "high-brow" amateur photography and popular photography was, of course, Alfred Stieglitz and his New York circle, which between 1892 and 1900 progressively broke away from the New York amateur clubs to create the Photo-Secession and the prestigious magazine *Camera Notes*. Stieglitz went on to found a distinctively American branch of photography—as well as modern art—on the premise that neither the limited, recipe-style, technical expertise of the professionals nor the haphazard and vulgar opportunism of the "button-pressers" constituted true photography. But at the same time, Stieglitz himself practiced the hand-held camera and other contrivances associated with popular photography, while also showing great meticulousness in his picture-taking choices, as well as in developing and printing procedures, and he thus served as the synthesis of the new diverging trends, and as an endpoint to several of the main traditions of 19th-century American photography. Ultimately, it may be argued that the American 19th century climaxed in the contradictory but complementary figures of Eastman and Stieglitz, who not only jointly revolutionized photography for the U.S. and for much of the world, but who paradoxically upheld some of the basic trends of the 19th century, most notably the profoundly political dimension that in the U.S. had attached itself to photography, making it the democratic art *par excellence*. This political dimension, indeed, was lost neither on Eastman nor on Stieglitz, both of whom viewed photography as the double expression of hard work and individual freedom.

URIE, JOHN (1820–1920)

John Urie was born in Paisley, Scotland, in 1820, the son of a weaver, and was apprenticed in the printing trade. In the 1840s he operated his own business hand-carving wooden type for use in the printing industry, and later working as a wood engraver making printing blocks.

Urie's engagement with photography was reputedly initiated by a visit to the Great Exhibition, and by 1852 he had established himself as a photographer in Glasgow.

In December 1852 he was mentioned in *The Practical Mechanics Journal* in connection with the application of photography to wood engraving.

By 1854 he occupied premises in Glasgow's Buchanan Street, at Nos. 33 and 35, producing portraiture. The *Mechanics Journal*, May 1854, published an account of Urie's *Relievotype* variation on the collodion positive, or ambrotype, in which the image was presented emulsion side up, with only the background of the actual portrait backed with black shellac. The image was then placed on a light paper or card background. This had the effect of creating a three-dimensional effect.

He later advertised studios in Edinburgh, Glasgow, Leeds, Perth, Dundee and Belfast and that he had 'agencies' in all important cities.

In 1885 he invented a photographic printing machine which could produce two hundred prints an hour by gaslight (*Photographic Times,* Nov 27 1885).

V

VACQUERIE, AUGUSTE (1819–1895)

French photographer and writer

Auguste Vacquerie was a very close friend of the Hugos, who considered him as a member of the family. His brother Charles married Leopoldine Hugo, the writer's elder and beloved daughter. The consorts both drowned in the river Seine near Villequier, in 1843.

After a classical education, he turned to critique and journalismHe co-founded in Paris the political newspaper L'Évènement, with Paul Meurice, his good friend from College Charlemagne, Charles, and François-Victor Hugo. On the 2nd of December 1851, threatened as a republican and opponent to Napoleon's dictatorial regime, he left France. Later he moved to Saint-Helier, Jersey Island, with the two Adeles, the wife and daughter of Victor Hugo, who joined them in August 1852. They stayed there till October 31 1855, when they had to move to Saint-Peter-Port, Guernsey Island.

In Jersey, Vacquerie had to adjust to his new condition of exile, as well as the Hugo family. Far away from his busy social life dedicated to political and journalistic activities, he mainly turned to literature. But along with Victor Hugo, Charles and François-Victor, he was part of the Jersey et l'Archipel de la Manche book, a project launched by Victor Hugo, supposedly in two volumes. The first one, rather inexpensive, included poetry written by Victor Hugo himself. The second volume, more luxurious, was to include texts on Jersey's history and institutions, and photographs taken by the Hugos sons and Vacquerie. For him, this book was a rather basic work, far from the interest he had at this time in theatre plays. He hoped it would be an opportunity to make money quickly.

Vacquerie greatly admired Delacroix aesthetic and was influenced by the latter's concept of photography. Vacquerie mostly worked with negatives on paper, which offered more delicate contours. Yet, he used glass plates as well. Positives were printed on salted paper, a technique he seems to have learnt from Charles Hugo. Not satisfied with his first attempts, he worked hard on improving his technical skills, as witnessed by letters to his friend Paul Meurice or to his family (see unpublished letters to his mother, sister (Mrs Lefèvre) and nephew Ernest Lefèvre, kept at Musée Victor-Hugo at Villequier).

Auguste Vacquerie usually used small size prints (roughly 10×7 cm.), organizing his pictures with great attention to harmony, according to curves, light and shadow balances. Although it is hard to discern Charles Hugo's or Auguste Vacquerie's authorship when not clearly established, Vacquerie's portraits end-up as a remarkable set.

Beside Victor Hugo's portraits, he shot pictures of many exiled people there (like the Le Flô children or Augustine Allix) or visiting friends (Paul Meurice and his wife) that the corresponding French colony in Jersey still looks very vivid. Focusing on details, he brings to life the daily routine of the exile, like Mrs Hugo reading Châtiments dressed in a peplum-like drapery, and the passing of the seasons, pictured in close-ups of the green house sofa with hanging roses above or the garden under the snow. In his images, Vacquerie never parted from his own sense of humor: he pictured his cat sleeping as a pendant to a portrait of Hugo, during a reading of Phèdre tragedy.

Vacquerie also made as many as 43 self-portraits. These images show a clear influence of Victor Hugo's portraits: the poses are strikingly similar. Many of Vacquerie's self-portraits are grouped along with portraits he did of his family (his mother, sister, nephew, etc.) in an album he gave them (now kept at the Bibliothèque nationale de France).

Lastly, Vacquerie developed a clear interest in still life, a genre that set him apart from the rest of the Jersey Atelier and the Hugos' photographic production.

Through photographs of casual objects (like Mrs. Hugo's purse, or her bracelet on her arm), or small compositions (including the reproduction of the Hugo's portrait or drawing done by the writer), Vacquerie gave a puzzling image of the family. This specific type of images, though, was never broadly circulated, and seemed to have stayed with the closest relatives the Hugos and Vacquerie had.

In 1854, 9 000 francs (in gold) had been spent already on the project mentioned above, without any return. No publisher could be found who was willing to issue the work. All were afraid of the cost, and of the possible censorship the volume might trigger.

Vacquerie's and Hugo's sons pictures were all taken in Jersey, except a very few number when they moved to Guernsey, in 1855. Then, although a lab was installed at their new place, Hauteville House, the photographic production slackened. The text Vacquerie had written to accompany the pictures in *Jersey et l'Archipel de la Manche* was published in 1856 and 1863, *Les miettes de l'Histoire*. Some of the reprints he had done later on were used by Vacquerie to illustrate his books (mainly *Profils et Grimaces*), in order to turn them into personalized gifts.

Dropping photography, he concentrated on journalism and literature, both of which he had never left behind.

MATHILDE LEDUC-GRIMALDI

Biography

Auguste Vacquerie (1819–1895), schoolmate and friend of Charles Hugo. After a classical curriculum, he was first a journalist and a literary critic, for French newspapers like *Le Globe*, *l'Époque.* Very early, he was introduced into the romantic coterie and became a devoted admirer of Victor Hugo. He became part of the family when his brother Charles Vacquerie married Leopoldine Hugo, the writer elder child. After their drowning, emotional ties grew even stronger between Vacquerie and the Hugos.

He joined Hugo's sons and friend Paul Meurice venture in publishing *L'Évènement* (1848) where he was more concerned in literature than politics. When, in 1851, this paper re-named *l'Avènement du Peuple* saw most of its staff jailed, Vacquerie took it over. Then the four of them were fined and jailed at the Conciergerie in 1851, and the Evènement was shut down under Napoleon's dictatorial regime (along with him was jailed his female cat Grise and again she was in Jersey where Vacquerie took a famous photograph of her). Sharing Hugos' political ideas, he fled from France, and lived in Jersey, Guernsey and Brussels. Part of his work, such as Profils et Grimaces (1856) or Les miettes de l'histoire (1863), and his many letters to his friends or sister in France depicted his life in Jersey with the Hugo family, and showed his interest in photography. Yet, this hobby actually lasted just a few years**.**

In 1869, he founded Le Rappel with Rochefort, Paul Meurice, Charles et François-Victor Hugo, unrelentingly fighting against Napoleon III Empire. After the Empire fell, he backed the uprising of Paris (1871), as did V. Hugo and his sons.

He also wrote poetry (*L'Enfer de l'Esprit*, in 1840), a comedy (Souvent Femme Varie, in 1859) and dramas (Tragaldabas in 1848, Les Funérailles de l'Honneur, in 1861).

Back in France (around 1867), he continued his activities as a journalist, writer, and was chosen (along with Paul Meurice and Ernest Lefèvre, Vacquerie's nephew) by Victor Hugo to overlook the publication of the poet's entire work after his death.

VALENTA, EDUARD (1857–1937)

Valenta was a professor at the Hohere Graphische Bundes-Lehr- und Versuchsanstalt in Vienna from the late 1800s to 1909 where he codirected with Josef Eder, founding director and author of famously detailed The History of Photography (Geschichte der Photographie), and later succeeded him as the school's head in 1923. The school is one of the oldest and most important with a specialty in photography and graphic arts in the world.

Valenta and Eder carried out and published in journals and annuals numerous studies of the spectra of elements and compounds, including many of the dyes important for photographic emulsions. They experimented with emulsions and published a number of photographic studies, including one of the earliest and most beautiful collections of highly detailed X-ray images (1896).

Valenta studied and published on the Lippmann process (1894–1912). Many of his Lippmann plates were held in the collection at the "Graphische." Those were mostly in the nature of lab trials, and most were failures with poor or no color. These plates, along with 60,000 others in the Graphische's collections, were donated to the Albertina in Vienna where they are in process of being cataloged.

WILLIAM R. ALSCHULER

VALENTINE, GEORGE D. (1852–1890)
Scottish photographer

George D. Valentine (1852–1890) was a son of the famous Scottish photographer James Valentine. He came to New Zealand in 1884 with the hope that the climate would improve his health. It seems that in the remaining years of his life, he was unable to suppress his sheer enthusiasm for photography and despite his fragile condition he committed himself to compiling an extensive series of landscape photographs. Beginning with views of Nelson where he initially settled, he then turned his attention to views of the Pink and White Terraces and Lake Rotomahana, both pre and post eruption 1886–1887. Moving to Auckland he broadened his coverage by making a series based on a summer cruise in the Pacific Islands, photographing Tahiti, Tonga and the Cook Islands. In 1889 he was one of the first photographers to descend into the Waitomo Caves at Otorohanga, an exploit which would have tested the physical endurance of a very fit person. Surprisingly none of his 12 × 10 inch views seem to have found their way back Scotland for his father¹s firm to distribute. Two years after he died in Auckland, Valentine & Sons dispatched a photographer to New Zealand where he made a series which were used for tourist souvenirs and postcards. These were marked with the initials of J.V. as distinct from George Valentine¹s photos who signed his prints with the initials of G.V.

WILLIAM MAIN

VALENTINE, JAMES AND SONS
Company

James Valentine and Sons of Dundee, Scotland, were a successful photo-publishing firm who derived the bulk of their income from the sale of topographical views and postcards. The firm had its origins in the activities of John Valentine, a one-time weaver who commenced the production of wood-blocks for the linen industry around 1825. In 1832 John's son James, who had been trained in the art of portrait painting in Edinburgh, was summoned to assist in the running of his father's printing firm. For a time father and son worked together, however, local directories show that they had parted company by 1840. Before James expanded into photography he produced bill-heads, engraved notices, prints of local scenes and illustrated propaganda envelopes for the American social campaigner, Elihu Burritt. James also became interested in the daguerreotype and travelled to France to study photography under M. Bulot. He was listed in the 1851 trade directories as a professional photographic artist. From the mid 1850s he supplemented his income from photographic portraiture by selling stereographs and carte-de-visites created by other photographers.

The public appetite for scenic views was evident in the growing sales of topographical lithographs after 1820. This audience was augmented by souvenir -hungry tourists whose holidays were made increasingly possible through the expansion of the railways. In the early 1860s, another member of the family, James's son William Dobson Valentine, entered the firm. He had just graduated in chemistry from University College, London, and had also trained with the renowned professional travel photographer Francis Frith at his Reigate Studios. It is thought that William encouraged his father to produce photographic views similar to those with which the firm's Aberdeen rival, George Washington Wilson, was having great success. In 1867 James Valentine was commissioned to produce a series of forty Scottish highland views for Queen Victoria and was subsequently appointed as Photographer to the Queen. William's brother George Dobson Valentine also entered the business where he concentrated mainly on portraiture. William was a thorough photographer and his topographical views show careful attention to composition. Two negatives were made of each scene and by 1878 the company's numerous views necessitated the introduction of a number dating system thereby attaching a unique number to each image within the collection.

By the 1870s Valentine's views covered the whole of Britain and were being sold singly in several sizes or in finely bound albums. The pricing of these exquisitely bound volumes demonstrated that they were intended for the middle and upper-classes. The company also sold more moderately priced individual views and inexpensive stereographs which were cheap to produce and in wide demand. The company changed its name from James Valentine to James Valentine and Sons in 1878. Following the death of James Valentine in 1879 his two sons became sole partners in the firm. This arrangement lasted until 1884 when, due to ill health, George emigrated to New Zealand where he was to become one of the earliest landscape photographers in the country. William was also keenly interested in technological advances in photography and contributed articles to periodicals such as Art Journal and the Photographic News. During the 1880s he was to write on a variety

of subjects including underwater photography and the photographing of winter scenes.

In 1886 an article appeared in the *British Journal of Photography* outlining the extent of the Valentine's operation which by then employed over one hundred people. By 1888, their catalogue included over 20,000 views of Scotland, England, Wales, Ireland and Norway. At around this time another generation of the family entered the business, William's son Harben Valentine. He was also keen to use any technological innovation which would give the firm an advantage over its competitors. By the 1890s Harben was employing the collotype process which allowed the mechanical reproduction of photographic images which would previously have been printed by hand. This greatly increased the speed at which the firm could operate. He was also to experiment with the photocrome and photogravure processes.

In 1897 the British post office permitted private cards to be sent through the mail for the first time and it was in that year that the Valentine firm were to enter the postcard market. Valentine and Sons were able to compete in the rapidly expanding market due to the technological advances which had been instigated by Harben. The combined the collotype process with the bitumen process to add colour. An indicator of their success in the production of postcards was the number of staff employed by the firm which rose from over 100 in 1886 to almost 1000 in 1900. The firm's activities spread overseas with branches opening in Canada, the United States, South Africa and Australia. William Dobson Valentine handed management of the firm over to Harben in 1900 though he was to retain an avid interest in the firm until his death in 1907. The early years of the twentieth century saw increased competition from German postcard manufacturers and Valentine responded by placing an emphasis upon the production of realistic views undoubtedly utilising their immense collection of negatives and their knowledge of topographical photography. In 1908 they became the official postcard publishers for the International Franco-British Exhibition. It was at this time that they took on the twin globe logo and its accompanying motto 'famous throughout the world.'

From about 1901 Valentine began to extend and diversify their interests to include the production of greeting cards, children's books and calendars. The number of views commissioned by the firm began to shrink in the 1950s and family interest in the firm declined with the death of Harben in 1949. The firm was eventually taken over by John Waddington and Co. Ltd. in 1963. In 1971 the archive containing Valentine's topographical views was deposited with St. Andrew's University, Fife, Scotland. Whilst the 150,000 views in the archive constitute only a remnant of the half a million which were recorded from 1878 to 1967 they provide a valuable record of popular taste and topographical photography.

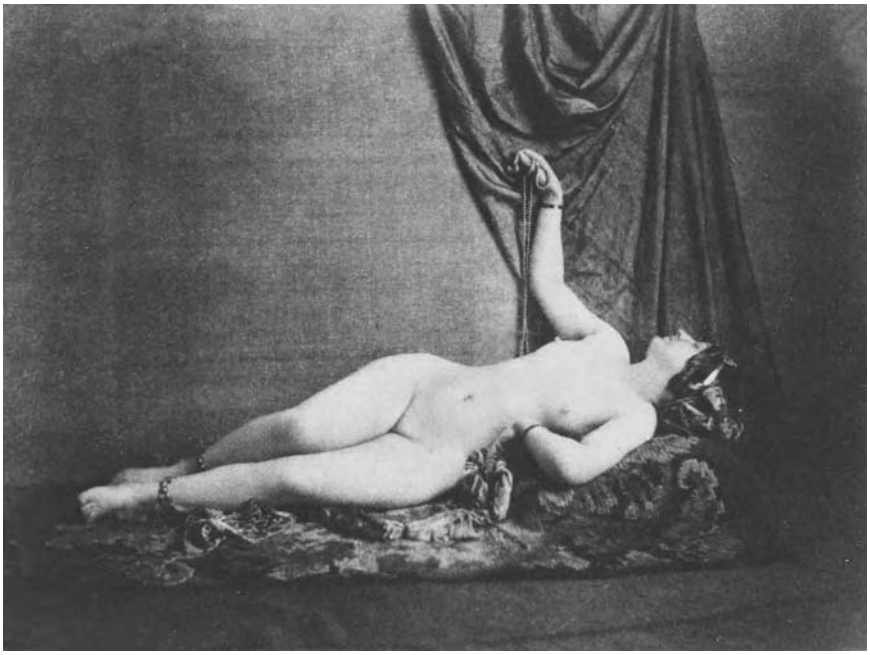
VALLOU DE VILLENEUVE, JULIEN (1795–1866)

French, artist, lithographer, and photographer

Vallou de Villeneuve was born in Boissy-Saint-Léger on 12 December 1795. From his début at the Salon of 1814 (to 1840) as a painter he regularly exhibited lithographed images of daily life, fashion, regional costumes and erotica, many done after the work of English and Dutch artists. Vallou, earlier a student of Millet and a lithographer of scenes of daily life, costume, and erotica, also published his own lithographed compositions, mostly 'female types.' From 1820 to 1830 he acquired great popularity for his engravings of fashions, costumes, every day scenes, and erotic images. Many lithographs based on his drawings were done by Raymond Noël and Régnier.

Despite a long artistic tradition and an obvious delight in the female nude, decorum in mid-century France, required that the subject be removed from the reality of the present—shown in mythological guise or as an exotic creature, distant and non-threatening. The need to provide a legitimate context for the depiction of the nude was particularly compelling in photography, and Vallou often appointed his models with the paraphernalia of the painter's studio (rugs, shawls, spears, beads, anklets, and turbans). His most successful pictures, however, are those least encumbered by artificial trappings; revealing more and borrowing less from painterly tradition,



de Villeneuve, Julien Vallou. Female Nude, #1940. Reclining, with arm raised.
The Metropolitan Museum of Art, Purchase, Lila Acheson Wallace Gift, 1993 (1993.69.1) Image © The Metropolitan Museum of Art.

these are the most poetic. While tantalizingly real in both weight and texture, Vallou's reclining nude seems nonetheless to float in an indeterminate and dreamlike space, a crescent moon in a starry sky.

In 1826 he showed at the Salon "Costumes des Provinces Septentrionales des Pays-Bas." He published in 1829 lithographs of "Types des Femmes," Souvenirs of an artist. In 1830 with Achille Deveria and Numas, Maurin and Tessaert, he contributed to the compendium of romantic erotica called Imagerie Galante (Paris, 1830), which provocatively updated an erotic mode found in 18th-century engravings. The subjects were pictorial versions of stock characters from popular novels and plays. Issued through several publishers. In 1839 he published the lithographs "Les Jeunes Femmes, Groupes de Têtes." He became interested in photography in 1842, shortly after the new medium's invention, as an aid to his graphic work. His subjects included fashion, costume, and daily life, as well as light erotica, sometimes published in conjunction with other artists. In 1850 he began to practice photography at 18 Rue Bleu, Paris (nudes, portraits of actors). He fixed prints with ammoniac after the process of Humbert de Molard. He liked to retouch his negatives. Durieu criticized him concerning this procedure. By 1850 Vallou de Villeneuve had begun to practice photography in his studio, primarily female nudes and portraits of actors.

In 1851 he became member of the Société héliographique. Between 1851 and 1855, Julien Vallou de Villeneuve, made a series of small-scale photographs of female nudes, which he marketed as models for artists.

Around the symbolism photography art in the 19th Century painters got already a rapid eye for the expressive possibilities of photography. Photographers ogled to the achievements of painted art. The photos mapped the wealth of this interaction. Already as from the first steps in the 19th Century photography had an enriching but also ambiguous link with painting art. Their respective histories were intertwined and revealed many similarities. The mutual teamwork formed the scope of the show, symbolism, as a result of the retrospective Fernand Khnopff in the Royal Museum for Fine Art in Brussels, Belgium.

In 1853-54 Vallou published a series of nude studies, Études d'après nature, which were sold as artists models and to the general public. Several were used for well-known works by Gustave Courbet. Vallou de Villeneuve's works are admired for their emotional restraint, as well as for their masterful orchestration of form. Gustave Courbet, Gustave Moreau and Eugène Delacroix inspired themselves on photograph's, which they let make the Villeneuve, Henri Rupp and Eugène Durieu by photographers such as Julien Vallou. Also the school of Barbizon brought painters and photographers closer to each other. Camille Corot and Théodore Rousseau, Eugène Cuvelier, Charles Famin and Paul Berthier literally walked the same paths at the Fontainebleau. Around the symbolism, the links between photography and painting art exposed the photographic penchant of symbolism in the painter by means of photographic portraits, studies to nature, mises-en-scène and tableaux vivants, and included as well was picturalism. Thanks to photography, artists discovered a totally new manner to capture reality. Vallou's nudes have long been associated with those of Gustave Courbet, who was known to have

used photographs in his painting process. Although no absolute one-to-one correspondence can be proven, the quality of Vallou's models is very close to Courbet's concept of the nude. J. Vallou de Villeneuve in his photographs organized zones of light and shade and worked in small formats intended for albums or "intimate" portfolios. His personages are without ornamentation in simple decors. His nudes are improved by studied lighting. Some accessories were placed within view to add simple graphics.

In his nude studies intended for artists, he was not content with habitual poses, but instead invented new ideas of attitudes.

From 1853 to 1854, he was a founding member of the Société française de photographie (S.F.P.) and in 1855 he gave his prints to this society.

On 4 May 1866, he died in Paris.

JOHAN SWINNEN

Biography

French lithographer, photographer and painter. Between 1851 and 1855 Julien Vallou de Villeneuve, a student of Millet and a lithographer of scenes of daily life, costume, and erotica, made a series of small-scale photographs of female nudes that he marketed as models for artists; evidence suggests that they were used as such by Gustave Courbet, among others.

VAN KINSBERGEN, ISIDORE (1821–1905)

Dutch-Belgian photographer and theatre maker in the Dutch East Indies

When Isidore van Kinsbergen arrived in Batavia in the Dutch East Indies (now Jakarta in Indonesia) on 26 August 1851, he described himself as an artist, lithographer, set painter and opera singer. Such a versatile background meant a great advantage in a small colonial town like Batavia where artists needed several skills in order to survive. Van Kinsbergen's leading role in the Théâtre Français de Batavia gained him support from the upper social classes of colonial society and through this interesting photographic assignments from the colonial government. "A capable and experienced photographer" was the opinion of the Amsterdam photographic pioneer Eduard Isaac Asser.

It is not known where and from whom Van Kinsbergen learned to photograph. However his background as a lithographer and his entrepreneurial spirit no doubt whetted his interest in the medium. His first photographic activities in Batavia date from 1855 when he briefly associated with the French photographer Antoine François Lecouteux.

Via his contacts in Batavia's artistic and scientific circles, it is certain that Van Kinsbergen was familiar with what was being published in Europe in the field of illustration. However, it is doubtful whether he saw there much photography of any kind of quality. In view of his links to the Parisian art world, it is well possible that he became acquainted with photography in the French capital when he resided there for a few months in 1854. Van Kinsbergen's sense of photographic monumentality evokes the work of his French contemporaries Edouard-Denis Baldus and Louis-Auguste and Auguste-Rosalie Bisson.

In 1844, the Dutch Ministry of Colonies, being far ahead of its time, commissioned the German photographer Adolph Schaefer to make daguerreotypes of Javanese antiquities including the Borobudur. When nearly twenty years later Van Kinsbergen picked up the thread where Schaefer left off, photography was already being used elsewhere for documenting ancient treasures and archaeological findings (Egypt, India etc.). He had come to the attention of the Dutch colonial government in September 1862 with photographs taken during a journey with the Governor-General on Java. These convinced the colonial government of his ability to make an extensive photographic survey of Javanese antiquities. Meanwhile the government was also aware of the photographs he had made of famous monuments and temples in Bangkok in Siam (Thailand), where he had been assigned as photographer to a diplomatic mission earlier that year.

In December 1862 the Batavian Society of Arts and Sciences (acting on behalf of the colonial government) drew up a contract with Van Kinsbergen. The Society did not give any directions as to how he should photograph the Hindu-Javanese and Buddhist antiquities. This was left entirely to his own technical and artistic insights. Between 1863 and 1867 Van Kinsbergen made more than 330 photographs which were published in the portfolio Oudheden van Java [Antiquities of Java] in a chronological and geographical order, commencing with the first photographs he made around Bogor on West Java and concluding with images of the Panataran temple complex on East Java.

Van Kinsbergen showed an immense interest in the antiquities he photographed. The Dieng Plateau was considered one of his personal rediscoveries. However, what he thought about the art of photography itself is not revealed. Information on his artistic motivation can only be gleaned by looking at the photographs themselves and from a few responses to his work by experts that specialized in antiquities or the East Indies. Apart from Eduard Asser, it is not known whether fellow photographers appreciated his work as it was hardly reviewed in photography magazines of the period.

Van Kinsbergen worked with different sized negatives (now preserved in the department of history and archaeology at the Ministry of Culture and Tourism in Jakarta) measuring 17 × 21 cm up to 30 × 40 cm. In as far as on-site conditions allowed, he always searched for a viewpoint that showed off the characteristic form of a building, sculpture or artefact to its best advantage. He often worked with images that filled the entire picture in order to do justice to the detailing of the reliefs on the richly decorated temples.

Van Kinsbergen worked deliberately with direct sunlight enabling him to give depth and liveliness to the sculpture he photographed. Often combined with a pitch-black background which he obtained by scratching away the layer of emulsion on the negative, this approach became his trademark. The highly contrasting tone and the theatrical effect that went with it, is typical of not only his archaeological photographs but almost all his topographical views as well. This characteristic makes his photographs easily distinguishable from those Woodbury & Page made for instance. This choice of lighting illustrates that Van Kinsbergen was not only interested in conveying detailed information, but wanted to bring out the dramatic, expressive powers of subjects he photographed.

Van Kinsbergen made a near complete documentation in more than 100 photographs of Candi Panataran, his tour de force of the Antiquities of Java series. However, Boro-Boedoer [Borobudur] is still considered the true pinnacle of his archaeological work. Supplementing the Antiquities of Java series, the Batavian Society had commissioned Van Kinsbergen in 1873 to photograph the Borobudur. The manner in which he immortalized the various Buddha types on this world famous monument enraptured the Dutch scholar G.P. Rouffaer: "If ever the concept of God, as we see it, has revealed itself to the Hindus in the language of sculpture than is it certainly in these depictions of the sitting Buddha."

Van Kinsbergen's assignment from the Batavian Society provided the artistic and financial opportunity to establish his reputation as a photographer with a diverse oeuvre comprising topographical photographs, portraits, peoples of the region, still lives and even nudes. Van Kinsbergen tackled these photographic genres with the same verve as the Javanese antiquities.

In his studio, the relaxed manner in which Van Kinsbergen had his models posing reveals the communicative skills of a theatre director. Each person or group that appeared before his camera offered him fresh opportunities to experiment with a range of poses and forms of expression. He saw the Javanese models who visited his studio more as objects of academic study rather than ethnographic curiosities. His portraits of rulers (Yogyakarta, Surakarta) also reveal how Van Kinsbergen tried not only to depict the symbolic function of a sovereign, but also to make a study of the person behind it. In 1865, he was the first photographer visiting Bali, where he made an exceptional portrait series of the Raja of Buleleng and his court representing all ranks of society.

In his object-oriented and monumental approach to his subjects Van Kinsbergen was closely allied to a photographer like Linnaeus Tripe, who worked in India under similar circumstances. Van Kinsbergen can be described as the only Dutch photographer working between 1850 and 1880 who internationally measures up to colleagues now counted among the top exponents of nineteenth-century photography.

Isidore van Kinsbergen acquired international acclaim with his work that was widely distributed to international institutions. Most of it is still being preserved in the collections of, among others, the KIT Tropenmuseum and the Rijksmuseum in Amsterdam, the National Museum of Ethnology, the Kern Institute and the KITLV in Leiden, the Royal Archives in The Hague, the British Library in London, the Bibliothèque Nationale de France and the Société Asiatique in Paris. His photographs were found in the legacy of the French painter Paul Gauguin, being a direct source of inspiration for several paintings and woodcuts. The French collector Prince Roland Bonaparte owned hundreds of Van Kinsbergen's photographs now kept at the Société de Géographie in Paris.

Saskia Asser
Gerda Theuns-de Boer

Biography

Isidore van Kinsbergen was born in Bruges in the southern Netherlands (now Belgium) on 3 September 1821, as the son of a Flemish mother and a Dutch father. In the 1840s Van Kinsbergen worked as an engraver in Ghent where he also studied Chant français at the Conservatory. In 1851 he moved to Batavia in the Dutch East Indies (now Jakarta in Indonesia), where he was appointed as a set painter for the Théâtre Français de Batavia. He would be closely involved in the theatre world until his death. In 1855 he took up photography, later opening a commercial studio in Batavia. Van Kinsbergen was one of the first photographers to visit Siam (Thailand, 1862), and to photograph the rulers of Yogyakarta, Surakarta and Bali (1862–1865). He became famous for his extensive photo series of Javanese antiquities commissioned by the Dutch colonial government and the Batavian Society of Arts and Sciences, published as the series Oudheden van Java [Antiquities of Java] (1863–1867) and Boro-Boedoer [Borobudur] (1873). He exhibited at the World Exhibitions in Vienna (1873), Paris (1878) and Amsterdam (1883). Van Kinsbergen died on 10 September 1905 in Batavia.

VAN MONCKHOVEN, DÉSIRÉ (1834–1882)

Belgian photographic scientist, writer, and industrialist

Désiré van Monckhoven was born in Ghent on 25 September 1834, the only child of an unmarried mother. Despite these inauspicious beginnings, van Monckhoven proved to be a gifted child, showing a marked interest in physics and chemistry. His academic promise earned him a transfer from the Quanonne Institute, where he was training to be a clerk, to the Atheneum [high school]. Van Monckhoven briefly became a bank clerk, but pursued his passion for photography, which enabled him to turn his knowledge of science to commercial use.

Van Monckhoven received a thorough grounding in photographic practice from Charles D'Hoy (1823–1892), one of the first professionals in Ghent, and by 1853 or 1854 van Monckhoven had supplied a view of the local gothic town hall for the series Variétés photographiques published by Louis-Désiré Blanquart-Evrard. However, van Monckhoven's predilection was for research and writing, rather than running a studio. Barely 20 years old, he published the first edition of his Traité de photographie sur collodion [Treatise on collodium photography], Paris: A. Gaudin et frère, 1855. An initial printing in March 1855 of 1500 copies sold out, and was following by a second printing of 750 copies later in the year. This success persuaded his publishers to bring out a second, greatly expanded edition of the textbook. Van Monckhoven's Traité général de photographie [General treatise on photography], Paris: A. Gaudin et frère, 1856, in a print-run of 3000 copies, consolidated the author's reputation as a leading photographic scientist in continental Europe, an independent researcher able to analyse and arrive at accurate, fault-free formulae, and to disseminate these in clear and unambiguous language.

In order to legitimize his standing in the eyes of the broader scientific community, van Monckhoven enrolled as a student at the University of Ghent in 1857, where he was awarded a doctorate in natural science in 1862. In parallel, he continued his output of handbooks, collecting data from an array of sources and setting out his tried-and-tested conclusions in practical form. His work Méthodes simplifiées de photographie sur papier [Simplified methods of paper photography], Paris: Marion et Cie; A. Gaudin et frère, 1857, was followed by Procédé nouveau de photographie sur plaques de fer [New process of photography on ferrous plates], Paris: A. Gaudin et frère; A. Secretan, 1858, a third edition of his magisterial Traité under the title Répertoire général de photographie Paris et Londres, A. Gaudin et frère, 1859, and a simplified version of the latter as Traité populaire de photographie sur collodion, Paris: Leiber, 1862. Van Monckhoven was also a joint founder of the monthly Bulletin belge de la photographie in 1862, contributing a column on technical innovations.

Van Monckhoven turned his attention to photographic optics. He took out a Belgian patent in August 1863 for "an optical apparatus intended for enlarging by projection." Running counter to diurnal motion, the sun's rays were reflected uniformly by means of a mirror propelled mechanically by clockwork. Further patent

applications were made in France and England, and van Monckhoven set up as a manufacturer of heliostat enlargers under the name "appareil solar dialytique" [dialytic solar apparatus]. He received a bronze medal at the Paris international exhibition of 1867 for his innovation, and published the fruit of his research as Traité d'optique photographique, Paris: V. Masson et fils, 1866. The Traité général quickly ran to fourth and fifth editions also under the Masson imprint in 1863 and 1865 respectively.

Van Monckhoven moved to Vienna in January 1867 to form a partnership with the portrait photographer Emil Rabending, constructing a state-of-the-art studio in the Wieden district, at Favoritenstrasse 3 "in the courtyard of the imperial iron foundry." About two years later van Monckhoven dissolved the partnership to pursue scientific interests in his own laboratory. Returning to Ghent in the autumn of 1870, van Monckhoven established a factory for the production of carbon paper, and published two works on the subject: Historique du procédé au charbon [History of the carbon process], Ghent: Annoot-Braeckman, 1875 and Traité pratique de photographie au charbon [Practical treatise on carbon photography], Paris: G. Masson, 1876. He also published a sixth edition of the Traité général, Paris: V. Masson, 1873.

The introduction of dry-plate photography stimulated van Monckhoven to make his most significant contribution to photo-chemistry. Realising that Richard Leach Maddox's invention was poised to revolutionise photography thanks to its ease of handling, he had the factory diversify into emulsion production. Pursuing his research into the properties of silver halides in 1879, van Monckhoven discovered that the ripening of emulsion on gelatine-bromide plates could be improved by adding ammonia, thereby enhancing the tonal range. He wrote Introduction sur le procédé au gélatino-bromure d'argent [Introduction to the silver gelatine bromide process], Ghent: C. Annoot-Braeckman, which went into four editions between 1879 and 1882. A seventh edition of the Traité général, Paris: G. Masson, 1880, contained a chapter on dry-plate photography summarising the author's findings. The factory was expanded in 1880, employing thirty female workers for coating plates, and reached an annual turnover of one million gold francs that year.

Désiré van Monckhoven married Hortense Tackels (1839–1911) on 12 December 1872, and they had two daughters. In his spare time, he devoted himself to astronomy, and constructed a private observatory. A telescope, equipped with a 23 cm Steinheil lens, was custom-built in 1880, and van Monckhoven began work on a star atlas. This work went unrealised, as Van Monckhoven died suddenly of a heart attack on the evening of his forty-eighth birthday, at his home in Ghent on 25 September 1882.

Hortense Tackels headed the firm after her husband's death, and was followed by her son-in-law, the engineer and future senator Jean-Alfred de Lanier-van Monckhoven (born 1852). The firm successfully marketed dry plates under the D.V.M. label from around 1886, operating out of Boulevard d'Akkergem 74 until 1908. Two posthumous editions of the Traité général appeared under the imprint Paris: G. Masson, 1884 and 1889.

The Museum voor de Geschiedenis van de Wetenschappen [Museum of the History of Science], Ghent, houses a dialytic solar apparatus, some van Monckhoven manuscripts and a virtually complete set of his publications. The University of Ghent acquired the 23 cm telescope in 1904, which is still operational in the observatory. The Nadar papers in the western manuscripts section at the Bibliothèque nationale de France—Département des manuscrits contain a substantial and lively correspondence by van Monckhoven.

STEVEN F. JOSEPH

Biography

Désiré Carolus Emanuel van Monckhoven was born in Ghent on 25 September 1834, the illegitimate son of Francisca Maria van Monckhoven. The birth certificate declares "father unknown." Early clerical training was followed by studies at the University of Ghent, where he gained a doctorate in 1862. A renowned photo-chemist, van Monckhoven published his initial research on collodium in 1855, and wrote numerous works on photography and optics. Also a pioneer of the photographic industry in Belgium, his factory, founded in 1870, produced carbon tissue, and later emulsion for dry-plate photography. He married Hortense Tackels (1839–1911) on 12 December 1872, and they had two daughters. Van Monckhoven died suddenly of a heart attack on his forty-eighth birthday, at his home in Ghent on 25 September 1882. His widow continued to run the factory successfully, which operated in Ghent, Boulevard d'Akkergem 74, until 1908.

VANCE, ROBERT H (1825–1876)

In 1849, gold was discovered in the workings of Sutter's Mill at Coloma, California, just ten years after the announcements of the inventions of photography in Europe. News of Daguerre's process travelled to America ahead of William Henry Fox Talbot's paper-based method; consequently, east coast practitioners soon began to specialise in daguerreotypes.

Robert H. Vance, who was born in Maine and inherited money from his father, learned about photography as a young man while working in portrait studios in New Hampshire and Boston. By February 1847, he had his own gallery in Valparaiso, Chile, and later opened a similar venture in Santiago. Much of Vance's commissioned work came from owners of the wealthy, silver mines of Atacama Province, but circumstantial evidence suggests he also documented landscapes for his own satisfaction, then a rare practice among professionals.

By 1850, Vance was 25 years old and the California gold rush was underway. He sold his South American studios and moved to San Francisco to take advantage of the commercial opportunities (of the gold rush). En route to America, he stopped at Cuzco in the Peruvian Andes, and one biographer (Abel Alexander of Buenos Aires) believes this body of work represented Vance's best photography whilst in South America.

Within twelve months of his arrival in northern California, Vance had opened portrait studios in Sacramento, Marysville and San José, and eventually expanded his interests to Nevada (Virginia City and Carson City), and Hong Kong. Declaring Vance's Sacramento location as the "finest Daguerreotype and Photograph Gallery in the world," the San Francisco Daily Times described the "magnificent chandeliers, lace curtains, orlet [bordered] carpets, and the richest style of furniture." There were "eight elegantly finished reception rooms, and twelve operating rooms [and] ladies sitting and toilet rooms, where family parties may go, with a perfect assurance of privacy, and the premises are so arranged that there are at least three distinct galleries, each separate from the other."

Vance was an expert practitioner of the daguerreotype process, but he advertised cartes-de-visite at his First Premium Gallery in San Francisco, very soon after they became popular in Europe. He also offered colour portraits, which used the photograph as a guide for an artist working via a solar camera, and marketed Ambrotypes by emphasising superiority over his rivals, because those "taken by me are upon thick glass, and are atmospherically sealed, and will stand forever." But Vance lost money by dabbling in the stock market, and sold his gallery in 1864. The following year, he returned to New York, where he lived for eleven years until a sudden death at the age of 51. He was buried in Augusta, Maine.

In an appreciation in 1946, Ansel Adams noted that "the photographers of earlier days were definitely unaware of being 'artists.' They worked as craftsmen, … and their comment was not concerned by conflicting influences of manner and style." Adams believed that Vance was not only a superb craftsman, but that he had other qualities—"careful thought and selection of viewpoint." That is, he combined technical ability with creativity.

Robert Vance excelled as an artist, but he must also be remembered for the twelve-month undertaking he began in 1850. Once settled in San Francisco, his entrepreneurial spirit reasoned that, beyond California, people were eager to learn about the gold rush and that he was well placed to provide a visual narrative of its people and the places. Leaving his studios to be run by managers, Vance secured over three hundred images of life in California, which were dominated by themes of the gold fields. He framed his work, arranged the layout, published a catalogue and, in 1851, opened the exhibition on Broadway, New York.

In the 8-page "Catalogue of daguerreotype panoramic views of California," Vance featured portraits of gold miners and native Americans, photographs showing aspects of gold prospecting, the gold mining camps and pictorial landscapes. The important segments illustrated the popular locations—the Stanislaus River, the Mokelumne Mines near Sonora, Sacramento, Nevada City, Yuba City and Coloma in El Dorado County. He included San Francisco—before the fire of May 1851, and afterwards. He also showed emerging styles of architecture and "almost every variety of scenery," said the editor of *Photographic Art Journal*, in a review which described the "three hundred daguerreotypes so arranged that a circuit of several miles of scenery can be seen at a glance." Vance had displayed "an exquisite taste for the sublime and beautiful."

From the outset of his career, Vance had favoured a large, whole-plate camera, although studios portraits were generally taken on a smaller format. (A portrait of Horatio G Finch in the Bancroft Library was taken on a "mammoth" plate measuring 32cm × 27cm.) That Vance was able to visit the mining camps of the gold fields and return with processed whole-plate images of excellent quality, speaks well for his mastery of the process.

In spite of Vance's abilities, and good reviews, the New York exhibition failed. There were three possible reasons:

The public had lost interest in West coast news
Vance set the admission price too high
Vance neglected to promote the exhibition adequately

In February1853, Vance attempted to sell his collection, but it took five months before being auctioned to an entrepreneur from St Louis, Missouri, who exhibited them with his own work in the spring 1854. A review appeared in the *Photographic and Fine Art Journal* two years later, but by then, all three hundred images had disappeared.

Scholars argue that they may have been destroyed by fire, or sold for their metal content, and optimists maintain Vance's Views of California may yet re-emerge to receive renewed recognition. In 1946, Ansel Adams had already acknowledged the master's touch when he praised "the clarity of line and edge, the simple arrangement of mass, the beauty and richness of tonal values [and] above all, the integrity and forthright simplicity of Vance's photography and the evidence of his devotion to the enduring qualities of the world about him."

Vance's work is located at:

The Bancroft Library's California Heritage Collection
The Getty Museum
California State Library, Sacramento
Oakland Museum of California

VARIN FRÈRES
Pierre-Amédée (1818–1883), Pierre-Adolphe (1821–1897), and Eugène-Napoléon (1831–1911)

French photographers and printmakers

Descendents of an old dynasty of tinsmiths and printmakers established in Châlons-sur-Marne, near Reims, Amédée, Adolphe, and Eugène Varin studied printmaking in Paris. They became very successful in the 1850's and created many reproductive prints after paintings from the Salon, mostly for the publisher Goupil. Amédée and Eugène worked collaboratively and often co-signed the prints. In the same vein, their photographs are difficult to attribute to one or the other brother.

Little is known about the Varin brothers' photographic activity, which began around 1845–46 (a few portrait daguerreotypes from this time have survived). During the 1850's, they produced salt paper prints: landscapes, family portraits and intimate scenes, and architectural views and cityscapes taken during travels in the provinces, especially in La Rochelle. Aesthetically, their photographs rely on a solid artistic education and are reminiscent of amateurs photography of this era. The Varin brothers were not involved in the photographic world, and their photographic practice appears disconnected from their careers as professional printmakers. They rarely used photography as an aid for printmaking, nor envisioned it as a publishing technique. However, Quentin-Dailly, a publisher in Reims, released a portfolio of their views of the city.

PIERRE-LIN RENIÉ

VEDANI, CAMILLO
(active 1853–1870)

Italian-born studio owner and teacher

An Italian photographer active in Brazil between 1853 and 1870, Camillo Vedani had two studios in Rio de Janeiro, first on Assembléia St. and later on Ouvidor St. He also taught drawing and Italian to make ends meet. He spent five years in Salvador, Bahia (1860–1865). The photographs he took there overlap with and complement views taken by Benjamin Robert Mulock (1859–1862). Vedani also photographed the Bahia and San Francisco Railway terminus after it was completed. He produced stunning images of the city of Salvador, characterized by a bold style and an esthetic that was ahead of its time. He returned to Rio in 1865 and put together two albums of views of Salvador and Rio dating from 1860 to 1870. A label on one album reads: "Landscape photographer…. Will travel anywhere to photograph views and establishments." Brazilian collector Gilberto Ferrez, the grandson of Marc Ferrez, discovered the albums in the 20th century, which are now at the Moreira Salles Institute, Rio de Janeiro. Vedani also produced an album of photographs of Rio taken between 1865 and 1875. Both Gilberto Ferrez and photographer Pedro Vasquez have published his photographs. His works have been exhibited in Rio and São Paulo.

SABRINA GLEDHILL

VERESS, FERENC (1832–1916)
Hungarian photographer

Ferenc Veress, the son of a civil servant reputedly of noble descent, was born in Kolozsvár, Transylvania, on 1 September 1832. At the age of 16, in 1848–49, he was a goldsmith's apprentice in Nagyenyed to Károly Budai, one of the first amateur daguerreotypists in Transylvania.

He reckoned his photographic career all started with the gift of a camera from his mother in 1850, when he mostly took talbotypes. From this point his career could have turned in two directions. He could have either taken photographs, made experiments similarly to the well-to-do amateurs of the age or could have chosen photography as a profession and taken commercial photographs in his studio. He took both ways and opened the first permanent studio of Transylvania in Klausenburg and never gave up experimenting. The money he earned from his studio portraits he spent on photographic experiments and his land- and cityscapes.

It was on April 21, 1852, that he contacted Elek Buda, the local squire who had tried out and modified all the photographic techniques of the age. Under him, Veress mastered the daguerreotype, and a year later, opened a studio in Kolozsvár, the first permanent studio in Transylvania. He used the wet collodion technique to make albumen prints of glass negatives. In the same year, he experimented jointly with count Zsigmond Kornis. The activity of this promising duo came to a halt in 1854, when the count died. Baron Károly Apor, who presided over the Marosvásárhely royal Court of Appeal, introduced him to Count Imre Mikó, a Transylvanian patriot. The three continued photographic experiments. Mikó helped him photograph the Transylvanian aristocracy and he compiled an album of the photographs he took, no original copy of which has survived.

In 1855, the aristocratic patrons made it possible for him to go on a tour of study to Munich and Paris where he visited several famous photo studios. As a result, his technical knowledge was well above the country's average, he could produce life-size portraits which were then coloured in watercolours or oils by his temporary partner György Vastagh. He made ferrotypes, pannotypes, but he could also create photos on leather and canvas. His cyanotypes have survived. In 1858, he married Josefa Stein, the daughter of a Kolozsvár publisher, who also owned the local press, book and stationery shop. The Veresses had seven children, five of whom survived to adulthood.

At the end of 1859, he was the first person in Hungary to use Disderi's 1858 Paris invention, the *cartes-de-visite*.

His first landscapes date back to 1859. He used the dry collodion process, which deviated form the generally-used wet process in that a cover protected the humidity of the collodion layer for a few weeks, keeping it ready for use at any time. Count Imre Mikó initiated and assisted in the establishment of the Transylvanian Museum Circle in the same year, with Veress as official photographer. He compiled several albums and series, such as the album "Kolozsvár in Pictures," in two volumes, now housed in the Sion Collection of Kolozsvár University Library. He took his stereo photographs, featuring fifty views of the city, at the same time. The technique he was the first to apply in Hungary, simplified the tedious tasks of landscape photography associated with the wet process.

In 1861, Veress built a new studio-cum-home in Kolozsvár, which was extended seven years later. He was to work there for 28 years without interruption.

In 1862, he photographed, and sold cartes-de-visite of the members of the Kolozsvár National Theatre. He published his call to all the country's photographers, who, at that time, numbered roughly 250, in the paper "Ország Tükre":

> Our photographers could do a great service to our homeland by photographing, and collecting pictures of, lesser and more important men in the sciences, arts, industry and trade, and submit their resulting albums to museums… Our photographers could also do a great service to our history by taking photographs of all our relics, fortresses, old castles and country seats, ruinous churches and caves, which, though still in existence at present, are doomed to perish within a brief decade.
>
> (Veress, "A fényképezés múltja, jelene, jövője hazánkban" [The Past, Present and Future of Photography on Our Country], Ország Tükre [Mirror of Our Country], 9, 1862, 132–133)

In 1869, he sent Queen Elisabeth an ornate album with pictures with the remark: "If only all historic sights of Hungary could be photographed and… stored in Her Majesty's special library, we should be doing future generations a great service."

In 1872, Veress took a hundred and fifty-six 25 × 30 cm glass negatives of Central Transylvania, and he exhibited 144 of them at the Vienna World Fair one year later.

Some of the above albums must have been realized. One of them belongs to the Vienna Höhere Graphische Lehr- und Versuchsanstalt. Seventy-eight of his landscapes and about the same number of pictures of Kolozsvár have survived in family archives, museums and in the collection of the Hungarian Museum of Photography.

His 1876 exhibition at the National Industry and Farm Produce Fair was the first to show the technique of porcelain decorated with photographs and, in 1879, he exhibited more than three hundred such pictures in Székesfehérvár and Deés.

In 1880, he published a work of fiction entitled "Álomképek" [Pictures in My Dreams], under the

pseudonym Ferenc Turul. He established also a model-farm, where he improved more than 800 different kinds of apple.

In 1881–1882 he taught photography as an associate of Franz Josef University, Kolozsvár.

He launched the journal *Fényképészeti Lapok* [Photographic Papers] on January 1, 1882, as its owner, editor, publisher and most industrious reviewer. This, the first professional photographic journal in Hungary was published regularly until December 1888, and extended 84 issues.

He is known above all for his experiments of heliochromy, the very first direct colour process. Five years of experiments to take colour photographs accelerated in 1884 when he first managed to fix a heliochrome image, which claimed due success at the Paris World Fair in 1892. He was the only Hungarian photographer of the time to acquire worldwide recognition. In 1891, he carried out his 2663rd colour experiment.

In 1890, he closed his studio, leased it to the photographer József Kató, and devoted the rest of his life to colour photography, slowly sinking into poverty. (The year 1811 saw his 6,056th experiment with heliochromy.)

His death on 3 April, 1916, came only months before Romania's declaration of war on the Austro-Hungarian Monarchy and the Romanian invasion of Transylvania.

KÁROLY KINCSES

Biography

Ferenc Veress was born on 1 September 1832 in Kolozsvár [Klausenburg, Cluj], Transylvania. He learnt to be a goldsmith, just like many of the early daugerrotype-photographers and obtained his first camera in 1850. In 1853 he opened a studio in Kolozsvár, the first permanent photographic atelier in Transylvania. In 1855, his aristocratic patrons made it possible for him to go on a tour of study to Munich and Paris where he visited several famous photo studios. As a result, his technical knowledge was well above the country's average. There is not a single process in photography that he left unnoticed, he tried out, corrected and improved them. (He made ferrotypes, pannotypes, but he could also create photos on leather and canvas. His cyanotypes have survived.) At the end of 1859, he was the first person in Hungary to use Disderi's 1858 Paris invention, the cartes-de-visite. According to his calculations he took the studio-photo of nearly 40.000 people. In the meantime he took fascinating land- and cityscapes. His first landscapes date back to 1859. He invented and applied a Taupenot-type semi-dry plate. He compiled several albums and series, some of them have survived in several museum's collections. He brought making photographs on porcelain to perfection. His 1876 exhibition at the National Industry and Farm Produce Fair was the first to show the technique of porcelain decorated with photographs. He is known above all for his experiments of heliochromy, the very first direct colour process. Five years of experiments to take colour photographs accelerated in 1884 when he first managed to fix a heliochrome image, which claimed due success at the Paris World Fair. He was the only Hungarian photographer of the time to acquire worldwide recognition. He published the first regular Hungarian photographic journal: *Fényképészeti Lapok* [Photographic Papers] between 1882 and 1888. He taught photography at the University of Kolozsvár between 1881-82. In 1890, he closed his studio, leased it to the photographer József Kató, and devoted the rest of his life to colour photography, slowly sinking into poverty. He died on 3 April, 1916.

VERNACULAR PHOTOGRAPHY

The term "vernacular" literally means the ordinary and ubiquitous but it also refers to qualities specific to particular regions or cultures. Its attachment to the word "photography" is a recent development, part of an effort to devise a way of representing photography's history that can incorporate all of its many manifestations and functions. Although all photographs are potentially vernacular in nature, the phrase "vernacular photography" is generally used to encompass all those photographic practices and genres that fall outside the standard art history of the medium. This might include, for example, all sorts of typical commercial portraits or views, but also amateur practices where photographs were combined with other media and turned into hybrid objects. It would also include distinctive regional photographic practices, including those found in such places as Africa, Asia or Latin America. From this perspective, vernacular photography encompasses the vast majority of the world's photographs.

A few selected examples give some idea of vernacular photography's variety of forms and meanings. Although not given much attention by historians today, photographic jewellery was a staple product of the pro-

fessional portrait photographer of the mid-nineteenth century. The practice of carrying a small painted portrait of a loved one predates photography itself by quite a few years. It was logical that, following the invention of photography in 1839, calotypes, daguerreotypes, ambrotypes, tintypes and albumen prints would also find their way into the pins, rings, pendants, brooches and bracelets that were then so fashionable. By this means, photography allowed the middle classes to adopt a cheaper version (twenty times cheaper in most cases) of the visual habits of their betters. Photographic jewellery seems to have fulfilled a range of different functions (and, of course, the same piece of jewellery could signify affection at one moment and mourning at another, depending on the fate of its subject). A single necklace pendant might have portraits of husband and wife on either of its sides, lying back to back, never to be parted. For the object to be experienced in full, it has to be turned from side to side, a form of perpetual caress preordained by its designer. Other examples include photographic lockets containing two facing but separate portraits, such that the man and woman inside initially lie hidden, kissing each other in the dark until liberated into the light of a loved one's gaze. Pieces of human hair, sometimes elaborately woven into patterns, were frequently added to this jewellery, turning them into modern fetish objects.

A similar gesture can be witnessed in an embellished daguerreotype from the collection of Matthew Isenburg in Connecticut, USA. In this object we find a combination of daguerreotype and dress fabric inside a daguerreotype case, put together in about 1850. When we open this case we are invited to literally touch a piece of the cloth that, we can see from the photograph, once also touched the skin of this long-departed girl. We touch what she touched, turning this square of fabric into a membrane conjoining past and present, the living and the dead. By this creative contrivance, absence and historical distance are temporarily bridged by a moment of shared bodily sensation, making the remembrance of this girl into an experience at once optical and haptic.

Vernacular photographic practices frequently involve the elaboration of the photograph through the addition of other materials and iconography. It was common in the nineteenth century, for example, to surround a photograph with a wreath as a sign of both mourning and faith in the eventual resurrection of the photograph's subject. One example comes in a large timber frame, with an albumen photograph of a young woman in its center. Under this rather formulaic studio portrait are the words "At Rest," impressed into a sheet of copper and pinned to the board behind. At each of its two top edges are rosettes, woven out of human hair (probably hers). Around all of this rests an extravagant wreath of flowers made from wax, with similarly waxen butterflies flitting decoratively amongst the petals. It was probably made in about 1890 by a group of women friends in memory of the departed. In another, similar example, a small tintype of a little girl sitting on what we take to be her father's knee has, after her death, been surrounded, first by some fancy metal edging and then by a lovingly embroidered garland woven into a background of black velvet. The labor of embroidery ensures that this act of mourning is a slow one, deliberated and extended through time. The same gesture was extended to a framed albumen portrait of General José Antonio Páez, a man centrally involved in securing the independence of both Colombia and Venezuela. In about 1873, after his death in New York, an official portrait of him in his uniform was surrounded by a wreath made out of one of his own shirts. Through this skillful act of remembrance, history is made personal, and an otherwise formulaic portrait is transformed into the equivalent of a sacred relic.

Framed and painted tintypes might also be described as vernacular. The research of American collector Stanley Burns has shown that these types of photograph were produced in large numbers from the 1860s through the 1890s in rural areas of the United States (indeed, this is a practice indigenous to that country), employing framemakers, photographers and 'folk art' painters whose portrait businesses had been driven into extinction by the cheaper and quicker tintype technology. The portraits that resulted have all the animation of a statue or wax effigy. This stiffness is not improved by the subsequent addition of paint, this being limited in colour range and usually covering whatever idiosyncratic detail may once have been present in the photograph. One consequence is that these portraits exhibit a certain sameness of expression, monotonous to a contemporary viewer but perhaps comforting to a clientele seeking familiarity of genre rather than artistic innovation. This clientele looks out at us from their standard gray backgrounds with the fixed stare of the blind, their facial and bodily comportment insisting above all on a dignified formality of presentation. Such formality is fitting for a procedure that may have only occurred once in a person's lifetime. In many of them the photographic base has been almost entirely covered by paint or, in the case of some of the backgrounds, erased through the application of a solvent. The resulting image was then often elaborately framed and matted, giving the final object both pattern and depth. This framing also allowed each example of an otherwise generic image-making process to take on a unique and distinctive appearance.

Painted photographs were also produced in India from the 1860s until the early twentieth century. Albumen and silver gelatin portraits were often covered in lavish and meticulous patterning and materials (including calligraphy and gold leaf) that transformed the perspectival space of the camera-picture into a flat, vertical surface.

Not much is known about the function of painted photographs in India, whether they were meant for the leaves of an album or a frame on a wall, for public or private space, although this form of portrait would seem to be an affectation adopted by the Indian ruling classes (similar pictures of Europeans living in India are unknown). If nothing else, their striking combination of local Indian painting traditions and a European image-form such as photography speaks to the tension generated when one culture seeks to accommodate the visual conventions, and political demands, of another.

We might look from India to Australia and find that paint was used to transform photographs there too. An albumen photograph was made to celebrate B.O. Holtermann's discovery of a gigantic gold nugget in 1873 after nine years of searching (he has helpfully added some relevant statistical information), a discovery which allowed him to go on to become one of Australia's most enthusiastic patrons of photography. What's strange about the addition of paint in this instance is that it turns what appears to have been a faithful record of Holtermann into an obviously fictitious scene, transporting him from the confines of a studio into a sweeping rural landscape. This landscape serves two functions: it claims to be the setting for Holtermann's discovery while also offering itself up as a prize that he can now acquire. Paint, it seems, helps overcome photography's obstinate realism, allowing fantasy full sway.

Memory and realism are uncomfortable bedfellows. Consider, for example, a cabinet card image of two sailors who worked on the Columbia River in Oregon in the 1880s, now held in the Stephen White Collection in Los Angeles. These sailors have obediently adopted the self-conscious poses one tends to adopt in a photographer's studio, each in uniform and with a hand in his left pocket, each gazing off over our right shoulder, as if looking out to sea, perpetually on watch for potential dangers. Anyone looking at this photograph in the 1880s would have known what we know—that these men are posing for a camera, pretending to be somewhere they aren't, sitting on an artificial rock in front of a painted backdrop. In this photograph, photography's realism is presented as an overt artifice.

What's interesting about this example, though, is that someone decided to play with this real artifice by adding a further bit of artifice of their own. For we can see that this someone has carefully painted in a piece of rope that starts from behind this photograph and then seemingly loops in and out of the right hand edge of the print, apparently puncturing it, before winding itself around a group of suitably nautical objects—a capstan, anchor and compass. This painted addition has a number of effects on the way we might read this picture. It merges the symbolic pictorial artifice of painting with the indexical reality of photography to produce a composite image that repeats and enhances the occupational themes expressed by both components. At the same time it draws attention to the reality of the actual photograph, to the physicality of the print before us, pretending to penetrate that print but also to hide behind it. So there's all sorts of play going on here with this photograph—it's being asked to act as a window onto another world set in the past, and simultaneously to declare itself to be a touchable and opaque object that has an edge and a thickness right here in the present, an object that is glued on to this board but also somehow stands away from it (such that the rope could be both behind and in front of it). This otherwise flat pictorial scene is anchored at its edges by a rectangle of ordinary thumb tacks that jut out from the cardboard mat, casting shadows back onto it and thereby giving this object a real, as opposed to an illusory, depth. If nothing else, the making of this object points to a critical, or at least skeptical, attitude to the photograph. It also provides evidence of a willingness to intervene to make this photograph a more compelling memorial experience. Indeed, it implies that, for the owner of this object, the photograph by itself was not able to provide a powerful enough memory trigger without this added enhancement.

Photograph albums could also be described as vernacular. Many albums are relatively banal depositories of carte-de-visite family portraits and pictures of celebrities. Some, however, show evidence of a strong degree of creativity on the part of their compilers. The album pages produced by English upper-class women in the mid-1860s, for example, rely on a remarkable degree of visual invention. They often combine an artful collage of shaped albumen prints with ink and watercolour drawings, sometimes arranged in rigidly symmetrical patterns and sometimes in a seemingly careless profusion of forms which recall contemporaneous trompe-l'oeil paintings or even the visionary fantasies of Lewis Carroll. The mechanical exactitude of the photographic portrait is transformed and elaborated into a personal tribute to these women's friends and family, and the desires and dreams associated with them. As with all collage practices, attention is drawn to the edges of each page's constituent images, disrupting the seamlessness of photography's representational claims to fidelity and realism as well as its role as an inscription of the past—these photographs are harshly located in the here and now of the page itself.

In the case of the Cator album, produced by an unknown member of that family, we find approximately 156 albumen prints have been mounted on its forty-six pages. These pages are often further decorated with ink illustrations and watercolour paintings. The album's cover is made from deeply carved wood, based on a geometric design of oak leaves and nuts. This cover speaks of the album's importance, as well as of its own

Englishness; it also creates a very theatrical entry to the pages that lie inside. The decoration on those pages often repeats their cover's overt appeal to nature, displaying detailed depictions of entwined blackberries, strawberries and even exotic lychie fruit encircling their photographs. Apart from these signs of an eternally fertile spring, the album maker is keen to emphasise family genealogies (adding names as ink captions to many of the portraits we find within). One page shows a collage of Cator family members facing us in front of a huge painted glass window, suitably framed by red curtains. Through the window we get to see an idyllic seascape occupied by two sailing boats. Another page shows a similar gathering in front of another huge piece of interior architecture, a fireplace. This scene of domestic bliss features an equally huge elliptical photographic portrait of a young child hanging over the mantlepiece in an ink frame while a more suitably-scaled dog curls up in front of the hearth. Some scenes are drawn from a more whimsical imagination. In one, the album maker has a man and a woman, each cut from a separate photograph, occupying a row-boat headed out to sea. But perhaps the most unusual image centers on a large jester figure dressed in a striped red, yellow and blue costume. With a sardonic expression on his face, the jester tosses eleven thumbnail-sized albumen portraits from his gathered apron, scattering them over the surrounding landscape like so much seed.

Vernacular photographic practices often took place in the home. In the years around the advent of the twentieth century, for example, it was not uncommon for women to turn their family snapshots into cyanotypes printed on cloth and then to sew them into pillow slips or quilts. One such pillow slip in the collection of Eastman House in Rochester, New York, consists of thirty of these blue images machine-sewn together, all but one showing typical outdoor scenes of the kinds everyone has taken on family holidays. Some feature male and female portraits, while others depict landscapes; one shows the interior of a house with its own complement of photographs sitting on top of a bookcase. Each image no doubt prompted a happy memory for the members of this family. But the pillow as a whole was also a reminder within the home of the outside world that it refers to, a constant reference to a picturesque elsewhere. The production of these kinds of photographic domestic keepsakes was encouraged by women's magazines of this period, and was influenced more broadly by an Arts and Crafts movement concerned to preserve hand-craft traditions in the face of expanding industrialisation. So the apparent ordinariness of this object belies the deeper social and cultural complexities embodied in its making. The physicality of this pillow's fabric, signalled in the unpredictable play of its straight seams and crumpled edges, is also a significant aspect of its capacity to induce a memory experience, giving these photographs substance and texture, making them touchable and warm, and allowing past and present to permanently cohabit as part of everyday domestic life.

These few examples are but the tip of an iceberg of vernacular photographic practices not often considered or even acknowledged in standard histories of photography. Although the emphasis here has been on practices that elaborate or add to the photograph, we could have as easily chosen to look at groups of unadulterated images drawn from advertising, ethnography, religion, pornography, science, leisure, journalism, criminology, tourism, business, government, or a host of other fields. What vernacular practices all have in common is that their photographs are typical and generic, rather than exceptional or innovative. They represent the visual culture of everyday life, sometimes poignant and creative but more often banal and utilitarian. Whether made by identifiable professional photographers or unknown amateurs, these are mostly conformist kinds of photographs, reproducing established social and aesthetic conventions in an effort to fulfill certain specific functions. These functions, ranging from the sentimental to the commercial, have little connection to the interests of high art. Nor do vernacular photographs lend themselves to the usual art historical systems of evaluation, based as these are on originality and rarity, masterpieces and great masters. As a consequence, if vernacular practices are to be included in photography's history, a whole, new way of doing that history will have to be devised.

VICTORIA, QUEEN AND ALBERT, PRINCE CONSORT

Victoria and Albert played an important role in the development of photography, most especially through being influential patrons during the 1850s. Upon the death of the Prince Consort in December 1861, Hugh Welch Diamond summed up their contribution to establishing the respectability of photography:

> As a manipulator in photography the Prince Consort was unsurpassed: in his practice of the art he was greatly assisted by his former librarian Dr Becker. . .Her Majesty is also a very good photographer. Certainly the art has no reason to complain of want of patronage and support from the Court; so extensive is the collection of negatives which have been taken by and for the Royal family, that it is necessary to have a private printer to keep them and print them when copies are wanted ("The Late Prince Consort and Photography," *Photographic News* 24 January 1862: 39).

Victoria and Albert's support existed firmly within the tradition of royal patronage of the arts. At the same time, though, as early practitioners, they epitomise the upper-class amateurs to whom photography was an affordable pastime. Royal support thereby stemmed from both a personal interest in the medium and a belief in its artistic and technological value.

The first ever photographs of the British monarchy were two daguerreotypes of Prince Albert that were taken by William Constable at Brighton on 7 March 1842. Later in the same month, Albert visited Richard Beard's daguerreotype studio in Parliament St., London. Other photographs taken during the 1840s included a series of daguerreotypes of the royal family by William Kilburn. Kilburn's success led to him being appointed "Photographer to Her Majesty and His Royal Highness Prince Albert." Many photographers subsequently went on to hold official warrants from the Court, including George Washington Wilson (1873) and André Disderi (1867), W. & D. Downey (1879), and Alexander Bassano (1890). Titles like "Photographer-in-Ordinary to Her Majesty" were attenuated versions of the appointments traditionally held by court painters: they demonstrate that traditional models of patronage continued to exist alongside the burgeoning mass market for royal photographs.

It was not until the early 1850s that Victoria and Albert became significantly engaged with photography. Prince Albert's interest in the union of art and manufacture fed naturally into his enthusiasm for the medium. Victoria's interest was more commemorative, founded around the camera's ability to record family occasions and events. Many early royal photographs were taken by Dr Becker, Prince Albert's librarian and a founding member of Royal Royal Photographic Society of London. Becker taught Victoria and Albert the calotype process and, although none of their photographs have survived, substantial amounts of photographic apparatus were supplied to Windsor Castle. A darkroom was built at Windsor in 1854 and, in 1857, the regular royal photographer, William Bambridge, was paid £643 3s 6d for his services.

The royal couple's association with Becker and Sir Charles Eastlake led to them becoming patrons of the Royal Photographic Society soon after its inception in 1853. They regularly visited its annual exhibition, purchasing pictures as well as aiding the society through their high profile presence. Notable photographs acquired for the Royal Collection include several copies of Oscar Rejlander's Two Ways of Life, and Henry Peach Robinson had a standing order from Prince Albert for a copy of every pictorial photograph he produced. In 1855, Albert also contributed £50 towards a study by the Royal Photographic Society into how to prevent the fading of photographs.

Victoria and Albert's patronage of the Photographic Society of London meant that they became acquainted with some of the most prominent photographers of the period. One typical example of the work carried out for the couple was a commission given to Francis Bedford by Victoria in 1857. Bedford was asked to travel to Coburg and take a series of pictures of Albert's homeland as a present for the Prince's birthday. Roger Fenton was another who took numerous royal photographs in the 1850s. These included a well-known set of Victoria's children in tableaux vivants in February 1854, and a series of pictures of Buckingham Palace, Windsor and Balmoral. Prince Albert also used his position to enable Fenton to obtain the necessary permission to take his Crimean war photographs. These were eventually published as *Dedicated by Special Permission to Her Most Gracious Majesty the Queen, Photographs by Roger Fenton Esq. M.A. of the Seat of the War in the Crimea* (1855). At the wedding of the Princess Royal in January 1858, T.R. Williams was requested to take a series of daguerreotypes. It is important to emphasise the photographs taken during this period were never intended for publication and were all private commissions by the royal family.

As well as Victoria and Albert's domestic use of photography, they continued to give public support to the medium. At the Art Treasures exhibition in Manchester, opened by Albert in May 1857, numerous photographs and paintings were lent from the Royal Collection. It

was also the first occasion that photographs of members of the royal family were put on public display. Pictures of both Albert and the Duke of Cambridge were amongst the exhibits. William Lake Price specifically took a portrait of Albert for the exhibition, probably as a sign of his approval and encouragement of the event. In 1852, Albert also initiated a project that would use photography to copy all the extant Raphael paintings and drawings, both in the Royal Collection and elsewhere. Photographers involved in the Raphael project included Rejlander, Philip Delamotte, and William Bambridge.

The death of Prince Albert coincided with the advent of the celebrity *carte-de-visite* and the growing market for celebrity photographs. These two events caused a fundamental change in the relationship between the monarchy and the camera. From being significant patrons, members of the royal family became valuable sitters who were much sought after by commercial studios. Patronage did continue in that the Prince of Wales, for example, became President of the Amateur Photographer's Association in September 1861. Victoria also maintained her strong personal interest in photography, particularly when it came to using pictures of the dead Prince as objects of mourning. She also accumulated many albums of pictures that document both her burgeoning extended family and the contents of the various royal palaces. However, after the early 1860s, royal photographs moved uneasily between being family pictures and media images. Photographers exploited the monarchy rather than relying on it for support.

VIDAL, LEON (1833–1906)

Leon Vidal is not well known today but during the latter half of the nineteenth century was heavily involved with public photographic display, instruction in photography, promotion of photography and the development of photographically linked printing processes in France. He published numerous books that covered topics in all these areas.

Vidal was born near Marseilles. His parents owned a salt works at Port du Buc nearby. He was educated at the Lycee St. Louis and the Sorbonne in Paris, majoring in engineering. He moved back to Marseille and became active in photographic endeavors. He invented the Autopolygraph, one of the first automatic photographic plate-changing magazine-type cameras, in 1861. He met Poitevin and edited his works for publication. Also in 1861 in Marseille he founded, published and edited the journal "Le Moniteur de la photographie," which he continued to do for the rest of his life, taking it with him to Paris when he moved there in 1875.

Perhaps the most beautiful, if not the most influential work by Vidal was his devising of a color photographic printing process in the early 1870s he called "photochromie," a term unfortunately used for a number of other processes, and as a general term for color photography around that time in Germany. His process was a three-color separation process printed on a Woodburytype black layer. It was put into use in Paul Dalox's Tresor Artistique de la France, Musee National du Louvre, Gallerie d'Apollon (Imprimerie et Librarie du Moniteur Universelle, Paris). The first volume appeared in 1872, the second in 1875. Copies of these volumes are held, among other places, in the collection of the Getty Research Institute. They are folio size. The images, while not extremely high resolution, look quite sharp. They appear to have almost the look of lacquer in their finish. They reproduce colors very well, with a somewhat cold tone. They shine (literally) in their reproduction of metallic surfaces. Each object is posed in rather even illumination in front of a uniform background. Some of the most outstanding images are the Casque de Henri II (Helmet of Henry the Second) in volume I, and the Epee de Charlemagne (the Dueling Sword of Charlemagne), Boite de Evangeliaire (Box of the Evangelist), and the Statue Equestre (Statue of the Equestrian), in Volume II. Reproductions of decent quality are to be found in *Farbe im Photo*, 204 and 207. The colors are good, but the surface luster of the original is absent. Of course, the photographic three color separation process was demonstrated in a famous experiment using projected lantern slides by Maxwell in 1861, envisioned in various

forms by Ducos du Hauron in his papers and patents in 1867–9, and was tried by many people. However, Vidal's addition of black as a fourth color seems to have been an important contribution.

Vidal published frequently. His books include: *Calculation of Exposure Times* (*Calcul des temps de pose*, 1865, 1884), *The Art of Photography Considered from the Industrial Point of Vie*w (*L'art Photographique considere au point de vue industriel*, 1868), *Practical Treatise on Carbon Photography* (*Traite pratique au photographie du charbon*, 1877), *Practical Treatise on Phototypie* (*Traite pratique de Phototypie*, 1879), *Photography Applied to the Industrial Arts of Reproduction* (*La Photographie appliquee aux arts industriels de reproduction*, 1880), *Practical Treatise on Photoglyptie* (*Traite pratique de photoglyptie*, 1881), *Practical Manual of Orthochromatism* (*Manuel pratique d'orthochromatisme*, 1891), *Color Photography* (*Photographie des Couleurs*, 1897).

He also sat on and wrote or edited reviews and jury results at a number of exhibitions and conferences. Some examples are: Rapport du Jury classe X, Exposition Internationale des Sciences et des Arts Industriels, 1886, La Photographie a l'exposition de 1889, Rapport du jury internationale, classe 12, Exposition Universelle Internationale de 1889, Discourse on photogravure and photochromographie at the Exposition Internationale de Photographie de 1892, Rapport du jury internationale, classe 12, at the Exposition Universelle in Paris, 1900, as well as a major portion of the Musee Retrospectif de la photographie a l'Exposition Universelle de 1900 (reproduced in Bunnell, P.C., ed., *The Universal Paris Exposition of 1900: Two Catalogs*, Arno Press, 1979).

In his book on Orthochromatism cited above Vidal reproduces opposite the title page three images of the same mixed-flower bouquet, taken with black and white film through three different color filters. In each one almost every bloom takes on a different shade from white to black, illustrating that the varied sensitivities of black and white film create an illusion of reality in the final image, which does not correspond to the truth. Only panchromatic film can capture the entire spectrum we see. Vidal quotes Hermann Vogel, the discoverer of photosensitizing dyes as his opening text. Vidal also provides one of the earliest compilations of sensitometry curves on pages 36 and 37, taken from the work of Josef Eder and others. There you can see the dyes with the farthest reach of sensitivity in the red are quinoline red and cyanine. These represent among the first of their chemical family, one that is still important in film sensitization.

Vidal taught at the Conservatoire des Arts et Metiers in Paris, in Limoges, and occasionally in Marseilles. He was an active member of the Societe francaise de photographie. He traveled to the International Photography Congress held at the 1893 Columbian Exposition in Chicago. There he proposed an idea for a museum of documentary photography. Later that he year he founded the Association du Musee de Photographies Documentaires in Paris.

He was an officer of Public Instruction and made a Chevalier of the Legion of Honor (Chevalier de la Legion d'Honneur).

In the *Moniteur de la Photographie* he wrote (no. 23, Feb. 15, 1866, 178–180 and no. 24, March 1, 1866, 186–88) "We want photography, so useful to all branches of knowledge, to become the domain of everyone…Industry should aim to make photography for everybody as mechanical as possible in use." He certainly did all he could throughout his life to make this wish to come true.

VIENNA INTERNATIONAL EXHIBITION AND VIENNA TRIFOLIUM (1892)

The Vienna International Photography Exhibition, Ausstellung Kunstlerischer Photographien, was held in Vienna from April 30 to May 31, 1891 [*The American Amateur Photographer*, Jan. 1891, 34] under the patronage of Archduchess Maria Theresia, and sponsored by the Club der Amateur-Photographien under the direction of Carl Srna, Dr. F. Mallmann, and Carl Ulrich.

Much of the event's importance revolved around the organizers' decision to limit the exhibition solely to artistic photography to the exclusion of technical

and scientific applications of the medium. Fittingly, it was juried by imminent members of Vienna's fine arts community who selected for display six hundred photographs by one hundred and seventy-six persons.

Among the eleven-member panel were Henry von Angeli, professor at the Imperial and Royal Academy of Arts, Vienna; John Benk, sculptor; Julius Berger, professor at the Imperial and Royal Academy of Arts, Vienna; K. Karger, professor at the Imperial and Royal School of Art-Industry, Vienna; Fritz Luckhardt, professor, imperial councilor, photographer to H.I. Majesty the Emperor; and Augustus Schaeffer, director of the Imperial Picture Gallery, Vienna. [*Am. Journal of Photography*, March 1891, 124] The preponderance of painters among the jury members drew criticism from the ranks of photographers who called for a more balanced representation.

The strategy initiated by the Vienna Exhibition established it as the first international group show dedicated to collecting the best aesthetic photographs, and one which recognized its creators without the use of traditional prizes and monetary awards that had come to be looked upon as undesirable methods of reward since the Pall Mall Salon in London. Underscoring the event was the Secession movement and its emphasis of art photography as opposed to scientific recording, leading to the formation of camera clubs devoted to advancing aesthetic production.

Its organizers carefully orchestrated the promotion and direction of the exhibition using considerable foresight to be the first to include the younger generation of photographers who were rising through the ranks. From America, there were ten appointees out of a field of forty. From New York City, the works of Alfred Stieglitz, James L. Breese, Miss Mary Martin and Henry B. Reid were represented. Others from New York State included John E. Dumont, Rochester and H. McMichael from Buffalo. Philadelphia's most promising young photographer, John G. Bullock, was selected along with George B. Woods, from Lowell Massachusetts, and Chicagoan Mary A. Bartlett [*Anthony's Photographic Bulletin*, June 27, 1891, 355].

The prominent British names were naturally given strong representation at the Vienna Salon. In fact George Davison was the star with eighteen pictures, followed closely by Henry Peach Robinson with fourteen works, suggesting that the eleven jurors were able to discern the key aesthetic currents—pictorialism and constructed art photography—and give them equal consideration. Frank M. Sutcliffe, although a seasoned professional, chose to be listed as an amateur and was exhibited beside the vast majority consisting of amateur ranking.

From Germany, a list of those photographers whose works were represented by fifteen or more photographs included Moritz Hahr and N. von Rothschild. Equally, distinction was given to works by the then prominent Countess Loredana da Porto Bonin.

The Austrian photographers played an important role at the Vienna Salon and continued to advance the photography Secession movement throughout the 1890s. Begun the same year of the exhibition, the Wiener Kamera-Club (Vienna Camera Club) promoted the tenets of art photography and was the artistic counterpart to the technically oriented Photographische Gesellschaft in Vienna. During the decade, the Weiner Kamera-Club published two journals, *Photographische Rundschau* and *Wiener Photographische Blätter* featuring some of the most beautifully executed photogravures.

An early member of the Wiener Kamera-Club was Hugo Henneberg. Through his association with French photographer Robert Demachy and the English photographer Alfred Maskell, Henneberg brought the gum bichromate process to the attention of his Austrian colleagues, Heinrich Kühn, and Hans Watzek. Henneberg's work most closely resembled the pictorial style of George Davison, then the only British member of the Kamera-Club in Vienna. Henneberg was Alfred Stieglitz's first contact in Vienna and the two had corresponded since 1890. In 1894, Stieglitz became a member of the Wiener Kamera-Club presumably at Henneberg's suggestion. In subsequent years, Stieglitz featured works by the Austrian photographers at his Photo-Secession Galleries in New York.

Early in 1896, Henneberg, Kühn, and Watzek began experimented with colored gum-bichromate prints making remarkable creative color constructions using up to three colors. Influenced by Impressionism's rejection of the objective in favor of visual impression, and motifs and methods of composition shared by contemporary painters of the Munich Secession, the group transformed masses of light and shadow to make pictures whose eminent qualities of mood prevailed over realism.

Associated with progressive art theories of the late nineteenth century, the group's artwork was featured early in 1898 along with all the other innovative arts when the Vienna Secession published the first volume of its journal *Ver Sacrum*. Calling themselves the Trifolium, Henneberg, Kühn, and Watzek exhibited together in the photographic section of the Munich Secession international exhibition in the fall of 1898. By this time their association led them to sign their prints with a cloverleaf monogram near their signature to symbolize the Trifolium. In the subsequent years following the Vienna Salon, Henneberg, Kühn, and Watzek submitted their photographs to salons in Paris and London. The three also became members of the prestigious British photographic association, the Brotherhood of the Linked Ring.

The Vienna International Photography Exhibition was perhaps the most successful and influential force

for drawing attention to photography's aesthetic role and affecting a shift within the industry toward art photography. Ideas emanating from the landmark exhibition established a model for a long string of salons that admitted only art photography and excluded technical and scientific work.

The rigorously juried international exhibition set a higher standard that would be applied to subsequent international and regional exhibitions. The consideration of photography as an art form versus a scientific tool of reportage prompted the formation of separate camera organizations devoted solely to art photography. The following year, in 1892, the Linked Ring was formed in Great Britain. The Photo-Club de Paris began in 1894. In America, Alfred Stieglitz followed the movement of secession from traditional photography societies when in 1902 he formed the Photo Secession group in New York. Intrigued by the Trifolium's identity, Stieglitz arranged to present the three in America. Their work came to stand for what most Americans would know of Austrian Secession photography.

VIEWING DEVICES

The origin of photographic viewing devices can be traced to the eighteenth century, when a 'show box,' or 'peep box' was employed to enhance the sense of depth within hand coloured engravings, thereby generating a more realistic viewing experience. Such devices tended to be of a basic construction where the viewer would look with both eyes through a single glass lens built into the front of a box which magnified the image. A similar effect was achieved using another eighteenth century device known as the Zogroscope. This consisted of an adjustable stand with a mirror and single large lens attached. The engraving to be viewed was placed upside down in front of the viewer. The Zogroscope was then placed alongside the engraving. The engraving would then appear reflected in the mirror, through the lens, the correct way up and hopefully with an added sense of realism. How effective such devices were is debatable, but the use of viewing devices, in one form or another, continued with the advent of photography. Early photograph collectors were often also collectors of engravings, and some viewed their newly acquired photographs in the same way they had always viewed their engravings. Viewing devices therefore form a link from the pre-history of photography through to the advent of photography itself.

In time, viewing devices became more elaborate. In 1862 the photographer, Carlo Ponti (1823–1893) took out a patent in England for his Alethoscope. This had a single magnifying lens intended for the viewing of large photographic prints showing architectural views of Italy. Ponti's imposing optical devices later came to be known under a variety of names, including the Megalethoscope, Dioramascope and Pontioscope. Ponti also made the impossible claim that his devices were able to show single photographs with a stereoscopic effect.

It is important to acknowledge the sheer variety of viewing devices that were produced throughout the nineteenth century, some of which were more successful than others. For example, in the 1870s Francis Frith & Co produced a series of large format photographs on coloured transparent paper. Entitled, Photoscopic Pictures, these look, from their design, as if they were intended to be viewed in a device similar to Ponti's Megalethoscope, but little mention is made of them nowadays.

At the opposite end of the scale are Stanhope viewers. Named after the English politician and scientist, Charles, Earl of Stanhope (1753–1816), these viewing devices can be found embedded in a wide range of small novelty articles: from needle holders to letter openers. They consist of microphotographs fixed to the flat end of a tiny glass rod, while the other end of the rod is curved, so that when the one peeps through the Stanhope viewer the microphotograph appears much enlarged through the convex lens at the other end.

In 1864 Charles Rowsell produced a device capable of handling stereoscopic photographs as well as single prints. The Graphoscope's mainly wooden construction comprised of a moulded rectangular plinth which supported a hinged platform which could be adjusted to various angles to aid the viewing of images through either a pair of inset stereo lenses, or a larger single double convex lens glass. The double convex lens was said to produce an illusion of relief, rather than a fully realised stereo effect. In an advertisement for the photographic supplier, P. Meagher from 1875 the Graphoscope is described as a device 'For viewing photographs, drawings and stereoscopic pictures on glass or paper. By a simple adjustment of the easel the instrument is readily focused to suit any sight."

Perhaps the most obvious example of a device designed to generate a realistic viewing experience is the stereoscopic viewing device, without which a

stereoscopic photograph stubbornly remains two-dimensional. However once seen though the correct viewing device the image is miraculously perceived in three dimensions. Such viewing devices therefore have the power to convert two separate, flat photographic images into one single three-dimensional image.

The first system capable of producing a photographic stereoscopic image is credited to Sir Charles Wheatstone (1802–1875). He successfully described the theory of stereoscopic vision and invented a device, known as a Wheatstone Reflecting Stereoscope, through which two large, separate photographic images could be simultaneously viewed in order to produce a single stereoscopic image. It was the first practical stereoscope, and because it was capable of accommodating large photographic prints (up to 27 × 40 cm each) it was particularly suited to the photographic connoisseur. Both Roger Fenton (1819–1869) and Benjamin Brecknell Turner (1815–1894) produced Wheatstone stereo images.

Stereoscopic photography was not introduced on a mass scale until the 1850s, when demand for images for use in Sir David Brewster's (1781–1868) Refracting, or Lenticular Stereoscope grew. Commercially produced by Louis Jules Duboscq in 1851, Brewster's system used two photographs taken of the same object from slightly different viewpoints at exactly the same time. This was an improvement on the stereo images created using Sir Charles Wheatstone's stereo pictures which were usually created using a single lens camera which had to be moved between two consecutive exposures. The difficulty in producing the stereoscopic image for Wheatstone's system was mirrored in the viewing device. The Wheatstone Reflecting Stereoscope was a rather insubstantial affair constructed from strips of wood and two mirrors set at an angle of 45° which resulted in an awkward and uncomfortable stereo viewing experience. Brewster's system, on the other hand, produced a handsome design which was much being better suited to a Victorian drawing room. It also produced a more effective, or pleasing stereoscopic effect.

Antoine Claudet's Folding Stereoscopic Viewer appeared on the market around the same time as Brewster's pattern for a Lenticular stereoscopic viewer. Claudet's design was the more limited of the two, as it came with a single stereo daguerreotype permanently built into the viewer. Its collapsible design meant it could be stored flat, however, Brewster's design proved to be more adaptable and formed the basis for most of the popular stereoscopic viewers that followed, and became the viewer of choice in the craze for stereoscopic images that was to continue into the latter part of the century.

Stereoscopic viewers based upon Brewster's pattern were popular throughout the 1860s and were known as Box Form stereoscopes. These simple hand-held devices, capable of holding one stereoscopic photograph at a time, were often highly decorated in keeping with the setting of the Victorian parlour. The stereo card fitted through a slot at the back of the device, while a mirrored flap could be raised and angled so that light was cast onto the stereo card thereby giving enough light for it to be viewed through the twin lenses at the front. The back of the stereo viewing device was often fitted with a ground-glass panel which allowed diaphanous stereo cards manufactured on hand coloured tissue paper also to be viewed, alternating between night and day, summer and winter, simply by raising and lowering the mirrored flap on top of the viewer.

In America, Dr Oliver Wendell Holmes devised a simplified stereo viewer in 1861 which is probably the design most people think of today when they imagine a nineteenth century stereoscope. It consisted of a wooden hood-like arrangement which covers the viewer's eyes, with a holder for the stereo card fixed at a set distance from the hood. This design was improved in 1864 by another American, Joseph L Bates of Boston, when he added an adjustable sliding holder for the stereo card, thereby making it possible for the instrument to be adjusted to suit the individual and maximise the three-dimensional effect.

More ornate 'pedestal' stereo viewers were manufactured by companies such as Negretti & Zambra. Although the actual stereo viewer was simple in design, and similar to the box form stereoscope described above, they were often constructed from high quality wood veneers and incorporated highly decorative figurative sculptural elements in the base. The third, and most substantial type of stereo viewer dating from this period and intended for use in the most lavish Victorian parlour setting was in the form of a cabinet. These cabinet stereo viewers were capable of accommodating a selection of up to twenty individual stereo view cards at the same time which moved through sequence on a carousel inside the cabinet.

The fact that companies such as Underwood & Underwood could produce up to ten million stereoscopic views a year in order to meet the Victorian parlour's huge demand for photographic images I order to ensure its viewing device was well stocked with photographic images is testimony to the importance of this sector of the photographic industry in the nineteenth century.

VIGIER, LE VICOMTE JOSEPH (1821–1894)

Louis Jules Achilles Vigier, known as Joseph Vigier, was Viscount, owner of the castle of Grand-Vaux à Savigny-sur-Orge. School-fellow of the duke of Aumale at the school Henri IV, he remained connected all his life to the family of Orleans. In 1872, after having sold his Grand-Vaux à Savigny-sur-Orge, he acquired the castle of Lamorlaye, close to Chantilly, where the duke of Aumale remained and where he could appease his passion for horses (developed with his training of thoroughbred racehorses of English origin).

Vigier was introduced to photography in the workshop of Gustave le Gray around 1848–1850. He first stayed in Seville in 1851, in the home of the duke of Montpensier; it is not known if he took photographs there. In September 1852, he went to England and took photographic portraits of the royal family in exile in Claremont: King Louis-Philippe, the queen Amélie, their children (duke of Nemours) and grandchildren posed, each one sitting upright or close to a table, some in front of a fabric painted with the exuberant decoration of flowers; the prince of Condé is illustrated on a horse. In the summer of 1853, he voyaged to Spain while passing by the Pyrenees (Luchon, Cauterets, Pau), from which he brought back several hundreds of scenes on negative paper. At the end of the year, he published the Album des Pyrénées (Album of the Pyrenees), which was a collection of about thirty prints. In February 1854, he showed six of them in London, with the Exhibition of Photographic Society, which created enthusiasm in the public and queen Victoria.

Vigier was the founding member of the Société héligraphique in 1851, then of the Société française de photographie in 1854 (he remained there until 1862); he was also member of the board of directors of the SFP from 1857 to 1862. He took part in the first two Exhibitions that the Society organized, in 1855 (views of the Pyrenees) and in 1857 (views of Dauphiné of 1855 on negative paper, a castle of Savigny of 1856 on dry collodion, a horse according to nature on wet collodion). He also took part in several Exhibitions in London (in 1852, Society of Arts, and in 1854 in Photographic Society) and in Brussels in 1856 (views of the Pyrenees and views of Dauphiné, on negative paper; portraits, monuments, horse on collodion; monuments and views of France, England, Spain on albuminous paper and waxed paper). The birth of a son in 1859, the management of his grounds, voyages, passion for the horses, and especially the evolution of the photographic processes in the years from 1860 diverted him perhaps definitively from his practice.

A major figure of the photo hobbyists of the 1850s, the personality and oeuvre of the Viscomte Vigier are still

Vigier, Vicomte Joseph. Path to Chaos, Saint-Sauveur. *The Metropolitan Museum of Art, Gilman Collection, Gift of The Howard Gilman Foundation, 2005 (2005.100.503.8) Image © The Metropolitan Museum of Art.*

not well-known. His body of work is for the moment only partially identified: portraits of the family of Orleans went on public sale in 2000, and especially scenes of Spain (Seville, Grenade) and of the Pyrenees, preserved at the SFP, the BNF, the Museum of Orsay (this last preserves the album of the Pyrenees, and the views captured in the Brébisson album). Because of his participation in two London Exhibitions, Vigier was apparently better known by the English public. It may be also that he met English amateurs at the time of his stay in the Pyrenees. His affinities with England are perhaps at the origin of his interest for Talbot's calotype process, which he used in alternation with the process of Le Gray (waxed paper). He considered the two techniques complementary, finding it easier to use Talbot's in particular for the impression, whereas that of Le Gray's, which gave more definition, of transparency in the shades, of truth in returned space. He sought to improve the processes on paper and communicated with the SFP on this subject in 1856. Vigier used the collapsible darkroom of Koch and resorted, for his printings, to the photographic printing works of H. Fonteny, directed by Alexandre Lachevardière, in Paris, principal rival of the printing works of Blanquart-Evrard. He signed his tests with a dry seal with his monogram, JV, surmounted by a crown. Negative paper agreed well with the primitive aspects of certain landscapes like arid valleys and rocks, and captured the textures of the rock and stone because of those atmospheric effects. The tones are warm, of a beautiful colour varying from pink to brown. His images are often very composed, with sets of lines, right-hand sides or curves (road, bridge), introducing a movement, making space and giving to the spectator the feeling of being in the scene (Sentier du chaos allant de Gavarnie à Saint-Sauveur). The foreground is often released (road, river, way) and the background occupied by a thrust created by a mountain or a church (Bridge of Slate with Luchon).

With their public appearance, the photos of the Pyrenees achieved the unanimous acclaim. With the occasion of the Exhibition of London in February 1854, the critic Ernest Lacan devoted an article to the album of the Pyrenees, in which he emphasized the difficulties encountered in traversing the various sites; he underlined the transparency, the strength of the tone of these images as well. In 1855, Eugene Durieu admired those same views, and in 1857, Paul Perier remembered their "broad and severe character." With the Exhibition of 1857, in front of a sight of castle in Dauphiné, Perier spoke about smoothness and frankness from execution: "the light was so fortunately chosen, that water, of a curious transparency, has their value everywhere, and is harmonized very well with all the other parts of the table. The avenue of trees of the castle of Savigny is not less remarkable; the foliage is returned perfectly, and the table has much of depth without presenting the exaggeration of prospect which often the avenues in photography give." By the masterly character of these tests, without anecdote nor picturesque, Vigier occupies a singular place in the production of the amateurs of the 1850s.

VIGNES, LOUIS (1831–1896)

French, active in Morocco, Sicily, Lebanon, and Palestine 1859–1864, photographer, naval officer

Vignes was a distinguished naval officer whose photographic work is limited to his early service in the Mediterranean and North Africa. He entered l'Ecole navale in 1846 and remained in the French Navy, retiring as an admiral. It is unclear where he learned photography, but he made over 50 calotypes of sites in Morocco, Sicily, and Beirut during the Syrian campaigns of 1860. It was this experience that led to his assignment to the archaeological expedition mounted by the Duke du Luynes, an eminent biblical archaeologist with an interest in photography. The group traveled from Beirut south through Sidon, Tyre, Nablus, and Jerusalem to the Dead Sea which they explored by ship from March through May of 1864. Vignes photographed throughout the journey, initially with collodion on glass at du Luynes behest. He returned to the calotype process he had used in Syria on the return journey, perhaps because the supply of glass plates had been exhausted. While there is no complete tally of photographs from this expedition, it may be estimated at 400. Sixty-four photographs were published by Charles Negre using his photogravure process to accompany, *Honoré d'Albert, duc de Luynes, Voyage d'exploration à la mer Morte, à Pétra et sur le rive gauche du Jourdain*, Paris, 1875. In addition there are a number of albums in public and private collections that include material not found in the publication—in addition to archaeological subjects, panoramas, interior views in French residences, and landscape studies.

KATHLEEN HOWE

VIGNOLES, CHARLES BLACKER (1793–1875)

Charles Blacker Vignoles was born in 1793 at Woodbrook, Ireland. His parents were Captain Charles Henry

Vignoles and Camilla Hutton, daughter of Dr Charles Hutton of Woolwich. A Civil Engineer with a wide range of interests, he was engaged in Railway Engineering in England, Ireland and on the Continent of Europe.

Vignoles was a founder member of the Royal Photographic Society, and was an early advocate of the use of photography as a means of recording construction activities.

In 1848 he employed John Cooke Bourne and in 1852 Roger Fenton to take record pictures of the Tsar Nicholas I Chain Bridge which he was constructing at Kiev.

In 1859 he encouraged John Watson, the contractor on the Bahia and San Francisco Railway in Brazil to employ a photographer to record the progress of the works. From 1859 to 1862 this was carried out by Benjamin Mulock.

In 1860, while working in Northern Spain, he facilitated an expedition to view the Eclipse of the Sun, when Warren de la Rue photographed the Corona for the first time.

President of the Institution of Civil Engineers from 1870 to 1872, Vignoles died in Southampton in 1875.

JOHN VIGNOLES

VILLALBA, RICARDO (active 1860–1880)

Ricardo Villalba (sometimes spelled Villaalba), was active in Perú and Bolivia, between 1860 and 1880. He may have been born in Corocoro Bolivia, but very little is known about his life. Villalba's images are found on cartes de visite and cabinet cards and his albumen prints include views of the Peruvian Southern Railroad, Lake Titicaca and the devastating 1868 earthquake of Arequipa and Arica. During the 1870s, Villalba had a studio in Arequipa and is thought to have been the first to photograph the city's famed volcano, El Misti. When Villalba left Arequipa, his studio and perhaps some of his negatives may have been acquired by the photographer Carlos Heldt. According to Dan Buck, Villalba relocated to Paris in the 1880s, where he was listed as a member of the Societe Francaise the Photographie. He also submitted several photographs for an exhibit sponsored by the Photo Club de Paris in 1894.

The Harvard Peabody Museum owns a Villalba album containing ethnographic cartes de visite of Bolivians. There are also over thirty Villalba photographs in the James Maxwell Collection at the University of Delaware. The ENAFER Corporation in Perú owns an album of images of the Ferrocarril del Sur (which ran from Mollendo to Puno). The William Darrah Collection at Penn State contains one carte de visite (c. 1872) of a sunken ship off of the port of Callao (near Lima). On this card the photographer's name is spelled Villaalba.

YOLANDA RETTER VARGAS

VOGEL, HERMANN WILHELM (1834–1898)

German inventor, photographer

There are not many 'firsts' in the history of German photography but there is one man who collected most of them: he wrote the first thesis on photo-chemistry in German language; with the Photographische Mitteilungen, he founded one of the first and most lasting periodicals; he gave photography the "second half of light" (J.M. Eder, 1880) by finding the substances for the colour sensitisation of photographic plates. In the German speaking countries, he was the first to criticize an exhibition at length, and among the firsts to curate another one, dedicated to the aesthetic qualities of photography gained throughout the first 25 years of existence. Hermann Wilhelm Vogel was a remarkable thinker about photography whose interests were as wide-spread as the medium itself:

> Thus we see photography active into the most diverse directions. Animals, plants, minerals have to draw their images onto the light sensitive plate as well as the products of art and industry, and as the motions of the barometer and thermometer. The photographer directs his instrument into the icy regions of the North Pole as well into the thicket of the tropical jungle; into the gorges of our high mountains as well as into the depths of the endless universe. His art is applicable to all branches of human knowledge and wisdom. There is no field in the great world of the visible where it [photography] could not be introduced fruitfully; it is shaping the history of towns and countries, and when we will be no more existant, our photographs—more loquacious the all historical works—will tell the cultural history of our time to our successors. (Hermann Wilhelm Vogel, Die Photographie auf der Londoner Weltausstellung des Jahres 1862, Braunschweig 1863, 28)

Neither photography nor fame were laid in his cradle. Hermann Wilhelm Vogel was born in 1834 in the small town of Dobrilugk (today: Doberlug-Kirchhain) fifty miles southeast of Berlin. He was the son of a material merchandiser who wanted him to follow in his footsteps, and so young Hermann became an assistant sales agent at the age of fourteen. In 1850 he finally managed, according to records, with the help of some of his father's friends, to inscribe at the trade school in Frankfurt/Oder which had a technical department. From 1852 to 1858 Vogel visited the technical school at Berlin, then the best-known institute for all kinds of applied science. After finishing this institute with a diploma in 1858, he was installed as a scientific assistant at the Mineralogical Museum of the Berlin University. It was there that he finally met his life-long interest: photography.

Two influences can be reported for this determination: At the Museum he had to reproduce cuttings of rock with the aid of photography, and a friend from the technical school, the architect Albrecht Meydenbauer,

asked him to help with advice for the setting-up of a photogrammetic inventory of buildings ready for preservation and reconstruction. Besides his work at the Mineralogical Museum, Vogel managed to write a thesis on the behaviour of silver halides under conditions of light which was finished by 1863. Later in the same year, he was named head of a newly established photographic laboratory of the Berlin technical school where he had studied before. This laboratory was opened in 1864, and from then on Vogel unfolded a wealth of activities within all fields imaginable in photography. In 1879, the Berlin technical school and the building academy were unified to the Technical University where Vogel was made Professor in Photo-Chemistry, a position he held until his death in 1898. The chair gained world-wide fame, and Vogel was succeeded by Adolf Miethe, Otto Mente, and Erich Stenger, each of them outstanding in their own fields.

Hermann Wilhelm Vogel's most important contribution to photographic chemistry and industry was the sensitisation of the emulsion for larger parts of the spectrum. In 1873, he described the enrichment of photographic emulsions with eosin dye pigments for dry plates which were to be named orthochromatic. As a typical product of the science of its time, his findings were easy transferrable into industrial use, and the benefits of Vogel's plate sensitisation helped the German photographic industry to both develop and achieve world-wide acclaim. As orthochromatic emulsions lacked sensitivity for red colours, Vogel continued this part of his research until his death. Adolf Miethe, his successor in the Berlin seat, was lucky to announce in 1902, four years after Vogel's death, the introduction of the panchromatic sensitisation which not only gave black & white photography a perfect gray scale for all colours but set the foundations for today's colour photography as well.

As head of the only department of photo-chemistry in Prussia, Vogel was a major influence in the development of German photography. He set up the first comprehensive exhibition of photography in Berlin in 1865 and organized the medium's half-centennial in 1889. While setting up the first exhibition, he stimulated a legal debate on photographic copyrights, a law installed with his help in Germany by 1897. For a gathering of photographers at the exhibition in 1865, Vogel co-authored a dramatic comedy in two sets. As a member of the jury, he took part in the preparation of the photographic departments of the world exhibitions in Paris 1867, Vienna 1873, Philadelphia 1876, and Chicago 1893. He instigated not only the career of master scientists like Miethe and Mente but of photographers as the young Alfred Stieglitz alike. He wrote a number of books, among them a four-volume comprehensive handbook of photography whose fourth part is the first overview on the medium's aesthetics in German language—and contains a chapter on reproducing sculpture which changed the views of art history. Vogel led photographic expeditions to view solar eclipses and to archaeological sites all over the world, and he brought home not only masses of scientific results but landscape and travel photographs as well. His own photographic work has still to be unravelled from the huge amount of records he left behind at his untimely death in 1898.

ROLF SACHSSE

Biography

Hermann Wilhelm Vogel, born in Dobrilugk, Lausitz, March 26, 1834. As the son of a merchant, he had to leave school at the age of 14 and became the assistant of a sales agent. From 1850 to 1852 he visited the trade school at Frankfurt/Oder, from 1852 to 1858 the industrial school at Berlin. From 1858 to 1864 he worked as a scientific assistant at the mineralogical museum of the University of Berlin, in 1863 he finished his doctorate on the theory of photography which is considered the first scientific work in German photo-chemistry. In 1864 he founded the photographic laboratory at the Berlin industrial school which was transferred into the Technical University in 1879. From then until his death on December 17, 1898, in Berlin, he was Professor and head of the Department of Photo-Chemistry in this institution.

VON ETTINGSHAUSEN, ANDREAS RITTER (1796–1878)

Austrian mathematician and physicist

Ettingshausen was born on 25 November 1796 in Heidelberg, where his father was stationed during the first World War as a member of the Austrian general staff. After the relocation of the family to Vienna in 1809 and the completion of high school he turned to a career as

an officer. In 1815 he turned to a scientific career too. When he entered the scene of Austrian photo history in 1839. He was among the most renowned scholars of the Habsburger monarchy and enjoyed the special protection of the State of Clemens von Metternich, securing himself in his independent study of modern math and physics problems. In 1839 Ettingshausen was in Paris and participated with the publication of the Daguerreotype, and later lectured at the Académie of the Sciences of the Académie Beaux, which had arranged for François Arago on 19 August at Institut de France.

During his stay in Paris Ettingshausen was introduced personally to the new photographic procedure of Louis Jacques Mandé Daguerre and acquired a Giroux camera (No. 26). His own print series were taken after October 1839 on Johannisberg at Ruedesheim on the Rhine, the summer seat of the prince Metternich. Metternich, as well as the entire Austrian public, was completely informed about Ettingshausen. An exciting exhibition from Ettingshausen's daguerreotype at the Institut of the Viennese University took place on 22 November 1839. After this, a club of photographic pioneers in Vienna formed briefly, consisting of scientists, technicians, medical professionals, and artists, in which Ettingshausen also worked. Here he showed his first micro photographs and experiments with polarized light.

The result of Ettingshausen's photographic activity was limited to what he created during his membership in the 1861 photographic society in Vienna (since 1863, starting from 1875 as an honorary member) and to several photography courses, which he taught from 1863 to 1866 at physical Institut of the Viennese university. However, his contribution remained important to the fastidious scientific culture of photography in Austria during the nineteenth century.

Maren Gröning

Biography

Andreas von Ettingshausen was born on 25 November 1796 in Heidelberg (Germany). His parents first intended that he have a military career, but he had already taken studies at the school to Vienna in higher mathematics. In 1817 he reached Adjunkt (assistant) for mathematics and physics at the University of Vienna. In 1819 he became a physics teacher at the High School Innsbruck and in 1821 became professor of higher mathematics in Vienna. Together with Andreas Baumgartner he published the magazine for mathematics and physics in 1826–1832. In 1834 he took over the chair for physics at the University of Vienna (1852 institute leaders). Temporarily he taught also at the engineer academy at the same time (1848 to 1852) and at the polytechnic institute (1852) in Vienna. In 1845 he took part in a petition by intellectuals to loosen the censorship in the Habsburger state. In 1847 he was selected as the first Secretary-General (until 1850) of the founders' meeting of the Austrian sciences. From 1861 to 1862 he led the Viennese university as a rector. After his retirement in 1866 he was raised into baron status (knight of Ettingshausen). He died on 25 May 1878. As a practical photographer Ettingshausen might have been active only in the months of his participation in the publication of the Daguerreotypie in Paris in August 1839 up to his work in the circle of the Viennese " round court " in March and April 1840.

VON GLOEDEN, BARON WILHELM (1856–1931)

Born Volkshagen Castle, Wismar, Germany, Baron von Gloeden contracted tuberculosis and moved to Taormina, Sicily c. 1879 and indulged a life of leisure until the family lost its fortunes at the instigation of Kaiser Wilhelm II. Forced to find money, von Gloeden turned his interest in photography into a business in 1888. Reputedly taught by his cousin, Wilhelm Plüschow (1852–1930) who had a studio in Naples from the 1870s, and Francesco Paolo Michetti, tourist prints soon gave way to collectors photographs of the male nude set in the landscape of antiquity, but created out of fin-de-siécle aestheticism. For a society still devoted to the Greek Ideal, he brought the myth to life, although his depictions were more Arcadian than Homeric. He achieved critical and financial fame and his photography entered the mainstream of European society. Using local peasant youths to create his ephebes, he opened savings accounts for his models and allocated royalties. Il Barone Fotografico was much loved in Sicily, until

Italian fascists, and then the War, destroyed many of his plates inspite of the attempts of his former model, go between, and heir, Pancrazio Bucini, to protect them. His influence was widespread: from his contemporaries Vicenzo Galdi, Gaetano D'Agata, Plüschow, to 1950s American Beefcake and David Jarmen's movie Sebastiane (1976). Post-Freud, post-1970s, and now regarded as the founder of male nude photography, Gloeden's homoerotic depictions have become part of contemporary gay culture.

ALISTAIR CRAWFORD

VON HERFORD, WILHELM (1814–1866)

Born in Soldin, Prussia (now Mysliborz, Poland), under the full name Friedrich Wilhelm Theodor von Herford, von Herford studied law in Berlin and Breslau and worked as a civil servant until 1846, at which time he began five years of travel and language study throughout Europe and the Middle East in preparation for a diplomatic career. While waiting for a post, von Herford traveled to Paris in 1853, where he sought out fellow Prussian Édouard Baldus for photographic instruction. Student and master traveled through Provence in September and October, working side-by-side as von Herford made his first successful pictures. Frustrated by the dull winter light of Paris, he moved to Rome before year's end, and the following fall received further instruction from an unidentified German photographer, likely Jakob August Lorent. From Rome, he traveled to Sicily in late 1854, to Sardis, Trabzon, and finally Beirut for the long-awaited consular position in 1855, photographing along the way, notably at Baalbek. He photographed extensively in Jerusalem in May and June 1856 and in Egypt in 1856 and 1857. In 1944 Erich Stenger reported the survival of 185 paper negatives (60 of Rome and elsewhere in Italy; 27 of Jerusalem; 44 of other sites in Palestine; 27 of Egypt; 5 of buildings in other countries; and 22 of portraits and costume studies) and 200 prints; what now remains is preserved at the Agfa Foto-Historama, Köln.

MALCOLM DANIEL

VON HUMBOLT, ALEXANDER (1769–1859)

Friedrich Heinrich Alexander, baron von Humboldt, brother to philosopher and linguist Wilhelm von Humboldt, was born in Berlin in 1769 and died there in 1859. One of the 19th century's scientific giants, often described as the last universal scholar, baron von Humboldt is considered one of the founders of geography. His extensive travels in South and Central America (1799–1804), recorded in a long series of publications, made him the century's most influential explorer. His final, monumental treatise *Kosmos* (1845–1862) aimed at a synthesis of knowledge on the natural and human world, and emphasized methods of observation. Von Humboldt's involvement with the beginnings of photography was brief but significant. Early in 1839, when he was in Paris, his long-time friend François Arago, the French scientist who sponsored Daguerre's and Niépce's invention, called upon the Prussian scientist to examine Daguerre's plates and testify before the French Academy. Von Humboldt was impressed. His letter of February 25, 1839 to fellow-polymath Carl-Gustav Carus, describing Daguerre's views of Paris, is one of the most eloquent of such early statements. His testimony in favor of Daguerre, and more generally his endorsement of photography's descriptive powers, influenced the adoption of the invention by explorers, especially in the United States.

FRANÇOIS BRUNET

VON KOBELL, FRANZ (1803–1882)

In January 1839, the first news of Daguerre's invention spread over Europe and the Academies took notice. Many professors attempted to recreate the experiement

to reproduce the same results. Carl August Steinheil, the Munich-based physicist and his colleague Franz von Kobell were amongst the academics who were interested in what Daguerre invented. It virtually took them only days to find a method of keeping light on paper; Steinheil constructed a small metal camera with a self-calculated lens and Kobell found a comparatively sensitive chlor-bromide process which produced negative images; these were reproduced for positive results. On Feb., 1, 1839, they published the first notice on their findings, and when Talbot released his own invention in March 1839, the two felt the obligation to surpass him by producing a number of actual images. Both presented their results—which were of photographs from Munich, reproductions of graphic arts, and images of smaller objects—to the Bavarian Academy of Science on July 3, 1839 with much acclaim. Their images were small, mostly 4 cm in diameter, but clear and sharp. Both did not think of their invention as more than a scientific experiment and did not develop their ideas further. While Steinheil stuck to photographic optics, Franz von Kobell left this field completely and concentrated on his two careers as mineralogist and as a playwright. His "Brandner Caspar" is still on the playlist of every Bavarian folk theatre.

Franz von Kobell was born on July 19, 1803 in Munich as the grandson of the painter and copper etcher Ferdinand von Kobell. He studied mineralogy in Landshut and started his professional career in the mineralogical state collection of Bavaria in 1823. In 1827 he was honoured as a member at the Bavarian Academy of Science. In 1834 he became professor of mineralogy at the Munich university, and in 1849 he was made director of the named state collection. His main concerns were of practical questions of crystallography and anorganic chemistry. Besides his cooperation with Carl August Steinheil in the invention of photography he is named for a "stauroscope" which he patented in 1855. From 1839 on, Franz von Kobell published numerous books as an author in both Bavarian and Palatinate dialect as well as in the standard language. Prior to his death on Nov.11, 1882, in Munich he was honoured with knighthood. In 1896 there was a memorial dedicated to him. His daughter Luise, then a well-known author, wrote a comprehensive biography on him and his life's work.

ROLF SACHSSE

VON LENBACH, FRANZ (1836–1904)

Franz Lenbach was born on Dec. 13, 1836 in the village of Schrobenhausen in Bavaria. Following short studies at the Augsburg polytechnic school he became a student of Karl von Piloty in 1857 for a short time, taught painting at Weimar in 1860, and began travelling to Italy and France for several years. From 1868 he devoted himself exclusively to portraiture. Within a short time, Lenbach had introduced photography as an aid to his work. There were a number of photographers working for him, most notably Karl Hahn. Lenbach gained enormous fame for his portraits of Otto von Bismarck for which he had more than 120 photographs made of the German chancellor; the result were more than 80 paintings. The use of photography in Lenbach's painting processes was threefold: first he had the heads of the photographs enlarged to copy them. Second he had slides made from the images which were then projected onto the canvas. And third, he used the Parisien method of "photo-peinture", a sensitively covered canvas with a faint images of the portraited over which he painted his picture. He believed in photography as an aid in the quick delivery of painting commissions. Only within the last two years of his life did he take photographs himself. He died in Munich on May 6, 1904.

ROLF SACHSSE

VON STEINHEIL, CARL AUGUST (1801–1870) AND HUGO ADOLF (1832–1893)

Astronomers and lens and camera manufacturers

Born in Rappoltsweiler, Alsace, Carl August Steinheil studied science and astronomy, obtaining a doctorate from Konigsberg University in 1825. In 1832 he became professor of mathematics and physics at Munich. In March 1839, after William Henry Fox Talbot had sent a copy of his paper, 'Some account of the art of Photogenic Drawing,' to the Bavarian Royal Academy of Sciences, Steinheil, together with a colleague, Franz von Kobell, conducted their own experiments in photography. Steineil designed a cylindrical camera, made from cardboard and resembling a telescope which produced circular negatives on paper sensitised with silver chloride solution. He later went on to make the first daguerreotypes in Germany.

Steinheil's son, Hugo Adolph, studied optics and astronomy in Munich and Augsburg. In 1854, father and son founded the Steinheil Optical Institute in Munich. Adolph designed a number of innovative lenses, including the Periskop in 1865 and the Aplanat the following year. In 1866 he bought out his father's interest in the Institute, which then became C. A. Steinheil Sohne, and he carried on the work of the Institute following his father's death in 1870. He continued to design lenses, writing an influential book on lens design in 1891, two years before his death.

COLIN HARDING

VON STILLFRIED-RATENICZ, BARON RAIMUND (1839–1911)

Austrian photographer, painter, soldier, diplomat, and restorer.

An adventurous aristocrat, Stillfried was one of the most important travel photographers of the Austro-Hungarian Empire. He was born at Komotau in Bohemia, Austria (now Chumotov, Czech Republic) on 6 August 1839, second of three sons of Baron August von Stillfried-Ratenicz, a decorated career soldier, and Countess Anna, née Clam-Martinicz. After spending most of his early childhood in the Austrian Military Frontier district (now Croatia), he began a formal education in 1851 at the prestigious Marine-Akademie in Trieste. During his five-year residence in the port, Stillfried received painting lessons from the accomplished Orientalist Bernhard Fiedler (1816–1904), who recognised his talent and attempted without success to convince his father to support the boy's artistic pursuits. After gaining a cadetship to the army's second Engineering Battalion, he moved to Linz in 1856 and attended the drawing classes of Joseph Maria Kaiser (1824–1893). Although rapidly promoted through the army ranks, he soon abandoned his military career "in order to satisfy his thirst for adventure and travel" [um seinen Durst nach Abenteuern und Reisen zu befriedigen] (A. Th.).

In January 1863, against his father's wishes, he voluntarily resigned from the Imperial army and travelled as a shipsboy to Callao, Peru. Financing his wanderlust through several odd trades, he eventually reached Nagasaki, probably in late 1863, where he worked for the Dutch silk firm Textor & Company, acquired some Japanese language skills, and met the Prussian landscape painter Eduard Hildebrandt (1818–1869). Although Stillfried later claimed to be self-taught, Fiedler, Hildebrandt, and to a lesser degree Kaiser, all built successful careers on the depiction of distant lands for the European market and their example perhaps inspired the young traveller towards a similar artistic vocation.

In mid-1865, Stillfried left Japan to join the volunteer forces of Emperor Maximilian of Mexico. A decorated officer, he remained in Mexico after the French withdrawal, serving in the beleaguered forces until the execution of Emperor Maximilian on 19 June 1867. After briefly returning to Austria, he travelled again to Japan and by July 1868 settled in Yokohama where he resided until 1881 (although he frequently travelled overseas). During the first two years, Stillfried worked for the North German Legation in Tokyo and sent regular reports on local affairs to the Austro-Hungarian Foreign Ministry. He also assisted the Austro-Hungarian diplomatic mission on their arrival at Yokohama in October 1869 (Wilhelm Burger acting as official photographer), for which he received the Franz Joseph Order on 15 March 1871. Aware of the booming local photographic market, Stillfried quit his diplomatic position in 1870 and opened a photographic supply shop in Tokyo. He obtained lessons in wet-plate photography from the experienced professional Felice Beato, before finally opening his own studio of Stillfried & Company at No. 61, Yokohama. Announcing the establishment of the new atelier, *The Hiogo News* noted on 9 August 1871: "A new photographer has started in Yokohama, Baron Stillfried was once a pupil of Mr. Beato and is now trying to undersell him." (Harold S. Williams Manuscript Collection, National Library of Australia, Canberra) As Beato's active interest in photography waned, Stillfried came to dominate the local market, catering for the influx of foreign tourists attracted to Japan during the 1870s. His work was widely reproduced in the overseas illustrated press and exhibited at several world exhibitions, including Vienna (1873), Philadelphia (1876), Paris (1878), Melbourne (1880) and Calcutta (1883). Although best known for his hand-tinted 'costumes' of generic Japanese 'types,' his first portfolio revealed a predilection for the landscape that brought a trained classical aesthetic to the Japanese views of Beato and Burger. A vastly underrated outdoor photographer, he further demonstrated his landscape capabilities in the later Hong Kong (1881–1882), Siam (1882–1883) and Balkan collections (1889).

Throughout his career, Stillfried's entrepreneurial ambition often led to scandal. In January 1872, he prompted a serious diplomatic affair after attempting to market an unofficial portrait of the Mikado taken during the emperor's inaugural public appearance at Yokosuka arsenal. The following year, he again courted controversy after transporting a seven-room teahouse to Vienna for the World Exhibition, accompanied by three Japanese women hired to serve tea to the prospective guests. The authorities refused to allow the building's reconstruction in the official grounds after reports associated the enterprise with Japanese prostitution. Despite losing a substantial amount in the venture and returning to Japan near bankruptcy, Stillfried quickly rebuilt his enterprise, now situated at No. 59, Yokohama, and soon promoted as the Japan Photographic Association. In November 1874 Josef Lehnert, a member of the Austrian expedition sent to Japan to record the Venus transit, pronounced in his travelogue: "As a photographer Baron von Stillfried achieves extraordinary things, really his atelier is the best and most important in the whole of East Asia." [Als Photograph leistet Freiherr von Stillfried Außerordentliches, thatsächlich ist sein Atelier das beste und bedeutendste in ganz Ostasien.] (Lehnert, Band II, 532) For his assistance photographing the astronomical event, Stillfried gained the title of court photographer on 25 April 1875 to the Austro-Hungarian Empire.

In 1875, Stillfried formed a partnership with a Prus-

sian accountant, Hermann Andersen, which allowed him to concentrate on his profession and leave the business operations to his associate. He travelled to Shanghai for a month in April 1876, returning to Yokohama with a large collection of Chinese genre images. Stillfried's products of the mid-1870s, most notably the albums generically entitled Views and Costumes of Japan were beautifully presented objects containing an equal number of hand-tinted studio 'types' and untinted 'views' (State Library of Victoria, Melbourne, Australia). Under his direction, the art of hand-tinting reached new standards rarely approached by subsequent studios, as he established select colours for each print chosen to highlight particular items of ethnographic interest. At its height, Stillfried claimed his studio employed thirty-eight full time Japanese workers, testifying to the firm's astounding popularity.

However, several business setbacks soon curtailed Stillfried's high standard Japanese work. On 14 January 1877, fire destroyed his studio and whilst most of his negatives were saved, at least some were probably destroyed. A week later Stillfried purchased Beato's entire stock, negatives and studio on the Yokohama waterfront, before departing on 6 June 1877 for a one-year international tour. He exhibited to considerable press attention at the annual salon of the Photographic Society of Great Britain in November 1877, before visiting several European cities, including Amsterdam, Berlin, Vienna, and Paris. In June 1878, he finally returned to Yokohama and promptly sold his share in Stillfried & Andersen to his business partner. In an extraordinary clause to the contract of dissolution, Stillfried agreed not to establish any future studio in Japan for a ten-year period. Andersen, however, continued to market albums under the Stillfried & Andersen banner containing an assortment of Beato and Stillfried reprints, as well as his own studio products, until 1883.

After a six-month Japanese government position teaching photography at the Department of State Printing, Stillfried opened a studio at his Tokyo residence in May 1879, but was forced out of business after Andersen issued a successful legal challenge for breach of contract. In response to the court decision, Stillfried invited his brother Franz to Yokohama, who shortly after his arrival on 25 October 1879 established the photographic studio of Baron Stillfried's Studio, No. 80. On 6 December 1879, Stillfried sold his remaining stock and photographic materials to Franz, prompting an acrimonious series of lawsuits between Andersen and the Stillfried brothers. Although Stillfried assisted his brother Franz in the studio's operations, his position was untenable and he soon left for continental Asia in search of new opportunities.

From September to December 1880, Stillfried operated a portrait studio in Vladivostock and produced a portfolio of Siberian studies, reputedly soon afterwards destroyed by fire. He returned to Yokohama for several months, before departing permanently on 4 May 1881, possibly once again for Siberia. He eventually arrived in Hong Kong on 15 October 1881, where he once again opened a portrait studio and gained a lucrative commission from the Governor-General, Sir John Pope-Hennessy, to document the decorations installed around the colony in preparation for the royal visit of Princes' Albert Victor and George of Wales. On 28 February 1882, Stillfried embarked for Siam (now Thailand) and remained thirteen months under the auspices of King Chulalongkorn, employed on several photographic commissions and the restoration of the royal oil painting collection until his permanent departure for Europe in April 1883.

von Stillfried und Ratenitz, Baron Raimund. Actor in Samurai Armor.

Although at first little known in Vienna, Stillfried quickly established his reputation with an exhibition in February 1884 at the Österreichische Museum für Kunst und Industrie of around four hundred photographs, paintings, and sketches of Japan, China, and Siam. Perhaps due to Emperor Franz Joseph's personal attendance, Stillfried received exclusive permission the following year to visit twelve Habsburg estates, resulting in an important series of interior room photographs and

paintings exhibited in February 1886 at Vienna's Österreichischer Kunstverein. In 1889, Stillfried travelled through Bosnia-Herzegovina, Dalmatia and Greece producing a collection of three hundred landscape, ethnographic, and archaeological studies, again exhibited in Vienna the following year. These exhibitions culminated in a large retrospective at Trieste in May 1891 comprising one thousand Asian and European images from the previous twenty years of work.

In the early 1890s, Stillfried established a large studio for the restoration of oil paintings at Feldsberg bei Lundenberg (now Czech Republic). He exhibited paintings regularly at several art societies, which some critics compared to the celebrated work of Rudolf von Alt. Although the Viennese city directory Lehmanns Adreßbuch continued to list Stillfried as an active photographer until his death, by the early twentieth century he was primarily occupied as a painter of architectural interior scenes until illness hindered further activities in 1908. He died from a heart attack on 12 August 1911 at his apartment in Gentzgasse 9, Vienna.

LUKE GARTLAN

Biography

Baron Raimund von Stillfried-Ratenicz was born into an aristocratic family on 6 August 1839 at Komotau, Bohemia, in the Austrian Empire (now Chumotov, Czech Republic). From his early childhood, he developed a penchant for maritime travel, art and distant cultures, nurtured in the thriving cosmopolitan port of Trieste. In broad terms, Stillfried's adult career can be divided into two periods. The first comprises the twenty years of travel between his resignation from the Austrian army in 1863 and his final return to Vienna. Eventually settling in Yokohama after five years spent in South America, Japan and Mexico, he established a photographic studio by August 1871, which soon gained international recognition for the hand-tinted genre scenes and untinted landscapes. He left the Japan Photographic Association in June 1878, and was later active in Siberia, Hong Kong and Siam. In the second period, from 1883 following his return to Vienna until his death in 1911, Stillfried continued to remain active, assembling important photographic portfolios of the Habsburg estates, the Balkan and Greek peninsulas, and numerous other European sites. His personal life, with separate families in Japan and Vienna, reflects these two phases in his career. A common aspect of treaty port life in Asia, Stillfried had a long-term liaison with a Japanese woman named Nishiyama Haru, with whom he had three daughters christened Mary, Anna, and Helen. After returning to Vienna, Stillfried married Helene Jankovich de Jeszenicze on 22 September 1884, with whom he had a further two children, Alice and Alfons. He died in Vienna on 12 August 1911, a few days after his seventy-second birthday.

VON VOIGTLÄNDER, BARON PETER WILHELM FRIEDRICH (1812–1878)

Viennese inventor and lens maker

Peter Wilhelm Friedrich von Voigtländer was born into a family of optical instrument makers in Vienna in 1812. His grandfather, Johann Christoph von Voigtländer (1732–1797) had established a small business in the Austrian capital in 1756 manufacturing microscopes, compasses and other optical instruments. Johann had three sons, the youngest of whom, Johann Friedrich (1779–1859), carried on the family business after his father's death in 1797. As a young man, Johann travelled to England to study optics and, after his return to Vienna, started to make lenses in about 1808. In 1823 Johann invented and patented the opera glass. In 1837, aged 58, Johann Friedrich retired and the management of the family business was taken over by his son, Peter Wilhelm Friedrich, then just 25 years old.

By this time the house of von Voigtländer had already gained a reputation of being one of the very finest European optical instrument makers. Peter, although still comparatively young, had a wealth of knowledge and experience. His early education and practical instruction came from his father. For his more advanced and theoretical education he later enrolled at the Vienna

Polytechnic Institute. Peter's practical experience and knowledge was broadened by travelling and working in Germany, France and England.

His primary area of interest was optical theory, including calculating the refraction and diffusion characteristics of various types of glass. It was inevitable, therefore that he soon befriended and began to collaborate with the mathematician Josef Max Petzval (1807–1891) who in 1837, the same year that Peter took over from his father, had become professor of higher mathematics at the University of Vienna. In 1840, Petzval, who had not designed a lens before, mathematically calculated the optimum arrangement for a lens intended specifically for photography. Up to this time, camera objectives were simple lenses that had been designed for other uses. The slowness of these lenses exacerbated the lack of sensitivity of the earliest photographic processes. Petzval entrusted the construction of his, at the time still theoretical, lens to his friend von Voigtländer. The first sample Petzval lens was completed in May 1840. It was made up of two separate asymmetrical lens components, a front lens with a forward-facing convex surface and a rear component consisting of one planoconcave and one biconvex lens, separated by a space. Definition and illumination was excellent in the centre of the field but deteriorated gradually towards the edge of the picture. However, this was not seen as a problem for portrait photography and could even be regarded as beneficial since it tended to emphasis the actual portrait area and suppress unwanted background detail. Petzval's design became the standard lens for portraiture until well into the twentieth century.

The original Petzval Portrait lens had an aperture of f/3.6. This made it sixteen times faster than the simple meniscus lenses that were currently in use and reduced exposure times from minutes to seconds. In 1841, von Voigtländer fitted a Petzval lens into an all-metal daguerreotype camera that he designed and manufactured. Of distinctive and unusual design, von Voigtländer's camera consisted of a conical brass body with the lens at its apex. A shorter conical focussing attachment with a ground glass screen and a magnifying eyepiece could be screwed into the other end. The camera rested on a cradle on top of a telescopic pillar. After focussing, the camera was removed from the stand and carried to a darkroom where the focussing attachment was removed and replaced by a plate-holder containing a sensitised circular daguerreotype plate, 94mm in diameter. The camera was repositioned on its stand and the exposure made by removing and replacing the lens cap. It is estimated that von Voigtländer produced about 70 of these cameras in 1841 and around 600 the following year. Today, however, only about a dozen are still known to exist.

Despite their initial friendship and shared interests, von Voigtländer and Petzval soon quarrelled, primarily because Petzval felt he had not received sufficient financial reward for his invention. By the end of the 1840s the two men had ceased to be on speaking terms. Petzval had taken out an Austrian patent for his lens but in 1849 von Voigtländer established a second factory in Braunschweig, Germany, which was his wife's hometown. Here, there were no legal restrictions and von Voigtländer continued to produce Petzval lenses in increasing numbers. In 1862 he produced his ten thousandth lens. In 1866 von Voigtländer closed his original factory in Vienna. That same year he was made a member of the hereditary peerage by Emperor Franz Joseph of Austria, which entitled him to use the prefix 'von' before his name.

Peter Wilhelm Friedrich von Voigtländer retired in 1876 at the age of 64, handing over the business to his son, Friedrich Ritter von Voigtländer (1846–1924), the last of four generations of von Voigtländers connected with the optical industry. Friedrich, a fine lens designer in his own right, ensured the continuing success of the company with the introduction of the Euryscope lens in 1886 and the Collinear lens in 1892. Around the turn of the century, von Voigtländer branched out into camera manufacture which was subsequently to become a major part of the company's business.

VUILLARD, ÉDOUARD (1868–1940)

French painter and lithographer

Édouard Vuillard, known primarily as a painter and lithographer, produced over 2000 photographs (1700 as original prints) during his lifetime. Vuillard began experimenting with a hand-held Kodak camera in the late 1880's along with fellow artists Pierre Bonnard and Maurice Denis. These photographs taken throughout his lifetime focused primarily on the artist's circle of family and friends, as was the case with his paintings. He used the camera as a witness, spontaneously asking those around him to "hold it please" when he wanted to record a casual everyday moment, as mentioned in "Vuillard et son Kodak."

Vuillard also utilized photography to experiment with spatial ambiguity often staging scenes he later recreated in his paintings. The artist composed many

scenes to place the women in his life on center stage. Either through foreground placement or by putting them in focus, numerous photos exist of the two infatuations of Vuillard's life: Misia Natanson and Lucy Hessel. The artist's mother, however, was the subject he shot most; it was also she, often more than the artist himself, who frequently developed his photographic works.

Vuillard did not exhibit his photographs during his lifetime. They have predominately been hidden from public view in family archives until over 80 were revealed in the international 2003 Vuillard exhibition. A catalogue raisonné of all photographs in the family archives is forthcoming.

WALKER, SAMUEL LEON (1802–1874)

Samuel L Walker was one of the earliest daguerreotype photographers in the United States and was widely regarded as one of the best photographers during the 1840s and 1850s. He lived and worked in Poughkeepsie, New York.

Walker was born in 1802 at New Salem, Massachusetts, and enjoyed careers as a daguerreotypist and photographer, writer and spiritualist. There is some evidence to suggest Walker was an assistant to Samuel F. B. Morse in New York; he then had a studio in Albany before moving to Poughkeepsie by 1847. He seems to have stopped photographing between 1854 and the early 1860s when wet collodion photography began to supersede the daguerreotype and poor health limited his activities. By May 1864 Walker had returned to photography and was practicing the collodion process in his Photographic Institute.

The only known collection of Walker's work is held by George Eastman House in Rochester, New York, and the twenty daguerreotypes there consist of portraits including studies of his own children which Sobieszek claims are 'some of the most exciting images created by the daguerrean artist.' His daguerreotypes of his daughters are reminiscent of the work of Lewis Carroll in their directness and latent sexuality.

He died on 25 April 1874 aged 72 years when he was described as a man of great artistic taste with a love for his profession.

MICHAEL PRITCHARD

WALKER, WILLIAM HALL (1846–1917)

William H. Walker began making a wooden pocket amateur camera in Rochester from 1880 and by 1883 he was successfully manufacturing dry plates. He gave up camera making, allowing his former partners to form the Rochester Optical Company which continued with the camera making side of the business.

George Eastman recognising Walker's skills as a chemist and experience with plate manufacturing offered him a job which he accepted from the beginning of 1884. He began work on developing what became the Eastman-Walker roll film holder which allowed a roll of film to be used with any plate camera. The roll holder was patented in Britain on 25 November 1884 and in the United States on 5 May 1885. Through its use of standardized parts it could be mass-produced and was made in Frank Brownell's works, being placed on the market in 1885. It was produced in eleven different sizes. The roll holder proved popular with the photographic press and with amateur photographers so that by 1888 35 percent of negatives at the London Camera Club's summer outings were made using it. Rival companies introduced their designs.

Walker, with Eastman, also designed a paper and film coating machine and this, with the roll-holder and the development of a film, was intended to give Eastman's company a complete system of film photography.

In 1884 Walker became Secretary to the Eastman Dry Plate and Film Company and in 1885 he was sent to London to supervise the company's European activities, leading to the establishment of the Eastman Photographic Materials Company Ltd which was incorporated in November 1889.

Walker's relationship with Eastman, which had always been testy, deteriorated and Eastman himself was forced to find a factory site rather than rely on Walker. The Harrow site was purchased, the first for the company outside of Rochester. Walker was not a businessman and Eastman found Walker's negative attitude and repeated threats to retire tiresome. He finally accepted such a threat and George Dickman was appointed to take over

from Walker from January 1893. Eastman soon forced Walker from the company completely.

Walker, a wealthy man from his Kodak stock, died in November 1917.

MICHAEL PRITCHARD

WALL, ALFRED HENRY (d. 1906)

According to his obituary, Alfred Henry Wall was born in London, date unknown, and had a childhood sufficiently unhappy that he ran away from home and went to work for a time for one of the earliest daguerreotype studios in the city before joining a theatre company—an activity he would return to for a period in the 1860s.

He opened his own studio in Cheapside c.1850, and another in the Strand (date unknown), but by 1851 was working as a photographic assistant at the Great Exhibition.

Photographic News reported in 1861 that he was working as an itinerant portrait painter under the name of R. A. Seymour, and coincidentally in that year he published *A Manual of Artistic Colouring as Applied to Photographs.* By 1862 he had returned to commercial photography and opened a studio in London's Westbourne Grove.

In 1864 and 1865 he published two annual volumes entitled *The Art Student* which discussed photography as an art form, a subject aired several times since 1859. From 1868 until 1870 he edited *The Illustrated Photographer*, which described itself as 'a weekly journal of science and art,' and his contributions to several contemporary journals did much to expand understanding of the photographic processes.

Wall's last photographic book *Artistic Landscape Photography* was published in 1896.

JOHN HANNAVY

WALL, EDWARD JOHN (1860–1928)

Edward John Wall was one of the leading writers on the theory and practice of photography in the closing decades of the nineteenth century. His 1889 *Dictionary of Photography* became a standard reference work and ran to many editions worldwide. Although not published until 1925, his *History of Three-Colour Photography* was the first reflective look at that subject, drawing on material he had first published in the *British Journal of Photography* in the early 1900s.

In the closing years of the 19th century he contributed a manual on carbon printing to *Amateur Photographer* magazine's *One Shilling Library* series of books, but one of his most significant contributions to the practice of photography was his published 1907 suggestion for the technique which became known as bromoil printing. Wall himself did not fully articulate the mechanics of the process, but his initial suggestions as to how it might work were realised in a practical sense by C Welbourne Piper, who published a working process later that same year.

Trained as a chemist, Wall initially worked for the plate manufacturers B. J. Edwards & Co. in London, before embarking on a career which embraced camera manufacture in the United States with the Blair Camera Company, journalism, photography, and motion pictures.

JOHN HANNAVY

WALTER, CHARLES (CARL) (c. 1831–1907)

Botanist, photographer, journalist

Born in Germany, he emigrated from Mecklenberg, Tokheim, to Victoria, Australia, in c.1856 where he worked as a botanical collector for the Victorian Government Botanist, Baron von Mueller. In 1858, he worled as a photographer and botanical collector, accompanied R.L.J. Ellery's geodetic survey party into eastern Gippsland.

In 1865, he advertised himself as a "Country Photographic Artist" of 45, Bell Street, Fitzroy, Melbourne, and began supplying photographs and reports of his travels in the bush to *The Illustrated Australian News.* Much of his early work was concerned with recording portraits of aborigines and he documented the mission stations of Ramahyuck (Lake Wellington), Coranderrk (Yarra Flats) and Lake Tyers. In 1867, he sent portraits of *Natives of Victoria* to the Anthropological Society of London.

Walter was, perhaps, Australia's first photojournalist, for as early as 1865 he sent a report of the "Salmon Tanks in Badger Creek" to the *Illustrated Australian News*. In the following year, he describes a trip overland to "Falls on the Niagara Creek, Mount Torbreck" with his "apparatus and tent upon his back—the whole weighing about fifty pounds."

Walter used a stereoscopic camera for most of his work but also produced some half-plate and whole-plate negatives. He registered photographs with the Victorian Copyright Office in 1870 and in 1871 he advertised "A very large stock of Stereoscopic Views of Aboriginal Life, Mining, Scenery and other Australian Subjects." The earliest extant photograph by Walter is dated 1862; his work continued to be published until the early 1870s.

BILL GASKINS

WAR PHOTOGRAPHY

Introduction

The medium of photography was generally accepted as a reflection of reality in the nineteenth-century. In truth, many photographic war scenes were manipulatively staged. At times this was because the artist wanted to reflect what they had seen with their own eyes, but were unable to capture with the camera. The creation of photographs was also incredibly arduous on the battlefield. Lighting had to be ideal, photographic equipment was cumbersome, and plates had to be processed quickly necessitating portable darkrooms. In addition, the slow development of the medium itself made it impossible to produce action photographs.

Even with the assumed veracity of photographic works, photographs were seldom printed in newspapers in the nineteenth-century. More likely they were seen when displayed in galleries, sold in books, or copied by engravers for newspapers. However, often engravers invented scenes of battle that had not been captured by photographers. The development of half-tone printing, which enabled the combining of text with photographs, fueled a rise of photos in papers during the Spanish-American War and Second Boer War at the end of the century.

Early War Photography

The earliest photographs of wartime events come from the end of the Mexican-American War (1836–1848). These images are not of battle scenes, but rather posed scenes of soldiers. "General Wool and Staff, Calle Real, Saltillo, Mexico," c. 1840, offers a good example of the kind of choreographed scene frequently produced. Wool's regiment paused for several minutes to accommodate the exposure time needed for the daguerreotype; one can see that the figures on the left are slightly blurred from having moved. The difficulties of obtaining photographic materials, the lengthy preparation time necessary, and the long exposure period for the daguerreotype, made photography rare in this period. Only around fifty photographs survive, and we have no record of specific photographers of the Mexican-American War images.

The first identifiable photographer who took pictures in a wartime environment was John McCosh. McCosh served as a British surgeon during the Second Sikh War (1848–1849) in India and the Second Burma War (1852). Using the calotype, McCosh photographed fellow soldiers, artillery, and ruins. Karl Baptist von Szatmari also exhibited some photographs of a battle between the Russian Army and the Turks in the Paris Exhibition of 1855; an engraving after one of these scenes survives, as do some of the photographs themselves.

1850s

Richard Nicklin had been hired by the British military to photograph government-sanctioned scenes of the Crimean War (1853–1856), but the photographer and his two assistants were caught in a hurricane and drowned

Wood and Gibson. Inspection of Troops at Cumberlanding, Pamunkey, Virginia.

in Balaclava Harbor in November of 1854. Photographs from other artists such as Gilbert Elliot, and two military officers, ensigns Brandon and Dawson, were also hired by the government to cover the war, but all of their works have since disappeared.

Roger Fenton produced over 350 images of the Crimean War during 1855. Thomas Agnew hired Fenton with aspirations of creating a profitable issue of photos similar to those that the military photographers had been hired to photograph but never produced. Roger Fenton wrote in letters of some of the horrors he witnessed during his time in the Crimean, but his photographs do not reflect the scenes he describes. Rather, Fenton mostly photographed heroic portraits of soldiers, positive scenes of life in the camps, and images of the surrounding landscape. Fenton may have felt compelled by Agnew, as well as Queen Victoria with whom the photographer had developed a warm relationship, to photograph encouraging images of the war to try and offset the negative impressions given to the British people by newspaper reporter William Howard Russell. Fenton was also limited by photographic materials of the time which did not yet enable spontaneous action shots. He was also challenged by the collodion wet plate process technique which required speed and virtuosity as he only had short time to develop the plates in his makeshift traveling laboratory after taking a scene.

Fenton's most recognized war image is one of the few in which he allowed a sense of sadness at the destruction of war to creep into his work. Arriving shortly after the brutal attack of soldiers of the British Light Brigade by the Russians on October 25, 1854, Fenton's "Valley of the Shadow of Death" showed the infamous valley as a desolate landscape filled with cannon balls. The exhibition of the photograph in 1855, and the popularity of Lord Tennyson's "Charge of the Light Brigade," written in 1864, marked this event in the memory of the British people.

James Robertson, Felice Beato, Charles Langlois, and Karl Baptist von Szatmari all photographed the final stages of the Crimean War. Of these, the sixty or so photographs taken by Robertson have become the most well known. Robertson's works showed more scenes of death, destruction, and violence, the kind of subject matter not in the work of Fenton. Although Thomas Agnew & Sons published both Fenton's and Robertson's Crimean photographs in 1856, Robertson does not seem restricted by Agnew to shoot only government-favored photos as Fenton had been, perhaps because of Robertson's other sources of income. In the end, Agnew's commercial adventure was not as successful as he had hoped. Fenton's and Robertson's photographs went on sale, both individually and as sets, as early as November 1855. However, the public had little interest in these images by the end of the war. By the end of 1856, Thomas Agnew & Sons sold all remaining prints and negatives from both photographers at auctions.

After photographing the end of the Crimean War, Felice Beato and James Robertson worked together in Calcutta and photographed the Indian Mutiny, of First War of Independence, of 1857. Beato's most striking images from this period are scenes of the execution of over 2000 Indian rebels by the British, and those of Secundra Bagh in which he recorded the devastation in the months that followed. In his photographs from the 1850s, Beato is often credited as the first to photograph corpses after a battle. Beato probably choreographed many of these scenes to heighten the dramatic effect, perhaps even excavating and arranging corpses. Beato became the most prolific photographer of war scenes of the Asian world in the nineteenth century including the recording of the Opium War in China (1860) and the Japanese attacks in the Simonaki Straights in September of 1864. Also during this decade, several photographers were sent to the battlefields during the War of the Triple Alliance in South America (1864–1870), in hopes for commercial success. Bate & Co. published Esteban García's work from this period in sets of ten titled La Guerra Ilustrada. However, it was the American Civil War (1861–1865) that was the first war to be extensively photographed.

1860s/American Civil War

It was the publishers' awareness of the public's desire for war scenes that caused the prolific photographic work produced during The American Civil War; at least five hindred photographers accompanied the soldiers of the North. Photographs were then made into engravings to be published in the papers, or sold to E. and H. T. Anthony and Co., who at times issued more than a thousand pictures a day. The photographs themselves would not be viewed by the public until they were displayed in galleries.

George S. Cook took images right after the fall of Fort Sumter, marking the beginning of the war between North and South. While Cook became one of the few photographers to shoot Confederate subjects, one of his most famous works is of a Federal troop leader, Major Robert Anderson who had been defeated at Fort Sumter. After the war, Cook collected over 10,000 photographs from the war; these are now in the collection of the Valentine Museum in Richmond, Virginia.

However, Matthew B. Brady is the name most synonymous with Civil War photography. He determined that he could make a profit organizing photographers to shoot the war and closed most of his galleries which had been highly successful portrait studios for the rich and famous. He had even done several sittings with President Lincoln who credited Brady with helping him win the

election with these fine portraits of the President. Brady claimed he was called to the war, "I felt I had to go. A spirit in my feet said 'go,' and I went."

Although suffering from poor eyesight, Brady initially went to the fields and was greeted with distaste from many of the soldiers who suspiciously saw his camera as some kind of weapon. Later, he organized other photographers to do most of the actual photographing. However, Brady managed to frequently place himself within photographs of military heroes. Throughout the course of the war, Brady hired over twenty photographers to shoot the troops, battle scenes, and the bodies after the massacres. He organized a complex system of equipping each of the photographers with a portable dark room and stocked chemicals and glass plates at the major battlefields. His team of photographers produced over 7000 negatives during the war.

One of Brady's best photographers was Alexander Gardner. Gardner followed the Army of the Potomac and captured most of their battles. His first war photographs were exhibited in Brady's studio in September of 1862 and captured the horrific results of the Battle of Antietam, the bloodiest battle of the war in which 26,000 soldiers were killed or wounded. The gallery received huge crowds desperate to see these first images portraying with veracity the costs of war. These photographs were dramatically realistic in contrast to heroic scenes that had been done of dead soldiers by painters in this period. Gardner showed the actual decay of the corpses and the inhumanity of their deaths. Eight of these photographs were also published in *Harper's Weekly* on October 18, 1862.

The *New York Times* praised the show, "Mr. Brady has done something to bring home to us the terrible reality and earnestness of war" and Gardner was disturbed by Brady's assumed ownership of these photographs. Each photograph was boldly marked with "Brady's Album Gallery" in contrast to Gardner's name written in small barely noticeable print. Gardner reacted by taking the negatives of his photographs along with Timothy O'Sullivan and James F. Gibson, some of Brady's best photographers, and opened his own studio. Once working for himself, some of Gardner's most intriguing works were those from his series on the execution of the conspirators who plotted the murder of President Lincoln.

Gardner clearly credited the photographers who worked for him in the publication of their work. For example, Timothy O'Sullivan, while working for Gardner, produced arguably the most famous war photograph, the "Harvest of Death" taken of the battlefield of Gettysburg. This scene shows a field covered with bodies, highlighting the numerous deaths from this battle. Yet O'Sullivan simultaneously shows the viewer one soldier's face, his contorted hand in the center of the photo, bringing a large inconceivable number down to the reality of many individuals. Other soldiers have their clothes partly removed as thieves have already been searching their bodies. The scene achieves the kind of accurate reportage which Gardner supported when he remarked that this photograph by O'Sullivan "conveys a useful moral: it shows the blank horror and reality of war, in opposition to the pageantry."

Photography also filled a unique role for families who sent their loved ones to battle. Portraits of soldiers were often taken before leaving for the war and makeshift studios were set up in many battlefields enabling soldiers to send home images of themselves. The recently developed and inexpensive tintype photographs were particularly popular. It should be highlighted that although a few photographs of African-American troops and the treatment of slaves were taken, the photographic record of this period for African-Americans is minimal in comparison to the copious photographs taken of the war.

Some of the many photographers not discussed in depth in this essay who photographed scenes from The Civil War include: George Barnard, Bergstresser Brothers, Sam Cooley, James Gardner, James Gibson, S.A. Holmes, David Knox, Theodore Lilienthal, Royan Linn, A.D. Lytle, William Pywell, James Reekie, George Rockwood, T.C. Roche, John Scholten, William Morris Smith, Julian Vannerson, David Woodbury, and J. A. Young. Andrew J. Russell is the only photographer during the Civil War to have been paid by the government.

After the war, photographs of the battlefields were difficult to sell as the public preferred to forget their tragic losses. Alexander Gardner's Photographic Sketch Book of the Civil War published after the Civil War, which included O'Sullivan's famous Harvest of Death, had little response. While many photographers struggled, perhaps none suffered more than Brady who had bankrupted himself from his investments to photograph the war and ended up destitute and mostly blind. Also after the end of the war, Frank Leslie's *Illustrated Newspaper* published images of Southern war camps and malnourished prisoners. Mary Warner Marien discusses the role of the North's blockade of the South as a cause for the extreme neglect of the prisoners of the Confederacy.

The 1870s and 1880s

During the 1870s and 1880s numerous regional wars took place throughout the globe. However, few photographers recorded these events, as there was little interest in them for purposes of print illustrations. Rather, most newspapers hired artists to sketch dramatic battle scenes believing photography lacked the ability to capture the

action. Louis Heller shot images of prisoners which were used, however, for the cover of Frank Leslie's *Illustrated Newspaper*, July 12, 1873. Eadweard Muybridge produced some dramatic images of the battle between the Modac Indians and the American Cavalry on the border of Oregon and California in 1872–1873. Muybridge frames individual proud Native Americans as they fight to keep their land; in truth, most of the tribe would be hung when this battle was lost. Bismark's war against Schleswig-Holstein was photographed by a handful of artists showing mostly views of the destruction of the landscape and corpses. Only negligible photos survive from the Russo-Turkish War (1877–1888).

While James Burke photographed many struggles in Afghanistan, the best are of the Second Afghan War of 1879 in which the British were fighting in the area of Kabul. In one of the most successful battles in British military history, their troops numbering only 5000 fought off an attack by over 100,000 Afghans. Although he did not shoot the actual battle, Burke's photos of the confident British troops a day before the attack were published as engravings in London Graphic. Burke is known for his sweeping views of troop formations placed against the exotic Afghan backdrop.

Few noteworthy photographs survived from the Franco-Prussian War of 1870; however, photography played a crucial role in the siege of Paris. First, balloons marked "Daguerre" and "Niépce" were used to drop communications into the surrounded city. Later, photographically reduced text was hidden in small containers tied to the tails of homing pigeons enabling those under siege within the city to communicate with French officials outside. Once they realized the French's secret weapon, the Prussians used falcons to attack the pigeons.

The Paris Commune ended with Bloody Week (May 21–May 28, 1871), a period in which 25,000 Parisians were killed by the French government. Various Parisians took some particularly intriguing photos of the Communards posed prior to and after removing the Vendôme Column, an action that symbolized the removal of Napoleonic military barbarism. Bruno Braquehais published 109 photographs, which he personally photographed, in a bound album titled *Paris During the Commune*. Unfortunately, these photographs were later used to identify rebels who were then punished or murdered by the French government. Charles Soulier photographed the city in ruins after the end of the Commune. Eugène Appert fabricated photographs in which he hired actors to stage various scenes from the time of the Commune, and then he would paste in heads of the Communards and reshoot the pasted photo. This handful of contrived images, designed from the perspective of the government, was compiled into a book called Crimes of the Commune.

1890s

The Spanish-American War (April 25–August 12, 1898) is the first war in which photographs of war scenes were quickly disseminated to the public through publication in newspapers. Due to the images in papers owned by Hearst and Pulitzer, Americans saw the atrocities of the Spanish occupation, although often inaccurately reported, and support increased for the Cuban rebel forces. The sinking of the U.S. battleship *Maine*, on February 15, 1898, in the Cuban harbor of Havana was blamed on the Spanish and fueled the decision by the United States to enter the war on April 25. "Remember the *Maine*" became a rallying cry as numerous photography firms marketed stereographs of the event; Keystone View Company in particular made a profit from the selling of such images.

Despite the American public interest in this conflict, few photographers were hired to document the battles. However, Jimmy Hare began a career in which he would become known as the paramount photographer of war. Working for *Collin's Magazine* and later *Collier's* and *Leslie's Weekly*, Hare worked in the field during numerous twentieth-century wars including World War I. While few of his surviving photographs from this period are remarkable, later he would be credited with being the first modern war photojournalist for his courageous efforts in documenting times of war.

International public opinion on the Second Boer War (1899–1902) was also greatly swayed by photographs of the battles and conditions in South Africa. Much of Europe and the United States supported the seemingly simple people of the Boer republic initially in their battle against Britain. Once realizing the power of the medium, the Boers began taking numerous photos of every aspect of the war. The Boers encouraged photos of their weaponry, trenches filled with dead British soldiers, and their prisoners including then war correspondent Winston Churchill.

Through manipulation of these and other photographic images, the British used the media to try and persuade the national and international public to support their troops. Horace Nicholls can be credited with shooting some of the most sentimental images during this period, which engendered sympathy for British troops. Nicholls described his desire to shoot and compose "photographs which would appeal to the artist sense of the most fastidious, knowing that they must as photographs have the enhanced value of being truthful." Numerous other photographers were sent to shoot this war, Reinholt Thiele and H.C. Shelley for example, but many scenes were shot by British soldiers and volunteers who brought their own Kodaks to South Africa. The deplorable conditions of British concentration camps, in which 40,000 women and children died of disease and starvation, were undeniable due to the many photographs taken within the camps of the victims.

Conclusion

While many battles from the larger wars were more frequently photographed, photographs also evidence the colonization by Europeans and Americans around the globe. In many countries, photos of famous cultural sights and exotic locales were taken once an area was conquered. Many of these images were used to lure westerners to become settlers in a certain area and to romanticize the prowess of western cultures at exploration.

Photography was also utilized as a military tool throughout the second half of the nineteenth century. Most military expeditions had a trained photographer as part of their troops. Some armies maintained an entire unit of photographers. Photographic technology was also used to reproduce maps, study military maneuvers and the terrain, and to train servicemen.

In the majority of battles, photographers were successful at performing their role as observers of both sides. Yet in some cases photographers were taken as prisoners when suspected of spying for the enemy. In addition, photographers were frequently warned against photographing any military details and could be imprisoned if such images were ever published. Some soldiers felt uncomfortable with the new technology, as discussed above during the American Civil War. Native American warriors, in fact, frequently avoided the camera for fear that the strange contraption would somehow capture their soul.

The time needed to set up the equipment, the slow development time, and the simple fact that a photographer had to shoot something before them rather than creating it in their mind, made photography a challenging medium to work with in the nineteenth century. Yet, the camera's seeming ability to capture reality also made the desire to take photographs of battlefields and soldiers simply irresistible. By World War II, photographs would be the primary source of images for newspapers informing the public about the war.

WARD, CATHERINE WEED BARNES (1851–1913)

Born in Albury, New York January 10, 1851, Catherine Barnes traveled with her parents to Russia in 1872. Introduced to photography in 1886, she built her own studio in the attic of her home. She was appointed associate editor of American Amateur Photographer, wrote and lectured extensively on photography, and became known as an advocate for women in photography with her talk

"Photography from a woman's standpoint" (1890). Her appointment as editor was followed by a visit to England, where she was enrolled into the Photographic Society of Great Britain, and married the photographic journalist Henry Snowden Ward (1865–1911).

Together with her husband, Ward edited *The Photogram* (1894–1905), continued as *The Photographic Monthly*, and *The Process Photogram* (1895–1905), continued as *The Process Engraver's Monthly*. They collaborated on a series of topographical volumes, with photographs taken by Mrs Ward, including Shakespeare (1896, 1897), Dickens (1903), Chaucer (1904), and Lorna Doane (1908).

Snowden Ward died suddenly in New York in 1911, while on a lecture tour to promote the Dickens centenary. Catherine returned to England, but her health deteriorated, and she died in Hadlow, Kent July 31 1913.

DAVID WEBB

WARD, HENRY SNOWDEN (1865–1911)

Henry Snowden Ward was born in Bradford. In 1884 he became associated with the Bradford photographic publishers and stationers Percy Lund & Co, for which he founded and edited *The Practical Photographer* in 1890.

In 1893 he left Lund and with his new wife, Catherine, started *The Photogram* which became *The Process Photogram* in 1895 and *The Process Engravers Monthly* from 1906. American edition and deluxe editions were also published. An annual *Photograms of the Year* also appeared from 1894.

Although his activities as a photographic technical author were extensive Ward was also an active participant in the [Royal] Photographic Society and the Photographic Convention and he was in demand at photographic societies as a judge. He was important in disseminating new discoveries and improvements, particularly in the area of photo-mechanical printing. He was one of the first experimenters with X-rays and wrote a handbook on the subject *Practical Radiography* (1896) and was a founder of the Röntgen Society. Ward was an enthusiastic proponent of record photography and was one of the first to draw attention to the use of photography in press illustration. He established a bureau to supply photographs to the press.

Although Ward's work with his process journals continued until his death from the later 1890s he began increasingly to explore the application of photography to the illustration of literary works. He authored books dealing with Shakespeare (1896), Dickens (1904), Chaucer (1904) and an edition of *Lorna Doone* (1908). These were usually illustrated with Catherine's photographs. He undertook extensive lecture tours on literary subjects and during one to New York he died on 7 December 1911.

His American wife Catherine Weed Ward (neé Barnes) who was an accomplished photographer and photographic journalist in her own right died on 31 January 1913.

MICHAEL PRITCHARD

WARNERKE, LEON (VLADISLAV MALAKHOVSKII) (b. 1837)

A Russian-born civil engineer, Warnerke moved to London before 1870 where he established himself as a photographer and opened one of the earliest photographic laboratories. By 1880 he had business interests in both the United Kingdom and Russia, living periodically in both south-east London and St Petersburg, where he opened a photographic manufacturing facility.

He is credited with the discovery (c.1875) of the tanning effect of pyrogallic acid when used in the development of collodion and, in 1880, with the development of the Warnerke sensitometer, the first effective device for the measurement of plate speed. This he used for pioneering sensitometric investigations of gelatine dry plates and early silver bromide emulsions.

In 1875 he designed a roll-holder for 100-exposure silver bromide collodion stripping paper, predicting the development of Eastman's stripping films in the following decade, and in 1882 he was awarded the Progress Medal of the Royal Photographic Society. From 1889 his factory manufactured silver chloride printing papers.

Warnerke's interests extended beyond photography. He is remembered in monetary circles as one of the greatest banknote forgers of all time, having been responsible for the forgery of several eastern European currencies, most particularly Russian roubles. He was never caught, and supposedly died in 1900—at the age of 63—but it is likely that he faked his own death to escape arrest.

JOHN HANNAVY

WASHINGTON, AUGUSTUS (c. 1820–1875)

Daguerreotypist and teacher

Augustus Washington was born in Trenton, New Jersey, in 1820 or 1821 to a former slave and his South Asian wife. His father Christian ran an oyster saloon in Trenton. Washington's mother probably died shortly after Augustus was born, as records show his father married a woman named Rachel in October 1821.

Attaining a solid education and sharing this knowledge with others dominated Washington's early life. He attended private schools in Trenton alongside white

children until the mid-1830s, when the activities of free blacks were restricted. At that time, educational opportunities for black students were suddenly limited due to the white population's fears about plans that called for the immediate abolition of slavery. In reaction, Washington briefly ran his own school for local African Americans.

Washington was able to further his education at Oneida Institute in Whitesboro, New York, one of only a few private schools that accepted African American students. With the help of abolitionists, he studied there for over a year before a lack of money forced him to leave school and seek employment. Washington's financial woes would continue to interfere with his academic dreams.

In 1838 Washington accepted a teaching position in Brooklyn, New York, at the African Public School. For the next three years he taught in Brooklyn, contributing articles and serving as a subscription agent for *The Colored American*, a new weekly newspaper written by blacks for a black audience. He also attended anti-colonization society meetings and organized voting rights meetings in New York and New Jersey.

Washington furthered his education, first at Kimball Union Academy in Meriden, New Hampshire, and later in the fall of 1843 at Dartmouth College, where he was the only black student. During the winter school vacation, Washington learned the daguerreotype process while visiting family in Trenton. He returned to Dartmouth, making and selling portraits to help pay his school expenses. Unfortunately, he did not earn enough money to continue his studies.

For the next ten years Washington lived in Hartford, Connecticut, working initially as a teacher for black children at the North African School from the fall of 1844 to 1846. Later that year, he opened a daguerreotype studio in Hartford. After the studio had been open a few months, he moved his operation to the city's business district on Main Street. Surviving images from this period indicate that his studio catered to Hartford's white population, attracting many prominent citizens, including Connecticut author Lydia Sigourney and Eliphalet Bulkeley, a Hartford lawyer and judge.

One of Washington's earliest and best-known extant portraits depicts the abolitionist John Brown. Washington posed Brown in an unconventional manner that accentuates the subject's importance. Brown stands with his right hand raised as if taking an oath, while his other hand holds a flag that might symbolize Brown's "Subterranean Pass Way," his plan for an Underground Railroad.

Washington generally posed his customers seated, with the sitter's right arm resting on a table. Men usually faced the camera straight on, while women sat at a slight angle, holding a daguerreotype case, book, or flowers. A broadside for Washington's daguerrean gallery published in July 1851 boasts that the studio "... is the only gallery in Hartford, that has connected with it, a Ladies' Dressing-Room, and has a female in constant attendance to assist in arranging their toilet." The broadside also mentions that Washington had just spent three months in New York,... and availed himself of all the latest improvements in the Art."

Washington's commercial success could not offset the racial problems he and other African Americans faced in the middle of the nineteenth century. In 1850 Congress passed the Fugitive Slave Act, which threatened the freedom of all African Americans. Washington expressed his dissatisfaction with life in America in a letter published in the *New York Times* writing, "Strange as it may appear, whatever may be a colored man's natural capacity and literary attainments, I believe that, as soon as he leaves the academic halls to mingle in the only society he can find in the United States, unless he be a minister or lecturer, he must and will retrograde."

In 1850 Washington married Cordelia Aiken. He searched for a better place to live with his family, and considered relocating to Canada, Mexico, the West Indies, British Guiana, or various countries in South America. In spite of his previous involvement with anti-colonization efforts, Washington ultimately decided to immigrate to Liberia under the auspices of the American Colonization Society. Since its founding in 1816, the American Colonization Society, a private philanthropic organization, had worked to relocate freeborn and emancipated blacks to Liberia on the west coast of Africa. In 1847 Liberia became an independent republic, run by many former African Americans.

In November 1853 Washington closed his successful daguerreotype studio in Hartford, Connecticut, and with his wife and two young children sailed for Liberia on the *Isle de Cuba*. He began making portraits shortly after he landed, and his business was an immediate success, selling roughly $500 worth of portraits during his first five weeks of operation. In a letter to John Orcutt, Traveling Agent of the American Colonization Society, Washington wrote: "I put my price down to what people consider cheap, $3 for the cheapest picture, and when I am able to work I go to my room and take some 20, 30, or 40 dollars worth of pictures in a day. I have hired boys whom I send to tell as many as I can attend to." Washington planned to spend six months of the year working as an artist and the remaining six months as a merchant.

Washington's Liberian work is more varied in both style and subject. For his portrait photographs, Washington used several different poses. He photographed Liberia's President Stephen Benson in a near profile. A series of portraits attributed to him, depicting members of Liberia's senate, are much less formal than traditional

studio portraits. The sitters are posed as if working in the Senate chamber. Liberian artist Robert K. Griffin used these images as studies for a watercolor painting of the Senate he created in the mid 1850s. Washington also worked outdoors, producing landscape views of Monrovia that were published by the American Colonization Society. Unfortunately, these images are known only through published engravings.

When business slowed in Liberia, Washington traveled to Sierra Leone, Gambia, and Senegal to ply his trade. Eventually, he exhausted his daguerreotype supplies. He placed orders with suppliers in the United States, but had to wait several months before he received supplies, causing disruptions in business.

Despite his early success as a daguerreotypist in Monrovia, Washington became convinced that the only practical means of securing wealth, prosperity, and political importance in Liberia lay in developing the country's agricultural resources. Washington established a farm on the St. Paul River, twenty miles from Monrovia, where he grew sugarcane and other crops. At its peak, his farm employed more than fifty workers. He also held various positions in Liberia's House and Senate, including speaker.

Washington died in Monrovia, Liberia on 7 June 1875. At the time of his death, he was the owner and editor of the *New Era* newspaper.

Approximately sixty-five portrait daguerreotypes by Augustus Washington are extant. His daguerreotypes are in the collections of the Library of Congress, the Connecticut Historical Society, and the Smithsonian Institution, as well as many private collections.

CAROL JOHNSON

Biography

Augustus Washington was born in 1820 or 1821 in Trenton, New Jersey. He married Cordelia Aiken in 1850. The couple had three children. Washington was one of a small number of African American photographers to work as a daguerreotypist in the middle of the nineteenth century. He initially pursued photography in order to finance his education, selling portraits while studying at Dartmouth College in Hanover, New Hampshire. In 1846 he opened a successful daguerreotype studio in Hartford, Connecticut, where his sitters included the abolitionist John Brown. In 1852 he was awarded a silver medal for his portraits from the Hartford County Agricultural Society. The following year, Washington and his family moved to Liberia, on the west coast of Africa, where he continued to make daguerreotypes until he established himself as a farmer, political figure, and businessman. Washington died on 7 June 1875 in Monrovia, Liberia.

WATERHOUSE, JAMES (1842–1922)

James Waterhouse was a career soldier who made significant contributions in a number of technical and historical areas of photography. He was an industrious writer who combined a desire to innovate with aesthetic awareness and an antiquarian's sensibility. His keenness to explore unusual avenues was tempered by a readiness to retract when they turned out to be cul-de-sacs. He showed a willingness to go back to first principles to learn lessons of contemporary relevance, as with his examination of the daguerreotype process. His reputation has not endured for a number of reasons: the specialised nature of the subjects he scrutinised; because many of his articles were published in India and did not achieve a wide circulation; and because his findings were often incorporated into the research of later historians without appropriate attribution.

Waterhouse began his military training at the East India Company's Addiscombe College, where he was probably introduced to photography. Most of his service was spent in India as Assistant Surveyor-General. Part of the work of the Survey of India was concerned with making the production of maps and engineering plans more efficient, and Waterhouse researched improved techniques of photo-mechanical reproduction, as described in Charles Black's 1891 overview of the work of the Indian Surveys.

In 1878 Waterhouse toured European photographic laboratories, notably the Military Geographical Institute in Vienna, augmenting his findings with his own experiments, as a result of which he introduced improvements in photo-collotype and photolithography. In 1882 he developed a heliogravure technique for producing halftone prints. In 1887, after another visit to Vienna, he introduced a photo-etching process that was a great im-

provement over photo-collotype because it had greater resistance to variations in temperature and humidity, and could make far more impressions.

He became an authority on photography under tropical conditions, making numerous chemical trials using ingredients available locally. After confirming Vogel's 1873 finding that the sensitivity of plates to red and green could be enhanced, he examined the efficacy of other dyes, notably eosine, which in 1875 he discovered had the effect of increasing the sensitivity of haloid salts of silver to yellow light. In his presidential review for the Asiatic Society of Bengal in February 1889 he was able to outline the usefulness of eosine in preparing orthochromatic plates for use in copying paintings and photo-spectroscopy. That year he also established the effect of alizarine blue in increasing the sensitiveness of gelatine dry plates to the red end of the spectrum.

As well as his scientific studies, Waterhouse undertook three trips around central India in 1862 during which he took large quantities of photographs under difficult conditions for the pioneering ethnographic study *The People of India*, published in eight volumes between 1868 and 1875. He participated in the observations of the total solar eclipses of 1871 and 1875. For the observation of the transit of Venus in 1874 he took 100 photographs at Roorkee in India, and was fortunate to take the only sharp image of all the expeditions.

In 1875 he published the results of experiments on the solar spectrum using an aniline blue dye he had obtained from a local market. This enabled him to record lines in the solar spectrum less refrangible than A, but reversed: absorption lines appeared opaque on the transparent body of the spectrum instead of the normal transparent on an opaque body. He amplified these findings in a paper read to the Royal Photographic Society (RPS) in 1898 in which he noted that the degree of reversal tended to be a function of length of exposure and varied according to the stain used.

In 1890 Waterhouse found that adding thiourea to an alkaline developer caused a reversal of the image on dry plates but without a significant increase in the length of exposure, and in the same year he examined guaiacol as a cheaper alternative to catechol as a developer for dry plates. The following year he examined the generation of electrical current during development of gelatine dry plates. He returned to guaiacol in 1893, reporting on chemical analyses of it and allied phenoloid compounds, and in an addendum noted that the Lumières in Lyon had found that guiaicol in its pure form was not a developer, and that any developing action was caused by impurities. He followed up a paper by the Lumères in 1899 on the efficacy of fatty amines as accelerating agents, establishing that dipropylamine was the best but of limited practical benefit because of its price.

In 1893 he published a paper on the effect of light on silver salts and devoted the 1899 Traill Taylor Memorial Lecture to an analysis of the daguerreotype process and the lessons it held concerning the action of light on silver haloid compounds. The theme was continued in a paper he presented to The Royal Society the following year on the degrees of sensitivity of metals to light, in which he reported a wide range of experiments conducted on different forms of silver surfaces, as well as other metals, in order to examine the chemical reactions involved.

During his retirement,Waterhouse engaged more in historical research, but always with an eye on contemporary relevance. He studied the early history of the telephoto lens, and his influential paper on the camera obscura gathered a large number of references, in the process demolishing Porta's claim to have invented the device. He surveyed the pre-history of photography in the Smithsonian Institution annual report of 1903. Significantly, his 1905 presidential address to the RPS was on "by-ways of photography."

As well as technical articles, he was happy to write for a more popular audience, for example contributing an article on Niepce's early photographic work with bitumen to *Penrose's Pictorial Annual* for 1913–1914. He organised the Victoria and Albert Museum's 1905 *Loan Exhibition of Process Engraving*, for which he wrote the catalogue's introduction. Waterhouse was awarded the RPS's Progress Medal in 1890 for his spectrographic work on dyes and the development of orthochromatic photography, and the Voigtländer Medal of the Vienna Photographic Society in 1895 for his contributions to scientific photography.

TOM RUFFLES

Biography

James John Waterhouse was born 24 July 1842 and joined the Royal Bengal Artillery at 17. From July 1866 he spent five months with the Great Trigonometrical Survey at Dehra Dun learning photozincography before becaming Assistant Surveyor-General in charge of the photography section in the Surveyor-General's Office in Calcutta. As well as writing on photography, he also published on general matters relating to the Survey. He retired in 1897 with the rank of Major-General, when he returned to England. He never married. Among other positions, he was President of the Asiatic Society of Bengal from 1888 to 1890, President of the Photographic Society of India from 1894 to 1897, and President of the Royal Photographic Society from 1905 to 1907. He became a Fellow of the Royal Astronomical Society in 1876. He died at Eltham on 28 September 1922.

A portrait of James Waterhouse appears in *The Photographic Journal*, vol. 27 (1903): 217.

WATKINS, ALFRED (1855–1935)

Following practical experience with the wet-plate process in the 1870s, Alfred Watkins welcomed the arrival of the dry plate, and within a few years, his accumulated skills encouraged him to address some of the perceived complications of photography. In the 1880s, he worked as a commercial traveller in Hereford, and annexed an out-building to set up the Watkins Meter Company, where he devised instruments to control bakery processes, as well as meters to simplify photographic tasks. His background knowledge allowed him to compress a number of associated factors into one single function.

On the death of his father in 1889, Watkins declined to join the family firm, but concentrated on local history and photography. In 1890, he addressed the Society of Chemical Industry to launch his Standard Exposure Meter, which combined an actinometer and calculator, in a tubular form. By analogy, the actinometer related the time to darken a sensitised paper, to camera exposure. A chain served as a pendulum for counting the actinometric record (that is, the strength of the ambient light) as well as timing seconds (for the chosen plate), and the calculator expressed five variable factors as the exposure recommendation. By dispensing with his "subject factor," Watkins introduced the simpler Junior Meter in 1895, along with the New Standard Exposure Meter, which was "absolutely complete for all problems," including copying, enlarging and contact printing. The compact Watch Exposure Meter followed and the pendulum survived, but the movements were simplified to a single scale. Watkins' ideas on photometry kept pace with improvements in photography, and in 1902, the design of the Watkins Bee Meter anticipated interchangeable printed discs at a later date to cope with cinematography, colour and studio conditions. (The Queen Bee Meters of 1903 and 1908 were de-luxe versions in a silver case and complete with a ball and chain pendulum.) Other meters included the Focal Plane (1907), the Colour Plate (1909), the Hand Camera and the Chronograph (1910), the Indoor (1911), and in 1920, the Watkins Snipe Meter, a simple meter for avoiding under-exposed snapshots.

All designs were supported by practical tests and Watkins' five axioms ("the standard truths"), identified the essentials of exposure, from which he determined a protocol to determine emulsion speed. That is, "an object of average colour twenty-five feet from lens" became the "standard" for two seconds of' exposure to mid-day June sunlight in England; his basic plate speed (1). Using this criterion, he issued annual lists of speeds, until he was able to derive his required values from speeds determined by the Hurter and Driffield method. In 1894, he promoted a simple system for correct development, which applied a factor (the Watkins Factor) to the appearance of the negative image.

In 1910, Watkins received The Royal Photographic Society's Progress Medal for his "methods and applications" relating to exposure and development. In spite of his photographic achievements, in many circles Alfred Watkins was better known as an antiquarian, who surveyed churches, pigeon-houses and standing crosses, prior to announcing controversial studies of ancient track ways, and founding the Old Straight Track Club in the 1920s.

WATKINS, CARLETON E. (1829–1916)

American photographer

Well-known photographers of the nineteenth-century American West such as Charles Roscoe Savage, Timothy O'Sullivan, Jack Hillers, Andrew Joseph Russell, and William Henry Jackson are all praised for a variety of reasons. They documented historical events, they traveled to the remote corners of the West and photographed its spectacular scenery, they furthered the budding science of geology, and they documented the natural resources of the West for the United States Congress and the American public. Carleton Eugene Watkins, however, in addition to doing all of the above also gained critical acclaim as an artist. Not only did Watkins win praise from his contemporaries in the Eastern United States and also in Europe, but he was also praised by subsequent generations of art historians and critics. Initially Watkins was recognized mainly for his photographs of the area now known as Yosemite National Park. Despite the difficulties of taking mammoth-plate negatives in an incredibly remote area, these images were known for their composition, flawless character, depth of detail, and excellent use of light. Watkins, however, photographed up and down the West Coast (as far north as British Columbia and as far South as Mexico) and also in Arizona, Nevada, Utah, Idaho, Montana, and Wyoming. While it is true that throughout his life he pursued nature's "grand view," Watkins also sought to show the subtle relationships between man and nature.

C. E. Watkins was born on November 11, 1829, in Oneonta, New York the oldest of eight children. In 1851 he left New York for California with another Oneonta native, Collis Huntington. Huntington was destined to become one of the most wealthy and powerful men in California and throughout Watkins' life he received financial support from his friend. Watkins initially worked as a clerk in Huntington's Sacramento store, but after a fire destroyed the store in 1852 he became a clerk in a bookstore owned by George W. Murray. Murray and Watkins would relocate to San Francisco in 1853 and in the fall of 1854 well-established daguerreotypist Robert Vance asked Watkins to temporarily replace an employee who had suddenly left his job.

Watkins learned the job so well that Vance kept him employed taking studio portraits. In 1856 Watkins left Vance to run a studio in San Jose (specializing in ambrotypes of babies), but apparently Wakins left that job as well before the end of the year. Watkins's activities

between 1856 and 1860 are not entirely clear. In 1858 he took photographs of the Guadelupe Quicksilver Mine for a land fraud case. In 1859 and 1860 he was hired by John C. Fremont and Trenor William Park to photograph their Mariposa estate. Watkins also took photographs of the New Almaden and New Indria Mines and Washerwoman's Bay at San Francisco. In 1861 his photographs were used as evidence in *U.S. v. D. and V. Peralta*. It was this experience that prompted him to build one of the earliest mammoth-plate cameras in America, capable of taking eighteen by twenty inch negatives.

By 1861 Watkins had established a more or less permanent studio in San Francisco. Although by that time he had earned a reputation as a competent outdoor photographer, it was the 30 mammoth-plate negatives and the 100 stereo-view negatives Watkins took of the Yosemite area that brought him national and even international praise. Watkins was not the first photographer to visit Yosemite (C.L. Weed had taken pictures there in 1859). He was, however, the first to use a mammoth-plate camera to achieve incredibly detailed views. In 1862 Goupil's Art Gallery in New York City featured the Yosemite photographs in an extremely popular exhibit. Copies of his Yosemite images won praise from Oliver Wendell Holmes, Ralph Waldo Emerson, and from the leading American photographic magazine, the *Philadelphia Photographer.* Watkins's photographs also no doubt played a part with legislation passed by the United States Congress in 1864 declaring Yosemite to be "Inviolate." Watkins became the first American photographer whose prints were displayed as fine art.

Due to the widespread interest with his Yosemite pictures, Watkins's other photographic exploits have not received as much attention. For three decades he crisscrossed California photographing railroads, mines, different species of trees, private estates, old Spanish missions, the Sierra Nevada mountains, the coastline, the San Francisco Bay area, and, of course, Yosemite. In 1867 Watkins also took the first of many out-of-state trips, photographing Oregon's coastline, settlements, mountains, and the Columbia River. On later trips he photographed the Comstock Lode mines in Nevada (1871 and 1875), scenes along the Central Pacific and Union Pacific Railroads in Nevada and Utah (1873), the Southern Pacific Railroad route in Arizona (1880), the coastlines of Washington and British Columbia (1882), and scenes in Idaho, Montana, and Yellowstone National Park (1884 and 1885). His last major trip was to the mines in Butte Montana in 1890.

Despite widespread acclaim, poor business decisions and bad fortune hurt the aging photographer financially. In the early 1860s he failed to identify and copyright his work and consequently many of his views were pirated and reprinted. In the mid-1870s his studio and collection of negatives were seized by creditors and sold to a competitor, I.W. Tabor, who reissued many of the images without credit. As tourism increased in the late nineteenth-century, his artistic style did not work well with tourists who wanted cheap and predictable images. Watkins' had trouble paying his bills and was forced to change studio locations on a number of occasions. Furthermore he did not advertise, instead relying on word of mouth, which no doubt created confusion for his would be customers. At the brink of almost complete destitution in the 1890s, his old friend Huntington stepped in and gave Watkins a small ranch near Sacramento as a retirement home. He lived at the ranch for several years before moving back to San Francisco. Unfortunately for posterity, the 1906 San Francisco earthquake destroyed all of his negatives along with a priceless collection of early California daguerreotypes. Tragically, this material was about to be transferred to the state for safekeeping. After the earthquake Watkins's health and mind continued to deteriorate and he died in 1916 at the Napa State Hospital for the Insane.

Daniel M. Davis

Biography

Carleton E. Watkins was born in 1829 in Oneonta, New York. He moved to Sacramento California in 1851 and worked as a clerk and as a carpenter before being trained by Robert Vance as a portrait daguerreotypist. He soon moved to outdoor photography and he took a variety of commissions around the San Francisco Bay area between 1856 and 1861. The images that would make him famous, however, were taken in 1861 of the spectacular Yosemite region. These photographs won praise throughout the United States and even in Europe and were probably the first photographs taken by an American to be considered fine art. Watkins was not only a technical expert at using a mammoth camera to produce incredibly detailed and flawless negatives, but he also had an eye for composition and light. Although Watkins is best known for his Yosemite images, he traveled throughout the West Coast and in other western states in the 1860s, 1870s and 1880s. These later views show a sensitivity to the relationships between the frontier American settlements and the natural resources that supported them. Although Watkins had a generous and warm personality, he was a poor businessman. He suffered a series of financial and personal setbacks, and at one point he and his family (he married Frances "Frankie" Henrietta Sneed in 1879) were living in a railroad car. He was fortunate though to have the support of Collis Huntington, Josiah D. Whitney and others who supported him fiscally and encouraged him artistically. He died in Napa, California in 1916.

WATKINS, HERBERT (1828–C.1901)
English portrait photographer

George Herbert Watkins was born in Worcester, England, on July 12, 1828, and was still alive at the time of the 1901 census, aged 73, and living in the Kensington Workhouse. At the same date, his wife Augustin was listed as a widow living alone.

Watkins' first studio opened at No.179 in London's Regent Street in the mid 1850s, producing high quality portraiture, and by 1858 had moved to No.215. His first public display of his celebrity portraits was at the 1856 Exhibition of the Photographic Society in London. In the 1857 Exhibition he included portraits of Owen Jones, George Cruikshank, and others, and a fine portrait of Charles Dickens working at his desk.

His *National Gallery of Photographic Portraits* with accompanying texts by Herbert Fry, a ten-part 'photographic serial' was published in 1857 continued publication into 1858, each issue containing four or five portraits. By 1857 he was additionally producing still life images and, most particularly, microphotographs. Along with John Benjamin Dancer, George Shadbolt and Alfred Rosling, he was a leading figure in the production of these tiny images. Watkins marketed many of his portraits as cartes-de-visite throughout the 1860s and 70s, subjects including celebrated portraits of Wilkie Collins, Michael Faraday and many others.

The 1871 census listed him as living alone in St. Pancras.

JOHN HANNAVY

WATSON, WILLIAM (1815–1881) & SONS
Optician and optics manufacturer

William Watson established his business as an optician in 1837 in London. It moved to 313 High Holborn in 1862 and remained there until 1957 before moving to Barnet, Hertfordshire, where it had had a manufactory since 1906. In 1957 the firm was acquired by Pye and in 1967 it was taken over by Philips, finally closing in 1981.

Watson's son, Thomas Parsons Watson, was responsible for extending the firm's business into optical instrument manufacturing in 1876 when it began making microscopes, one of its most successful and long-lived product lines. A manufactory was established at Dyer's Buildings at the rear of the main premises. The manufacturing of cameras and photographic equipment commenced about the same time. By 1888 extra manufacturing capacity was acquired at Fulwood Rents in Holborn, and finally in 1906 all manufacturing was moved to High Barnet. The factory at Barnet was destroyed by fire in 1910, was rebuilt, and further extended in 1936 and 1950.

Although microscopes continued to be important, photography increasingly occupied an equal position within the firm and in 1878 Watson was appointed the exclusive selling agent for Charles Bennett's gelatine dry plates. The firm's cameras included traditional mahogany tailboard such as the Tourist of 1883 and field cameras for studio and outdoor use with the patented Acme of 1889 being one it's most successful lines. In 1886 their Detective camera was one of the earliest hand cameras available. A number of patents were taken out relating to various photographic improvements.

The firm was an early adopter of standardisation in camera manufacturing and in January 1888 announced that all their own cameras would be built to standard gauges with interchangeable fittings and dark slides. These cameras were identifiable with serial numbers from 6000 onwards starting from January 1, 1888.

Watsons introduced the Vanneck hand camera in 1890 which used an Eastman-Walker roll holder. The camera was still being made in 1902. The Alpa of 1892 was a popular drop-baseboard camera and the 1898 Gambier-Bolton camera was a specialist reflex camera for use with long focus lenses. It had been designed by F W Mills and named after a well-known nature photographer. A twin lens camera appeared in 1894. The firm retailed more complex mechanical cameras from other manufacturers, such as the stereo binocular and monocular models made in Germany.

Their own wood cameras were usually made up in batches of fifty. Watson sold directly in Britain and overseas, and made cameras for other companies to sell under their own name. An Australian sales office

was established in Melbourne in 1886 which operated semi-independently for many years.

It also made a series of portrait, rapid rectilinear, wide-angle and landscape lenses which were later fitted with iris diaphragms. Their Holostigmat Convertible of 1905 was computed by Alexander E Conrady (1866–1944) the firm's optical advisor who was later professor of optics at Imperial College.

Watson was active in areas allied to photography. In 1895 it entered the new area of Röntgen (or X-ray) photography making apparatus in its own works and giving demonstrations in London hospitals. In 1911 a separate branch was established to handle this field and Watson & Sons (Electro-Medical) Ltd was incorporated in 1915, eventually becoming part of GEC. It was briefly involved with cinematography, introducing in late 1896 its Motograph, a well-regarded compact 35mm camera/projector for amateur use. Films were also supplied.

During the early twentieth century until the Second World War, the firm continued to sell its Premier tailboard, Acme field and Alpha hand and reflex cameras but photography became secondary to the manufacture of scientific and optical instruments. One notable exception was the granting of a patent (current untraced) to the company with A C Edwards in 1909 for an antinous release, more generically known as a cable release. Watson was the sole licensee and had sales in the hundreds of thousand.

During the Second World War, it subcontracted the making of cameras to Gandolfi while it concentrated on producing optical munitions. After the war the last family connection with the firm was severed in 1949 when W E Watson-Baker sold his interest to Captain James Cook, a financier and other than the standard Premier camera only special purpose cameras were then advertised.

WATTLES, JAMES M. (B. 1812)

The only reference to James Wattles in contemporary accounts of the evolution of photography comes from a meeting between Wattles and Henry Hunt Snelling, recounted in Snelling's 1849 book *The History and Practice of the Art of Photography*.

According to Snelling, Wattles, of New Harmony, Indiana, claimed to have successfully made paper negatives with his camera obscura as early as 1828, at the age of only sixteen.

After meeting Wattles, who was 'wholly ignorant of even the first principles of chemistry, and natural philosophy,' Snelling became convinced of Wattles' claim to have produced 'solar picture drawings' on paper soaked in what Wattles described as 'caustic' and then 'common potash.' After exposures of 45 minutes, he then fixed them in a salt solution and assured Snelling that he 'plainly perceived the effect, in the gradual darkening of various parts of the view, which was the old stone fort in the rear of the school garden, with the trees, fences, &c.' Despite the imperfection of his efforts, Wattles reportedly persevered with his experiments and was increasingly satisfied with the results. He offered Snelling several names who could support his claim, but no further account of his experiments have been traced.

John Hannavy

WATZEK, HANS (1848–1903)

German photographer

Hans (Johann Josef) Watzek was born on December 20, 1848, in Bílina/Tschechien to a buyer. He visited the academies of arts in Leipzig and Munich and worked toward end of the 1860s as a freelance artist. In Vienna Watzek received training as an art teacher in 1872 at the college of arts and crafts. He taught in Boehmen and established himself starting from 1875 in Vienna. In 1891 he joined a group of amateur photographers in Vienna (the later Camera Club Vienna). By experiments with a simple pinhole camera and the "Monokel" (a simple achromatic eyeglass lens, which is used as a lens in a camera) he, began to consciously use Unschaerfe (blurring) as style means. He dedicated himself to the landscape of his immediate surroundingsof Vienna. In 1893 he was accepted as a member of the Linked Ring Brotherhood London. Together with Heinrich Kühn and Hugo Henneberg, Watzek developed in 1896 multiple gum prints. He was, with Kühn and Henneberg one of the Vienna trifolium from 1897, marking his work with a three-leafed clover symbol. Watzek is considered one the most important Austria Pictorialists. He published numerous articles on primarily technical topics in German-language technical periodicals. Watzek died on May 12, 1903, in Vienna after a long illness.

Astrid Lechner

WAXED PAPER PROCESS

When Gaspard Feix Tournachon called, Nadar (1820–1910) wrote in his memoirs "Photography whistled and Le Gray came running." He characterized the exuberant

spirit of one of the most zealous and creative artists to try their hand at photography. The painter Gustave Le Gray (1820–1882) began experimenting with the daguerreotype as early as 1847 and the following year was using variants of Henry Talbot's calotype process. Within three years, he had produced a highly innovative photographic system, the waxed paper negative process. Although the process is part of the paper negative family, it uniquely stands apart from the decade-old calotype announced in 1841.

The crucial difference between the calotype and the waxed paper process is in the preparation of the paper. In the calotype process, a sheet of high quality paper is sensitized with a combination of silver halides, exposed in a camera (either in a dry state or slightly damp), removed, developed, and fixed with sodium thiosulphate. After processing, the translucency of the paper negative could be increased by saturating with wax. This helped increase the contrast and shorten printing times.

In most respects, the preparation of the waxed paper negative parallels the preparation of the calotype, except for one important difference: in Le Gray's waxed paper negative process, the paper is saturated with wax *before* the chemical sensitization. This simple reversal of one step profoundly alters the qualities of the paper. First and foremost, saturating the paper with wax evens out the texture of the paper and fills the interstices of the paper fiber matrix. In its natural state, paper is an overlapping, random web of fibers, held together by chemical and physical interactions. Light can and will travel through this matrix, but will be reflected off of each paper fiber in its path, decreasing in intensity as it passes through. By filling in the interstices of the fiber matrix, the wax changes the sheet's refractive qualities, allowing the light to pass through in a more direct path. The treatment with wax renders the paper negative more homogenous then the calotype and the individual paper fibers will not be as visually pronounced in the final print. The wax, however, does not completely fill the paper, and the sensitizing chemistry is still able to bond and anchor to the cellulose.

A second advantage of the waxed paper process was improved wet strength. The time required to develop a paper negative could be considerable, an hour or more, especially if the photographer was trying to compensate for underexposure. This meant prolonged submersion in an aqueous solution, at the end of which the operator had to handle a water-logged sheet of paper. With the waxed paper negative, much thinner, machine made papers could be employed without the fear of tearing.

Finally, the most practical advantage offered by the new negative process was its impressive longevity. Because of the protective qualities of the wax, a week's supply of fully prepared paper could be stored, ready for photographic excursions. This was an incredible boon to travelling photographers who could prepare negatives ahead of time and consequently lighten the load of photographic equipment required for travel. There were, however, contradictory reports from those travelling in extreme climates. Some accounts suggest difficulty with the process, such as Maxime duCamp (1822–1894), who, despite being instructed by Le Gray himself, failed all attempts at the waxed paper process once he reached Egypt and turned to a variant of the calotype, the wet paper process.

Paper negatives are hand made objects, subject to variations at every stage of preparation, from the selection of paper to sensitizing, processing and printing. However, during the first decade of photography, the range of off-the shelf photographic supplies increased and by mid 1850, waxed paper negative devotees could purchase pre-waxed and pre-iodized papers. In some products, quality was suspect, as noted by the Scottish surgeon and photographer Thomas Keith (1827–1885):

> I have always waxed my own paper, as what I bought waxed was so bad that the half of it was generally useless. By doing it yourself you have it much better done, and it is much more economical then buying it waxed. (*Photographic Notes*, June 10, 1856)

Post-processing manipulations paralleled those of the calotype, including re-fixing, chemical intensification and even reheating the already waxed sheet in an effort to improve weak negatives. Flaws in the image such as spots and stains could be retouched, although the waxy surface made soft graphite stick and powder the media of choice: gouache and watercolor would not readily adhere. Like all other paper negatives, the substrate would easily tear and crease, but was considered robust and durable when compared to the breakable and heavy glass plate negative.

The final image can appear on both the recto and verso of the sheet, and a waxed paper negative can be much darker in normal reflected illumination than its sister process, the calotype. When viewed through transmitted light, however, the dark muddy sheet is transformed into a bright, glowing negative of astounding detail.

Le Gray's endless experimenting led to other innovations and fostered a school of followers who in turn promulgated numerous and unusual modifications to the photographic formulas of the day, such as the turpentine waxed-paper process. Most of the formulas altered the basic process by adding organic components such as gelatin, albumin, collodion, sugar, or lactose. Although the exposures times were reduced, the wax-saturated paper lengthened the processing times and in the hands of a skilled operator, the results were breathtaking.

Some of the greatest photographers of the 19th

century practiced the waxed paper negative. In France, Charles Negre (1820–1880) and Henri Le Secq (1818–1882) followed Le Gray from painting to photography. Victor Prevost (1820–1881) was also trained by Le Gray and traveled to New York. In England, Roger Fenton (1819–1869) was a key photographer in the development of the process, and the young American John Beasley Greene, distinguished himself ca 1856.

Le Gray practiced the wet collodion and waxed paper processes side-by-side throughout much of his photographic career, but by the 1870's he and the rest of the photographic community had completely turned to glass plate photography.

WEDGWOOD, THOMAS (1771–1805)

English experimenter

Wedgwood, collaborator with Humphry Davy on the first published account of photographic experiments, was the son of the famous English potter and industrialist Josiah Wedgwood. Educated largely at home under the direction of his wealthy and doting father, Tom Wedgwood was given expert tutoring in almost every field of knowledge, from science to art, and counted as friends some of Britain's leading intellectual figures. Although handicapped by a lifelong illness that eventually was to take his life at an early age, he nevertheless worked on a number of projects that attracted the attention of his peers, some practical and some merely philosophical. However it is for his experiments towards a photographic process that he is best remembered today.

It is unclear when he began these experiments. In November 1790, for example, he was working with nitrate of silver at his father's ceramics business, leading to his invention of a 'silvered ware' in about February 1791. He also had essays on his observations of light read at the Royal Society, and wrote speculatively about optics and "Time, Space, and Motion." These last interests he shared with his close friend, the English poet Samuel Taylor Coleridge, whom he first met in 1797. So close were they that Tom and his brother granted Coleridge a lifetime annuity that enabled the poet to travel to Germany in 1798 and study German idealist philosophy at first hand. Exposure to these radical new ideas undoubtedly stimulated Tom Wedgwood's thinking during the period in which he experimented with photography.

Despite the existence of some undated letters referring vaguely to "Silver Pictures," the only noncircumstantial evidence of these experiments is an essay that appeared in the first issue of the *Journals of the Royal Institution of Great Britain* in June of 1802. Co-written with its editor, the twenty-four year old Davy, the essay was titled 'An Account of a Method of Copying Paintings Upon Glass, and of Making Profiles, by the Agency of Light Upon Nitrate of Silver,' and describes various experiments the two men had undertaken with white paper or leather moistened with a solution of silver nitrate and exposed to light.

> White paper, or white leather, moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but, on being exposed to the day light, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black...
>
> The condensation of these facts enables us readily to understand the method by which the outlines and shades of painting on glass may be copied, or profiles of figures procured, by the agency of light...
>
> The images formed by means of a camera obscura, have been found to be too faint to produce, in any moderate time, an effect upon the nitrate of silver. To copy these images, was the first object of Mr Wedgwood, in his researches on the subject, and for this purpose he first used the nitrate of silver, which was mentioned to him by a friend, as a substance very sensible to the influence of light; but all his numerous experiments as to their primary end proved unsuccessful.... Nothing but a method of preventing the unshaded part of the delineation from being coloured by exposure to the day is wanting, to render the process as useful as it is elegant.

Despite their inability to make their images permanent, in the space of five short pages Davy and Wedgwood describe an impressive range of photographic ideas and applications. Wedgwood apparently began by attempting to capture the image formed by the camera obscura, and only subsequently moved on to the problem of copying pre-existing images. Of these, the

two experimenters attempted to copy paintings on glass (such as those used for projection devices) and "profiles of figures" (perhaps a reference to silhouette portraits). They also made contact prints using leaves and insect wings as well as engraved prints. Davy tells us that he himself made images of small objects using a solar microscope and "prepared paper." Their friend Anthony Carlisle recalled in 1839 that he had also undertaken several experiments with Wedgwood in about 1799 "to obtain and fix the shadows of objects by exposing the figures painted on glass, to fall upon a flat surface of shamoy leather wetted with nitrate of silver, and fixed in a case made for a stuffed bird."

Amidst these creative variations on the basic idea, Wedgwood and Davy also undertook numerous comparative experiments using different materials, solutions and processes. They exposed both white paper and white leather moistened with a solution of nitrate of silver in direct sunlight and then in shade, as well as under red, yellow, green, blue and violet glass. They tried, unsuccessfully, to remove the delineations so produced with both water and soapy water, and attempted, equally unsuccessfully, to prevent further development by covering the image with a thin coat of varnish. Davy also experimented with different solutions of nitrate and water, and with muriate of silver (a chloride which he found to be less suited to the task than the nitrate). He even gives practical advice about how best to apply the resulting solution to one's paper or leather. Finally, he not only recognizes the lack of image permanency as a problem but also suggests a plausible theoretical answer to it—on which subject, he tells us, "some experiments have been imagined" (although, it seems, never undertaken). So, thirty seven years before Daguerre and Talbot were to announce their own discoveries to the world, the 'Account' gives us many elements of the concept of photography. Sadly, Wedgwood was to die only three years later, and Davy, then in big demand as an experimental scientist, went on to other projects and did no further work on photography. However their 'Account' was republished in numerous European and American journals and informed the later and more successful experiments of, among others, William Henry Fox Talbot.

WEED, CHARLES LEANDER (1824–1903)

American photographer

Charles Leander Weed was born on July 17, 1824, in New York State. Raised in Wisconsin, he traveled to

Attributed to Charles Weed or Eadweard J. Muybridge. Mirro View of El Captain. Yo-Semite Valley.
The J. Paul Getty Museum, Los Angeles © The J. Paul Getty Museum.

California at an unknown date. His photographic career began in 1854 as a daguerreotypist, and he later formed a partnership with Robert Vance between 1858–1859. Weed rose to prominence after his June 1859 trip to Yosemite Valley and publication of some of his photographs as engravings. Carleton Eugene Watkins was inspired by these images to create his own large prints of Yosemite. Both Weed and Watkins exhibited their prize-winning "mammoth-plate" prints at the 1867 Paris International Exposition. A remarkable aspect of Weed's career were travels to Hong Kong, China and Honolulu where he established four studios between 1860 and 1866, returning to California in 1861 before going back to Hong Kong via Honolulu in 1865. From 1864 to 1870 Weed associated himself with publisher Lawrence & Houseworth (later Thomas Houseworth & Co.), then operated his own studio or worked for other photographers and photo publishers in the 1870s. Married to Sarah P. Weed (born March 30, 1833) in the mid-1870s, they resided in Oakland, California, until his death on August 31, 1903. Weed's photographs survive only as prints in various formats, principally stereographs and albumen prints, with the Bancroft Library, University of California, Berkeley, and the New York Public Library, holding significant examples, including the 1864 Yosemite Valley mammoth-plate prints.

DAVID MATTISON

WEGENER, OTTO (1849–1922)

Otto Wegener was born in Helsingborg, Sweden, and moved to Paris, France, 1867. Nothing is known about his introduction to photography; all we know is that he opened his magnificient studio at the fashionable address 3, Place de la Madeleine in 1883, successfully competing with Nadar and Reutlinger for the elite audience.

He had then already simplified his name to Otto, a signature that gleamed in gold above the sixth floor on the building. He maintained contacts with the Swedish colony of artists and the writer August Strindberg dined in his house 1894.

A Swedish journalist wrote an appendix to a book about Paris and described him as the leading photographer in the capital, representing France at the Paris World Exhibition in 1900. Only one photographer made more money than Otto, and still did not have his aristocratic customers, nor his artistic merits. Visitors lined up outside his gallery on Rue Royale—where one of his apprentices, Edward Steichen, was given an exhibition. Otto even represented France in international photo exhibitions in Dresden 1908 and Leipzig 1914.

That year, 1914, the leading Swedish pictorialist Henry B. Goodwin visited him and wrote a piece in a monthly photo journal describing his four storey combination of studios, parlours, dark-rooms and living quarters, all filled with antiques, paintings and the art noveau furniture he loved to design.

He had studied the new reproduction methods as oil transfers and gum prints with Robert Demachy and Constant Puyo, and he still photographed with an Eidoscope soft focus lens.

Despite this success, he is usually overlooked in major works on the history of photography, and only few of his negatives can be traced in French archives.

PÄR RITTSEL

WEHNERT-BECKMANN, BERTHA (1815–1901)

Bertha Beckmann was born January 15, 1815, in Cottbus; there is no knowledge about any training until she met the "mechanicus," Eduard Wehnert in 1839 at Dresden. He opened a photographic studio in Leipzig in 1842 which she operated until 1843 in Dresden. She married Eduard Wehnert in 1845 and carried on his business after his sudden death in 1847 under the name of Wehnert-Beckmann. From 1849 to 1851, Bertha Beckmann owned a studio in New York City, and around 1866 there seemed to have existed a branch of her businesses in Vienna. Bertha Wehnert-Beckmann seemed to be the female entrepreneur par excellence in 19th century photography, any business she founded had prospered within a year or two, mostly concentrating on hitherto unusual aspects of portraiture like children photography. Basically, her work was of very good quality but in no way different from typical work, with the exception that she had a sensitive approach to human beings. She never seemed to have aimed at any fate but fulfilling the needs of her clients; her historical importance lies in the fact that she successfully practised photography in a male world for nearly half a century. She practised photography until 1883, with the assistance of her brother Rudolf Julius Arnold Beckmann. Bertha Beckmann died in Leipzig on Dec.6, 1901.

ROLF SACHSSE

WELFORD, WALTER D. (d. 1919)

Welford was born in Newcastle, and began his career as a journalist for the newly established sport of cycling. He founded and edited *Cycling* (1878–82), and issued a pioneer annual *Wheel man's Yearbook* in 1881. In 1884, persistent ill health forced his move to London, where he quickly immersed himself in photography, starting as sub- editor on *Photography*, in the late 1880s.

In rapid succession, Welford founded and edited the *Photographic Review of Reviews*, later revamped as

Photographic Review (1892–1897); the *Junior Photographer*, later entitled *Practical & Junior Photographer* (1894–1903); and *Photographic Life* (1897, published for 3 months), a title which Welford then reorganised to combine his twin interests as "Cycle & Camera" (1897–1898, published for 9 months). None of them, apparently, was particularly successful.

Welford wrote a standard manual on the hand camera (1892, 6th ed., 1901), and compiled with Henry Sturmey, the pioneer cycle manufacturer and publisher, encyclopaedias on photographic apparatus (1887), and optical lanterns (1888).

Ill health blighted his later years, though he remained a member of the staff of *Kinematograph Weekly* throughout World War I, and wrote a number of plays for the cinema. He died at his home in Islington in July 1919. Welford's wife Jeanie (1855–1949) was a talented photographer in her own right, specialising in topographical views, many of which were published in her husband's journals.

David Webb

WELLINGTON, JAMES BOOKER BLAKEMORE (1858–1939)

J. B. B. Wellington was trained as an architectural draughtsman, but following an early association with George Eastman, his career was entirely concerned with photography and photographic manufacturing.

He first met Eastman in the 1880s, and became the first manager of Eastman's British factory in Harrow, England.

During a short but successful career with Kodak, Wellington was responsible for, amongst others, a popular printing-out paper, and, in 1889, one of the first intensifiers for photographic negatives—formulated from silver nitrate, ammonium thiocyanate and sodium thiosulphate.

In 1896, after a short period of time with Elliot & Sons of Barnet, Wellington and his brother-in-law H. H. Ward, established the company Wellington & Ward, manufacturing dry plates. Wellington was scientific and technical director of the company, with Ward taking responsibility for engineering. This company was eventually taken over by Ilford Ltd in 1929.

Wellington, however, was also a photographer of note, joining the Linked Ring Brotherhood in 1892 with the pseudonym of 'Duke.' Like all 'links' he was expected to perform the honorary role of 'Centre Link' for about a month—a presidential role with no authority whatsoever—and assumed that position for three weeks in February 1894.

His finest images, some printed in carbon, were produced in the early decades of the 20th century.

John Hannavy

WERGE, JOHN (unknown)

John Werge arrived in America from Scotland in June 1853. Whilst travelling in the United States, he became acquainted with the leading exponents of the daguerreotype, amongst them Samuel Root, Matthew Brady, Platt D Babbitt and Jeremiah Gurney. He used examples of his work to gain employment in the New York studio of the Meade Brothers as a colourist and 'teacher of colouring' and, in his 1890 book *The Evolution of Photography* recalled demonstrating his skills in colouring daguerreotypes to Gurney and others. He met Babbitt at Niagara Falls, and later recalled that his own photography at the falls had been lost when a fire destroyed the Glasgow exhibition to which he had loaned them. He eventually returned to Scotland.

Werge took over the Monteith Rooms in 1856, the Glasgow photographic studio which had been established in 1846 by John Bernard, and later operated by Bernard and (from 1848) Cornelius Jabez Hughes. He established himself as one of Glasgow's leading portrait photographers, operating the studio for three years.

He returned to America in 1859, and operated a photographic and publishing business at 805 Broadway until at least 1861. Moving to England, he served on the committee of the South London Photographic Society 1868–70, and managed London's Berners Portrait Company 1874/5. *The Evolution of Photography*, published in London by Piper & Carter 1890, offered a first comprehensive history of photography's first fifty years.

WET COLLODION NEGATIVE

The wet-collodion negative process was developed in 1848 by F. Scott Archer (1813–1857) and first published in 1851. The process achieved popularity by the mid-1850s, dominating all other negative processes until 1881, gradually displacing both the daguerreotype and the calotype processes. The wet-collodion on glass negative process was desired both because the transparency of the glass yeilded high-resolution images, and because exposure times were shorter than for Daguerreotype or calotypes. Finished negatives were generally usually to produce albumen or salt prints.

The process derived its name from the use of collodion in liquid suspension to coat glass plates at the beginning of the sensitizing process before exposure. In the nineteenth century, the collodion used to coat glass plates was made from guncotton, a commercially-available medical dressing. Guncotton was derived from ordinary cotton that had been soaked in nitric and sulfuric acids, thoroughly washed, and dried. The guncotton was then dissolved the in a mixture of alcohol and ether to which potassium iodide had been added. The resulting collodion was a syrupy mixture. This mixture could be

prepared in advance in a shop or laboratory and transported into the field.

Immediately before the image was to be made, collodion was poured onto a clean glass plate, which was continuously tilted to produce an even coating. The size of the plate was dependent upon the required size of the finished print, and plates varied in size from under two inches square, to mammoth plates, measuring in excess of 20 × 24 inches. When the collodion had set but not dried (a matter of seconds), the plate was sensitized by bathing it in a solution of silver nitrate. During this bath, the silver nitrate reacted with the potassium iodide in the collodion to produce light-sensitive film of silver iodide. This sensitizing process could be carried out under yellow light.

While the plate was being sensitized, the camera operator finished composing the scene, set up the camera, and focused on the subject. After removal from the silver nitrate bath, the glass plate, now light-sensitive, was placed in a light-proof holder and transported to the camera while still wet. When the subject was ready and the film holder loaded into the camera, the "dark slide," a movable cover on the film holder, was moved to uncover the plate. The plate was finally exposed to the subject by removing the lens cap; exposure times ranged from less than one second to several minutes, depending upon the intensity of the light, and the age and quality of the collodion. When the proper exposure was made, the lens cap was replaced, and the "dark slide" returned to its closed position.

After exposure, the holder containing the plate was removed from the camera, returned to the darkroom and immediately developed in a solution of pyrogallic and acetic acids (a later refinement of the process used ferrous sulfate as a developer). The image became visible within a few seconds as the areas struck by light in the camera turn to metallic silver. When development was complete, the developing solution was removed by a wash of clean water. After fixing—usually in a tray of sodium thiosulfate (commonly called sodium hyposulphate in the nineteenth century)—to remove the unused silver halides, the plate was no longer sensitive to light, and could be removed from the darkroom and washed in fresh water. An alcohol lamp was then used to dry the plate. Once dry, and while still warm, the plate was coated with a protective varnish made from gum sandarac, alcohol and oil of lavender. The glass plate was then a negative, and could be used to make a wide variety of paper prints.

WET COLLODION POSITIVE PROCESSES

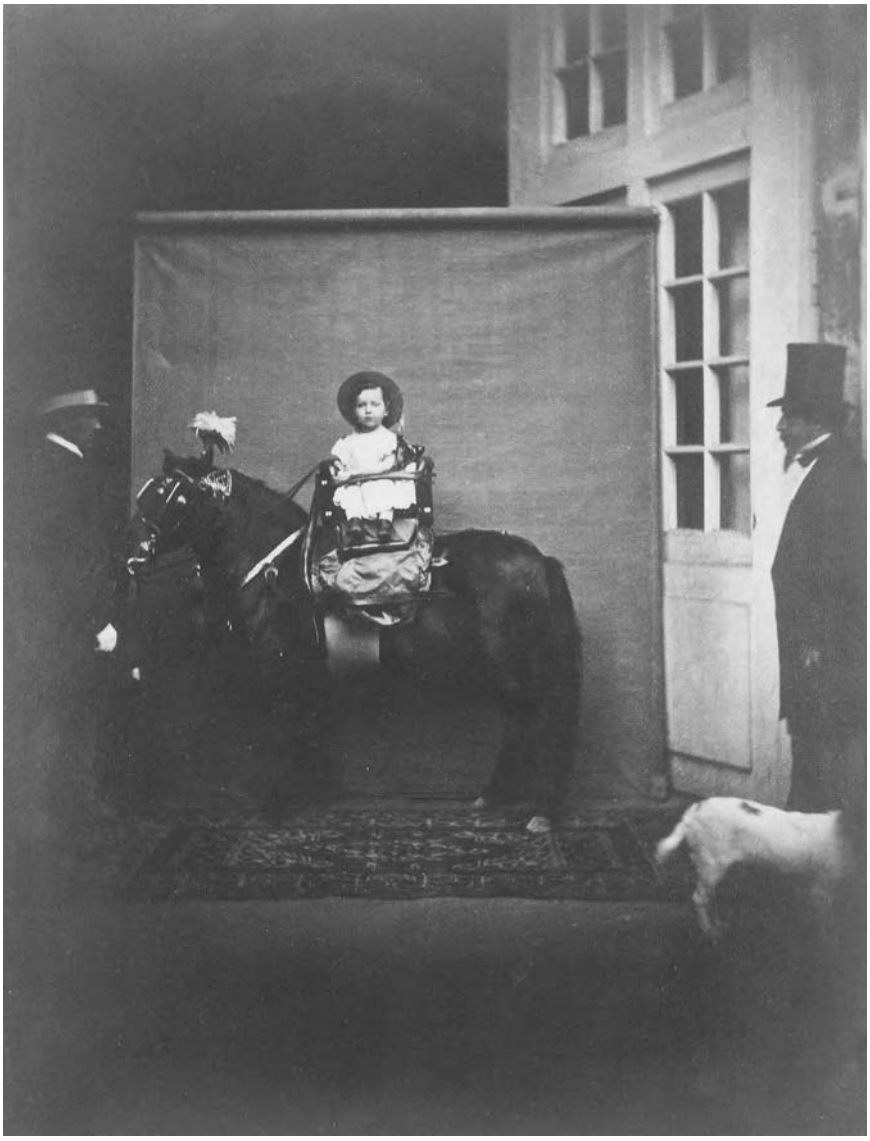
(Ambrotype, Pannotype, Relievotypes)

The latest fashion in photographic portraiture, the wet collodion positive process on glass (also known in the United States as the ambrotype), was introduced in 1854. The images had a warm tone and did not have the mirror-like reflection that made daguerreotypes difficult to view. The images were the same standard sizes as daguerreotypes, and in Western countries and colonies they were usually presented in a similar manner, with hinged cases, and a glittering brass mat. "The closed, hinged case introduced the element of surprise, a sense of drama as one held it in one's hands, wondering what was going to be pictured inside. As the case was opened this sense of theater became part of the viewing experience."

The wet collodion positive process was derived from the collodion negative process described by English Frederick Scott Archer in1851. In the second edition of his manual (1854), Archer included a chapter, "The Whitening of Collodion Pictures as Positives." In the United States, the ambrotype process was patented by James Ambrose Cutting in 1854. Cutting's patents were largely ignored and had little effect in the rapid spread of this process across the United States.

The investment on the part of photographers to adapt their equipment and studios to the wet collodion positive process was inconsequential. The glass plates were the same standard size as the daguerreotypes; cameras were easily adapted to accommodate the glass plate and the investment in supplies and equipment was minimal. The chemicals required in preparing the collodion emulsion, and assorted paraphernalia including trays, beakers and funnels were readily available in cities and port towns.

The preparation and exposure of a wet collodion positive was a well choreographed dance that required timing and confidence in handling chemicals. The photographer prepared a collodion emulsion by dissolving gun cotton,



Pierson, Pierre Louis. Napoleon III and the Prince Imperial.
The J. Paul Getty Museum, Los Angeles

and modifying its "glutinous" consistency so that it would remain viscous. A how-to-manual noted that "it is hardly necessary to caution the student when using Gun Cotton, as he is aware of its explosive nature; a single spark of fire in it might cause serious consequences." The collodion solution was then poured onto a glass plate and the trick was to evenly distribute the viscous solution on the plate surface allowing the collodion to "set" but not become completely dry. The photographer moved into a darkroom (or dark tent) to dip the plate in a silver solution, and load into a negative holder. After the plate was exposed, the photographer immediately returned to the darkroom to develop and fix the image before the collodion emulsion would dry and harden.

The ambrotype, like the daguerreotype, is a unique image. Photographers created a negative image (the darkest areas were transparent, and the lighter areas had a greater density of silver) by under exposing the plate in the camera or under developing it in the final processing. A dark background was necessary to transform the image from a negative to positive before it was presented in a case to the patron. A variety of backings provided dark tones that brought out the image details and create the positive image: velvet fabric, black paper or "japanned black" paint either painted on the back of the case or the glass base of the image. Some photographers used opaque surfaces including ruby red glass, and leather as the base surface to prepare a wet collodion image. The images on leather were known as pannotypes. A more sophisticated process used by some studios in large cities, was the relieveotype process invented in 185 by Thomas C. Lawrence. In order to make the portrait stand out, the photographer removed the background and only blackened the area of the figure. The plate was backed with glass and a white background, to provide a greater illusion of depth.

The wet collodion positives, generally produced on glass, were introduced as ambrotypes in American cities. Itinerant photographers learned the process and moved across the United States. It was still faster to travel to the California by following well established shipping paths from New Bedford and other eastern port towns. In the October 1856, Hawai'i daguerreotypist Hugo Stangenwald, advertised that "having recently returned from a visit to San Francisco, [he] takes pleasure in informing the public that he has introduced, and is now prepared to execute, those splendid and permanent pictures on glass, well known as the improved ambrotypes."

In the Pacific, Andrew Garrett (a naturalist) earned his living by collecting, natural history specimens for individual scholars and U.S. and European institutions. In 1863, while living in Hawai`i, he "began to perfect himself in the relatively new art of photography, in order to go prepared to record the vegetation, flora, fauna, and inhabitants of these remote regions… An associate in San Francisco S. Hubbard… sent him a supply of photographic materials… and offered to act as his agent in San Francisco." An associate in San Francisco S. Hubbard purchased photographic materials for Garrett. Hubbard sent five boxes of photographic materials, and in his letter he requested that "if you should ever take any views I wish you would send me some and I will pay you for them, I should like a few pictures of the distinguished natives of the South Seas." By 1864, Garrett was collection images and specimens in the Tahitian, Marquesan, and Samoan Islands. A colleague in Honolulu wrote: "…not a day passes… without my dreaming over your fortune and success. I have imagined that the missionaries might decide that your photographs were a useless article of furniture and discourage the natives from patronizing you, and then again I think I see you surrounded by a crowd of natives dancing and shouting with pictures." Although not attributed, it is likely that Garrett made a beautifully hand colored ambrotype portrait of a native Tahitian man posed with a coconut in his lap, and a coconut frond artistically placed in the background.

The ambrotype process entered Japan through economic and political paths across the Pacific Ocean from San Francisco to the port of Yokohama. John Thomas Gulick, son of an American missionary in Hawai`i, was at loose ends in the winter of 1862, when he decided to learn photography in San Francisco from "Mr. [Carlton] Watkins" while waiting to find transportation to Japan. After arriving in Japan, Gulick noted that on May 2, 1862, he took his first successful picture: "After dinner took my first portrait. It was an ambrotype of Mr. Louder. It was taken when the sun was behind the hill and is therefore lacking in contrast of shades." Gulick left Japan in 1863, and noted in his recollections that "under my teachings a Japanese learned to take photographs and … I passed my camera and photographic material to him; and he became one of the first to spread the knowledge of that kind of picture taking among his countrymen." In Japan, ambrotype portraits were housed in specially made wood boxes, with a wood mat. This soft, light colored *kiri* wood (paulowina) was also used to make boxes to store scrolls and other valued items. Ambrotype portraits were common even after paper prints were available in Japanese studios, indicating the popularity of this style for family portraiture. The Meji period, beginning in 1868, was the height of the ambrotype process in Japan, although portraits continued to be made in rural areas until 1888.

Wet collodion positives were a transition process between daguerreotypes and paper prints. It was seldom used in the Western countries for portraiture after 1862, when paper prints made from wet collodion negatives became the latest fashion, and patrons collected carte-de-visite portraits to include in photographic albums. In addition, the U.S. Civil War (1861–1865) also contributed to a shift from wet collodion positives on glass to more durable carte-de-visite and the wet collodion image popularly known as the "tintype" (melainotype or ferrotype).

WEY, FRANCIS (1812–1882)

French writer and critic

Francis Wey arrived in Paris from his native Franche-Comté in 1830 to prepare for a life of business at the Ecole des Arts et Manufactures. In 1832 he left his studies to become a writer. He began penning essays on Romantic topics such as the Abbey of Noirmoutiers, for journals such as *L'Artiste*. In the long career that followed, Wey covered almost every mode of writing available to an ambitious Parisian in the nineteenth century.

Around 1833, Wey came under the protection of Charles Nodier, fellow Franc-Comtois and friend of the Wey family. Nodier introduced Wey into the literary circle which gathered around him at the Bibliothèque de l'Arsenal; there the young writer encountered most of the major and lesser lights of the Parisian literary scene. In 1834, perhaps on the recommendation of Nodier, Wey entered the Ecole Royale des Chartes. Thereafter his writing was facilitated (and often generated) by his secure career as an archivist. He published novels, tales, and travel narratives, but also erudite studies of the French language, articles on history and archaeology, and literary and art criticism.

In 1851 Wey wrote often for the new photographic journal *La Lumière*. His involvement with the magazine ended with its dissolution and reformulation at the end of the year. In 1853 he wrote an essay on the history of photography for *Le Musée des familles*; he did not write about photography again. Wey's attention to the medium lasted little more than a year, and went unremarked by his biographers and bibliographers. Yet his twenty-three articles on various photographic matters constitute an early and self-conscious formulation of the terms for photographic criticism. His suggestions for photographic subjects and projects were taken seriously by his peers. And his critical project was inflected by his devotion to Realist and Naturalist painting, and his friendship with Gustave Courbet, another Franc-Comtois. Their alliance was perhaps at its height in 1851, the year Courbet's portrait of Wey was hanging in the Salon along with *The Stonebreakers* and *A Burial at Ornans*, among other works.

Wey wrote technical, scientific and historical articles for *La Lumière*, but the themes of his photographic criticism emerge in his reviews and his writing about art. Above all Wey wanted to elucidate photography's relationship to painting and printmaking, and to identify subjects and genres for which photography was well-suited. The clearest statement of his ideas appears in one of his last articles, "Photographes et Lithographes" (*Photographers and Lithographers*), which appeared on 19 September:

Art has already exercised a very notable influence on photography. It has taught it the science of effects, the manner of composing a picture, and diverse procedures for elevating itself, in its literal interpretation of nature, to the impression that results from the sentiment for color.

Wey was sympathetic to photography that took its cues from painting by the *coloristes*—whether the recent flowering of landscape, which he saw as one of the most important artistic developments of the day, or portraits by old masters such as van Dyck and Titian, who achieved pictorial unity through atmosphere and judicious use of highlights. In a 17 August review of photographic publications Wey praised the lines in calotype photography, "which leave the leading role to effect and the modeling of planes." So photography offered proof of color's dominance over line. But although photography was to follow painting's paradigm, it was only in order to establish one of its own. Further into "Photographes et Lithographes" Wey enumerates subjects for which photography is the superior medium to painting, engraving, or lithography: "Subjects swarming with details, monuments loaded with arabesques, the crossroads of old neighborhoods, birds-eye views of the great cities put [photography] above all rivalry." What is more, Wey finds photography capable of effects that would in turn nourish painting:

> We have watched landscapists in admiration before prints taken in winter forests, prints whose planes had been formed from a prodigious tangle of bare brambles, boughs, tree trunks, bristling patches of grass, and small branches. We have watched painters contemplate, amazed, certain effects that were reputed almost unattainable, yet which were rendered by photography with a clarity, a simplicity of means which art had not imagined.

Wey had introduced some of these ideas in his first article for *La Lumière*, "Sur l'influence de l'héliographie sur les beaux-arts" [On the Influence of Photography on the Fine Arts], and he developed them in other essays—"Du naturalisme dans l'art: de son principe et de ses conséquences" (On Naturalism in Art: Its Principle and Its Consequences), "Théorie du portrait" (Theory of the Portrait), "Album de la Société héliographique" (Album of the Heliographic Society). He repeatedly claimed that photography would "renew" painting through the fresh relationships it recorded in studies of landscape, the nude, and drapery. He also somewhat teasingly used

photography to establish grounds on which to appreciate Realist and Naturalist painting.

It is tempting to speculate about Courbet's influence on Wey's writing for *La Lumière*. In two novels, *Biez de Serine* (1850) and *Le Bouquet de cerises* [The Bouquet of Cherries] Wey had written descriptions of stonebreakers which are probably based on Courbet's painting. If his novels of that moment are an effort to work through the fresh example set by the painter, his defense of new painting often seems coached by Courbet. In *Du naturalism dans l'art* Wey writes about the exhaustion of the academic tradition, and he asserts that subject matter and canvas size no longer hold the importance they once did. Here and elsewhere he claims that the excesses of the Romantics and the coloristes were launched in reaction to the impoverishment of the classical school, with the dogmatism of Realism and Naturalism forming another reaction in turn. And photography? The new medium would introduce a necessary control on Realist and Naturalist tendencies, allowing the proper return of imagination to painting.

Wey also directed his criticism toward practical developments. In addition to the subjects listed above, he advocated photography as the best means to reproduce works of art, especially sculptures and bas-reliefs. In some cases he also thought it was superior to lithography for the reproduction of paintings. In "Un voyage héliographique à faire" [A Heliographic Voyage to Make], he extolled the painting of the little-known Flemish primitives, especially Memling and van Eyck. He wanted this art to receive more critical attention, and he also felt that the paintings' crisp linearity lent them to photographic reproduction. Louis-Desiré Blanquart-Evrard paid attention, and works by the early Flemish painters soon appeared in his albums. Wey often addressed Blanquart-Evrard in his writing, egging the publisher to finish his first album, which was late in appearing and which the writer needed for a critical touchstone, and subsequently offering tough assessments of individual photographs and categories of subject matter. Finally, Wey passionately promoted photographic journeys to record the sites and monuments of France and the world. He also advocated official patronage of such trips: he wrote a long review of Maxime Du Camp's Nile photographs made under the auspices of the Ministry of Public Instruction, and in several articles he praised the Mission Héliographique, still underway when his relationship with *La Lumière* ended.

PETER BARBERIE

Biography

Francis Alphonse Wey was born in Besançon in 1812, into a commercial family of German origin. The Wey family had suffered significant losses during the Revolution and Terror, but maintained its business in Indian trade. In 1830, the eighteen-year-old Wey was sent to Paris to enter the Ecole des Arts et Manufactures. In 1832 he abandoned his studies against his family's wishes and turned to writing. In 1834 he entered the Ecole Royale des Chartes, graduating to become an archivist and paleographer at the National Archives in 1837. In 1853 he was named Inspector General of Departmental Archives, a post that he held until 1879.

Wey was a prodigious writer. Beginning in the 1830s he authored more than twenty novels and short stories, as well as two theatrical comedies. He also wrote over a dozen pieces of travel literature, which divide into distinct categories of light reportage and rather serious historical and archaeological accounts. Much of his writing appeared in popular journals such as *Musée des Familles* and *Revue de Paris*. In 1858, his biographer Eugène de Mirecourt characterized Wey as "the Christopher Columbus" of the *roman-feuilleton*: his skill with cliffhangers for his serialized novel *Les Enfants du Marquis de Ganges* [The Children of the Marquis of Ganges], published in 1838 in *La Presse*, had inspired dozens of imitators.

Wey also wrote reviews and philological and historiographical articles for learned societies. In his lifetime he was most honored for his studies of the French language, especially *Remarques sur la langue française, sur le style et la composition* [Remarks on the French Language, on Style and Composition; 1845] and *Histoire des révolutions du langage en France* (History of Revolutions of Language in France; 1848). In 1846 he was made a Chevalier of the Legion of Honor in recognition for the former work. Other books that were especially esteemed include *Le Bouquet de cerises* (1852) and his long travel book *Rome, descriptions et souvenirs* [Rome, Descriptions and Memories; 1871–1875].

Although Wey supported the politicized new painting of the 1850s, and even took up Courbet's subject of stonebreakers, he was himself a moderate Republican. He published two books related to the political upheavals of his period, *Manuel des droits et des devoirs, dictionnaire démocratique* [Manual of Rights and Responsibilities, Democratic Dictionary; 1848], and *Chronique du siége de Paris* [Chronical of the Siege of Paris; 1871].

In 1839 Wey joined the Société des Gens de Lettres, founded the previous year. He was the society's president from 1852–1854, 1857–1858, and again from 1861–1863. In 1864 he was made honorary president.

In 1858 Wey became a member of the Comité des travaux historiques, a national commission parallel to the Commission des monuments historiques, but dependant from the Ministry of Public Instruction. Like the Commission, the Committee had concerned itself with photography of monuments since 1849.

Francis Wey died in Paris in 1882.

WHATMAN, JAMES & CO.

The *Whatman's Turkey Mill* watermark, which appears on many calotypes taken by Henry Fox Talbot and by Hill and Adamson, and on cyanotypes by Anna Atkins, dentifies a paper that was produced by a long-established manufacturer in Maidstone, Kent, England.

Turkey Mill, originally a fulling mill in which woollen fleeces were washed before spinning, was built in the 17th century, and was converted into a paper mill in the 1730s by Richard Harris.

On Harris's death, James Whatman, a tanner, married Ann in August 1740, just a few years after Harris had completed the mill conversion, and James and Ann determined to make their paper mill the finest in the country. At that time most of the finest papers for artists were imported into Great Britain from France and the Whatmans sought to change that.

James Whatman died in 1759, and his son, also James, took over the mill in 1763 aged only 21. In the following years, James introduced many innovations in paper-making—including discoveries which lead to improved whiteness in the papers—and built what he called his 'contrivance' to make paper which he named 'antiquarian size'—more than 50 inches by 30 inches—the paper-making process requiring a team of eleven men to operate it.

In the 1770s, James Jr. and his second wife took in William Balston, and Balston became his protégé and was groomed to become his successor. A stroke caused James to pass the operation of his mills—three by that time—to Balston, then 31, in 1890, and Balston remained with the business after it was sold to local businessmen in 1794.

In 1805 Balston left to form his own business, building a new mill at Springfield, and became the first to employ steam rather than water to power the processes of paper-making.

The Whatman name remained with the original company, and became enormously popular with artists of the day—amongst them J. W. M. Turner, for whom Whatman paper was a preferred choice claiming it gave particular qualities to his watercolours.

After 1840 Whatman's Turkey Mill paper also became the first choice of material for many pioneer British photographers, and the dated Whatman watermark can be seen in a few negatives produced by early calotypists, including Talbot, Hill & Adamson, Reverend George Wilson Bridges, Calvert Richard Jones, John Dillwyn Llewelyn and others.

Despite its popularity, however, Whatman's Turkey Mill paper was not ideally suited to photography. For a start there was the distinctive watermark, which intruded sometimes aggressively, into the composition. In the early days, this does not seem to have been seen as a serious problem, but later calotypes were made on paper specially cut from larger sheets to avoid it. The sheets bearing watermarks were retained for printing, where the watermark did not present such a problem. The paper had other drawbacks for photography as well—being largely made from rags, it was not uncommon for it to contain invisible traces of metal from buttons etc which had been introduced during the manufacturing process. While irrelevant in a writing paper, the chemical processes through which the calotype paper was passed caused those metal fragments to corrode and stain.

In 1857, an article in *The Liverpool and Manchester Photographic Journal* (vol. 1, 214) recounts a visit to see paper being made at "Hollingsworth's, formerly Whatman's Turkey Mill" and offers singular praise for the product stating that "the best paper ever made for the Talbotype process was made at Turkey Mill" and that "This paper was successfully used by the Rev. Calvert Jones, about 1844, at Malta, in very hot weather, and also in the East by the Rev. Mr. Bridges. It is strange to relate that such paper has *never* been obtained since, even from the same mill, and that is why I dwell so much upon it at this moment. Could we get such a paper again, with certainty the Talbotype would take a new start." Written at a time when the wet collodion process was in its ascendancy, that is quite a statement!

After a series of mergers—starting with Houldsworth and Balston in the early 1850s—the Whatman name was revived in the 20th century, and the company continues

papermaking today, and is one of the largest employers in Maidstone.

WHEATSTONE, CHARLES (1802–1875)

English physicist and inventor

Sir Charles Wheatstone was born in Gloucester on 6 February 1802, the son of W. Wheatstone, a music seller. He attended a local private school, where he early manifested an interest in mathematics and physics. At the age of 21, he and his brother established a musical instrument-making business in London, a trade that allowed him to pursue his experiments with devices to measure and record sound. Wheatstone's first scientific paper, entitled "New Experiments on Sound," appeared in 1823, and his acoustical research continued with his invention of the concertina and a small form of accordion. In 1828 he presented the kaleidophone, a philosophical instrument that demonstrates the regularity of acoustic patterns by visual means. Although not intended to be a marketable device, the kaleidophone had utilitarian heirs in the photometer and the phenakistiscope, which likewise depend on the persistence of vision.

Wheatstone was part of a new generation of "natural philosophers" who believed in the value of practical research. For him, the construction of a functional device was both a means of working out an idea and an end in itself—a method that would prove central to the emerging discipline of physics. In 1834, still listed as a "musical instrument maker," he was appointed professor of experimental physics at King's College, London. He was only 32 years old. Hampered by acute shyness, Wheatstone seldom lectured after his first year in the post, instead using the institutional resources provided by his professorship to continue his research. Yet he was not socially or intellectually isolated. His publications in various scientific journals earned him immense respect (and election to the Royal Society in 1836); and he maintained close friendships with colleagues such as Michael Faraday and Sir John Herschel, and with artists including John Martin and George Cruickshank. Martin's son recalled that Wheatstone's home at 19, Park Crescent was "one of the most scientific and the most charming in the metropolis, and the resort of all distinguished in art, science or literature."

Wheatstone's importance for photographic history lies in his invention of the stereoscope. He apparently constructed prototypes as early as 1831, and presented it formally to the Royal Society in 1838. The stereoscope illustrated Wheatstone's revolutionary idea that the perception of solidity depends on the mental combination of the different images seen by the two eyes—the principle of binocular vision. The device itself is a symmetrical arrangement of mirrors (hence its common designation as a "reflecting stereoscope") and easels. In the center of a platform, two upright mirrors are placed at a 90° angle to one another, with two upright easels (to which images are affixed) placed at equal distances from the mirrors. The viewer places the eyes close to the vertical axis, where the mirrors are fixed together; looking at reflections of two flat pictures in the mirrors, one perceives a single, three-dimensional image about 6 to 8 inches away from the face. Wheatstone initially used pairs of simple line drawings—free of artistic conventions for indicating three-dimensionality—and predicted that more complex images might be introduced to even greater effect. The nearly simultaneous invention of photography immediately suggested itself as the ideal means of achieving such images.

The fact that Wheatstone did not comment on his own use of photography until 1852 has resulted in some confusion about the date and maker of the first stereoscopic photographs. Wheatstone's correspondence with William Henry Fox Talbot proves that the latter did make some experimental calotypes for use in the reflecting stereoscope by December 1840. During this initial period of trial and error, before the development of stereo cameras, successive exposures were made from slightly different positions with a single camera to produce a stereo pair. Wheatstone explained to Talbot that his photographs differed by too great an angle; he also pointed out that the two pictures must be taken under conditions when shadows would fall in exactly the same way in each. Experiments resumed in August 1841, when Henry Collen, under Wheatstone's direction, produced calotype portrait and still-life pairs. Earlier in the year, in the spring or summer, Wheatstone had gone with John Frederick Goddard to Richard Beard's

newly opened daguerreotype studio, where he had a pair of daguerreotype portraits of Beard's son taken to his specifications, and in 1842 Wheatstone commissioned Antoine-François-Jean Claudet in London and Louis Armand Hippolyte Fizeau in Paris to produce stereo daguerreotype pairs. However, he did not publicize any of these experiments.

By this time Sir David Brewster had devised an alternative stereoscope, somewhat similar to opera glasses in construction and employing lenses instead of mirrors. Brewster's highly marketable refracting stereoscope essentially determined the design parameters of stereo cameras and the standardized format of stereograph cards. Wheatstone had little involvement in the question of stereophotography once it became commercialized. In 1858 Brewster drew him into a dispute about the originality of the stereoscope, which the two scientists argued in letters to the *Times*. As this was not a patent dispute, no money was at stake; and the general consensus among commentators was that Wheatstone had proposed the theory and invented a device to prove it, while Brewster had refined the device so as to transform it from a philosophical toy into a viable commodity.

Wheatstone did not, in any case, need to earn money from the stereoscope. He had invested wisely in the Hammersmith Bridge Company and in various British and American mining concerns. Most significantly, he had taken care to patent (with William Cooke; 1860–1879) various improvements to the electric telegraph, the technology for which he is best known today. He carried out experiments with submarine telegraphy at Swansea Bay, in 1844, with photographic pioneer John Dillwyn Llewellyn. Other achievements include the Wheatstone Bridge (1843), which accurately measures electrical resistance; and the Playfair cipher, a cryptographic method based on digraph substitution.

Wheatstone married Emma West on 12 February 1847, and the couple had five children. He was named a chevalier of the French Legion of Honor in 1855 and became a foreign associate of the Academy of Sciences in 1873. He was knighted on 30 January 1868, and throughout his career earned some thirty-four honorary diplomas from a variety of institutions, including Oxford and Cambridge. Wheatstone died in Paris on 19 October 1875, leaving his collection of books and instruments to King's College.

Britt Salvesen

Biography

Charles Wheatstone was born on 6 February 1802, the son of a Gloucester music seller. He entered the musical instrument-making trade in London, but early made a name for himself in scientific circles by publishing his experiments on sound. In 1834, at age 34, he was appointed professor of experimental physics at King's College, London, where he conducted research on acoustics, optics, and electricity. He made an important contribution to photographic history with his invention, announced in 1838, of the reflecting stereoscope. In the early 1840s, Wheatstone called on various pioneers of photography to produce experimental pairs of calotypes and daguerreotypes produced for the stereoscope. Other technological innovations with which Wheatstone is associated include telegraphy, electric chronography, and cryptography. He was elected to the Royal Society in 1836 and knighted in 1868. He died in Paris on 19 October 1875.

WHEELHOUSE, CLAUDIUS GALEN (1826–1909)

As a recently qualified doctor, Wheelhouse was the medical attendant on a cruise yacht in the Mediterranean in the late 1840s, and used the opportunity to produce one of photography's earliest travelogues, entitled *Photographic Sketches from the Shores of the Mediterranean*. One of the guests on board was Lord Lincoln, later the Duke of Newcastle and Minister of War at the time of the Crimean War.

In the three years in which he pursued photography as a hobby, he travelled to Greece, Egypt, Malta, and Spain, producing some of the earliest photographs of Thebes, and fine images of Cairo, Athens, and Seville. Using the calotype process, he photographed the greatest sites of Egypt, at the same time as, or even before, the better-known pioneers of early photography in the region.

The demands of calotype photography as a hobby soon outstripped the time available to the young doctor, who was destined to carve out a significant career for himself in surgery. He studied medicine at Leeds medical School in the 1840s, where he and his fellow students are reported to have experimented on each other to assess the anaesthetic effects of ether. He advocated the use of Lister's carbolic spray as an antiseptic and presented a major paper on surgery to the British Medical Association in Bath in 1878

Wheelhouse gave all his negatives to Lord Lincoln, and they were reportedly destroyed during a fire at Lincoln's house in 1879.

JOHN HANNAVY

WHIPPLE, JOHN ADAMS (1822–1891)

American photographer and inventor

Whipple was born in Grafton, Massachusetts, on 10 September 1822. As a boy he became interested in chemistry and attempted to reproduce the newly discovered invention of daguerreotypy. He came to Boston in 1840 and began manufacturing chemicals for daguerrean artists. When the fumes later caused him to abandon this practice he turned to the making of pictures although as his numerous inventions show, he always maintained an interest in improving the photographic process.

Whipple entered into partnership with Albert Litch in 1845, and they opened a studio at 96 Washington Street, a center of picture-making activity and industry in Boston. Litch left in 1847, and Whipple continued under his own name at the same address. Between 1856 and 1859 he partnered with James Wallace Black; the quality of work produced by their studio rivaled that of the well-known firm of Southworth & Hawes. Whipple's studio was located on the top floor so that he could take advantage of the natural light. Display cases at street level alerted passers by to the studio's presence. One of its special features was a "Miniature Steam Engine" that powered the buffing wheels used in preparing the plates and operated the revolving sign in the form of a sun that Whipple used to entice visitors. His portrait clientele included the highest of Boston society (he made a group of daguerreotype portraits of the Harvard class of 1852, the first class to be photographed, and continued to do so through 1860). Whipple was known for the psychological content of his portraits, for his ability to put clients at ease by telling little stories, and for his skill in arranging sitters.

Whipple was a pioneer in the field of astronomical photography. In the late 1840s and 1850s he collaborated with Professor William Cranch Bond and his son George Phillips Bond at the Harvard College Observatory. The first successful representation of the moon was taken on March 14, 1851, by mounting the daguerreotype plate in the focus mechanism of the Great Refractor, one of the largest telescopes in the world at the time. Made by synchronizing the exposures with the pauses between the movements of the clockwork mechanism, the resulting image had an exposure time of thirteen seconds and measured three inches in diameter. A daguerreotype enlargement of the view exhibited at the Crystal Palace in London in 1851 awed audiences with the incredible details of the lunar surface and won a medal for excellence of production, "indicating the commencement of a new era in astronomical representation." Whipple and his partners, first William B. Jones and then Black, made about seventy exposures of different subjects, including the planet Jupiter. Whipple and Black worked again with the Harvard Observatory in 1857 producing over two hundred photographs of stars using the collodion wet plate process.

Whipple contributed many inventions that advanced the cause of photography. In 1846 he began experimenting with slides of microscopic insects and specimens, which a contemporary observer described as "the most delicate tissue of the tiniest animal." In 1849 he patented the crayon daguerreotype portrait, a technique he developed to create an effect of softness around the sitter as if the figure was floating in space. He achieved this by posing his subject against a light background and then placing in front of the lens a card with an aperture, which he moved in a circular motion during exposure so as to avoid any hard-edged lines.

Whipple's biggest contribution was the crystalotype process, which debuted in 1850. In 1844 Whipple, building on the experiments of early photographic pioneers, began exploring the possibilities of making paper photographs from glass plate negatives. On June 25, 1850, he and Jones patented the crystalotype process in which light sensitive materials were suspended in a mixture of egg white and honey, poured onto a glass plate, and exposed. In 1852 a writer for the *Photographic Art Journal* noted that the crystalotype presented "all the beauty of an actual painting with the unerring accuracy of the daguerreotype likeness." Indeed, the name crystalotype comes from the crystal clear transparency of the glass negatives.

Because of the long exposures, the crystalotype was first used for copying daguerreotypes. The process's reproductive capabilities enabled Whipple to produce prints for use in periodicals and book publications. His crystalotypes were mounted as frontispieces in the 1853 and 1854 issues of *The Photographic Art Journal* and the publication *Homes of American Statesmen* (New York, 1854), which has been described by one scholar as the first photographically illustrated book published in the United States. In 1852 examples of Whipple's process were on view at Root's Gallery of Daguerrean Art in

New York, and in 1853 his crystalotypes of the moon were awarded a silver medal at the Crystal Palace exhibition in New York. Whipple was generous in encouraging the use of the crystalotype and sold the rights to the process for $50; training was also provided for $50. The photographer Josiah Johnson Hawes and William James Stillman, a landscape painter, are said to have learned from Black, who was the principal instructor.

For unknown reasons Whipple and Black dissolved their partnership in 1859. Whipple kept the studio at 96 Washington Street and in 1865 moved to 297 Washington Street, establishing himself in rooms in three buildings with every modern convenience, including the largest skylight in the country according to one visitor. During this period he created a group portrait of the National Congregational Church Council at Plymouth Rock, a contact print measuring approximately 15 × 19 inches and containing over 1,000 figures. Whipple later photographed the aftermath of the Great Boston Fire of 1872.

Whipple retired from photography on June 1, 1874, after a family problem forced him into debt. Until his death from pneumonia on April 10, 1891, he was a bookseller and publisher of religious books. Whipple's photographs can be found in the following collections: Boston Athenaeum, Boston Public Library, Massachusetts Historical Society, Society for the Preservation of New England Antiquities, Harvard Observatory, International Museum of Photography, George Eastman House.

MICHELLE LAMUNIERE

Biography

Whipple was born on 10 September 1822 in Grafton, Massachusetts. Interested in chemistry as a boy, after moving to Boston in 1840 he began producing chemicals for daguerreotypists before beginning to take photographs himself. Whipple was instrumental in the development of the glass negative/paper positive process in America. He became known for his portraits, as well as views of the moon, buildings and ceremonial events in Boston. Whipple was married to a Boston-born woman named Elizabeth who bore a son William in 1861. By the time of his death, he had five children. Whipple exhibited frequently at exhibitions held by the Massachusetts Charitable Mechanic Association beginning in 1841 through the late 1860s, often receiving awards, and assisted in the formation of the National Photographic Association in 1868. After retiring from photography in 1874 he became a bookseller and publisher of religious books. Whipple died in Boston on 10 April 1891.

WHITE, CLARENCE HUDSON (1871–1925)

American photographer

Born in Ohio, Clarence White was renowned both as a pictorialist photographer and as an inspirational teacher of photography. He is best known for his soft-focus photographs, often depicting women and children in domestic or natural settings.

After leaving school, White worked a book-keeper for a wholesale grocery business, taking up photography as a hobby in about 1893. Self-taught, he was a founder member of the Newark Camera Club in 1898. He met prominent figures in the photographic world, such as Fred Holland Day, who became a lifelong friend, and his work began to be shown at national and international exhibitions. He became a member of the Linked Ring in 1900 and was also a founding member of the Photo-Secession, having his work reproduced in *Camera Work* in 1905.

Increasingly involved in photography, he decided to give up his job and support his family through commercial photography and teaching. In 1906 he opened a studio on Fifth Avenue, New York and from 1907 until his death he lectured on photography at Columbia University Teachers College. In 1914 he founded the Clarence White School of Photography in New York, and his students included Dorothea Lange, Margaret Bourke White and Paul Outerbridge. He died suddenly, from a heart attack, in 1925, during a trip to Mexico with a group of students.

COLIN HARDING

WHITE, HENRY (1819–1903)

Henry White was born in 1819, the son of Richard Samuel White. He became a lawyer and went into practice with his father as White and Son. He took up photography and began exhibiting albumen prints

made from wet collodion negatives in 1855, and he showed his photographs at the various photographic societies in England and Scotland as well as the 1857 Manchester Art Treasures Exhibition and the 1862 International Exhibition. He also exhibited at the 1855 Paris Exposition Universelle and the 1856 Brussels international photography exhibition. A member of the Photographic Society, he served as its treasurer. In the late 1850s, his subject matter consisted of rural scenes, rivers and streams, fields of crops, and close-up views of vegetation, often in Surrey. He also exhibited some photographs of sculpture. In the early 1860s, his subjects included Welsh landscapes. His best-known photographs include "Hunford Mill";, " Surrey"; "The Lledr Bridge, near Bettws y Coed"; and "The Cornfield." His work is found at the Victoria & Albert Museum, the Metropolitan Museum of Art, and the Getty Museum, among others. He died in 1903.

Diane Waggoner

WHITE, JOHN CLAUDE (1853–1918)

John Claude White, Companion of the Indian Empire (CIE), was born on 1 October 1853 in Calcutta, the son of a British doctor in the Government of India. Educated at the Royal Indian Engineering College, Cooper's Hill, England, he entered the Government of India as a civil engineer; photography was his vocation. In 1883 he was assigned for a year to the British Residency in Kathmandu, Nepal, where he photographed Nepal's architecture and monuments. Named political officer in 1889, he moved to Gangtok, Sikkim where he oversaw British interests in Sikkim, Bhutan and Tibet for nearly 20 years. He carried his camera everywhere, photographing the Himalayan mountains, architecture and people. A member of the 1904 British invasion of Tibet, he was the only expedition member permitted to photograph Lhasa's monasteries. He made five trips to Bhutan, photographing its architecture and the 1907 coronation of its first king. His landscapes, glaciers, and architectural studies form a remarkably comprehensive documentation of important events in the history of the political development of the North-East Himalayan Frontier. His photographs were published by the studio Johnston and Hoffman: *Sikkim* (1902), *Bhutan* (1905–06), and *Tibet and Lhasa* (1908). His writings, including his memoirs *Sikhim and Bhutan: Twenty-one Years on the North-East Frontier 1887–1908 (*London: Edward Arnold, 1909) and three articles in *National Geographic Magazine* illustrated by his photographs opened the window on the Himalayan region to the west. *In the Shadow of the Himalayas: Tibet-Bhutan-Nepal-Sikkim, a photographic record by John Claude White 1883–1908* (Mapin, 2005) contains over 100 of his photos, including his best known image, a panorama of 1904 Lhasa. He died in London on 19 February 1918.

Pamela Deuel Meyer

WHITE, JOHN FORBES (1831–1904)

English photographer

A miller, art collector, and amateur photographer, John Forbes White was born in Aberdeen, the son of a flour miller, and was educated at Marischal College in the city, where he first met Thomas Keith with whom he would take many of his photographs in the 1850s. Between 1854 and 1858, the two men travelled extensively together with their cameras. They married sisters, Ina and Elizabeth Johnston, the cousins of Sir James Young Simpson.

Like Keith, from whom he had learned photography, White used Le Gray's waxed paper process for all his known output, and his subjects ranged from local views around Aberdeen and the Balgownie estate near the family's flour mills, to views in Central Scotland, Northern England, and North Wales. By the time of his interest in photography, he was running the family business, and it was the pressure of that responsibility which prompted him to abandon photography in 1859, the year of his marriage.

His photographic output consists of little more than eighty large paper negatives, many of them never printed until very shortly before his death.

White's work remained unseen for over forty years until James Craig Annan printed several of his negatives and displayed them to critical acclaim at the Glasgow International Exhibition of 1901 alongside images by Thomas Keith, and by Hill and Adamson.

John Hannavy

WHITE, MARGARET MATILDA (1868 –1910)

Margaret Matilda White (1868–1910) emigrated to New Zealand from Belfast with her family in 1886. She was a friend of John Robert Hanna, a skilled Irish photographer who conducted a very successful portrait business in Auckland. It is thought that this friendship resulted in her acquiring skills as a photographer, which she demonstrated while working as a ward sister in a Mental institution. Her job provided her with subject matter that was very challenging because of the psychological undertones that the images invoke. She later married and moved to the West Coast of the South Island where she continued to use her camera to record her life and times. Because of her premature death in 1910, there isn¹t what one would call a very extensive files of negatives to draw upon

for an assessment of her abilities with a camera. Those that have been preserved are housed in the Auckland Institute and Museum. A study of these proves that she was capable of a lighter mode, photographing her workmates and friends in risqué situations, drinking and smoking in the company of men! There is also a very historically important reportage series on the funeral of the important Maori Chief Rewi Maniapoto, including a *morte* study.

William Main

WILLÈME, FRANÇOIS (1830–1905)

Draughtsman, painter, and sculptor (he made models for the bronze manufacturers of art), François Willème also practiced photography. His various experiments gave him the idea of a new process, the photosculpture, which he developed beginning in 1859, and for which he registered several patents. The photosculpture consisted of producing a statue, a statuette, or a bust starting from a series of photographic negatives taken of a live person or a model in sculpture in the round. This involved a device that was comprised, as installed in a salon, of a circular platform ten meters in diameter, lit by a canopy; on the other side of the circular wall, in a corridor, were laid out 24 cameras (the lenses were concealed by carved busts), which made it possible to photograph the model at the same time from every angle possible (the shutters were connected and could be opened and closed at the same time). In the workshops, the negatives were then projected in a "lampascope" on a translucent screen, increased to the desired size; on the back of the screen, a workman traced the silhouette with a point fixed at a pantograph; at the other end, the pantograph was equipped with a knife which cut out the silhouette in a block of clay, poised on a revolving base; after each layout, the resulting image was projected and translated in the same way into three dimensions, and so on until the sum of the profiles was obtained. A sculptor completed molding and perfecting the image; the statue could then be cast. The resemblance was guaranteed, with proportions exact.

In 1861, François Moigno spoke about the process in his *Cosmos* review, but it was only in 1863 that the invention was made known to a larger audience. The Société générale de photosculpture was formed that year thanks to capital brought by different financiers; the first establishment opened on boulevard de l'Etoile, in a large building crowned with a cupola of glass, and with the facade decorated with statuettes; two years later, a branch opened on the boulevard des Italiens. To launch his company, Willème accepted the support of the press and writers. Willème's businesses were attended by the good company of the Second Empire, beginning with the imperial couple and its entourage, the personalities of the artistic and literary world, as well as society women. The vogue of photosculpture exceeded the French borders: similar establishments opened in London (Antoine Claudet introduced the process in England by proposing some improvements, and showed examples in 1864) and in the United States (branch opened in 1866 in New York by Huston and Kurtz). Willème went to Madrid to make the portraits of the royal family of Spain.

Willème showed specimens of photosculpture to the Société française de photographie in 1863 and 1864 (with his associate De Marnyac), and at the World Fair of Vienna in 1864, and to the exposition of the central Union of arts in Paris in 1865. Each time he had a great public success. The judgments of critics were divided. Ernest Lacan, always enthusiastic, compared a bust in terra-cotta with the "more charming oeuvres of the XVIIIe century" (*Monitor of Photography*, September 15, 1865), whereas Theodore Pelloquet spoke about "stiff figurines, gauche, of a soft design" and exclaimed: "All that is extremely ugly, all that feels mechanical and misses character and of life" (*Time*, August 13, 1865).

At the Exposition Universelle of 1867, Willème had a share of a house in the park. But the passion for photosculpture had already reached its end and the company collapsed; in 1868, Willème closed his workshops and returned to live in his native area of Sedan.

Even if it were transitory, the glory of Willème and his invention attests to the vogue of the photographic portrait under the Second Empire and of the inventiveness of the medium of photography; it also testifies to the entrepreneurship which could animate an even obscure artist, since he proposed a new idea and had effective support, in particular that of the press, which represented a true power then.

If it seems an invention without future, even like a salon entertainment for an avid society to contemplate its image, the photosculpture had at least the ambition to put sculpture, noble art, within the range of more modest purses; the duration of the sittings were short, the execution was fast and reduced the total cost. In that, it falls under the vast movement in favour of the industrial arts; but Willème undoubtedly failed insofar as there was never a true market for photosculpture, the victim of the competition of the more accessible photographic portrait, the format calling card. In addition to the portrait, Willème also made attempts at reproductions of old sculptures. The specimens of photosculpture now preserved are in plaster: portraits of personalities or unknown, adults and children (Rochester: collection Gabriel Cromer, SFP, Compiegne, Museum of decorative Arts, Museum of Arts and Trades).

WILLIAMS, THOMAS, RICHARD (1825–1871)

British professional photographer

Thomas Richard Williams was a London-born professional photographer who was particularly known for the quality of his stereo-photography. Born in 1825, Williams was one of the few British photographers to make use of the daguerreotype process to produce news photographs. He specialised in making stereoscopic daguerreotype still-life studies and portraits. He also produced a large range of conventional stereocards from collodion negatives.

It is thought that Williams gained his professional experience by acting as assistant to pioneer daguerreotypists Richard Beard (1801–1885) and Antoine Claudet (1797–1867). Claudet was the first professional to use the stereo-daguerreotype in England and Williams was able to learn his trade from a skilled master and later go into direct competition with him.

Williams married Elizabeth in ca.1848–49 and went on to have nine children; his wife, three boys and three girls aged between five and twenty-one survived him at the time of Williams' death at his home, Sellar's Hall, in Finchley north London. Williams made a good living from his photography; as well as his large family there were several servants employed, including a coachman.

Williams' earliest photographic work seems to have been stereoscopic still lives produced by the daguerreotype and collodion processes. Many objects reappear in several of these elaborate set pieces. Musical instruments, stuffed animals, statuettes, fruit and vegetables, barrels, dead game, skulls and books all feature heavily, reflecting mid-Victorian taste.

A guitar, a table decoration within a glass dome and a Brewster pattern stereo-viewer all feature in one of his early tableaux, taken before his move to his Regent Street studio in the West End of London in around 1854. A small label on the reverse gives his early details: 'Mr. T.R. Williams, Photographic Artist, 35, West Sq. St. George's Rd. Lambeth.' At this time Lambeth was a poor area of London, an unfashionable district south of the River Thames.

If Williams was to make money from his photography he needed to move to a richer area of the capitol and Regent Street was the hub of fashionable photographers. Claudet was at number 107, Mayall (1810–1901), who also at one time assisted Claudet, was in the nearby Strand (and later in Regent Street) and W.E. Kilburn had a studio at number 234.Williams moved next door, to number 236 Regent Street.

At his portrait studio, which was patronised by royalty, aristocracy and the upper middle-classes, Williams also advertised views taken in and around the Crystal Palace (built originally in Hyde Park for the 1851 Great Exhibition and later moved to south London). He also offered a service to copy paintings, watercolors, crayon drawings, sculptures, and daguerreotypes.

Williams photographed Queen Victoria at the opening of the Crystal Palace Exhibition in June 1854 and again in 1855 when she was in the company of Napoleon III.

Williams went on to undertake several royal commissions including, in 1855, the launch of HMS Marlborough at Portsmouth and the return of servicemen from the Crimea. The following year he produced a few superb hand-colored stereo-daguerreotypes of the Queen's daughter, Princess Victoria, in her wedding dress.

Like Claudet Williams offered his stereo portraits with their own folding, leather viewing case, embossed with his name. He often subtly initialled his stereo-daguerreotypes 'T.R.W.' in pencil on the black paper surround, his earlier work was sometimes marked in the image itself.

Williams exhibited his commercial work at several London photographic exhibitions between 1855–1864. Stereo work was shown (from collodion negatives), along with a wide selection of carte de visite, and larger portraits.

Williams' reputation was largely built on the stereo-daguerreotypes and the wide selection of card- mounted stereos he produced at the Crystal Palace in 1854. Many of his views were distributed by the London Stereoscopic Company, as well as other publishers.

By Christmas 1856, a series of around sixty views (plus a few variations) entitled 'Scenes in Our Village' were available. This series showed life in a typical rural village in the English countryside and were accompanied by lines of poetic verse, probably penned by Williams himself.

Research by Brian May has shown the village photographed by Williams was Hinton Waldrist, just south of Oxford and about forty miles from London. May has also shown that Williams was, unusually, taking at least two pairs of negatives of the same posed rustic scenes, either using a single camera with two lenses mounted above each other, then moving the camera to one side and making another exposure, or by using two

identical cameras set up around six inches apart. There is evidence that this arrangement was used earlier, at the Crystal Palace in 1854, whether or not by Williams himself is unclear. The main reason was to produce two pairs of negatives of the same scene. William's strange arrangement made some sense; it allowed him to make two negatives, in case one became spoilt in processing or broken, also, it would also be possible to provide two different publishers with a negative each for printing. May argues that Williams found the 'sequential' effect of one image varying slightly from the other improved the three dimensional stereo effect.

Of course Williams might have used this unusual arrangement before; to produce both a glass stereo negative and a daguerreotype at the same time, in fact Williams is probably unique in offering photographs on metal and card of the same scene. This method of working was not necessary with still-lives or scenes with no figures, as Williams would have plenty of time to expose two or more plates. However, with the posed 'Village' scenes it was paramount to make the exposures quickly. The 'Village' series were taken with collodion on glass and there are a few known as glass positive transparencies, as well as conventional card-mounted examples.

Following this series of stereo views Williams concentrated on portraiture at his Regent Street studio, producing good quality cartes-de-visite and larger portraits. By the end of his career he was being assisted by his son Alfred, who was 18 at the time of his father's death in 1871.Williams was at one time in partnership with William Mayland, who appears to have taken over the Regent Street studio on Williams' death. Mayland went on to produce good-quality seascapes in carbon, in the style of Col. Stuart Wortley (1832–1890).

Williams died aged 46 on April 5, 1871 at his north London home from the effects of diabetes, which was at that time untreatable.

IAN SUMNER

Biography

T.R. Williams was a London commercial photographer mainly known for his stereographic work, often in the style of his mentor Claudet. He made an extensive series of photographs of the Crystal Palace exhibition of 1854, patronised by Queen Victoria. Williams produced 'news' photographs of the exhibition's opening ceremony and operated a successful studio and photographed many well-known personalities.

WILLIS, WILLIAM (1841–1923)
British inventor

His name is synonymous with the invention of platinotype—the finest process in the entire repertoire of 19th century photographic printing. Born in 1841 at St. Austell, Cornwall, the elder son of William Willis senior, engraver and inventor of the 'aniline' process, William junior was trained and employed in engineering and banking before devoting himself to tackling the problem of photographic impermanence. His prime choice of platinum as image substance achieved slight success in 1873, followed by many years of persevering research and development in his private laboratory at Bromley, Kent, which yielded five British patents and brought the process finally to perfection and universal acclaim by 1892. To market his invention, Willis had launched his Platinotype Company in 1879, and he remained continually responsive to public taste and commercial demand by inventing new variations: sepia platinotype, 'japine' paper, palladiotype, and 'satista' paper. He travelled widely, including the United States, and business interests notwithstanding, delivered instructive lecture-demonstrations to the Camera Club and the Royal Photographic Society, which awarded him its Progress Medal in 1881, and elected him to Honorary Fellowship in 1905. Willis's dedicated lifetime of research has endowed photographic history with a legacy of the most permanent and beautiful images. He died a bachelor, at Brasted Chart, Kent, in 1923.

MIKE WARE

WILSON, EDWARD LIVINGSTON (1838–1903)
Publisher, advocate, teacher

A tireless advocate for professional photographers' rights and a prolific author, Edward Livingston Wilson was born in Flemington, New Jersey, on March 4, 1838. He began his photographic career working in the studio of Philadelphia photographer Frederick Gutekunst in the early 1860s. In 1864 he established the first photographic magazine in America, the *Philadelphia Photographer*, later known as *Wilson's Magazine*, and

remained its editor until his death. He published other photographic periodicals and authored several books including *Wilson's Photographics* (1881), *Wilson's Quarter Century in Photography* (1887), and *Wilson's Cyclopaedic Photography* (1894). He also wrote and lectured extensively about his 1881–1882 Middle Eastern photographic journey. Throughout his career, Wilson worked to establish fair photographic practices and to elevate the profession. He led the fights against a photographic tax and many restrictive patents. As a founder of the National Photographic Association in 1868 and its successor organization the Photographers' Association of America, he helped organize exhibitions and conventions around the country. Through Wilson's efforts, a separate Photographic Hall was built at the 1876 Centennial Exposition to display photographs and equipment. In addition to his publishing and advocacy work, Wilson manufactured and sold photographic equipment and supplies. After almost a decade of ill health, Edward Wilson died in Vineland, New Jersey, on June 23, 1903.

SARAH J. WEATHERWAX

WILSON, GEORGE WASHINGTON (1823–1893)

This pioneering Scottish photographer trained as a miniature painter before taking up photography as a career. He was one of the first photographers to produce photographs on a scale large enough to operate in a mass-market capacity.

George Washington Wilson was the second of eleven children. His father was a crofter, George Wilson (1777–1848). His mother, Elspet Hurd (1798–1883), was his father's second wife.

From 1830 to 1835 George Washington Wilson was educated at the local Parish school.

At the age of twelve he was apprenticed to a local carpenter, but moved to Edinburgh to follow a career as an artist in 1846. Little is known about his time in Edinburgh.

In 1849 he moved to London and became a pupil of the painter, illustrator and sculptor, Edward Henry Corbould (1815–1905), who also tutored the royal family in History painting. When George returned to Aberdeen he set up business as a miniature portrait painter. At the time, photography was on the ascendance, and threatened the livelihood of portrait miniaturist painters. In 1853 George took the unusual, but sensible decision to combine his talents with those of his friend, the photographer, John Hay, and they set up a business which offered portraiture in both media. Furthermore, he established many relationships with other local studios and because of his commercial links with them, published and disseminated their work as well. Always developing his connections with the photographic community, Wilson was a member of the Photographic Society of Scotland which met in Edinburgh in the 1850s and 1860s.

In 1855 Queen Victoria and Prince Albert commissioned Wilson and Hay to record the construction of their new residence which was being built at Balmoral. This was the start of a long association between Wilson and the royal family. He was granted a Royal Warrant in 1873.

In the late 1850s improvements in photographic technology allowed Wilson to use his Dallmeyer camera to become a pioneer in the field of instantaneous photography. This allowed him to capture landscape and sky without recourse to the artificial device of combination printing, which was standard practise at the time. In 1859 it was reported in the photographic press that Wilson had succeeded in taking the first 'instantaneous view' of Princes Street in Edinburgh. There is also a large print in the RPS Collection at the NmeN by Wilson which claims to be the first instantaneous photograph ever taken. Scotland had become a popular travel destination due to the success of Sir Walter Scott's romantic novels, combined with the growth of the railways, and Queen Victoria's patronage of all things Scottish. Wilson took the opportunity to provide photographic views of Scotland for the burgeoning tourist trade. Eventually he also began to provide topographic views of England and parts of Northern Ireland, to the extent where he rivalled the domain of the photographer, Francis Frith, who was also involved in the same business.

George Washington Wilson became a household name after he was able to take advantage of the craze for stereoscopic photography and produced an extremely popular range of stereoscopic views of the 1862 International Exhibition in London. In 1864 alone, Wilson's photographic business sold over half a million prints. The company continued to grow and became one of the largest photographic firms in the world. To accommodate this growth, larger premises were built in Aberdeen and Wilson embraced mass production techniques in order to meet the demand for his images. Despite such a high turnover, Wilson produced high quality, gold-toned prints. As a result it is not uncommon for his images to remain in excellent condition to this day.

Described as genial and good-natured, Wilson had two illegitimate sons with Isabella Johnstone in 1841 and 1844. Although they never married, Wilson did raise and educate the elder of his two sons, Alexander Johnson Wilson (1841–1921), who eventually became a well-known economist in London. In 1849 George Washington married Maria Ann Cassie, daughter of an innkeeper in Banff. They had five sons and four daughters together. Wilson died on 9 March 1893 at Queens

Cross, Aberdeen. He is buried at Nellfield Cemetery in Aberdeen.

The largest collection of George Washington Wilson's work was discovered in the attic of a house in Aberdeen in 1970, and is now held at the University of Aberdeen. Aberdeen Art Gallery and Museums now care for a second major collection of Wilson's work which was originally donated to Aberdeen Public Library by his son, Charles.

At the time of Wilson's death his photographic business employed forty staff. It continued for another nine years, until it was forced to close in 1902, primarily as a result from competition from less expensive, and easier to reproduce half-tone reproductions of photographs which became then became the standard format for postcards at that time. Even so, Wilson's negatives were purchased by Fred Hardie, a former employee of Wilson and used to produce postcards until 1920.

WINTER, CHARLES DAVID (1821–1904)

French lithographer, painter, and photographer

Born in Strasbourg in 1821, Charles David Winter trained as a lithographer and painter before establishing a photographic studio at 1, rue des Calves, Strasbourg, that specialized in daguerreotype portraits. By 1851, he had adopted the paper negative process and by 1854, had mastered the wet collodion technique and was running a successful studio making portraits and *cartes de visite*. Winter's greatest accomplishments, however, are his photographs documenting the urban transformation of Strasbourg in the second half of the nineteenth century, including the building and demolitions in the city center (1855–80), the construction of a railroad bridge over the Rhine (1858–61), and the restoration of the Cathedral (1857–59). Winter exhibited at the Société française de photographie in 1857 and 1859. Striking for both their large size and their fine detail, his photographs revealed the formal beauty in new forms of architecture and engineering. Winter also recorded, in wrenching detail, the devastating destruction of Strasbourg following the Franco-Prussian war of 1870. After 1870, Winter illustrated and served as the editor of the *Bulletin de la Société de la Conservation des Monuments Historiques d'Alsace.* The largest holdings of Winter's photographs and albums are at the Municipal Library, Strasbourg, and at the Museum of Modern and Contemporary Art, Strasbourg.

Sarah Kennel

WITTICK, (GEORGE) BENJAMIN (1845–1903)

American photographer

Wittick established himself as a photographer in 1878 in New Mexico, working first for the railroad in the partnership of Wittick and Russell, later establishing studios in Albuquerque, Santa Fe, Gallup, and Fort Wingate, New Mexico, as well as in Arizona. Although he photographed the construction of the railroads and the growth of towns along the railroad route, he is best known for Native American subjects—both studio portraits and ethnographic studies of life and ceremonies. His portrait of Apache war chief Geronimo (Goyathlay) is one of the most famous images of a Native American. The portrait in which the chief poses against a studio backdrop with rifle in hand was made in 1887 after Geronimo's capture and was widely circulated. Wittick photographed many of the Apache and Navajo leaders as native groups were resettled. He was the first to photograph the Hopi snake dance ceremony, including the washing of the snakes and other rituals that took place in *kivas,* out of sight of observers. He died at Fort Wingate, New Mexico, in 1903, after being bitten by a rattlesnake which, it was reported, he had captured to transport to Hopi for the snake dance.

Kathleen Howe

WOLCOTT, ALEXANDER SIMON AND JOHNSON, JOHN (active 1839–1844)

Both involved in mechanics before the advent of the daguerreotype, Alexander Simon Wolcott and John Johnson were among the few significant American inventors in daguerreotypy from 1839 to Wolcott's early death in 1844. In this short period, the two partners' research and strategy were focussed on two goals that more broadly characterized the daguerreotype era in the United States: to devise a practicable method of making portraits, and to use it towards creating a profitable business; in both directions, they reached a marked—if short-lived—success.

Wolcott and Johnson began experimenting around October 6, 1839, after learning about Daguerre's method. The more mechanically-inclined Wolcott set out to design a new camera—one with an internal mirror instead of a lens—and within twenty-four hours he was able to secure a small portrait of Johnson. Although it is regarded as the first daguerreotype portrait made

in North America, this picture is lost and was probably mediocre, but it testified to the potential of the new camera, which was and remains the duo's main claim to fame. "Wolcott's camera" or the "mirror camera," as it came to be known after an improved version was awarded the first U.S. patent in photography in 1840, was indeed revolutionary, in that it incorporated, in lieu of a lens, a small concave reflector at the back of the box, which reflected the light coming in through the front opening onto a small plate (2 × 2½ inches) fastened near the front and facing back. This crude design was intended not only to palliate the cost of quality lenses, but to maximize the amount of light reaching the plate, so as to render portraits feasible by reducing exposure times. Although the mirror design had the added (and culturally more significant) advantage of redressing the lateral inversion of early daguerreotypes, augmenting the available light was clearly the primary concern, as was also the case in the sophisticated system of studio lighting Wolcott invented by coupling mirrors outside of the room's bay windows, and in many other improvements intended to produce more horizontal, more even, or less brutal lighting. Indeed, the intensity of the light concentrated on the sitter's eyes was unbearable for any length of time, which explains why the early portraits produced by Wolcott's camera were profiles, and why various means were attempted to soften the impact. In spite of this problem, the mirror camera was the principal asset of the studio that the pair opened on Broadway in March, 1840, probably the first commercial daguerreotype portrait studio in the world, and one that presented a remarkable internal architecture, embodying precocious thinking on lighting and extending the structure of the camera to the room's organization. This was true technical thinking on photography, and significantly it originated in a concern for the control of lighting in portraiture, thus departing from the abstract bend of many early responses to the invention of photography. Thus, it is inconsequential that Wolcott's mirror design may have been predated by earlier European publications on the subject, as was in fact the case with some other methods developed by the tandem, such as Wolcott's "accelerator," a mixture of bromide and chloride for increasing plate sensitivity. Whether or not they were aware of such publications, Wolcott and Johnson were most efficient on a strictly technical level, for instance in developing various methods of polishing silvered plates (by grinding and, later, by buffing), which earned them a second U.S. photographic patent in 1841. In this consistent effort to make the daguerreotype a practical and artistic portrait process, they contributed to an important pattern in the U.S., where the application of ingenuity to the handling of light, as well as the perfecting of daguerreotype plate surfaces, were durable trends.

Similarly, the entrepreneurial drive of the pair was precocious and characteristic, although their commercial career was short-lived. Along with the New York studio, the two associates created an establishment in Washington, D.C. (where basic equipment was still very scarce in the summer of 1840), and one in Baltimore. More significantly even, as early as February 1840, the duo sent Johnson's father to England to secure a patent for the mirror camera (which could only be done by paying a fee to Daguerre's agent) and to develop a daguerreotype business in partnership with the investor Richard Beard, with whom they opened a studio in London in March 1841. Although the Wolcott-Johnson business in New York met with heavy competition and indifferent success (the studio being sold in the fall of 1841), in London the Beard studio was for a time the only one to compete with Antoine Claudet's, and thanks to the mirror camera it attracted a good deal of business and attention in 1841–1842, while in other British cities the Beard-Johnson partnership successfully operated subsidiaries until 1843–1844, to the extent that the associates engaged in local factory production of mirror cameras and polished plates. In fact, much of the pair's time was spent in England in the years 1841–1843, and in March 1843 they obtained a British patent for a method of copying and enlarging daguerreotypes, while letters that were published later show that by 1843 Wolcott was working on a system of coating glass plates with egg whites, subsequently hailed as a near-invention of the albumen process. Had Wolcott not come to an early death in 1844, he would likely have renounced his mirror camera, which produced mediocre images and painful effects on sitters, which never seriously threatened the classic lens camera, and which was definitively superseded after the new Petzval lens (coupled with a prism that reversed the image) was introduced in 1843. Nonetheless, its bold and simple design remains a major example of American technical ingenuity in the era of the "dag'type," while the partners' insistence on patenting their improvements and expanding their business announced the professional and commercial course of 19th-century American photography.

François Brunet

Biography

Born in 1804 in Connecticut, Alexander Simon Wolcott had, before 1839, been active as a mechanic in optics, dentistry, and steam engines; in October 1839, he went into partnership with John Johnson, who was born in 1813 in Maine and had previously been a "machinist." As early as October 6 or 7, Wolcott made the first daguerreotype portrait in the United States with a prototype of the "mirror camera," which was patented on May 8, 1840 (U.S. patent #1,582), and put into service on March 13, 1840, in a commercial studio on

Broadway in New York, as well as in branch offices in Washington, D.C., Baltimore (under Henry Fitz, Jr., a telescope maker who had collaborated in the design), and several cities in Britain (in partnership with Richard Beard). The duo obtained the second U.S. photographic patent for a method of polishing plates (December 14, 1841, #2,391), and sold an accelerator called "Wolcott's mixture." After Wolcott died in 1844 in Connecticut, Johnson turned to other mechanical activities, although he remained involved in photography and published documents on his partnership with Wolcott. He died in Maine in 1871.

WOLLASTON, WILLIAM HYDE (1766–1828).

English chemist, natural philosopher, physiologist, inventor

Born August 6, 1766, in East Dereham, Norfolk, England to the Rev. Francis Wollaston (1731–1815) and Althea Hyde, he attended Cambridge University and, awarded a degree in medicine 1793. He became a Fellow of the Royal Society, 1793 and Foreign associate of the French Academy of Sciences. Wollaston published scientific papers in the 1790s.He gave up his London medical practise in 1800 to pursue scientific research and, with Humphry Davy, investigated physiology. Wollaston discovered the metals palladium and rhodium, and devised a lucrative process to produce malleable platinum. His electrical work included an improved battery. Wollaston's optical work included investigations of the solar spectrum. In 1806 he designed and patented the camera lucida, a glass prism on a support which enabled an artist to trace an impression of a view, ensuring accurate perspective. Fox Talbot's difficulty in producing acceptable drawings using the camera lucida, which required artistic skill, spurred his chemical experiments in photography. In 1812 Wollaston produced a camera obscura with improved 'periscopic' (meniscus) lens. Niépce used one of these lenses, made by Chevalier, in his 1828 photographic experiments. A Wollaston-type lens was used in the 1839 Daguerre-Giroux camera. In 1806 Wollaston was elected Secretary of the Royal Society, and interim President 1820. He died in London, December 22, 1828. The mineral Wollastonite, a Canadian town, and a Geological Society (London) medal are named in his honor.

STEPHEN HERBERT

WOMEN PHOTOGRAPHERS

Historians have downplayed the role of women photographers even though they were among its earliest practitioners and took an active part in all areas of photographic endeavour during the nineteenth-century. The economic, social, and cultural constraints, which governed women's lives, were also to shape their choice of subject matter and the manner in which their photographic work was perceived. The Victorian emphasis upon the domestic role of women narrowed the range of experiences that were available to many women, however, this does not lessen the work of those amateurs who utilized photography to record and construct accounts of their lives and those of their families. Photography also provided women with a way of earning a living beginning with the pioneer studio owners and itinerant daguerreotypists of the 1840s and expanding to include the legions of women workers who were the preferred employees in certain sectors of the photographic industry.

On an artistic level, women perhaps benefited from the fact that the new medium of photography was not a subject for academic study. It was therefore freed from the hierarchy and regulations which were attached to the Fine Arts and which often precluded women's full participation within them. In some respects this freedom made it easier for women to play a notable role in international photographic movements such as Pictorialism**.**

A small number of women contributed to the pre-history of conventional photography and were engaged to a limited extent in the scientific experimentation which preceded the announcement of the Daguerreotype and paper negative processes in 1839. In the late eighteenth and early nineteenth century it was not altogether unusual for some wealthy women to have some popularized knowledge of science and to cultivate this interest on a limited basis. Elizabeth Fulhame, who published a book in London in 1749 outlining her attempts to create permanent images by light, could be numbered among

these women. So too could Friederike Wilhelmine Von Wunsch, a German artist who in 1839 claimed to have discovered a method for producing photographic portraits. Women also formed a substantial part of the growing middle-class clientele who commissioned silhouettes, miniatures and camera lucida drawings in the decades before 1839 thereby creating a demand for the production of likenesses which the photograph was to satisfy.

The earliest women amateurs who used the Calotype process belonged to the upper strata of society as only they were privy to the expertise and know- how required to master this difficult process. In England, they included the relatives and friends of the physicist William Henry Fox Talbot, who announced his positive/negative process in 1839. His wife, Constance Talbot, printed her husband's Calotype or Talbotype negatives whilst occasionally making her own exposures and prints. Her engagement with photography alongside that of Talbot's Welsh relations Emma and Mary Llewelyn typifies the elitist circle of friends who used the calotype process. In Ireland, Louisa Tenison and her husband of Kilronan Castle, County Roscommon and Mary, Countess of Rosse, Birr Castle, County Offaly, were amongst the first women to use the process. Due to the complicated nature of taking calotypes and printing negatives those who used the medium often worked with partners. For women, the societal emphasis upon the work of their spouses often meant that their role was unacknowledged. For example, Harriet Tytler worked with her husband to record the aftermath of the Indian Mutiny of 1858. Yet their work using large paper negatives has been attributed solely to her husband.

Debates concerning the nature of photography took place in journals throughout the nineteenth century. One of the earliest and most important commentators was Lady Elizabeth Eastlake (1809–1893) whose husband Sir Charles was the first president of the Royal Photographic Society. Among other aspects of photography, she explored its relationship with the fine arts. A piece by her which was published in the *London Quarterly Review* in 1857 revealed an astute understanding of the photographic medium. Eastlake decided that photography could not be considered as a true art, however, she astutely points to some of its possible uses.

> She (photography) is made for the present age, in which the desire for art resides in a small minority, but craving, or rather the necessity for cheap, prompt, and correct facts in the public at large. Photography is purveyor of such knowledge to the world. (Eastlake 1857, 93)

Frederick Scott Archer's invention of the wet collodion process in 1848 and Louis-Désiré Blanquart-Evrard's introduction of the albumen print in 1850 resulted in an increased number of women taking up photography on an amateur basis. Women amateurs were still chiefly drawn from aristocratic or well-to-do backgrounds and the wet plate process was far from straightforward. This was particularly so for outdoor work as the glass plates had to be coated and developed immediately. These lady amateurs added photography to other female hobbies such as sketching and needlework. That photography was considered a suitable pursuit for such genteel ladies is perhaps incongruous given the fact that they had to mix their own chemicals. They gained access to technical information through informal networks of friends and family or from the many technical manuals which were available by the 1850s.

The subject matter chosen by most women amateurs reflected their leisured lifestyles and confinement within the domestic sphere. They used photography as a form of personal biography and tended to make straightforward formal portraits of their children and family within domestic settings. Their domestic imagery provides a direct link to later women's snapshot photography. That they recorded their environment in a selective way is evidenced in the exclusion of the staff, who facilitated their lifestyles, from most photographs. Many were aware of their families special position within society and asserted their relationship with the land through photographs of the family home and its surrounding parkland. Their photographs were mostly destined for albums which were produced and circulated in a private environment. These albums had origins in the earlier keepsake or sentiment albums which contained poems, pressed flowers and water-colours. They were often intricately decorated and were shown to an audience of family and friends. Examples of this genre include the early work of Lady Clementina Hawarden (1822–1865), at Dundrum, County Tipperary, Ireland; Augusta Crofton Dillon at Clonbrock House, Ahascragh, County Galway, Ireland and the photographs taken by the sisters Lady Augusta Mostyn and Lady Caroline Nevill. They were also part of the Amateur Photographic Association whose members exhibited their work in London and also sold and exchanged prints. The work of Mary Paraskeva at Baranovka in the Crimea covered similar country house subjects.

The albums created by Lady Frances Jocelyn in the 1850s, and Charlotte Milles and Lady Mary Georgiana Filmer (1838–1903) in the 1860s, demonstrate the creative energy and inventiveness that could be invested in the production of photographic albums. These women produced photographic collages, a process which involved the cutting up of photographs and their insertion among painted backgrounds. The placing of images of different sizes and the use of different mediums such as watercolours subverted the realistic nature of photography. As careful consideration was given to the order and sequence of images within such personal albums,

it is important that institutions and collectors maintain the referential integrity of these volumes. Such albums should be considered as a single item rather than a series of unrelated images.

One woman who departed from the typical themes of amateur image making was Lady Clementina Hawarden (1822–1865). From 1857 until her untimely death, she created over eight hundred photographs mainly of her adolescent daughters caught in private moments of reflection or in fancy dress. Hawarden's atmospheric and sensual images were carefully constructed through the use of fabric and props and reveal an inner private world rather than a mere record of family life. Hawarden's original treatment of the domestic realm is in contrast to previous amateur practice. Although they utilised the same wet-plate process and albumen printing as Hawarden most amateurs chose more formal and stiff poses. The themes of the Pre-Raphaelite art movement are reflected in her photographs and she demonstrated a sensibility that is not visible in much of the amateur practice of this era.

In the mid-1860s another Englishwoman was to commence the production of distinctive photographs within her home. Julia Margaret Cameron's (1815–1879) romanticised portraits were influenced by the Pre-Raphaelite painters. She used family, friends, and servants to re-create biblical scenes and Arthurian legends. She also created idealised portraits of her many famous friends and acquaintances. . Like Hawarden she used the wet plate process and made albumen prints. She experimated with close-up shots and was not overly concerned about the precision of her images preferring to capture atmosphere and expression using a soft focus. Critics were divided as to the merits of her work mainly due to its lack of sharpness. Both Cameron and Hawarden entered their work into exhibitions held by the Photographic Society of London. Cameron also made money from her photography consequently blurring the lines between amateur and professional practice. Her pioneering artistic vision widened the notion of what constituted a good photograph. Another woman who interacted with the photographic medium in a unique and creative way was Virginia, Countesse de Castiglione (1837–1899). She commissioned over four hundred portraits of herself from the Mayer & Pierson studio in Paris. She chose elaborate costumes and backgrounds to create vibrant tableaux. These images, which she then hand-coloured, re-created scenes from her own life or from novels. Although she did not take the photographs her input represents an example of the use of photography as a tool for self-expression.

Lady Eastlake's exploration of the uses of photography included reference to its application within scientific research. Anna Atkins (1799–1871) was one of the earliest female botanists to use photography to illustrate their work. She worked with the Cyanotype contact printing process which was invented by Sir John Herschel. The brilliant blue cyanotype prints, which result from the action of light on paper sensitized by iron salts, were used by Atkins to accurately depict her collection of botanical specimens. She painstakingly illustrated her work *Photographs of British Algae; Cyanotype Impressions* over a ten year period from 1843. This work is considered to be the first photographically illustrated book and constitutes a formidable piece of research and contribution to scientific knowledge. Atkins's work demonstrated that women were capable of undertaking serious research within the natural sciences. It also reflects the Victorian preoccupation with the collection and classification of natural phenomena. Alice Le Plongeon (1851–1916) and her husband Augustus took photographs of archaeological finds from their excavations in the jungles of Mexico and these images which date from between 1873–1885 are amongst the earliest uses of photography in the field of archaeology. Both Atkins and Le Plongeon provide evidence of women's participation in a wide range of photographic practices.

The female members of several royal families promoted photography either through their patronage of certain photographic formats or by taking pictures themselves and compiling albums. In England, Queen Victoria precipitated the craze for stereoscopic photography by admiring a set at the Great Exhibition in 1851. By permitting the sale of royal portraits she started the trend in collecting cartes-de-visites of famous people. In Austria in the 1860s Empress Elizabeth collected and commissioned hundreds of portraits. Queen Victoria's daughter, Princess Victoria who married Crown Prince Friedrich in 1858, was a committed amateur photographer. Alexandra, Princess of Wales, acquired a Kodak roll-film camera in 1889 and created many images which she even exhibited. Several members of the Russian royal family also took photographs.

Women were also involved in the production of commercial portraits from its inception. A small number of women ran their own daguerreotype studios in England in the early 1840s. There is evidence of work undertaken by Marie Chambefort, an itinerant daguerreotypist, who was active in France around 1850. Some of these women may have been previously engaged in the production of miniatures and were merely combating the threat to their living posed by photography. Others had the role thrust upon them through the tragic event of widowhood or the death of their fathers. In the United States, where the daguerreotype attained the peak of its popularity, women were also establishing and managing studios during this formative period.

The number of portrait studios increased between the 1850s and the 1870s as tintypes and cartes-de-visites cut the cost of photography. During this boom, there was

naturally a rise in the number of women listed as proprietors of photographic studios in both the United States and Europe. It appears that societal constraints were lessened in the United States and that women were more likely to set up businesses and travel independently than in Europe. Hannah Maynard (1834–1918) set up a studio in Victoria, Vancouver Island in 1862 and proceeded to make a record of the landscape and people of Canada. She also embraced a wide variety of photographic techniques. These included montages, figures in motion, photosculpture, multiple exposures, composite images and the use of mirrors. She pioneered the use of these artistic techniques to investigate the notion of the self and her involvement with the spiritualist movement led to the creation of unconventional and surreal images.

An African American woman, Mary E. Warren, was listed in a Houston, Texas, directory for 1866 as a photograph printer. In 1867 Marie Lydia Bonfils and her husband Felix set up La Maison Bonfils in Beirut where they had relocated to from France. The studio was responsible for portraits and topographical views of the Middle East. Lydia took many of the studio portraits and continued to run the business after her husband's death. Clémence Jacob Delmaet was involved in the running of the Delmaet & Durandelle studio which specialised in architectural and engineering subjects and was active between 1854 and 1890. Geneviève-Elisabeth Disdéri worked separately to her husband to create views of the countryside in Brest between 1852 and 1872. Swedish studio photographers included Bertha Valerius (1824–95) and Rosalie Sjöman (1833–1919). From 1890 the Letter-Verein Photographic School in Berlin taught women a variety of photographic techniques. By the end of the century, there were several very successful society portrait photographers including Catherine Barnes Ward in the United States and Christina Broom in England. Broom was also considered to be England's first photo journalist taking photographs of suffragist events and specialising in photographs of London. Both women were advocates and role models for professional women within photography.

Women also found employment behind the scenes in portrait studios. They were involved in routine work on assembly lines where they were employed in activities such as the cutting of cartes-de-visite images. For example, the William Notman studio in Montreal employed a large number of women as retouchers and printers. Women worked as dressers attending to the hair and attire of female sitters. They were engaged at several levels within the studio either as receptionists or as hand tinters. Portraits printed on albumen were often over-painted in oils, watercolours or pastels. These over-painted photographs were reminiscent of the higher status portrait painting. Later women were to be employed in the processing and production of photographic materials in large scale factories, such as those run by the Lumière Brothers and Kodak.

Pictorialism which imitated the conventions of fine art, attracted American women such as Gertrude Käsebier and the Englishwomen Agnes Warburg and Emma Barton. This international movement whose tenets were debated by H.P. Robinson and Peter Henry Emerson sought to create photographs which rivalled painting in its expression of emotion and atmosphere. Some advocates manipulated negatives or used the gum bichromate process. American practitioners of the 1880s included Mary F.C. Paschall, Mary T.F. Schaeffer, Eva Watson, and Louise Deshong Woodbridge. The American Anne W. Brigman was a central figure in this movement photographing female nudes in the spectacular natural surroundings of the of the Sierra Nevada mountains of Northern California. She was a founder member of the Photo-Seccession and influenced later photographers such as Louise Dahl-Wolfe. Gertrude Käsebier opened her New York studio in 1897 and her work repeatedly explored the mother-child relationship and allegorical themes. The Brotherhood of the Linked Ring was founded in England in April 1892 and sought to advance the field of art photography, however, it did not admit women until after 1900. Käsebier was the first female to be elected and was also a founder member of the Photo-Secession. Her simple portrait style was widely emulated. She also succeeded in coupling her artistic ambitions with financial success. Zaida Ben-Yusuf was another successful fine art photographer who was active from 1897 to 1907. Pictorialism also had an impact on the work of the Dührkroop studios in Berlin and Hamburg where Mina Dièz-Dührkroop worked with her father.

Female documentary photographers included Alice Austen and Frances Benjeman Johnston in the United States. Alice Austen was an avid amateur photographer based in Staten Island. Her sharp focused images of upper-middle-class life and those of immigrants at the Hoffman Island quarantine station and on the Lower East Side of Manhattan prefigured later documentary styles. Johnston combined studio portraits of notable figures with prize winning documentary photographs of the Washington School system. Jessie Tarbox Beals worked in newspapers and as an itinerant photographer in Massachusetts. Geraldine Moodie (1854–1945) photographed the life of pioneers in the Canadian West. In addition to her mother and child portraits, Gertrude Käsebier photographed Native Americans in the Pictoralist tradition.

For the most part images of Africa, Australia, and Asia were constructed from a colonial viewpoint as women photographers tended to be the European wives or daughters of those employed in the maintenance of Empire. One such woman was Lady Hariot Dufferin (1843–1936), Vicereine of India, who recorded her ex-

perience in India between 1884 and 1888. She published a two volume account of her time in India and also photographed the Indian people and landscape. Whilst travelling in Iran in the 1880s, the Frenchwoman Jane Dieulafoy photographed everyday life and people. The detailed and informative descriptions which accompanied her images reveal a documentary rather than a tourist agenda.

The technological innovations which heralded the true popularisation of photography enabled millions of women to take up photography. George Eastman's famous advertising slogan 'You press the button, we do the rest' referred to his roll-film Kodak camera. From 1888, photographers could return their camera containing exposed films to Eastman's factory where the film would be developed and printed. Advertisers were quick to recognise that women were a large part of the market and many campaigns were aimed at the young mother or the independent young woman who was free to combine the new hobby of cycling with the taking of snapshots.

WOOD, JOHN MUIR (1805–1892)

Scottish pioneer of photography

John Muir Wood was a pianist, music teacher, musicologist, and impresario, who was educated in Paris and Vienna. Moreover, he had wide interests in recent developments in science and the visual arts, which he combined in his photographic experiments. Although he had no direct access to Talbot and was not an official member of any photographic societies, he undoubtedly had connections with British pioneers such as Hugh Owen, Joseph Cundell, Charles John Burnett and with scientists dealing with the chemical and optical aspects of photography. In addition, Wood had close contacts with artistic circles. Besides his affiliations in the music world, he was close friends with the painters James Eckford Lauder and Charles and Henry Cundell. As a photographer, he remained an amateur throughout his entire life. This, undoubtedly, gave him a far greater freedom than most professional photographers, who often had to specialize in portraits and tourist views that answered to stereotypical formulas determined by public demand. Wood's oeuvre, by contrast, was far-ranging in subject-matter. It included portraits, figure-compositions, studies of sculpture and architecture,

and, more importantly, townscapes and landscapes. In addition, he experimented abundantly with inventive techniques. However, this dilettantism, displaying the true spirit of the pioneer, did not imply a sloppy output. On the contrary, highly educated and sophisticated both in his knowledge of chemistry and in his experience and understanding of the visual arts, Wood made some exceptional photographs in the 1840s and 1850s. These pictures are original accomplishments, both on the scientific and artistic sides of photography. It still is a mystery why his name does not turn up in most general surveys of the history of the medium.

His portraits and group portraits, which sometimes depict his friends from art circles, are typical for the early years of photography. Showing some similarities with the work of David Octavius Hill and Robert Adamson, they can be considered as exercises in finding appropriate positions while dealing with relatively long exposure times. Some of his group portraits are situated in a garden setting, taking the photographic portrait away from the studio and insisting on giving the figures a context in which their lives and day-to-day existence could be suggested and felt. Nevertheless, his figures are often isolated and they show a frozen and oddly sculptural effect. Wood, for that matter, photographed sculptures as well, just as Daguerre and Talbot did. A bust of Bacchus, for instance, is photographed from different viewpoints and under different lighting conditions. This interest in rendering three-dimensional volumes by means of light and shadow is also present in some of his portraits, in which even a Caravagist *claire-obscure* is achieved.

In the summer of 1847, John Muir Wood made a trip to the continent. After a brief stopover in York and London, he visited Belgium, which was developing into an important tourist stop for English and Scottish travellers. Not only was it the inevitable first stop on a *Grand Tour* on the continent but the romantic predilection for the Middle Ages also stimulated the interest in the old Flemish cities with their belfries, cloth halls, cathedrals and castles. Muir, just like George Moir of the Edinburgh Calotype Club or Talbot, contributed to this tourist exploration by taking pictures of medieval city centres. He also wrote a kind of travel report, in which he carefully noted which pictures were taken on which day. His trip brought him to Bruges, Ghent, Mechelen, and Brussels. After Brussels, he did no longer include remarks on photography, but his diary indicates that he also visited the battlefield of Waterloo, and the cities of Namur, Charleroi, Huy, and Liège, where his report ends abruptly. Probably, this travel report is incomplete because his estate also contains pictures of Antwerp and Leuven. It is also possible that he continued his journey in Germany, where he photographed the cities of Cologne, Heidelberg, Nuremberg, and Munich—it is also possible that these pictures were made during another trip since the dates are not indicated and probably prints were made years after the negatives were taken. His pictures of Flemish cities are both important historical documents and examples of an original photographical approach to the motif of the city. His depiction of the Groene Rei in Bruges is one of the oldest photographs of that city but also an example of Wood's consummate skill to make a balanced composition. Wood, playing with the diversity of tones, clearly had the photographic capacity to imagine the final result of his shooting. This is also the case in his Ghent pictures, which give us valuable information because they show the city before its major urban transformations of the later nineteenth century: the belfry has still its old wooden crowning and the castle is mostly hidden behind the houses built against it. The picture of the Ghent castle is a perfect example of Wood's response to the picturesque disorder of medieval towns. Unmistakably, he is more interested in the all-over pictorial effect than in architectural details or construction.

This aesthetic of the picturesque also turns up in his photographs of the ruins of Melrose Abbey and his evocations of the Scottish landscape, which was presented, both in the work of native and foreign artists and poets, as the ultimate romantic landscape. Wood also tried to register the sublime vagueness and freakishness of the Scottish scenery, answering to the romantic sensibility of his musical preferences. Often, he refers to traditional pictorial conventions, of which he had a sophisticated understanding. In other cases, he created remarkable unconventional and impenetrable compositions of woodlands without subject matter.

Throughout his career, Wood used the calotype instead of the highly polished metal daguerreotype or the later albumen process on glass. Even long after the introduction of glass negatives, he continued to use paper negatives. The calotype, of course, suited perfectly his picturesque way of seeing, which favoured the vivid all-over effect and subtle gradations of light over details and sharpness. His attention to light and hues lay also at the base of his experiments with different printing processes in the 1850s and 1860s, which resulted in an unparalleled chromatic intensity and vibrancy of color.

STEVEN JACOBS

Biography

John Muir Wood was born in Edinburgh in 1805. Being part of a family of piano-makers and music publishers, he became a pianist, music teacher, musicologist, and impresario. After an education in Paris and Vienna in 1826–1828, he set up as a music teacher and joined his brother George in the family business. He organized concerts for famous musicians including Chopin and Listz and did research on the history of Scottish music.

In 1848 he moved to Glasgow, where he married Helen Kenlo Stephen in 1851, who bore him thirteen children. Most of the pictures of his varied photographical oeuvre were taken in the late 1840s until mid 1850s but he continued to experiment with printing processes until the mid-1860s. He died in 1892 in Cove on the west coast of Scotland. His work is preserved in the Scottish National Portrait Gallery in Edinburgh.

WOODBURY, WALTER BENTLEY (1834–1885)

English photographer and inventor

Walter Bentley Woodbury, inventor of the Woodburytype photomechanical printing process, was born in Manchester, England on 26 June 1834. He showed signs scientific tendencies and, as a youth, mastered the difficult wet-collodion process soon after it was published in 1851.

Woodbury arrived in Melbourne in October 1852, but instead of going to the goldfields as planned, he decided to put his photographic skills to use. He was one of the earliest wet-plate photographers in Australia and at the 1854 Melbourne Exhibition won a medal for a set of '9 views of Melbourne, taken by the Collodion process on glass.' A versatile photographer, he took panoramas and stereo photographs as well as conventional views, and even made his own collodion. He set up a studio in North Melbourne and for a time operated studios on the Victorian goldfields.

In 1857 Woodbury, with his associate James Page, travelled to Java. After Woodbury solved the problem of working the collodion process under tropical conditions their photographic business became highly successful. In addition to their commissioned work they travelled the country taking photographs for sale. Woodbury's stereo views, published by Negretti and Zamba, were favourably reviewed in the *British Journal of Photography*.

Shortly after returning to England in 1863 with capital from his Java business, he devoted himself to solving the serious problems which were inhibiting the sale of photographic books—the slow production rate of albumen prints and their tendency to fade. He moved from silver-based chemistry to the permanent but imperfect dichromate-based carbon process of Alphonse Poitevin, the main shortcoming of which was the poor rendering of half-tones. After much arduous work he was successful in combining Poitevin's process with aspects of Fargier's carbon process and innovations of his own. Woodbury arrived at an entirely novel solution to photomechanical printing for which he filed British Patent no. 2338 of 1864. He later improved the process by incorporating the technique of nature printing in which the hardened gelatin matrix was forced into a sheet of lead under high pressure. Prints in pigmented gelatin were then cast from the resulting lead mould. The salient features of the Woodburytype printing process were that it was suitable for high production rates of high quality images while avoiding the use of introduced grain or the half-tone screen. The half-tones and delicate detail were reproduced smoothly and precisely by the varying thicknesses of pigmented gelatin.

To publicise his process Woodbury himself printed several thousand images for an insert in *The Photographic News* of January 26, 1866, and enthusiastically promoted his invention by means of demonstrations to learned societies, entries in exhibitions and articles in the photographic press. In 1875 he produced a photobook *Treasure Spots of the World* as a demonstration of the superb quality of well-made Woodburytype reproductions. Although the cost of the necessary machinery put Woodburytype out of the reach of small operators, it became the process of choice for high quality illustrated books as well as being equally suited to the mass production of ephemeral items such as *cartes-de-visite* of stage personalities to be given away as advertising material. In one notable instance 30,000 prints were made in one day. Woodbury licensed the process in several countries. It was also adapted successfully for the production of lantern slides in large quantities.

Described as 'technically perfect' and the most beautiful printing process ever invented-it was, however, not without its problems. The afterwork on the prints was labour-intensive as each sheet had to be hardened in an alum bath, washed, dried, trimmed, and mounted. Furthermore, the prints could not be combined with letterpress.

In 1879 Woodbury patented the simplified Stannotype process but the modification came too late to compete with cheaper but inferior processes. The 1884 Woodburygravure process was more compatible with book production but also failed to gain acceptance. Woodburytype was highly successful in England and on

the Continent until about 1890 but was less adaptable to the extremes of temperature found in North America and Australia. Woodbury also adapted the process for watermarking paper.

When visiting the United States in 1871, Woodbury acquired the English rights to the popular Sciopticon lantern projector. He was a prolific and versatile inventor, holding more than twenty patents, including improvements to optical lanterns and photography from a balloon. His last patent was for a method of making paper transparent for use as a support for the emulsion.

Woodbury was awarded many honours including a gold medal at the 1872 Moscow Polytechnic Exposition and the 1883 Progress Medal of The Royal Photographic Society.

Although widely acknowledged and respected, he lacked the business acumen needed to capitalise on his inventions. Woodbury contracted diabetes and died on 5 September 1885 at Margate, England, from an accidental overdose of laudanum.

Woodbury's importance as a photographer lies in his photographs of Australia and Java which are now of historical value. His fame as an inventor is assured by the legacy of superb prints made by the process which bears his name. Time has proved that the claim to permanence of Woodburytype prints was essentially correct.

ALAN F. ELLIOTT

Biography

Walter Bentley Woodbury, born in Manchester UK in 1834, joined the Australian gold-rush in 1852 but turned to photography. In 1857 he opened a successful photographic studio in Java. Returning to England in 1863 he devoted his life to inventions including the Woodburytype photomechanical printing process. He died at Margate, UK, in 1885.

WOODBURYTYPE, WOODBURYGRAVURE

Woodburytype is one of the finest of all photomechanical reproduction processes, producing continuous tone images that resemble carbon prints. Originally known as the photo-relief process (or, in France, *photoglyptie*), woodburytype was invented in 1864 by Walter Bentley Woodbury, although Joseph Wilson Swan**'s** photo-mezzotint process, conceived earlier but published later, is virtually identical. The end product is a relief image in semi-transparent pigmented gelatin, thick in the shadows and thin in the highlights, giving excellent photographic gradation.

The process of making woodburytypes begins with the exposure and development of a positive relief image in a thick film of dichromated gelatin. Exposure through a negative differentially hardens the sensitized gelatin, which is developed by washing away the unexposed parts in warm water. This master relief is then used to produce a shallow negative intaglio printing mold with the highlights as hills and the shadows as hollows, usually by sandwiching the dried, hardened relief against a sheet of lead in a powerful hydraulic press, an idea Woodbury took from nature printing. Considerable pressure is required: about 4 tons per square inch, or 500 kilograms per square centimeter, depending on the thickness and hardness of the lead, and the size and nature of the image. In the early 1870s, a hydraulic press capable of 450 tons pressure cost £156, although a short time later, Tangyes of Birmingham began manufacturing a compact woodburytype hydraulic press with a short throw, suitable for 10 × 8 inch (25 × 20 cm) plates, which sold for about £60 (by way of comparison, an Albion press, suitable for letterpress printing, cost about £10).

Woodburytype prints are cast (rather than conventionally printed) using a special, less powerful, hand press capable of positioning paper perfectly flat against the mould. A small amount of warm pigmented gelatin "ink" is poured onto the center of the lightly greased, carefully leveled mould, and covered with a sheet of specially-prepared, waterproof paper. The top plate of the press is swung down and closed, forcing the gelatin into the contours of the mould. After about a minute (to allow the gelatin to set and adhere to the paper), the print is peeled out of the press, plunged into an alum bath to harden, rinsed, dried, and finally trimmed and mounted onto either a book page or printed card mount.

To increase productivity while waiting for the gelatin to set, printers usually worked a number of presses, either on a rotating turntable, or in the case of larger presses, lined up along a bench. However the extra work involved in trimming and mounting, necessitated by the excess colored gelatin squeezed out around the edges of the woodburytype image during printing (and a tendency for prints to curl), reduced efficiency, and mounting on thin text paper could produce an unattractive cockle.

The color used in woodburytype "ink" is generally Indian ink with a small amount of pigment added to suggest a gold-toned albumen print. Unusually colored woodburytypes, or prints on specially tinted paper (and even wood and ivory), are rare considering the ease with which they could be produced. However the woodburytype process is particularly well suited to glass, and firms such as John Carbutt**'s** American Photo-Relief Printing Company and George Smith's Sciopticon Company marketed highly regarded lantern slides and stereo transparencies.

Woodbury's slightly simplified stannotype process, introduced in the early 1880s in an attempt to make woodburytype more attractive on a smaller scale, differed only in the method used to produce a printing mould. Stannotype eliminated any need for an expensive hydraulic press for the production of lead moulds by the expedient of printing directly from a tinfoil-coated negative dichromated gelatin relief. However stannotype was only a limited success, as most amateurs found the production of gelatin reliefs difficult and time consuming, and large scale professional woodburytype printers preferred the old method, as they already had the necessary equipment to produce multiple lead moulds from a single relief (limited by eventual crushing of the relief), in order to simultaneously print, for example, either eight cartes-de-visites or four cabinet cards, depending on the size of the press.

When justified over albumen for larger print runs, woodburytype offered the permanence of the carbon print and the productivity of traditional hand-inked printmaking. In 1877, the 8,500 prints needed for a frontispiece to the *British Journal Photographic Almanac* were run off in three days "with the *nonchalance* characteristic of a photographic portraitist whose transactions are on an extensive scale, when requested to furnish half-a-dozen prints from any particular negative." However maximum print size was limited: although 10 × 14 inches (25.5 × 36 cm) was achievable with special mammoth hydraulic presses, most woodburytypes are far smaller. Difficulties distributing the gelatin "ink" during printing further limited both size and the reproduction of highlights: although capable of rendering exquisite, luminous shadow details, unfortunately clear skies and other large white areas can appear mottled. These drawbacks forced practitioners such as Adolphe Braun or Friedrich Bruckmann to adopt alternative processes for larger sizes or specific subjects.

Woodburytype flourished from about 1870 to 1900, although because of the initial patent restrictions (Woodbury took out patents in Great Britain, France, Austria, Belgium, Italy, Prussia, and the United States), large capital equipment costs, and its technically demanding nature, use was limited to a small number of specialist firms, mainly in Great Britain and France, and on a smaller scale, in Belgium, Germany, and the United States. In Portugal and Australia, the process failed to meet expectations. In France, Goupil & Cie and later Lemercier dominated, while in England, the then sole licensee, the Woodbury Permanent Printing Company apparently saw nothing remarkable in producing one and a half million prints in the first six months of 1876.

At its peak in the 1870s and 1880s, woodburytype was extensively used to photographically illustrate books and journals. Most were portraits, and appeared as book frontispieces, or supplements to periodicals such as *Galerie contemporaine* (1876–84) and *The Theatre* (1878–97), but additional applications included landscapes and architecture (*Treasure Spots of the World,* edited by Walter B. Woodbury, 1875; William de Wivleslie Abney**'s** *Thebes and its Five Greater Temples*, 1876), social documentary (John Thomson**'s** *Street Life in London,* 1877–78) as well as reproductions of works of art (*Tresor Artistique de la France,* 1877, contains some very large woodburytypes as well as examples of Léon Vidal**'s** related photochromie process). However in 1890s, woodburytype seems to have been increasingly displaced in the high quality sector of the market by collotype and photogravure, both of which offered the advantage of being able to be directly printed onto plate paper suitable for binding into books.

Woodburygravure (so named because the matte-surfaced results resembled photogravure, although on close inspection the image appears slightly raised, especially in the darker areas) was a transfer process introduced in 1891. After printing on a temporary support given a special waxy coating to facilitate release, prints were trimmed, transferred to their final support, and the backing sheet peeled away after the application of a solvent. These extra steps were, however, expensive: Henry W. Cave's *The Ruined Cities of Ceylon*, first published in woodburygravure in 1897, cost 38 shillings, but a slightly smaller 1900 reissue in collotype cost only 12 shillings.

Other processes derived from woodburytype include Woodbury's photo-filigrane, which used a woodburytype relief to impress images resembling watermarks in already manufactured paper; Woodbury's photolithophane, which used a woodburytype relief to cast photographic intaglio transparencies in translucent porcelain; and Henri Rousselon's Goupil gravure, which used some form of granulation in a woodburytype relief

to create the grain for conventional intaglio printing. However photo-filigrane and photo-lithophane remained mere novelties (although Leon Warnerke apparently adapted photo-filigrane to forge Russian banknotes), and Goupil gravure, while producing beautiful velvet blacks, ultimately proved too costly even for the high end of the art market.

Around 1900 two German inventors, Paul Charles and Stephan Faujat, attempted to revitalize woodburytype by automating the process (they also produced a few reportedly remarkable three-color prints), but it was too late. Despite its delicacy and beauty, woodburytype remained a transitional technology for publishing photographs, a labour-intensive means of mass-producing reproductions of carbon prints that partially replaced the pasted-in albumen silver photograph, but was itself replaced by faster, cheaper, type-compatible processes like the half-tone.

WORTHINGTON, ARTHUR MASON (1852–1916)

Physicist and scientific photographer

Born 11 June 1852, Arthur Worthington, FRS, became Professor of Physics and then Head Master of the Royal Naval Engineering College, Devonport. Having published papers in 1877 and 1882 on the physics of surface tension, especially the stretching of liquids, Worthington introduced photography into his experimentation in 1894, following in the footsteps of the stroboscopic work of C. V. Boys and Ernst and Ludwig Mach. Worthington and his assistant R. S. Cole established a method for taking individual frames of drops illuminated with a Leyden-jar spark, which they executed and exhibited at the Royal Institution in May 1894. Having decided that photography was a more practical method for the study of surface tension, Worthington conducted the full range of his experiments again, this time documenting each one photographically, one frame at a time. He was the first to make the experiment of the falling milk drop, which has since become the visual icon of fluid dynamics. Although Worthington's early work was more a comparison of one sort of drop to another, he carried on to track all phases of a single drop. In 1908, Worthington published his book, *A Study of Splashes*, which was used extensively by D'Arcy Wentworth Thompson in his extraordinarily influential *On Growth and Form* (1917). Arthur Worthington died 5 December 1916.

KELLEY WILDER

WOTHLY, JACOB (active 1850s–1860s)

Jacob Wothly's name is associated with a short-lived attempt to introduce a printing process based on uranium in addition to silver, as a method of overcoming the recognised impermanence of albumen paper. In the event, the Wothlytype, patented in 1864, proved to suffer from the same problems of fading, and fell out of use. One of the first to publish criticism of the process, William Henry Fox Talbot, shared photography's disappointment that the prints were not more permanent. The printing-out-paper was coated with a mixture of uranium ammonio-nitrate and silver nitrate in collodion, but was superseded by collodio-chloride papers before the end of the 1860s.

Wothly, originally a portrait photographer producing ambrotypes, with a studio in Theaterplatz in Aachen, appears to have been in business before 1853.

By the late 1850s, working with collodion negatives, he had developed an interest in making enlargements, and designed a significant improvement to Woodward's Solar Enlarger, simplifying the means of keeping the reflected light focussed on the back of

the equipment. He presented his ideas to the Societé Française de Photographie in early November 1860, and within a week *La Lumière* reported that he had sold his design to A. A. E. Disdéri for a reported 20,000 francs.

John Hannavy

WRATTEN, FREDERICK CHARLES LUTHER (1840–1926)

Very little is known about the life of Frederick Charles Luther Wratten, except that he initially embarked on a career as a school teacher, yet his legacy to the development of the modern photographic process was significant, and his name lives on in the industry eighty years after his death.

Wratten started his photographic career in 1861, aged twenty-one, as a clerk in Joseph Solomon's Photographic & Optical Warehouse in London's Red Lion Square, and by the mid 1870s, he had become convinced that the future of dry plates lay not with collodion but gelatin. In 1877 he established the company Wratten & Wainwright based in Great Queen Street, London, in partnership with Henry Wainwright. In their first year they marketed their own brand of collodion dry plates and in early 1878 they marketed their first gelatin dry plates—*London Ordinary Gelatin Dry Plates*—which were fifteen times as fast as their collodion equivalents. Four British companies pioneered the manufacture of gelatine dry plates, all launching products in that same year—Mawson & Swan in Newcastle (who had pioneered the process in 1877), The Liverpool Dry Plate and Photographic Printing Company, Samuel Fry & Co. of Kingston-on-Thames, and Wratten & Wainwright. In these early stages of mass-production, emulsion manufacture was beset by many problems, not least of which was batch-to-batch consistency.

Wratten's pioneering innovation in the preparation of the gelatine silver bromide emulsion sought to tackle those variations. Early attempts at manufacturing dry plate emulsions had failed to recognise the problems of effectively washing the emulsion to rid it of the excess bromides and other chemical impurities. Wratten introduced the idea of 'noodling' as an aid to cleansing the emulsion. By chilling and setting the gelatine silver bromide mixture, shredding the resulting jelly and then washing the shredded 'noodles'—resetting and re-noodling as required—Wratten's emulsions were thus washed much more effectively, resulting in their plates exhibiting enhanced purity and enhanced consistency from batch to batch. This in turn gave greater consistency in emulsion speed and therefore in exposure reliability.

Their plates were aggressively marketed throughout Europe, and Eder (1932) identified them as the first gelatine dry plates to be marketed in Austria. And yet, it was still a 'kitchen sink' business. According to Mees (1961), Mrs Wratten made the emulsion in her kitchen, and the emulsion was hand poured on to the plates. A batch of emulsion filled twenty teapots, and the pouring was done through the narrow teapot spout.

Wratten & Wainwright later advertised their 'London' brand dry plates as the oldest-established brand in the world, and their retail premises sold a wide range of photographic materials and accessories. By 1879 they had introduced their *London Instantaneous Plates*, with a sensitivity over forty times as great as collodion.

In the mid 1880s, Wratten 'Slow,' 'Ordinary' and 'Instantaneous' plates were amongst the first commercial brands to be subjected to rigorous testing by Hurter & Driffield. Driffield used Wratten Slow plates as the standard when testing the effectiveness of a range of developers, surely a tribute to their consistency.

From 1887 Wratten & Wainwright also marketed a range of own-branded cameras, and although there is no conclusive evidence that they manufactured the cameras themselves, they did advertise themselves as 'apparatus makers' in the London Post Office Directories between 1887 and 1894. Channing and Dunn (1995) list Wratten & Wainwright cameras as early as 1879—when they advertised their *New Double Camera* 'for instantaneous work' and four other designs between 1886 and 1895. Some researchers have suggested that the cameras may have been made for them by other London makers, including, perhaps, William Morley of Islington.

By 1896, their 'Photographic Depot' advertised that it supplied plates and chemicals, and photographic accessories. No mention is made of the 'Photographic Apparatus Department' which had figured in early listings.

A move to Croydon in 1890, to a factory in three converted houses in Canterbury Road, put emulsion manufacture and coating on to a proper commercial footing, with a coating machine made for them by Smith of Zurich. The company continued to develop improved emulsions and, in 1906, became the first company in Britain to manufacture and market panchromatic plates, incorporating the work on dye sensitisation which had been done by other researchers. The dye sensitisers used in their early pan plates were produced for them by Höhst in Germany.

At that time a young chemist had recently been appointed to the position of Joint Managing Director of Wratten & Wainwright Ltd, who by that time had expanded their manufacturing facility at Canterbury Road in Croydon. Dr. C. E. Kenneth Mees (1882–1860) had joined the company as a researcher, and within a few months had developed their first panchromatic plate. Attempts by earlier companies at dye sensitisation had involved bathing the coated plate in the sensitisers. Mees

was the first to propose sensitising the emulsion before coating, producing a much more reliable result.

Wratten's name, however, lives on in the working lives of present-day photographers in the classification code which he and Mees developed for the range of camera and safelight filters which Wratten & Wainwright introduced before 1909.

The rationale behind the numbering of his filter system seems somewhat arbitrary, but does have a basic structure to it. He started with low numbers applied to yellow filters, higher numbers for oranges, red and magentas, and higher yet for greens and blues. Numbered between 80 and 85, he listed filters which adjusted the colour temperature of the light reaching the film, with a range of miscellaneous filters occupying the range from 87 upwards. Of course, with the introduction of colour films, the Wratten filter list has been updated and expanded but, almost a century after their introduction, Wratten numbers are still the most commonly used to denote a filter's colour and character.

Wratten & Wainwright's plates so interested George Eastman that he visited Croydon to see the company's facilities in 1912, and was so impressed by Mees that he offered him a post in New York. The company was bought out by Eastman Kodak later that year—one of the specified conditions upon which Mees would agree to work for Kodak's new research department—and the workforce, including Wratten, transferred to the staff of Kodak Ltd. Mees ultimately became Kodak's Director of Research.

Frederick Wratten died in London on April 8, 1926 at the age of 86.

WYNFIELD, DAVID WILKIE (1837–1887)

British painter and photographer

David Wilkie Wynfield was born in 1837 in India, the son of Captain James Stainback Winfield of the 47th Bengal Native Infantry, and Sophia Mary Borroughes. The family returned to England in the early 1840s, upon Captain Winfield's retirement. Wynfield's mother was the niece and adopted daughter of acclaimed Scottish painter of genre scenes Sir David Wilkie. Yet the young Wynfield did not immediately follow in the footsteps of his namesake (and godfather), initially intending to enter the priesthood.

In 1856, Wynfield decided to study art with historical painter James Mathews Leigh. Leigh's studio fostered the St. John's Wood Clique, a group of young artists—Philip Hermogenes Calderon, J. E. Hodgson, G. D. Leslie, Henry Stacy Marks, Val Prinsep, George A. Storey, Fred Walker, William Frederick Yeames, and Wynfield—who would meet weekly at each other's homes to sketch a set theme and critique the results. These men, many of whom had taken an initial study tour of Europe, had gravitated to London in the mid-1850s, where they formed a uniquely British, gentlemanly version of bohemia in which like-minded coteries of painters, illustrators, and writers dedicated themselves to establishing a "British School." Following Leigh's teaching, Wynfield adopted historical subject matter and highly illusionistic rendering. He first showed at the Royal Academy in 1859 and appeared regularly thereafter, gaining a modest reputation and a steady income as a specialist in subjects from English history, though never achieving the rank of Academician. He changed the spelling of his surname around 1860, probably to avoid confusion with the slightly older painter of historical genre scenes J. D. Wingfield.

A social group above all, the St. John's Wood Clique dabbled in amateur theatricals; they also participated together in the 38th Middlesex Corps of the Artists' Volunteer Rifles, one of many such companies that sprung up in the spring of 1860 in response to Napoleon III's expansionist policies. Most participants abandoned the Corps after a brief period, but for Wynfield (who never married) the comradeship was clearly important, for he remained in the Corps into the 1880s, rising to the rank of captain. It is not known exactly when or why Wynfield took up photography, but his friendship with Frederick Richard Pickersgill—painter, amateur photographer, and son-in-law of Roger Fenton—may have been influential.

Wynfield's most significant photographic project, begun around 1861, was a series of portraits of artists—not only painters, but also architects and graphic artists—in Tudor and Renaissance costume. He registered ten of these for copyright on 8 December 1863 and exhibited a selection at a meeting of the Graphic Society in mid-January 1864. Henry Hering of Regent Street published a series of the portraits under the title *The Studio: A Collection of Photographic Portraits of*

Wynfield, David Wilkie. George Grederick Watts. *The Metropolitan Museum of Art, Warner Communications Inc. Purchase Fund, 1977 (1977.537) Image © The Metropolitan Museum of Art.*

Living Artists, Taken in the Style of the Old Masters, by An Amateur in the late spring of 1864; each issue sold for a guinea and included four photographs in the style of a continental school. *The Studio* attracted little notice in the photographic press, and two positive notices in more general periodicals, *The Reader* and the *Illustrated London News*, seem to have been insufficient to encourage future publication and indeed Wynfield withdrew the images from circulation about six months after their initial exhibition.

Wynfield's photographic portraits comprise a consistent body of work. All are albumen prints from wet-collodion negatives on 8 × 6-inch plates, and all except one are busts of male sitters (the exception is a head study of his sister Annie Yeames). The sitters occupy very shallow spaces, before backgrounds that function mainly as patterns of light and dark, setting off corresponding features in the heads or clothing. Most of the costumes refer to the fifteenth, sixteenth, or seventeenth centuries, and often bear some connection to the subject: for example Marks, painter of many Shakespearean subjects, appears in Elizabethan costume. Wynfield made many visual references to Holbein and Van Dyck, but did not re-create specific works and frequently combined elements from various styles and periods in a single image. Most sitters were Wynfield's contemporaries and friends, many of whom had yet to make their reputations at the time they were photographed. Associating his fellow artists with the Old Masters, Wynfield projected their shared desire to be seen as humanists who could bridge past and present, soul and intellect, commerce and nobility, fame and its renunciation. He also expressed, much more clearly than in his paintings, the notions of breadth and idealism then attached to the Old Masters—qualities that stood in direct opposition to the focus, detail, and specificity that characterized most genre paintings and all commercial photographic portraiture. As seen from the perspective of a generalist art critic of the 1860s, David Octavius Hill was photography's Old Master, and Wynfield a worthy heir. The Photographic Society of London, meanwhile, was inhospitable to a practice they saw as insufficiently advanced technically and therefore unworthy of institutionalization. Wynfield never became a regular participant in the Society's annual exhibitions.

The relationship between Wynfield's painted and photographic production is far from straightforward. In appearance and construction they are totally different—and indeed Wynfield must have been concerned to avoid the charge that he relied on photographs when composing his paintings—but both were motivated by a vision of the literary and historical past. Assessment of Wynfield's achievement has been compromised by association with Julia Margaret Cameron, who approached him as a pupil in 1864 and later declared that "to his beautiful photography I owe all my attempts and indeed consequently all my successes." There is no doubt that Wynfield's photographs exhibit, in fact pioneered, many of the qualities now associated with Cameron's work, such as close-up format, soft focus, impressionistic atmosphere, and strong chiaroscuro. Historians—following the lead of nineteenth-century commentators—have applied the label of "amateur" positively to Cameron, using it to imply freedom from convention; with regard to Wynfield the term seems pejoratively to connote dilettantism, frivolity, and technical ineptitude.

Wynfield's abandonment of photography is as undocumented as his embrace of it. It is not known if he continued to make photographs into the 1870s and 1880s. He died of tuberculosis in 1887, at age forty-nine. Examples of his portraits are found at the Royal Academy of Arts (given by his fellow artist and brother-in-law W. F. Yeames), the National Portrait Gallery, and the Victoria and Albert Museum.

BRITT SALVESEN

Biography

David Wilkie Wynfield was born in India in 1837, the namesake of his mother's uncle and adoptive father, the

renowned Scottish painter David Wilkie. After considering the priesthood, Wynfield decided to become an artist and entered the studio of James Mathews Leigh. There he learned to practice a style of historical genre painting and met the young artists with whom he would form the St. John's Wood Clique. Wynfield exhibited at the Royal Academy for the first time in 1859, and continued to do so regularly thereafter. Taking up photography around 1860, he produced a number of soft-focus, bust-length portraits of artists from wet-collodion negatives on albumen paper, some of which were published in 1864 under the title *The Studio*. Although Julia Margaret Cameron credited Wynfield as her major influence, he received little acclaim in Photographic Society circles. It is not known if he continued to make photographs into the 1870s and 1880s. Wynfield died of tuberculosis in 1887.

X

X-RAY PHOTOGRAPHY

X-ray photography was one of the most important discoveries of the 19th century. Developed in November 1895 by German scientist Willhelm Conrad Röntgen (1845–1923), the x-ray thus straddles the cusp between two centuries. The phenomenon captured the public's imagination to an extent not experienced; its fascination was not to be eclipsed until the hydrogen bomb in 1945. The aesthetic and theoretical ramifications of x-rays also proved fertile ground for artists seeking new ways to picture inner realities. Röntgen won the first Nobel Prize in Physics in 1901 for his breakthrough, yet declined to seek a patent and remained modest about his remarkable discovery for the rest of his life. Interestingly, Röntgen disliked being photographed, therefore few images of him exist.

Röntgen, like many other researchers of his time, was interested in the nature of cathode rays. To accomplish his light experiments, he used vacuum glass tubes, commonly known as Crookes tubes after William Crookes, a British scientist who perfected them in the 1870s. Working in the Physical Institute laboratories of the University of Wurzburg, Röntgen studied emissions produced from an electrical current passed between the cathode (negative) and anode (positive) terminals. The cathode rays normally caused the walls of tube or other internal objects to glow, but did not seem to be able to penetrate the glass. Röntgen was astonished when his cardboard shrouded tube caused a barium platinocyanide screen across the room to fluoresce. Placing various objects between the tube and screen, he saw the bones of his hand through his flesh, which he subsequently captured on a photographic plate. What followed was seven straight weeks of intense experimentation. He remarked to a friend, "I have discovered something interesting, but I do not know whether or not my observations are correct."

On December 28 1895, Röntgen gave a preliminary report to the Physical-Medical society of Wurzburg, and by New Year's Day he sent copies of his report to colleagues across Europe. Newspapers and magazine quickly picked up the story and by January, the whole world was caught up in x-ray fever. Other non-existent rays were posited—including N-rays, black rays, and Becquerel Rays (later found to be the alpha, beta, and gamma rays produced by radioactive materials). Every imaginable substance, including animals and objects, were exposed. Eager for news of each new photographed organ, cartoonists and poets lauded the humorous new possibilities of seeing people's thoughts and peering through underwear. By 1896, over 60 articles had been featured in the popular press as well as the first angiography, cinematic x-ray, and military radiology performed.

The first generally-accepted x-ray photograph is that of Mrs. Röntgen's ringed hand from December 22, 1895. (After learning of the discovery, A.W. Goodspeed and William Jennings recreated one they had made by accident in 1890.) X-rays were seen as extension of the photographer's craft and were included in many manuals and journals. After Thomas Edison's invention of the fluoroscope in 1896 (a kind of hooded camera fitted with a screen), many x-rays were performed as demonstrations. People lined up at department stores, high schools, and other public venues to get "bone portraits." Dubbed "shadow photographs," X-rays soon after needed no camera, a capacity shared with some of the earliest forms of photography, and no film. Still, the evidentiary nature of a photograph proved irresistible, especially to photographers, scientists, and the press. Eadweard Muybridge made stop action photographs and films of frog's legs in motion in 1896. Edison even claimed that the rays would eventually show the activity of the human brain.

As x-rays are radiation, they can both diagnose and cure. Enthusiasts, not having a precedent, exposed themselves regularly to test strength and perform demonstrations. Reddening of the nose and hands of practitioners was common. The early decades of the 20th century saw the death of many early pioneers due to numerous amputations and burns resulting from overexposure. It was not until the death of Edison's assistant in 1904 that the spotless record of the rays began to wear thin. The novelty and pure aesthetics of the rays gave way to medical applications—both legitimate and illegitimate. Medical schools added x-rays to their curricula; likewise, correspondence courses offered programs for photographers and electricians to gain training in "Röntgenology." "Do-it-yourself" kits were even sold in popular magazines.

Röntgen initially described x-rays as "longitudinal vibrations in the ether". The ether was a commonly held scientific hypothesis that a mysterious substance occupied the air and was the media through which waves and a whole host of other as yet inexplicable phenomena moved. At the turn of the last century, science and occultism occupied a much closer range than they do today and x-rays were thought by many to give credence to extra-sensory perception and psychic ability. If such non-perceptible spectacles could be captured on a photographic plate, it was argued, so too could thoughts, auras, ghosts, and even the human soul. Philosophically, the discovery of x-rays caused a scientific sea change. No longer did the senses seem an adequate platform for analysis; scientific positivism was at a standstill. Furthermore, these rays could also kill as well as cure, presenting a medical and moral conundrum.

It was not until the 20th century that x-rays were confirmed to be a part of the electromagnetic spectrum. Röntgen had covered his tube to keep the fluorescent effects contained; yet he found that the new rays could not be reflected, polarized, or refracted. It was later proved that x-rays have shorter wavelengths than visible light (around one billionth of a meter) and are related to radioactivity (discovered in 1896 and later studied by Marie and Pierre Curie). A trained glass blower, C.H.F. Muller was the first to construct commercially viable x-ray tubes and was later granted a patent in 1899. His firm expanded until another company took over in 1927, eventually setting the foundation for the new and improved x-ray apparatus we know today.

Y

YEARBOOK OF PHOTOGRAPHY

The *Yearbook of Photography* was published by the weekly periodical *Photographic News* and was usually edited by that publication's editor. It was for many years the alternative to the *British Journal of Photography's Photographic Almanac* (1859–1963) but never quite grew in the same way or gained the same following. By 1894 the *Almanac* numbered 1336 pages against the *Yearbook's* 612 pages. It remains important as there were advertisers who only took space with one publication and the editorial content provides a useful alternative to the *Almanac*.

The *Yearbook* first appeared as the *Photographic News Almanac,* known as *Almanack* in 1859, *or the Year Book of Photography* in 1859 a title that it kept until 1863. The 1859 *Almanack* was published on 10 December 1858 at a cost of 6d and described in the *Photographic News* of 17 December 1858 (177). The intention is to 'disseminate useful and important information, alike to the practised operator and amateur… It will be found to be of the greatest assistance not only to the private amateur, but also to the professional photographer; to the former, on account of the numerous hints it contains, which if attended to, will ensure success under the most unfavourable circumstances; and to the latter, for the information on subjects which are so liable to escape memory.'

It became the *Yearbook of Photography and Photographic News Almanac* in 1864 and last appeared with the 1907/08 edition after which it's parent, the *Photographic News*, was absorbed by *Amateur Photographer*.

The original *Almanack* absorbed William Lay's *Photographic Almanac and Ready Reckoner for the Year of Our Lord 1859* which appeared for one year only. It was incorporated into the second volume of the *Photographic News Almanac* for 1860. Lay's *Almanac* and the first issue of the *Photographic News Almanac* lay claim as the world's earliest photographic almanacs.

The first editor was G. Wharton Simpson (1825–1880) who remained in that position until the 1880 edition; H. Baden Pritchard (1841–1884) edited the years 1881–1884; Thomas Bolas (1848–1932) edited 1885–1889; T. C. Hepworth (died 1905) edited 1892–1893; E. J. Wall (died 1928) edited 1897-1898; Percy R. Salmon (died 1959) edited 1901–1905 and F. J. Mortimer (1874–1944) edited 1906–1908. The missing years were not credited.

The content of the *Yearbook* was remarkably constant over its history from the 1859 *Photographic Almanac*. The editorial pages usually began with a calendar for the year and astronomical information, followed by a list of the principal photographic societies and their officers for Great Britain. A review of advances within photography for the previous year provided a useful survey of new processes, apparatus and survey of the profession as well as the principal deaths for the year. This was followed by an extensive list of photographic processes and formulae. A number of essays by noted amateur and professional photographers on practical aspects of photography completed the book. In, for example, the 1866 volume the essays included J. H. Dallmeyer on lenses, Jabez Hughes on constructing a photographic darkroom, Rejlander reflecting on photography and art, Thomas Richard Williams on portraiture and Henry Peach Robinson on managing sitters amongst others. All volumes contained substantial advertisement sections. In later volumes the amount of formulaic information was reduced to make way for surveys of new equipment and a trade directory. The essays during the 1880s and 1890s began to become more technical in nature reflecting the editors' own interests and the general editorial slant of the *Photographic News*.

YOKOYAMA MATSUSABURO (1838–1884)

Japanese painter, photographer

The Japanese photographer Yokoyama Matsusaburo was born in Etorofu Island (now disputed territory with Russia), but spent his childhood in the port city of Hakodate. His lifelong love was painting, but when Commodore Perry's ships visited Hakodate in 1854, Yokoyama was intrigued by the photography of Eliphalet Brown. This interest was reinforced when, later that year, the Russian photographer Aleksandr Mozhaiskii took daguerreotypes of the streets of Hakodate. Thinking that mastery of photography would help him to become a better artist, he traveled to Yokohama and studied under Shimooka Renjo. Returning to Hakodate his technique was further refined by the Russian consul and amateur photographer, Iosif Goshkevich. In 1868, Yokoyama opened his own lavish studio in Tokyo. In 1871 he famously photographed the partially destroyed Edo Castle, and in 1873 Japanese art works destined for the Vienna Exposition. In the same year he began to concentrate on teaching art and photography students at his studio. In 1876 he gave up his studio and taught photography and photolithography at the Japan Military Academy until 1881. There he experimented with printing techniques and developed a form of photographic oil painting, shashin abura-e. In 1882 he contracted tuberculosis and spent the last two years of his life painting (particularly photographic oil painting) and immersing himself in a photolithography company which he founded. [Examples of Yokoyama's work can be found in the Tokyo Metropolitan Museum of Photography, Tokyo.]

TERRY BENNETT

YORK, FREDERICK (1823–1903)

Lantern slide manufacturer

York was born at Bridgwater, Somerset, England, in 1823. At 16 he was apprenticed to a Bristol pharmacist, where he came into contact with the new art of photography. He established and ran a photographic business in South Africa, 1853–1861. Returning to England, in 1863 he set up a stereoview and lantern slide business at 87 (later at 67) Lancaster Road, Notting Hill, London. The firm soon concentrated on photographic slides, and son William joined the business in 1877. York & Son's slides, by the 1890s over 100,000 per year, were manufactured in Bridgwater. Subjects included Travel, Comic, Science, Education, and Life Models. Travel scenes were produced with negatives 'bought-in' from other photographers. Life Model sets were photographed by the York company, whose only serious competition in this genre was Bamforth & Co. Costumed 'actors' posed in front of painted backdrops or, occasionally, exterior scenes to create a series of tableaux. Many scenes were photographed in a garden studio at Lancaster Road. Themes included temperance, popular songs, services of song, and 'tearjerker' stories. After Frederick York's death in 1903 William carried on, but the firm was dissolved in 1907. Newton & Co used the York name until the late 1940s.

STEPHEN HERBERT

YOUNG, THOMAS (1773–1829)

English physician and natural philosopher

Thomas Young is chiefly acknowledged for providing the decisive arguments against Newton's particle theory of light, leading eventually to widespread acceptance of the wave or undulatory theory. He also developed theories of interference and three-color composition of light which were important for the development of colour photography. Born 13 June 1773 to a Quaker family in Somerset, Young exhibited a prodigious intellect, studying literature, ancient and modern languages, engineering, chemistry, optics, mathematics and medicine. Having studied at both Edinburgh University and at the University of Göttingen, he became widely read in a number of Continental philosophers, including Leonhard Euler. Euler proposed that colors were created by the frequency of vibration in the ether, the longest wavelength corresponding to the red end of the spectrum. Young adapted his own analogies of light and sound to form a defence of a general wave theory of light in 1801. In his publication of 1804, *Experiments and Calculations Relative to Physical Optics*, Young published proof of the extension of the spectrum into the 'invisible' region beyond the violet. Like many investigators of light he employed the well-known sensitivity of silver nitrate, casting the image from a solar microscope on strips of paper soaked in the solution. Thomas Young died 10 May 1829 in London.

ZANGAKI BROTHERS (active 1870s–1900s)

The Zangaki brothers produced some of the finest images of late Victorian Egypt, yet so little is known about them. They were probably Greek Cypriots, although it has been suggested they may have come from Crete. Nothing is known of them before their first photographs were published in Egypt in the late 1870s, and even the names of the brothers themselves is unknown. It has been suggested their initials were 'C' and 'G,' and indeed early 20th century photographic postcards bearing the name 'C Zangaki' have been located.

Their photographs, however, were simply identified as 'Zangaki,' the letter 'Z' being frequently mistaken for a stylised 'L' in several books, resulting in their work being incorrectly ascribed to 'Langaki.' Indeed, until relatively recently, there was assumed to be one photographer with the name of 'A Zangaki' until the discovery of a signboard bearing the legend 'Adelphoi Zangaki' confirmed that the images were the work of brothers.

While their Greek—Cypriot or Cretan—roots are confirmed, the horse-drawn darkroom van with which they toured the length of the Nile bore the legend 'Zangaki Brothers,' and to further confuse matters, the majority of their images are titled (in the negatives) in French.

Amongst many fine images are photographs taken after the bombardment of Alexandria in 1882, and some eloquent commentaries on the popularity of the Grand Tour of Egypt in the 1880s.

JOHN HANNAVY

ZEISS, CARL (1816–1888)

The name of Carl Zeiss is synonymous with quality photographic optics, and has been for well more than a century and a half. Throughout the twentieth century, cameras fitted with Zeiss optics were used by the major figures in photography. But during Carl Zeiss's lifetime, the company made its name through the design and manufacture of the highest quality microscopes.

However, it is to Zeiss and his associates that we owe the emergence of the science of optical design and manufacture—a science which had a direct and enduring impact on the development of photographic lenses.

Carl Zeiss himself was born in Weimar on 11 September 1816, and apprenticed to Dr Friedrich Körner, a microscope and scientific instrument maker, before opening his own workshop in 1846, repairing optical and scientific equipment. After Körner's death in 1847, Zeiss took over some of his former employer's business interests, developing the first 'compound microscope' in that same year. It is recorded that in his first year of operation, he sold twenty-three microscopes! Twenty years later he sold his one thousandth, and a further twenty years later, 1886, saw the ten thousandth microscope sold!

1866 was a key year for Zeiss and marked the beginning of his working relationship with Dr. Ernst Abbe, then a physics lecturer at the University of Jena. With Abbe, Zeiss would become a major player in lens manufacture, and the Zeiss Optical Works, established in that same year, soon had Abbe as its Director of Research. The marriage of Zeiss's manufacturing experience, and Abbe's scientific understanding proved pivotal. Between them, the two men would develop the design and manufacture of high quality lenses into a precise science where, as Abbe noted, lens design was based on

> *'a precise study of the materials used,* [and] *the designs concerned are specified by computation to the last detail—every curvature, every thickness, every aperture of a lens—so that any trial and error approach is excluded.'*

Within six years the company had developed a significant number of new microscope lenses, all based on Abbe's

theoretical research and mathematical modelling. They combined high quality, large apertures, colour accuracy and minimal distortion—all essential characteristics in a microscope lens.

In 1881, Abbe met Dr. Friedrich Otto Schott, who had achieved his doctorate in glass science a few years earlier. Combining Abbe's scientific approach with Schott's researches into the manufacture of high quality mineral-rich glasses—using phosphorus, lithium and boron—paved the way for the development a whole new generation of lenses, including the first apochromatic (or fully colour-corrected) lenses, eliminating chromatic aberration, the bane of microscope users. Before then, achromats had been corrected for only two of the three primary colours.

Schott and Associates Glass Technology Laboratory, a partnership between Zeiss and Schott, was formed in 1884. With Abbe's scientific approach applied to the manufacture of glasses, and the introduction of new and precisely computed ingredients, over a hundred new types of glass were developed. Zeiss lenses by the 1880s were recognised the world over for their optical purity and accuracy.

Carl Zeiss died in 1888 and control of the Zeiss Optical Works passed to Abbe, who had been a partner since the mid 1870s. In the following year Abbe transferred ownership of the company to the Carl Zeiss Foundation, together with their interests in Schott's glassworks. The purpose of the foundation was to fund research, and also to initiate social and workplace reforms. It is reported that by 1900, Zeiss workers enjoyed profit-sharing, an eight hour working day, paid annual holidays, a basic health-care plan, and retirement pension. A century ago such benefits was revolutionary.

The first years after Carl Zeiss's death saw the company develop a series of camera lenses which were to endure for a century and more. The Zeiss Planar (1896) and Tessar (1902) are perhaps the most long-lived lens designs in the history of photography.

ZIEGLER, JULE (1804—1856)

Jule Ziegler was a celebrated painter of the July Monarchy, ceramist, and photographer. His contribution to photography is manifold. Of an inventive spirit, Jules Ziegler performed many experiments on techniques, optics, and color. From the early 1840s, he was devoted to the daguerreotype and improved its coloring. In 1851, he was one of the first in France to use wet collodion. The same year, he joined the management committee of the Société heliographique and he was awarded a certificate for his photography at the Great Exhibition at the Crystal Palace, London 1851. He wrote many articles for *La Lumière* and a report on photography for the Paris Exposition Universelle of 1855. Ziegler's work exhibited similarities with that of his friend Hippolyte Bayard, who did his portrait with the daguerreotype in 1844 (SFP), as well as with the topics of the compositions: still lifes, sculptures, reproductions of antiques (*Venus de Milo*), and views of his garden. He used photography to emphasize his work as ceramist; sandstone vases of his manufacture are reproduced in several negatives (girl in front of the Vase with the twelve apostles). The museum of Langres preserved a set of his photographs, including compositions with sculptures and vases and the Pallet of the painter.

HÉLÈNE BOCARD

ZILLE, HEINRICH (1858–1929)

Heinrich Zille was a draughtsman and famous Berlin engraver, author of albums, and collaborator of satirical newspapers. In about 1887, he started photography as a way to aid. He initially photographed his family, then chronicled the proletariat with a series of the women at the market, men returning home from work, children in the streets, and fairs. He also took portraits of artists in their workshops and he completed nude studies as well. By 1914, he took hundreds of negatives on glass plates of gelatine-bromide. Zille never published his photographs, which he regarded as working tools. Discovered in the 1960s, they were appreciated for their modernity: instantaneous with the characters captured in full action, sometimes seen from the back, walking. His images also had a persistent flat spaces, inscriptions, and lines that created dynamic effects (crossroads, scaffolding).

Through his unique artistic eye, Zille drew attention to the grounds, the palisades, and the walls thought to be common. His images of the poor district, Krögel were described as having direct vision, without an aesthetic research or anecdote. Dependent on the Berliner Secession, Zille always remained outside of any aesthetic contemporary category. If his work is connected with naturalism, it is only because he approached the expressionists by simplifying the human form to the point of making a prototype of it. The originality of his vision on certain topics (shops) was pointed out by Eugene Atget. These images in fact are documents of great value on the social dimension of Berlin in 1900.

HÉLÈNE BOCARD

ZOLA, EMILE (1840–1902)

"In my view you cannot claim to have seen something until you have photographed it." This is a rather curious sentiment, since it came from its author, Emile Zola, after most of his incredible writing career, which was largely based on good old-fashioned visits, conversations, and note-taking, was over. Zola was virtually a writing machine who became famous by turning out mostly great and in any case best-selling novels at the rate of more than one per year for more than 30 years. He wrote many of them for serialization, keeping just ahead of their journal publication, and then they were published as books. The biggest project was *Les Rougon-Macquart*, a more than 20 volume set of familial and social disasters that ran from 1871-93. He novelized the urbanization and modernization of France. He also wrote many journal articles, essays, criticism, and plays. A number of his books were successfully put on stage.

Zola became friends with Cezanne as a youth, with many of the Impressionists, and with Nadar (Felix Tournachon), Petit, Carjat, and other photographers in the 1860s. Nadar took many portraits of him between 1876 and 1898. Zola apparently took up photography on a particular trip in 1888, but did not start taking photographs seriously until 1894, and took perhaps 5000 images up to his murder in 1902. He was passionate about photography in writing and in speaking. He collected about a dozen cameras, including large and small formats, stereo and panoramic equipment. He did his own darkroom work, from mixing his photochemistry to enlarging and printing. His subjects included portraits, mostly of his family, especially his paramour and their children; his wife; some friends, and then landscapes, railroad scenes, street scenes in Paris and London, and the Paris World's Fair of 1900. He considered himself a member of the naturalist (or realist) school in his writing, and that is reflected in his photographic compositions. One of his best photos of Paris, of Place Prosper-Goubaux on a rainy day, shows from its camera angle, mistiness, shadows, carriages, pedestrians and buildings strong similarity to Caillebotte's famous painting, *Rue de Paris, temps de pluie* (*Paris street in Rainy Weather*, 1877). It is extremely likely Zola had seen the painting and knew Caillebotte.

Zola also publicly and famously defended Capt. Alfred Dreyfus after he was unjustly and falsely accused of treason. In 1898 Zola wrote a front page open letter to the French President in the Paris newspaper *L'aurore,* under the banner "J'accuse...!" that ripped apart the Army's case. Zola was tried and convicted of slandering the Army, and fled to exile in England for 11 months, where he continued to photograph. Zola returned in 1899. Dreyfus was tried and convicted again, but almost immediately pardoned by the President and reinstated by the Army. In the 1920s a stove fitter confessed on his death bed to stuffing the chimney of Zola's country house one night. Carbon monoxide killed him in his sleep.
